

Regional Conference on Geomorphology

"Geomorphology of Climatically and Tectonically Sensitive Areas"

Athens, September 19-21, 2019.

OBJECT-BASED MAPPING OF GULLY EROSION IN KARSTIC AREA THROUGH THE USE OF MEDIUM SPATIAL RESOLUTION MORPHOMETRIC PARAMETERS

Fran Domazetović, Ante Šiljeg, Nina Lončar, Ivan Marić

Geospatial Analysis Laboratory

Department of Geography, University of Zadar

S04. Denudation in the Mediterranean Zone

Introduction

- Mapping of **gully erosion** is important for better understanding of erosion **spatial distribution** and **characteristics**
- Inaccessibility and disperse spatial distribution of gullies often makes terrain mapping **challenging** (time and cost consuming process) → **not suitable for large areas**
- Several studies successfully used **VHR satellite** imagery for **object-based mapping** of gully erosion → *morphometric parameters not used*
- Detailed and accurate gully erosion mapping is especially challenging in **remote areas** → high spatial resolution data **not** available

How can medium spatial resolution data be used for mapping of gully erosion ?

Representation of gullies in
medium resolution
hillshade

Gullies located in **Eastern part** of Pag island

*Medium spatial resolution → **2 m - 30 m**

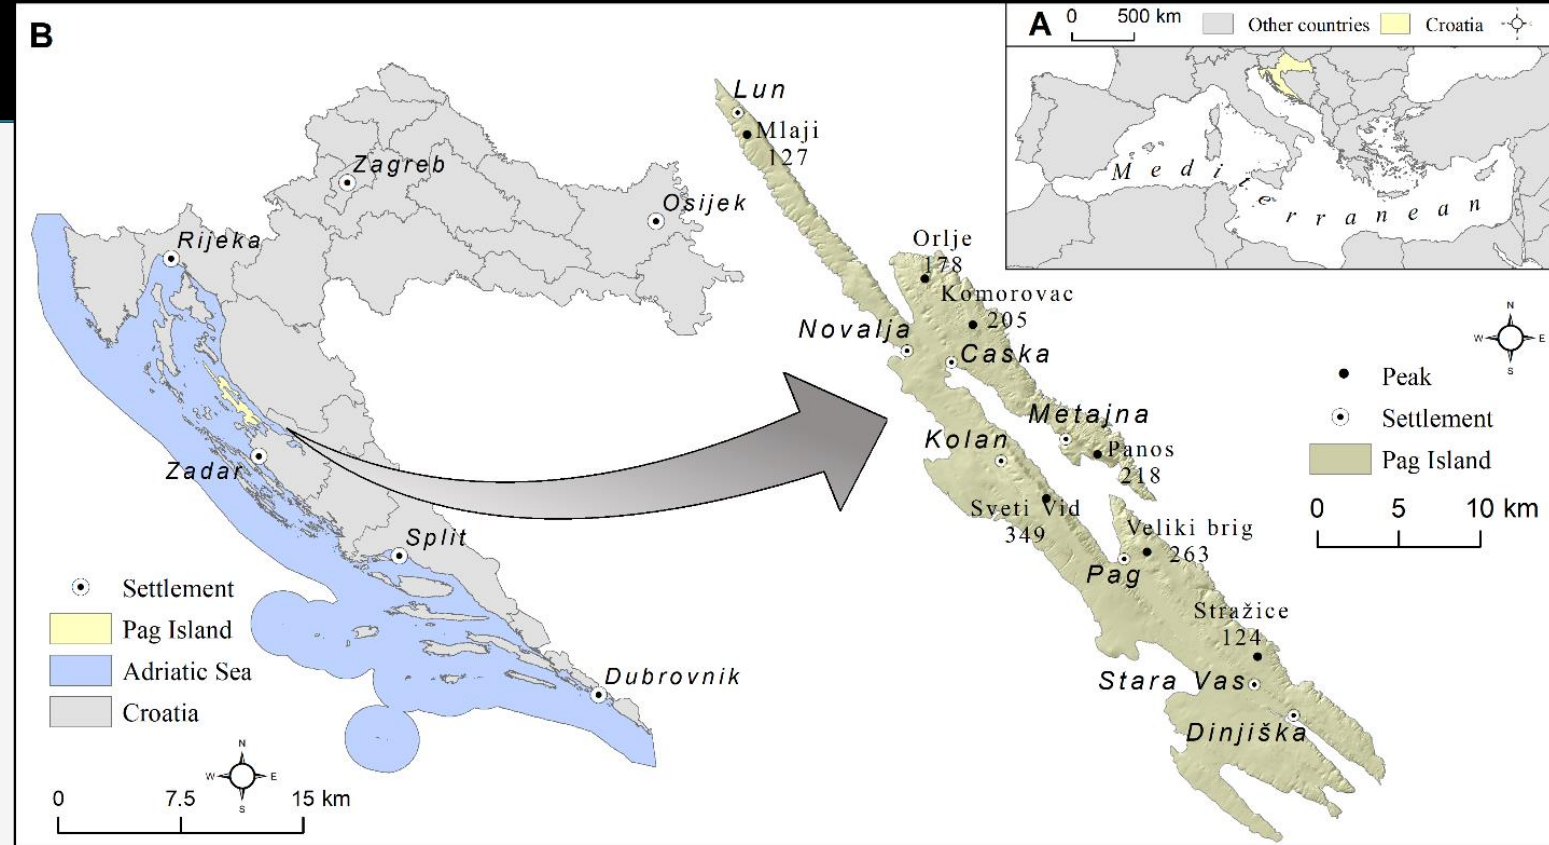

Study aims

- I. Test the possibility for gully erosion mapping based on different morphometric parameters derived from medium resolution digital elevation data
 - H1: *Gullies **can be mapped** from medium resolution morphometric parameters*
 - H2: *Short gullies (<100 m) **won't be mapped** from medium resolution morphometric parameters*

- II. Determine the number, spatial distribution and basic characteristics of gullies
 - H3: *Total number of detected gullies will be **higher** than determined by previous research*

Study area

- **Pag Island** (284 km²) is situated within Northern Dalmatia archipelago, Croatia
- Scarce vegetation and harsh climatic conditions (bora wind) → development of **specific karst landscape**

Location of Pag Island within Croatia

- Widespread denudation processes → gully erosion present in almost **all** parts of island

