On Worley’s theorem in Diophantine approximations
Andréj Dujella and Bernadin Ibrahimpasić

Abstract

In this paper we prove several results on connection between continued fractions and rational approximations of the form $|\alpha - a/b| < k/b^2$, for a positive integer $k$.

1 Introduction

The classical Legendre’s theorem in Diophantine approximations states that if a real number $\alpha$ and a rational number $a/b$ (we will always assume that $b \geq 1$), satisfy the inequality

$$|\alpha - \frac{a}{b}| < \frac{1}{2b^2}, \quad (1)$$

then $\frac{a}{b}$ is a convergent of the continued fraction expansion of $\alpha = [a_0; a_1, \ldots]$. This result has been extended by Fatou [3] (see also [5, p.16]), who showed that if

$$|\alpha - \frac{a}{b}| < \frac{1}{b^2},$$

then $\frac{a}{b} = \frac{p_m}{q_m}$ or $\frac{p_{m+1} \pm q_m}{q_{m+1} \mp q_m}$, where $\frac{p_m}{q_m}$ denotes the $m$-th convergent of $\alpha$.

In 1981, Worley [12] generalized these results to the inequality $|\alpha - \frac{a}{b}| < \frac{k}{b^2}$, where $k$ is an arbitrary positive real number. Worley’s result was slightly improved in [1].
Theorem 1.1 (Worley [12], Dujella [1]) Let \( \alpha \) be a real number and let \( a \) and \( b \) be coprime nonzero integers, satisfying the inequality

\[
|\alpha - \frac{a}{b}| < \frac{k}{b^2},
\]

where \( k \) is a positive real number. Then \((a, b) = (r_p m + 1 \pm sp_m, r_q m + 1 \pm sq_m)\), for some \( m \geq -1 \) and nonnegative integers \( r \) and \( s \) such that \( rs < 2k \).

The original Worley’s result [12, Theorem 1] contains three types of solutions to the inequality (2). Two types correspond to two possible choices for signs + and − in \((r_p m + 1 \pm sp_m, r_q m + 1 \pm sq_m)\), while [1, Theorem 1] shows that the third type (corresponding to the case \( a_{m+2} = 1 \)) can be omitted.

In Section 3 we will show that Theorem 1.1 is sharp, in the sense that the condition \( rs < 2k \) cannot be replaced by \( rs < (2 - \varepsilon)k \) for any \( \varepsilon > 0 \). However, it appears that the coefficients \( r \) and \( s \) show different behavior. So, improvements of Theorem 1.1 are possible if we allow nonsymmetric conditions on \( r \) and \( s \). Indeed, already the paper of Worley [12] contains an important contribution in that direction.

Theorem 1.2 (Worley [12], Theorem 2) If \( \alpha \) is an irrational number, \( k \geq \frac{1}{2} \) and \( \frac{a}{b} \) is a rational approximation to \( \alpha \) (in reduced form) for which the inequality (2) holds, then either \( \frac{a}{b} \) is a convergent \( \frac{p_m}{q_m} \) to \( \alpha \) or \( \frac{a}{b} \) has one of the following forms:

\begin{align*}
(i) \quad & \quad \frac{a}{b} = \frac{r_p m + 1 \pm sp_m}{r_q m + 1 \pm sq_m} \quad & (r \geq s \quad \text{and} \quad rs < 2k,) \quad \text{or} \\
& \quad \frac{a}{b} = \frac{r_p m + 1 \pm sp_m}{r_q m + 1 \pm sq_m} \quad & (r \leq s \quad \text{and} \quad rs < k + \frac{r^2}{a_{m+2}}),
\end{align*}

\begin{align*}
(ii) \quad & \quad \frac{a}{b} = \frac{s_p m + 1 - 4p_m}{s_q m + 1 - 4q_m} \quad & (s \leq t \quad \text{and} \quad st < 2k,) \quad \text{or} \\
& \quad \frac{a}{b} = \frac{s_p m + 1 - 4p_m}{s_q m + 1 - 4q_m} \quad & (s \geq t \quad \text{and} \quad st \left(1 - \frac{4}{s^2}\right) < k),
\end{align*}

where \( r, s \) and \( t \) are positive integers.

