

# **High temperature optical spectra of diatomic molecules: quantum-mechanical, semiquantum and semiclassical approach**

**Robert M. Beuc, Berislav Horvatić and Mladen Movre**

INSTITUTE OF PHYSICS

**Zagreb, Croatia**

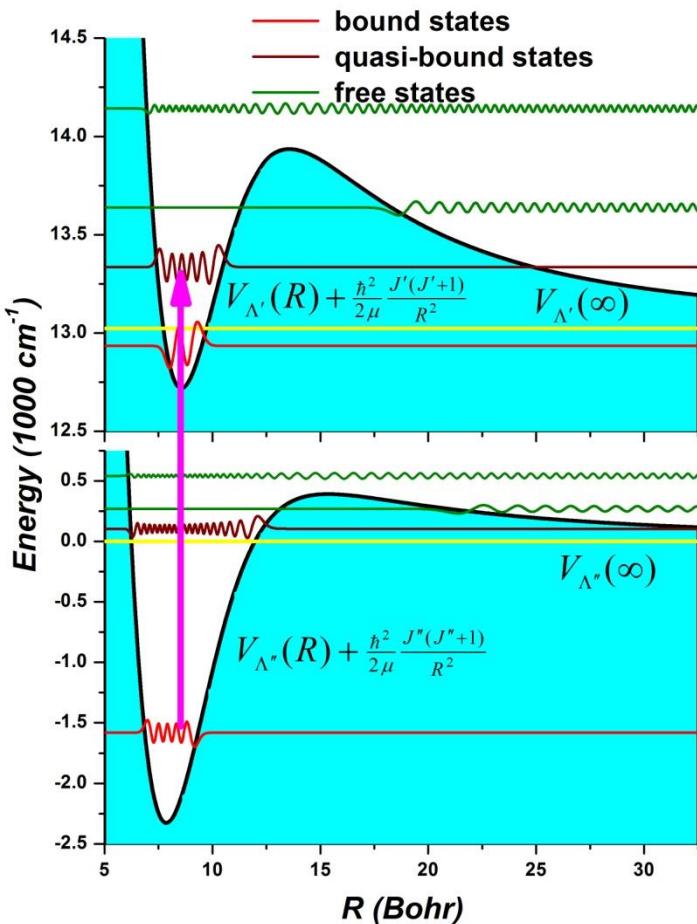

# Outline

- Reduced absorption coefficient of a dimer
- Quantum calculation on the Fourier grid
  - Sodium resonance 3s-3p line pressure broadened by helium atoms
- Semiclassical approximation
- Semiquantum approximation
  - Absorption spectra of potassium molecule
  - Cesium emission and absorption spectra
- Hybrid approximation
  - Absorption spectra of rubidium molecule

# Reduced absorption coefficient of a dimer

According to the Beer-Lambert law, in terms of binary collisions, the transmittance  $\tau(\nu, T)$  of a uniform atomic gas layer with a number density of atoms  $n$  and length  $L$  is  $\tau(\nu, T) = \exp(-n^2 k(\nu, T)L)$  where  $k(\nu, T)$  is the reduced absorption coefficient of atomic dimer,  $\nu$  is frequency of absorbed photon and  $T$  is temperature.

$$k(\nu, T) = \sum_{i,j} k_{\Lambda_i'', \Lambda_j'}(\nu, T)$$

$\Lambda''$  and  $\Lambda'$  label the lower and the upper electronic state.  $V_\Lambda(R)$  is the *interaction* potential

**Bound (quasi-bound) states:** energy  $E_{v,J,\Lambda}$ , unity-normalized wave function  $\Phi_{v,J,\Lambda}$ ,  $v$  vibrational and  $J$  rotational quantum number

**Free states:** asymptotic kinetic energy  $\varepsilon$ , energy-normalized wave functions  $\Psi_{\varepsilon,J,\Lambda}$

$$\left( -\frac{\hbar^2}{2\mu} \frac{d^2}{dR^2} + V_\Lambda(R) + \frac{\hbar^2}{2\mu} \frac{J(J+1)-\Lambda^2}{R^2} \right) \Phi(R) = E \Phi(R)$$

$$k_{\Lambda'', \Lambda'}(\nu, T) \propto \sum_{\text{transition}} \begin{bmatrix} v''(\varepsilon'') \rightarrow v'(\varepsilon') \\ J'' \rightarrow J' = J'', J'' \pm 1 \end{bmatrix}$$

Neglecting the differences between *even* and *odd J*, assuming the applicability of the *Q*-branch approximation  $\Delta J=0$ , the thermally averaged absorption coefficient [H.-K. Chung, K. Kirby, J.F. Babb, Phys. Rev. A, 1999, 2001]:

$$k_{\Lambda'',\Lambda'}(\nu, T) = k_{bb}(\nu, T) + k_{bf}(\nu, T) + k_{fb}(\nu, T) + k_{ff}(\nu, T)$$

