# The Role of Infrared Thermography in Nondestructive Testing of Concrete Structures

Bojan Milovanović, PhD candidate

Faculty of Civil Engineering,  
University of Zagreb

Zagreb SPIN Meeting, 7-12 May, 2012

# Introduction

---

- Infrared thermography
  - one of the non-destructive thermal methods which is becoming ever more popular in non-destructive testing of materials and structures
  - completely noncontact and may be faster than many other techniques that are being used.

# Introduction

---

- In Civil Engineering, the application of infrared thermography is **not limited to passive investigations of the quality of thermal insulation of building envelopes.**

# Introduction

---

- Defects like voids in concrete or masonry, delaminations at interfaces of composites can be localized and characterized
  - different **heat capacity** and/or **heat conductivity** in comparison to the bulk material.

# IR thermography in civil engineering structures

---

- Examples are inspections of bridge decks and of paving in general.
  - **ASTM standard** “Standard Test Method for Detecting Delaminations in Bridge Decks Using Infrared Thermography”

# ASTM D 4788-03

---

- Method intended for **use on exposed and overlaid concrete bridge decks**, asphalt or concrete overlays as thick as 100 mm
- The standard has **no Precision and Bias statement** and *should not be used for acceptance or rejection of a material* because comparative data is not available.
- Deck should be **dry, minimum of 24h** prior to the test
- The **temperature difference must be at least 0.5 °C** between the delaminated or deboned area and solid concrete.

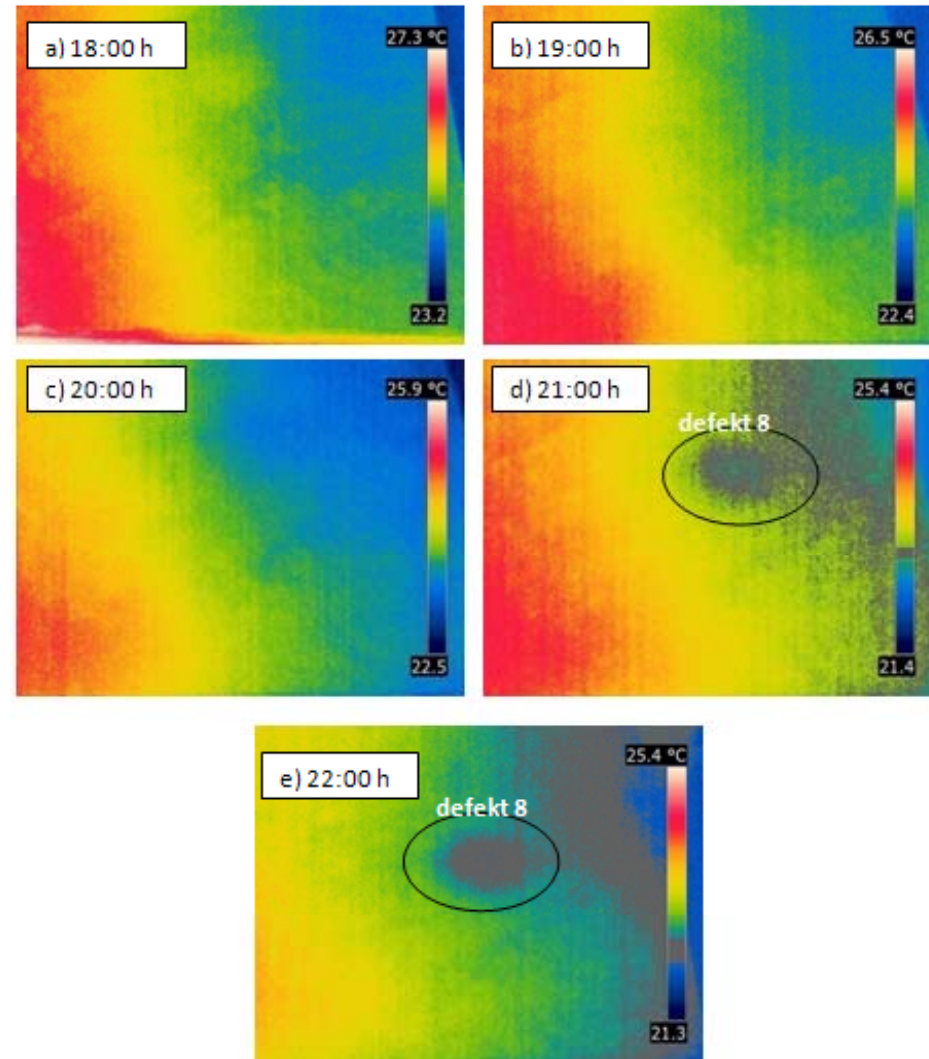

# Location of voids in concrete

- To investigate the detectability of voids in concrete, two concrete test specimens were built, having a size of 1.8 x 2.0 x 0.25 m.
- Before concreting, voids, simulated by polystyrene cuboids with different sizes were positioned by polyamide threads in the wooden formwork.