Worley [12, Corollary, p.206] also gave the explicit version of his result for \( k = 2 \): \( |\alpha - \frac{a}{b}| < \frac{2}{b^2} \) implies \( \frac{a}{b} = \frac{p_m}{q_m}, \frac{p_{m+1} \pm p_m}{q_{m+1} \pm q_m}, \frac{2p_{m+1} \pm p_m}{2q_{m+1} \pm q_m}, \frac{p_{m+1} + 2p_m}{2q_{m+1} \pm 2q_m}, \frac{p_{m+1} + 3p_m}{3q_{m+1} \pm 3q_m} \). This result for \( k = 2 \) has been applied for solving some Diophantine equations. In [7], it was applied to the problem of finding positive integers \( a \) and \( b \) such that \((a^2 + b^2)/(ab + 1)\) is an integer, and in [2] it was used for solving the family of Thue inequalities

\[
|x^4 - 4cx^3y + (6c + 2)x^2y^2 + 4cxy^2 + y^4| \leq 6c + 4.
\]
On the other hand, Theorem 1.1 had applications in cryptography, too. Namely, in [1], a modification of Verheul and van Tilborg variant of Wiener’s attack ([10, 11]) on RSA cryptosystem with small secret exponent has been described, which is based on Theorem 1.1.

We will extend Worley’s work and give explicit and sharp versions of Theorems 1.1 and 1.2 for \( k = 3, 4, 5, \ldots, 12 \). We will list the pairs \((r, s)\) which appear in the expression of solutions of (2) in the form \((a, b) = (rp_{m+1} \pm sp_m, rq_{m+1} \pm sq_m)\), and we will show by explicit examples that all pairs from the list are indeed necessary. We hope that our results will also find applications on Diophantine problems, and in Section 4 we will present one such application. In such applications, it is especially of interest to have smallest possible list of pairs \((r, s)\). It is certainly possible to extend our result for \( k > 12 \), but even this short list of results is enough to observe certain patterns, and also results for \( k \leq 12 \) will suffice for our Diophantine applications.

2 Explicit versions of Worley’s theorem

We start by few details from the proof of Theorem 1.1 in [1], which will be useful in our future arguments. In particular, we will explain how the integer \( m \) appearing in the statement of Theorem 1.1 can be found. We assume that \( \alpha < \frac{a}{b} \), since the other case is completely analogous. Let \( m \) be the largest odd integer satisfying

\[
\alpha < \frac{a}{b} \leq \frac{p_m}{q_m}.
\]

If \( \frac{a}{b} > \frac{p_m}{q_m} \), we take \( m = -1 \), following the convention that \( p_{-1} = 1, q_{-1} = 0 \). Since \( |p_m q_m - p_{m+1} q_{m+1}| = 1 \), the numbers \( r \) and \( s \) defined by

\[
a = rp_{m+1} + sp_m, \\
b = rq_{m+1} + sq_m.
\]

are integers, and since \( \frac{p_{m+1}}{q_{m+1}} < \frac{a}{b} \leq \frac{p_m}{q_m} \), we have that \( r \geq 0 \) and \( s > 0 \). From the maximality of \( m \), we find that

\[
\frac{sa_{m+2} - r}{bq_{m+2}} = \left| \frac{p_{m+2}}{q_{m+2}} - \frac{a}{b} \right| < \left| \alpha - \frac{a}{b} \right| < \frac{k}{b^2}. \tag{3}
\]

From (3) we immediately have

\[
a_{m+2} > \frac{r}{s}, \tag{4}
\]
and we can derive the inequality

\[ r^2 - sra_{m+2} + ka_{m+2} > 0 \]  \hspace{1cm} (5)

(see [1, proof of Theorem 1] for details, and note also that (5) is exactly the inequality from Theorem 1.2(i) - the second case).

Let us define a positive integer \( t \) by

\[ t = sa_{m+2} - r. \]

Then we have

\[ a = rp_{m+1} + sp_m = sp_{m+2} - tp_{m+1}, \]
\[ b = rq_{m+1} + sq_m = sq_{m+2} - tq_{m+1}, \]

and \( s \) and \( t \) satisfy analogs of (4) and (5):

\[ a_{m+2} > \frac{t}{s}, \]
\[ t^2 - sta_{m+2} + ka_{m+2} > 0. \]  \hspace{1cm} (7)

If \( r > t \), i.e. \( rs > st \), then we will represent \( a \) and \( b \) in terms of \( s \) and \( t \) (which corresponds to \( - \) sign in Theorem 1.1).