Medium spatial resolution data source

USED DIGITAL ELEVATION MODEL (DEM)

- **DEM** was made from height data collected by the **photogrammetric restitution** (DGU, 2017).
- Ordinary kriging (OK) interpolation of 148 518 height points
→ 15 m spatial resolution of DEM (284 km²)
- Optimal interpolation method chosen by cross-validation results → **RMSE = 1,0279**

Workflow of object-based gully erosion mapping

APPLIED OBIA WORKFLOW

1. Determination of parameters
2. Parameter standardization
3. Segmentation
4. Object classification
5. Gully candidate filtration
6. Model validation (reference data)

- In total **seven** parameters (SPI, MBI, TPI, PLAN, SLO, TWI, VDC) were chosen for OBIA mapping
- All chosen parameters were **standardized** to the same scale:
 - a) SPI, MBI, TPI, PLAN → scale A [-1, 1]
 - b) SLO, TWI, VDC → scale B [0, 1]

Chosen morphometric parameters

STREAM POWER INDEX (SPI)

- Represents the measure of the erosive power of surface runoff
- Influences the intensity of gully erosion

Higher SPI

→ higher erosion

potential (EP)

TERRAIN WETNESS INDEX (TWI)

- Measure of potential humidity of given terrain
- Allows the differentiation of saturated and unsaturated areas

Higher TWI

→ lower EP

MASS BALANCE INDEX (MBI)

- Measure used for classification of accumulation and erosion processes
- Negative MBI → depressions (accumulation)
- Positive MBI → slopes (erosion)

Chosen morphometric parameters

SLOPE (SLO)

- Influences the intensity of the gully erosion
- Too gentle or steep slopes are less suitable for gully erosion

Optimal slope for gully erosion is between 12° and 32°

PLANAR CURVATURE (PLAN)

- Affects the homogeneity of the surface runoff
- Convergence or divergence of runoff

Concave slopes
→ runoff convergence
→ higher EP

VERTICAL DISTANCE TO CHANNEL NETWORK (VDC)

- Determines the vertical distance from pixel to given channel network
- Gullies related to surface runoff → low VDC values

TOPOGRAPHIC POSITION INDEX (TPI)

- Determines the position of central pixel in relation to its neighbourhood
- Gullies → linear features lower than surrounding terrain