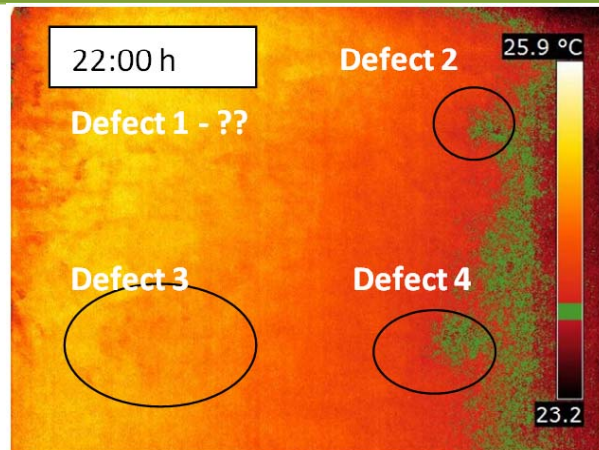

# Location of voids in concrete

- Thermal imaging performed according to ASTM D 4788-03 in the summer period, **between the 18.00 and 22.00 hours** with the periodic imaging every hour.
- During the day both specimens were **exposed to direct insolation** while the shades moved over the specimens when the sun was setting.
- The day was sunny, and there was no rain for at least a week before the thermal imaging.

# Location of voids in concrete

*Thermogram of specimen 1, defects 1 to 4, at 22.00 hours*

*Thermogram of specimen 1, defect 5, at 22.00 hours*

*Thermogram of specimen 2, defect 11, at 22.00 hours*

*Thermogram of specimen 2, defect 13, at 22.00 hours*

# Location of voids in concrete

- It can be seen that the small voids (Defect No. 1 to 4) are **not visible** or just barely visible.
- Defects which are covered by 3 - 4.5 cm of concrete as well as the shallow larger voids (Defects No. 5, 11 and 13) are **visible with maximum contrast** at the end of thermal imaging process, 3 hours after the time shade has covered the sample and 2 hours after the sunset.

# ASTM D 4788-03 - problems identified

---

- Relatively **low thermal conductivities** of materials and **large dimensions** of civil engineering structures contribute to difficulties in achieving **homogenous cooling** of the monitored surface.
- By using the **passive thermography**, defects in the construction elements that are not exposed to direct sunlight **cannot be located**.

# ASTM D 4788-03 - problems identified

---

- Engineers seek to determine **whether voids and delaminations in such reinforced concrete elements can be detected** through the use of **active infrared thermography**.
- Also, by using active thermography techniques, quantitative measurements of defect depth and dimensions can be conducted

# Pulsed thermography - PT

---

- Basically, PT consists of heating the specimen briefly and then recording the temperature decay curve.
- Thermal stimulation method
  - a short thermal stimulation pulse lasting from a few milliseconds for high-conductivity material, such as metal, to a few seconds for low conductivity specimens, such as plastics, is used.

# Lock-in thermography

- Based on thermal waves generated inside a specimen and detected remotely.
- Wave generation is performed by **periodic deposition of heat on a specimen's surface** while the resulting **oscillating temperature field** in the stationary regime **is recorded** remotely through thermal infrared emission

# Defect detection

- The **temperature profile** for a non-defective area **decays** approximately as the **square root of time**
- Thermal effusivity  $e$ , is greater for sound material than for air - **sound material acts better than air as thermal sink.**
- once the thermal front has reached the defective area (air), surface temperature **will be higher above the defective zone than above the sound area**, from this moment to a given stabilization time.

# Defect detection

---

- Several data processing algorithms have been developed for defect characterization:
  - determination of the size,
  - depth and thermal resistance of a defect
- Most of these techniques use **thermal contrast calculations**.

# Defect detection

---

- The basic definition of thermal contrast is the *Absolute Thermal Contrast*, which measures the difference between defective and non-defective regions :

$$\Delta T = T_d - T_{Sa}$$

- Thermal contrast based analysis provide
  - a good indication of defect characteristics (qualitative and quantitative) *when working with relatively shallow defect in homogeneous materials*

# Non-uniform surface heating

- Given that defect detection principle is based on temperature differences, **non-uniform heating may produce confusion**, especially for defect quantification.

# Conclusions

---

- Infrared thermography, due to its **non-contact character** that allows for **quick 2D surface mapping**, represents a powerful tool for non-destructive evaluation (NDE) of materials and structures.
- Infrared thermography is still **not completely exploited**.

# Conclusions

---

- Passive infrared thermography **strongly depends on weather conditions**
- The most important result from presented research is that
  - *simulated defects can be detected by using passive infrared thermography under certain conditions and only few of the existing defects are visible*

# Conclusions

---

- By using active infrared thermography and appropriate post processing techniques, **detection of near-surface inhomogeneities and common subsurface defects in typical structural elements is possible.**

**Spearhead Network for Innovative, Clean and  
Safe Cement and Concrete Technologies**

# Thank You for Your kind attention!