Let us consider now the case \( k = 3 \). Hence, we are considering the inequality

\[ |\alpha - \frac{a}{b}| < \frac{3}{b^2}. \]  \hspace{1cm} (8)

By Theorem 1.1, we have that \((a, b) = (rp_{m+1} + sp_m, rq_{m+1} + sq_m)\) or \((sp_{m+2} - tp_{m+1}, sq_{m+2} - tq_{m+1})\), where \( rs < 6, st < 6 \), \( \gcd(r, s) = 1 \) and \( \gcd(s, t) = 1 \). However, the inequalities (5) and (7) for \( r = 1 \), resp. \( t = 1 \), show that the pairs \((r, s) = (1, 4), (1, 5)\) and \((s, t) = (4, 1), (5, 1)\) can be omitted. Therefore, we proved

**Proposition 2.1** If a real number \( \alpha \) and a rational number \( \frac{a}{b} \) satisfy the inequality (8), then

\[ \frac{a}{b} = \frac{rp_{m+1} + sp_m}{rq_{m+1} + sq_m}, \]

or

\[ \frac{a}{b} = \frac{sp_{m+2} - tp_{m+1}}{sq_{m+2} - tq_{m+1}}, \]

where

\( (r, s) \in R_3 = \{(0, 1), (1, 1), (1, 2), (1, 3), (2, 1), (3, 1), (4, 1), (5, 1)\} \),

or

\( (s, t) \in T_3 = \{(1, 1), (2, 1), (3, 1), (1, 2), (1, 3), (1, 4), (1, 5)\} \)

(for an integer \( m \geq -1 \)).
Our next aim is to show that Proposition 2.1 is sharp, i.e. that if we omit any of the pairs \((r, s)\) or \((s, t)\) appearing in Proposition 2.1, the statement of the proposition will no longer be valid. More precisely, if we omit a pair \((r', s')\) \(\in \mathbb{R}_3\), then there exist a real number \(\alpha\) and a rational number \(\frac{a}{b}\) satisfying (8), but such that \(\frac{a}{b}\) cannot be represented in the form \(\frac{a}{b} = \frac{r_{m+1} + sp_m}{s_{m+1} + sq_m}\) nor \(\frac{a}{b} = \frac{sp_{m+2} - tp_{m+1}}{sq_{m+2} - tq_{m+1}}\), where \(m \geq -1\), \((r, s) \in \mathbb{R}_3 \setminus \{(r', s')\}\), \((s, t) \in \mathbb{T}_3\) (and similarly for an omitted pair \((s', t') \in \mathbb{T}_3\)).

We will show that by giving explicit examples for each of pairs. Although we have found many such examples of different form, in the next table we give the results for numbers \(\alpha\) of the form \(\sqrt{d}\), where \(d\) is a non-square positive integer.

**Proposition 2.2** Let \(k \in \{4, 5, 6, 7, 8, 9, 10, 11, 12\}\). If a real number \(\alpha\) and a rational number \(\frac{a}{b}\) satisfy the inequality (2), then \(\frac{a}{b} = \frac{r_{m+1} + sp_m}{s_{m+1} + sq_m}\), where \((r, s) \in \mathbb{R}_k = \mathbb{R}_{k-1} \cup \mathbb{R}'_k\), or \(\frac{a}{b} = \frac{sp_{m+2} - tp_{m+1}}{sq_{m+2} - tq_{m+1}}\), where \((s, t) \in \mathbb{T}_k = \mathbb{T}_{k-1} \cup \mathbb{T}'_k\) (for an integer \(m \geq -1\)), where the sets \(\mathbb{R}'_k\) and \(\mathbb{T}'_k\) are given in the following table. Moreover, if any of the elements in sets \(\mathbb{R}_k\) or \(\mathbb{T}_k\) is omitted, the statement will no longer be valid.