Segmentation and classification

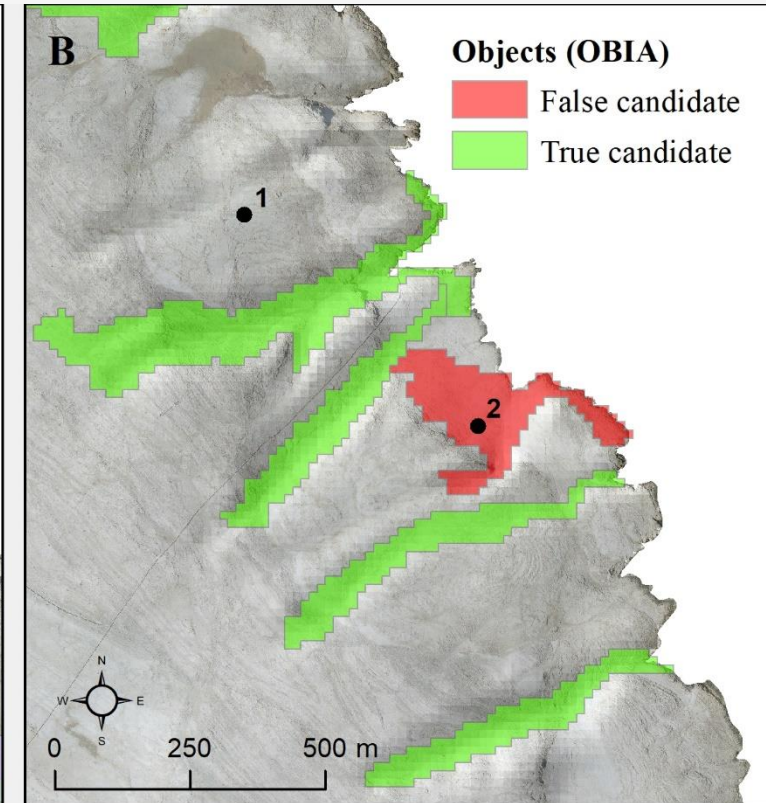

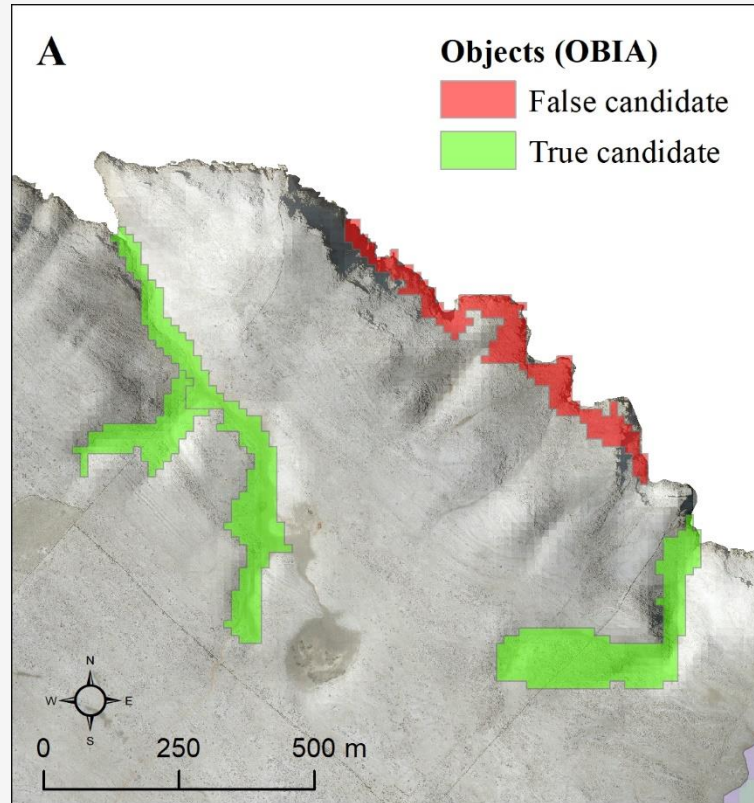

- **Multiresolution segmentation (MRS)** algorithm applied
- User-defined parameters were set according to the visual interpretation of results
- **Threshold classification** used for all 7 parameters