</tbody>
</table>
Proof: By Theorem 1.1, we have to consider only pairs of nonnegative integers \((r, s)\) and \((s, t)\) satisfying \(rs < 2k, st < 2k, \gcd(r, s) = 1\) and \(\gcd(s, t) = 1\). Furthermore, as in the case \(k = 3\), it follows directly from the inequalities (5) and (7) for \(r = 1\), resp. \(t = 1\), that the pairs \((r, s) = (1, s)\) and \((s, t) = (s, 1)\) with \(s \geq k + 1\) can be omitted. Similarly, for \(r = 2\) or \(3\), resp. \(t = 2\) or \(3\), we can exclude the pairs \((r, s) = (2, s)\) and \((s, t) = (s, 2)\) with \(s \geq \frac{k}{2} + 2\), and the pairs \((r, s) = (3, s)\) and \((s, t) = (s, 3)\) with \(s \geq \frac{k}{3} + 3\).

Now we show that all remaining possible pairs which are not listed in the statement of Proposition 2.2 can be replaced with other pairs with smaller products \(rs\), resp. \(st\). We give details only for pairs \((r, s)\), since the proof for pairs \((s, t)\) is completely analogous (using the inequalities (6) and (7), instead of (4) and (5)).

Consider the case \(k = 4\) and \((r, s) = (2, 3)\). By (5), we obtain \(a_{m+2} < 2\). Thus, the pair \((r, s) = (2, 3)\) can appear only for \(a_{m+2} = 1\). However, in that case we have \(t = sa_{m+2} - r = 1\), and therefore the \((r, s) = (2, 3)\) can be replaced by the pair \((s, t) = (3, 1)\).

Analogously we can show that for \(k = 7\) the pair \((r, s) = (3, 4)\) can be replaced by \((s, t) = (4, 1)\), for \(k = 8, 9, 10\) the pair \((r, s) = (3, 5)\) can be replaced by \((s, t) = (5, 2)\), while for \(k = 11, 12\) the pair \((r, s) = (4, 5)\) can be replaced by \((s, t) = (5, 1)\).

We have only three remaining pairs to consider: the pair \((r, s) = (5, 3)\) for \(k = 8\) and the pairs \((r, s) = (5, 4)\) and \((r, s) = (7, 3)\) for \(k = 11\). For \((r, s) = (5, 3)\) and \(k = 8\), from (4) and (5) we obtain \(\frac{5}{2} < a_{m+2} < \frac{25}{7}\), and therefore we have two possibilities: \(a_{m+2} = 2\) or \(a_{m+2} = 3\). If \(a_{m+2} = 2\), we can replace \((r, s) = (5, 3)\) by \((s, t) = (3, 1)\), while if \(a_{m+2} = 3\), we can replace it by \((s, t) = (3, 4)\). Similar approach works for two pairs with \(k = 11\). For \((r, s) = (5, 4)\), from (4) and (5) we obtain \(\frac{5}{4} < a_{m+2} < \frac{25}{9}\), which implies \(a_{m+2} = 2\). Then we have \(t = 3\) and the pair \((r, s) = (5, 4)\) can be replaced by the pair \((s, t) = (4, 3)\). For \((r, s) = (7, 3)\) we obtain \(\frac{7}{2} < a_{m+2} < \frac{49}{10}\), which yields \(a_{m+2} = 3\) or \(a_{m+2} = 4\). If \(a_{m+2} = 3\), we can replace \((r, s) = (7, 3)\) by \((s, t) = (3, 2)\), while if \(a_{m+2} = 4\), we can replace it by \((s, t) = (3, 5)\).

It remains to show that all pairs listed in the statement of the proposition are indeed necessary (they cannot be omitted). This is shown by the examples from the following tables:
### 3 Cases $r = 1, s = 1$ and $t = 1$

The results from the previous section suggest that there are some patterns in pairs $(r, s)$ and $(s, t)$ which appear in representations $(a, b) = (rp_{m+1} + sp_m, rq_{m+1} + sq_m)$ and $(a, b) = (sp_{m+2} - tp_{m+1}, sq_{m+2} - tq_{m+1})$ of solutions of inequality (2). In particular, these patterns are easy to recognize for pairs of the form $(r, s) = (r, 1)$ or $(1, s)$, and $(s, t) = (s, 1)$ or $(1, t)$. In this section we will prove that the results on these pairs, already proved for $k \leq 12$, are valid in general case. This fact will allow us to show that the inequality $rs < 2k$ in Theorem 1.1 is sharp.

We will assume that $k$ is a positive integer. From Theorem 1.1 it directly follows that among the pairs the form $(r, 1)$, only pairs where $r \leq 2k - 1$ can appear. Similarly, for pairs $(1, t)$ we have $t \leq 2k - 1$. On the other hand, from (5) and (7) it follows that for pairs $(1, s)$ we have $s \leq k$, and for pairs $(s, 1)$ we have $s \leq k$. These results follow also from Theorem 1.2. We
will show that all these pairs that do not contradict Theorem 1.2 can indeed appear.

Let \( \alpha_m = [a_m; a_{m+1}, a_{m+2}, \ldots] \) and \( \frac{1}{\beta_m} = \frac{q_{m-1}}{q_{m-2}} = [a_{m-1}, a_{m-2}, \ldots, a_1] \), with the convention that \( \beta_1 = 0 \). Then for \( \frac{a}{b} = \frac{rp_{m+1} + sp_m}{rq_{m+1} + sq_m} \), we have

\[
\begin{align*}
\left| \alpha - \frac{a}{b} \right| &= b \left| \frac{rq_{m+1} + sq_m}{\alpha_m + 2\beta_m + \beta_m} - \frac{rp_{m+1} + sp_m}{\alpha_m + 2\beta_m + \beta_m} \right| \\
&= \frac{|s\alpha_m + \beta_m - r(r_{m+1} + sp_m)|}{\alpha_m + 2\beta_m + \beta_m} = \frac{|s\alpha_m + \beta_m - (r_{m+1} + sp_m)|}{\alpha_m + 2\beta_m + \beta_m}, \quad (9)
\end{align*}
\]

We start with the pairs of the form \( (r, 1) \). Let us consider the number \( \alpha = \sqrt{4k^2 + 1} \). Its continued fraction expansion has the form

\[ \sqrt{4k^2 + 1} = [2k; 4k] \]

(see e.g. [8, p.297]). Take first \( m = -1 \), i.e. consider the rational number \( \frac{a}{b} \) defined by

\[
\frac{a}{b} = \frac{r \cdot p_0 + 1 \cdot p_{-1}}{r \cdot q_0 + 1 \cdot q_{-1}} = \frac{2rk + 1}{r} = 2k + \frac{1}{r}.
\]

Hence, \( a = 2rk + 1 \) and \( b = r \). We claim that for \( r \leq 2k - 1 \) it holds \( |\alpha - \frac{a}{b}| < \frac{k}{2}\sqrt{k} \). By (9), this is equivalent to \( \left( 1 - \frac{r}{\beta_m} \right) r \leq k \). For \( m \geq 1 \) we have \( \alpha_m = [4k, 4k, \ldots] > 4k + \frac{r}{4k} \). Thus, it suffices to check that \( 4kr^2 - (16k^2 + 1)r + 16k^3 + k > 0 \), what is clearly satisfied for \( r \leq 2k - 1 \).

More precisely, this is satisfied for \( r \) less than \( \frac{16k^2 + 1 - \sqrt{16k^2 + 1}}{8k} \geq 2k - \frac{3}{4} \).

We can proceed similarly for \( m \geq 0 \). Only difference is that \( k < \frac{1}{\beta_m} = [4k, \ldots, 4k] < 4k + \frac{1}{4k} \). Hence, by (9), we obtain that it suffices to check that for \( r \leq 2k - 1 \) it holds

\[
\left( 4k + \frac{1}{4k} - r \right) r + \frac{1}{4k} \left( 4k + \frac{1}{4k} \right) < k.
\]

But this condition is equivalent to \( (256k^4 + 16k^2)r^2 - (1024k^5 + 64k^3)r + (1024k^6 - 64k^4 - 32k^2 - 1) > 0 \), which holds for \( r \) less that \( 2k - \frac{3}{4} \), so in certainly holds for \( r \leq 2k - 1 \).

The same example \( \alpha = \sqrt{4k^2 + 1} \) can be used to handle the pairs \( (s, t) = (1, t) \). The relation (9) can be reformulated in terms of \( s \) and \( t = sa_{m+2} - r \):

\[
\left| \alpha - \frac{a}{b} \right| = \left| t + \frac{s}{\alpha_{m+3}} \right| s - \frac{t}{\alpha_{m+2} + \beta_{m+2}}. \quad (10)
\]

Now, for \( m = -1 \) we are considering the rational number

\[
\frac{a}{b} = \frac{s \cdot p_1 - t \cdot p_0}{s \cdot q_1 - t \cdot q_0} = \frac{8k^2 + 1 - 2tk}{4k - t} = 2k + \frac{1}{4k - t}.
\]
By (10), the condition $|\alpha - \frac{a}{b}| < \frac{k}{b^2}$ leads to $16k^2t^2 - 64k^3t + 64k^4 - 12k^2 - 1 > 0$. Similarly, for $m \geq 0$, we obtain the condition $8k^2t^2 - (32k^3 + 2k)t + 32k^4 - 4k^2 - 1 > 0$. It is easy to see that both conditions are satisfied for $t \leq 2k - 1$.