Influence of user-defined parameters on segmentation result

Gully candidate filtration

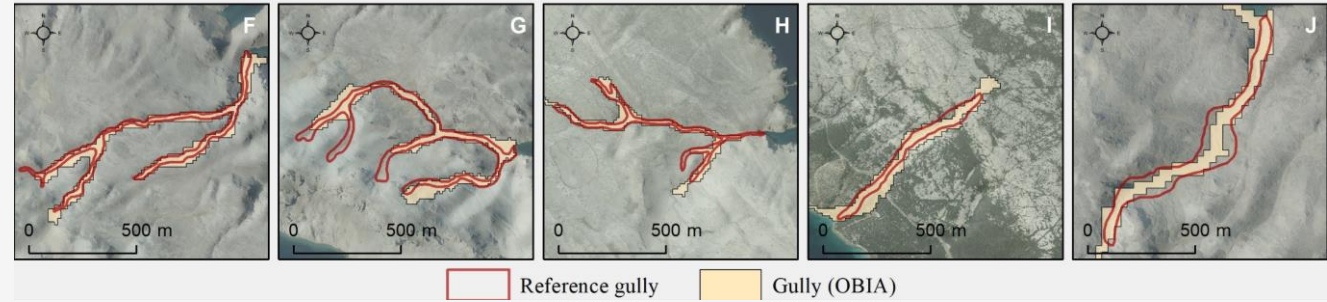

- Filtration of **384 gully candidates** performed by visual interpretation → DOF (0.5 m)
- Most "false candidates" occur in **steep coastal areas**, while most small gullies (**length <200 m**) were not mapped
- 134 true objects → 120 gullies

(A and B2) - false candidate in steep coastal areas;
(B1) - small gully undetected by OBIA

Model validation

- Model validation performed by overlapping of extracted gullies with **12 manually vectorized gullies** → DOF (0.5 m)

Extracted gullies (OBIA) overlapped with reference gullies

- 4 mapping quality indices used:

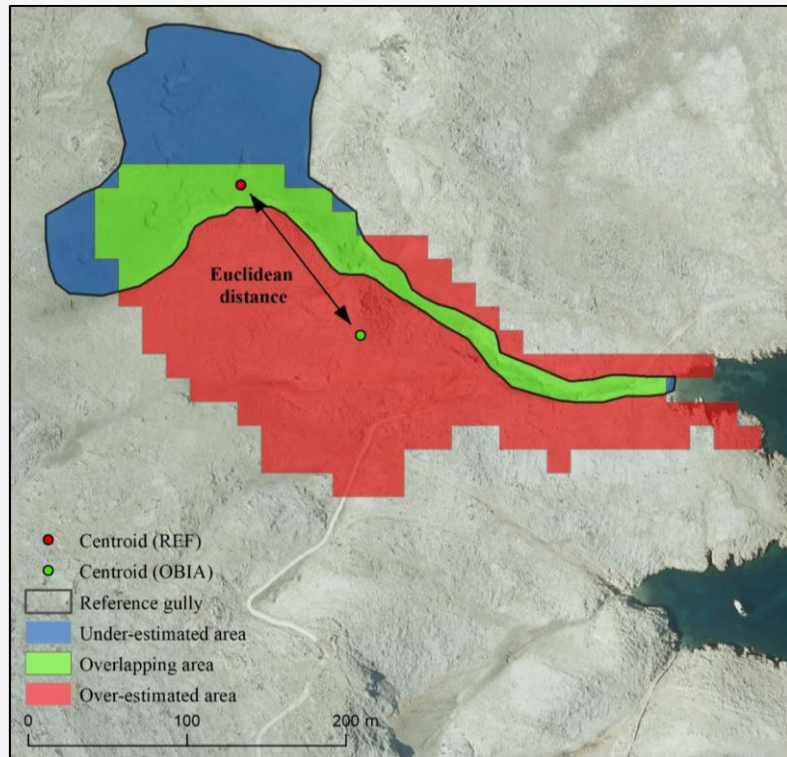

$$\text{Correctness (COR)} = \frac{A_p}{A_e}$$

$$\text{Overall Quality (OQ)} = \frac{A_p}{A_r + A_e - A_p}$$

$$\text{Completeness (COM)} = \frac{A_p}{A_r}$$

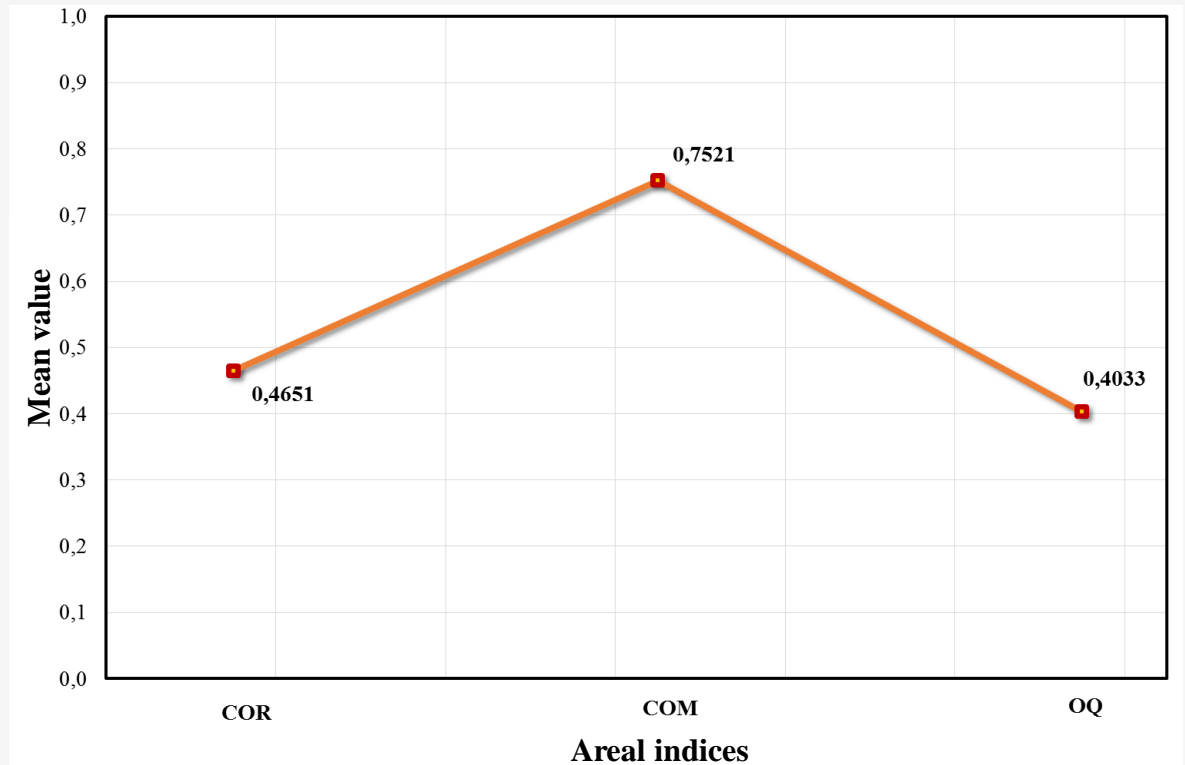

$$\text{LOC measure (LOC)} = \sqrt{(X_e - X_r)^2 + (Y_e - Y_r)^2}$$

A_p - overlap area; A_e - area of OBIA gully; A_r - area of reference gully

Validation results

- **Relatively low values of areal indices** → area of mapped gullies is **exaggerated** in comparison to the reference gullies
- MeanLOC value = 55 m → **horizontal location error of 3,6 pixels**
- Inverse proportion between mapping errors and gully size → gullies with length <200 m not mapped

Mean values for three **areal indices**

(Value 1 shows perfect overlap between reference and extracted data)

Number and characteristics of mapped gullies

- In total **120** gullies have been mapped within Pag Island →
337 gullies mapped by manual vectorization (DOF 0,5 m – Lončar, 2009)
- Most of mapped gullies occur in **eastern parts** of Pag Island
- Gullied areas cover **5,9 km²** of total island area (**2,091%**)
- Simple, unbranched gullies prevail (88,2 %) over longer branched gullies
- In 49,16 % of mapped gullies traces of active gully erosion detected (DOF)

Conclusion

- Object-based mapping of gully erosion from medium resolution morphometric parameters have provided *satisfactory detection rate* but *modest areal accuracy*
- Proposed methodology *suitable for large gullies and remote areas with lack of VHR data* → inverse proportion between mapping errors and gully size
- More work should be done on *morphometric parameter thresholding* → easier with VHR data
- Conducted research didn't account short gullies → most common at Pag island
- Similar object-based mapping should be performed on *VHR data* if possible → acquisition of *Worldview-2* multispectral and stereo imagery (*DigitalGlobe Foundation*)

Questions ?

Thank you for your
attention

What would I eat
if gully erosion
continues ?