For pairs of the form $(1, s)$ and $(s, 1)$ we use $\alpha$ of the form $\alpha = \sqrt{x^2 - 1}$, where an integer $x$ will be specify latter (if necessary). For $x \geq 2$, we have the following continued fraction expansion

$$\sqrt{x^2 - 1} = [x - 1; 1, 2x - 2]$$

(see e.g. [8, p.297]). Let us consider the pairs of the form $(r, s) = (1, s)$. We take $m = -1$ and define the rational number

$$\frac{a}{b} = \frac{1 \cdot p_0 + s \cdot p_{-1}}{1 \cdot q_0 + s \cdot q_{-1}} = \frac{x - 1 + s}{1}.$$

Hence, $a = x - 1 + s$ and $b = 1$, and for $s \leq k$ it holds

$$|\alpha - \frac{a}{b}| < (x - 1 + s) - (x - 1) = s \leq \frac{k}{2}.$$

The same result for pairs $(r, s) = (1, k)$ holds also if $m \geq 1$ is odd and if $x$ is sufficiently large. Indeed, from (9) we obtain the condition

$$\left( k \left( 1 + \frac{1}{2x - 2} \right) - 1 \right) \left( \frac{1 + \frac{k}{2 - 2}}{1 + \frac{2}{2x - 1}} \right) < k,$$

which is satisfied for $x \geq \frac{k^2 - 2k + 5}{2}.$

Finally, consider the pairs of the form $(s, t) = (s, 1)$ for $s \leq k$. Take $m = -1$ and define the rational number

$$\frac{a}{b} = \frac{s \cdot p_1 - 1 \cdot p_0}{s \cdot q_1 - 1 \cdot q_0} = \frac{sx - x + 1}{s - 1} = x + \frac{1}{s - 1}.$$

Hence, $a = sx - x + 1$ and $b = s - 1$. We have $\sqrt{x^2 - 1} > \frac{p_2}{q_2} = x - \frac{1}{2x - 1}$.

Thus,

$$|\alpha - \frac{a}{b}| < \frac{1}{s - 1} + \frac{1}{2x - 1},$$

and we obtain the condition

$$\frac{1}{s - 1} + \frac{1}{2x - 1} < \frac{k}{(s - 1)^2}.$$  \hspace{1cm} (11)
If we choose $x$ to be greater than $\frac{k^2-2k+2}{2}$, then we have $\frac{1}{x-1} < \frac{1}{(k-1)^2}$, while for $s \leq k$ it hold $\frac{k}{(s-1)^2} - \frac{1}{s-1} \geq \frac{k}{(k-1)^2} - \frac{1}{k-1} = \frac{1}{(k-1)^2}$, and we showed that for such $x$'s the condition (11) is fulfilled.

Again, the analogous result for pairs $(s, t) = (k, 1)$ holds for all odd $m \geq 1$, but $x$ has to be larger than in the case $m = -1$. Namely, the relation (10) yields the condition

\[
\left(1 + \frac{k}{2x-1}\right) \left(k - \frac{1}{1 + \frac{2}{2x-2}}\right) < k,
\]

which is satisfied for $x \geq \frac{k^2-k+4}{2}$.

Our results for the pairs $(r, s) = (2k-1, 1)$ and $(s, t) = (1, 2k-1)$ (with $\alpha = \sqrt{4k^2+1}$) immediately imply the following result which shows that Theorem 1.1 is sharp.

**Proposition 3.1** For each $\varepsilon > 0$ there exist a positive integer $k$, a real number $\alpha$ and a rational number $a/b$, such that

\[
|\alpha - \frac{a}{b}| < \frac{k}{b^2},
\]

and $a/b$ cannot be represented in the form $\frac{a}{b} = \frac{pm+1}{qm+1} \pm \frac{spm}{sqm}$, for $m \geq -1$ and nonnegative integers $r$ and $s$ such that $rs < (2-\varepsilon)k$.

**Proof:** Take $k > \frac{1}{\varepsilon}$, $\alpha = \sqrt{4k^2+1}$ and e.g. $\frac{a}{b} = \frac{2k(2k-1)+1}{2k^2-1}$. Then $|\alpha - \frac{a}{b}| < \frac{k}{b^2}$. If $m = -1$, then $r = 2k-1$, $s = 1$, $t = 2k+1$, and thus $rs = 2k-1 > 2k - k\varepsilon = (2-\varepsilon)k$, while $st = 2k+1$. If $m \geq 0$, then from $s = -bp_{m+1} + aq_{m+1}$ it follows that $|s| \geq \left|\frac{a}{b} - \frac{pa}{qa}\right| = 2k+1$, and therefore $|rs| \geq 2k+1$ and $|st| \geq 2k+1$.  

\[\blacksquare\]

### 4 A Diophantine application

In [2], Dujella and Jadrijević considered the Thue inequality

\[
|x^4 - 4cx^3y + (6c+2)x^2y^2 + 4cxy^3 + y^4| \leq 6c + 4,
\]

where $c \geq 5$ is an integer (cases $c = 3$ and $c = 4$ require somewhat different details, and we will omit them in this section). Using the method of Tzanakis
On Worley’s theorem in Diophantine approximations

[9], they showed that solving the Thue equation $x^4 - 4cx^3y + (6c + 2)x^2y^2 + 4cxy^3 + y^4 = \mu$, $\mu \in \mathbb{Z}\setminus\{0\}$, reduces to solving the system of Pellian equations

\[
\begin{align*}
(2c + 1)U^2 - 2cV^2 &= \mu \quad (12) \\
(c - 2)U^2 - cZ^2 &= -2\mu, \quad (13)
\end{align*}
\]

where $U = x^2 + y^2$, $V = x^2 + xy - y^2$ and $Z = -x^2 + 4xy + y^2$. Assuming that $x$ and $y$ are relatively prime, we have that $U$, $V$, $Z$ are relatively prime. Since $4V^2 + Z^2 = 5U^2$, we see that $\gcd(U, V) = 1$, while $\gcd(U, Z) = 1$ or 2. It is clear that the solutions of the system (12) and (13) induce good rational approximations of the corresponding quadratic irrationals. More precisely, from [2, Lemma 4] we have the inequalities given in the following lemma.

**Lemma 4.1** Let $c \geq 5$ be an integer. All positive integer solutions $(U, V, Z)$ of the system of Pellian equations (12) and (13) satisfy

\[
\begin{align*}
\left|\sqrt{2c + 1} - \frac{V}{2cU}\right| &< \frac{2}{U^2} \quad (14) \\
\left|\sqrt{c - 2} - \frac{Z}{cU}\right| &< \frac{6c + 4}{U^2\sqrt{c(c - 2)}} < \frac{9}{U^2}. \quad (15)
\end{align*}
\]

Using the result of Worley [12, Corollary, p. 206], in [2, Proposition 2] the authors proved that if $\mu$ is an integer such that $|\mu| \leq 6c + 4$ and that the equation (12) has a solution in relatively prime integers $U$ and $V$, then

$$\mu \in \{1, -2c, 2c + 1, -6c + 1, 6c + 4\}.$$ 

Analysing the system (12) and (13), and using the properties of convergents of $\sqrt{\frac{2c + 1}{2c}}$, they were able to show that the system has no solutions for $\mu = -2c, 2c + 1, -6c + 1$. Applying results from the previous sections to the equation (13), we will present here a new proof of that result, based on the precise information on $\mu$’s for which (13) has a solution in integers $U$ and $Z$ such that $\gcd(U, Z) \in \{1, 2\}$.

The simple continued fraction expansion of a quadratic irrational $\alpha = \sqrt{d}$ is periodic. This expansion can be obtained using the following algorithm. Multiplying the numerator and the denominator by $f$, if necessary, we may assume that $f|d - e^2$. Let $s_0 = e$, $t_0 = f$ and

\[
a_n = \left\lfloor \frac{s_n + \sqrt{d}}{t_n} \right\rfloor, \quad s_{n+1} = a_nt_n - s_n, \quad t_{n+1} = \frac{d - s_{n+1}^2}{t_n} \quad \text{for } n \geq 0 \quad (16)
\]
(see [6, Chapter 7.7]). If \((s_j, t_j) = (s_k, t_k)\) for \(j < k\), then
\[
\alpha = [a_0; \ldots, a_{j-1}, a_j, \ldots, a_{k-1}].
\]

Applying this algorithm to \(\sqrt{\frac{c-2}{c}} = \sqrt{\frac{c(c-2)}{c^2}}\), we find that
\[
\sqrt{\frac{c-2}{c}} = [0; 1, \ldots, c-2, 2].
\]

According to our results (Proposition 2.2 for \(k = 9\)), applied to \(\alpha = \sqrt{\frac{c-2}{c}}\), all solutions of \((13)\) have the form
\[
\frac{Z}{U} = \frac{rp_{m+1} + sp_m}{rq_{m+1} + sq_m}
\]
an index \(m \geq -1\) and integers \(r\) and \(s\). For the determination of the corresponding \(\mu\)'s, we use the following result (see [2, Lemma 1]):

**Lemma 4.2** Let \(\alpha \beta\) be a positive integer which is not a perfect square, and let \(p_m/q_m\) denotes the \(m\)th convergent of continued fraction expansion of \(\sqrt{\frac{\alpha}{\beta}}\). Let the sequences \((s_m)\) and \((t_m)\) be defined by \((16)\) for the quadratic irrational \(\sqrt{\frac{\alpha}{\beta}}\). Then
\[
\alpha (rq_{m+1} + sq_m)^2 - \beta (rp_{m+1} + sp_m)^2 = (-1)^m (s^2 t_{m+1} + 2rs s_{m+2} - r^2 t_{m+2}).
\]

Since the period of continued fraction expansion of \(\sqrt{\frac{c-2}{c}}\) is equal to 2, according to Lemma 4.2, we have to consider only the fractions \((rp_{m+1} + sp_m)/(rq_{m+1} + sq_m)\) for \(m = 1\) and \(m = 2\). By checking all possibilities, we obtain the following result.

**Proposition 4.3** Let \(\mu\) be an integer such that \(|\mu| \leq 6c + 4\) and that the equation
\[
(c-2)U^2 - cZ^2 = -2\mu
\]
has a solution in integers \(U\) and \(Z\) such that \(\gcd(U, Z) = 1\) or 2.

(i) If \(c \geq 15\) is odd, then
\[
\mu \in M_1 = \{1, 4, 2c, 4c + 1, 6c + 4, -2c + 4, -4c + 9, -6c + 16\}.
\]

Furthermore, if \(c = 5, 11, 13\), then \(\mu \in M_1 \cup \{-8c + 25\}\); if \(c = 9\), then \(\mu \in M_1 \cup \{-8c + 25, -10c + 36\}\); if \(c = 7\), then \(\mu \in M_1 \cup \{-8c + 25, -10c + 36, -12c + 49\}\).
(ii) Let $M = M_1 \cup M_2$, where
\[
M_2 = \left\{ -\frac{11}{2}c + 36, -\frac{9}{2}c + 25, -\frac{7}{2}c + 16, -\frac{5}{2}c + 9, -\frac{3}{2}c + 4, -\frac{1}{2}c + 1, \\
\frac{1}{2}c, \frac{3}{2}c + 1, \frac{5}{2}c + 4, \frac{7}{2}c + 9 \right\}.
\]
If $c \geq 108$ is even, then $\mu \in M \cup \{\frac{9}{2}c + 16, \frac{11}{2}c + 25\}$.

For even number $6 \leq c \leq 106$, we have $\mu \in M \cup M^{(c)}$, where $M^{(c)}$ can be given explicitly, as in the case (i). E.g.
\[
M^{(6)} = \left\{ -\frac{21}{2}c + 25, -10c + 36, -8c + 25, -\frac{15}{2}c + 16 \right\}.
\]

Comparing the set $\{1, -2c, 2c+1, -6c+1, 6c+4\}$ from [2, Proposition 2] with the sets appearing in Proposition 4.3, we obtain the desired conclusion.

**Corollary 4.4** Let $c \geq 5$ be an integer. If the system (12) and (13) has a solution with $|\mu| \leq 6c + 4$ in relatively prime integers $U$, $V$ and $Z$, then $\mu = 1$ or $\mu = 6c + 4$.