**bound (quasi-bound) - bound (quasi-bound) transitions:**  $h\nu_{tr} = E_{v',J,\Lambda'} - E_{v'',J,\Lambda''}$

$$k_{bb}(\nu, T) = w_{\Lambda'',\Lambda'} \frac{8\pi^3 \nu}{3hc} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{3/2} \sum_J (2J+1) \sum_{v'',v'} \left| \langle \Phi_{v''J\Lambda''} | D(R) | \Phi_{v'J\Lambda'} \rangle \right|^2 \exp(-\frac{E_{v''J\Lambda''}}{k_B T}) g(h\nu - h\nu_{tr})$$

**bound (quasi-bound) -free transition:**  $\varepsilon' = E_{v'',J,\Lambda''} + h\nu$

$$k_{bf}(\nu, T) = w_{\Lambda'',\Lambda'} \frac{8\pi^3 \nu}{3hc} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{3/2} \sum_J (2J+1) \sum_{v''} \left| \langle \Phi_{v''J\Lambda''} | D(R) | \Psi_{\varepsilon'J\Lambda'} \rangle \right|^2 \exp(-\frac{E_{v''J\Lambda''}}{k_B T})$$

**free - bound (quasi-bound) transitions:**  $\varepsilon'' = E_{v',J,\Lambda'} - h\nu$

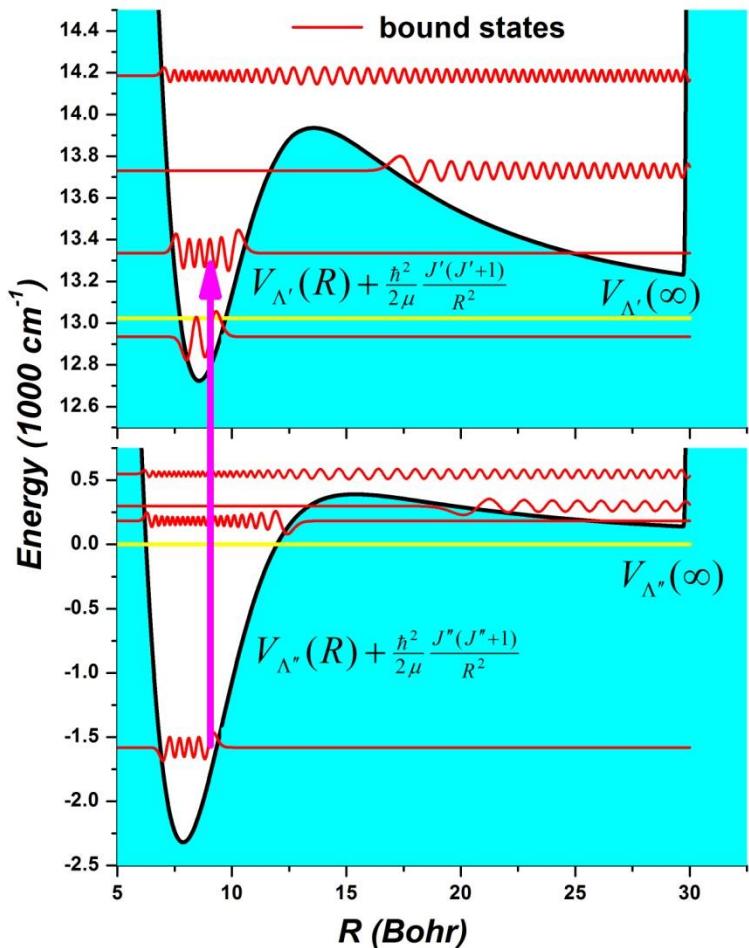

$$k_{fb}(\nu, T) = w_{\Lambda'',\Lambda'} \frac{8\pi^3 \nu}{3hc} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{3/2} \sum_J (2J+1) \sum_{v'} \left| \langle \Psi_{\varepsilon''J\Lambda''} | D(R) | \Phi_{v'J\Lambda'} \rangle \right|^2 \exp(-\frac{\varepsilon''}{k_B T})$$

**free-free transitions:**  $\varepsilon' = \varepsilon'' + h\nu$

$$k_{ff}(\nu, T) = w_{\Lambda'',\Lambda'} \frac{8\pi^3 \nu}{3hc} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{3/2} \sum_J (2J+1) \int_{D_e}^{\infty} d\varepsilon'' \left| \langle \Psi_{\varepsilon''J\Lambda''} | D(R) | \Psi_{\varepsilon'J\Lambda'} \rangle \right|^2 \exp(-\frac{\varepsilon''}{k_B T})$$

$D(R)$  is electronic transition dipole moment,  $w$  is statistical factor dependent on the symmetry of electronic states,  $\mu$  is molecular reduced mass,  $g$  line profile.

# Quantum calculation on the Fourier grid (QC)

The FGR method can be considered as a special case of Discrete Variable Representation where functions are represented on finite number of grid points  $R_i$  ( $i=1\dots N$ ). We used a grid of uniformly spaced points,  $R_{j+1} - R_j = \Delta R$ , [D.T. Colbert, W.H. Miller, J. Chem. Phys. 1992]. Energies and wave functions can be determined by diagonalization of  $N \times N$  Hamiltonian matrix  $H = T + P$ :

$$T_{i,j} = \frac{\hbar^2}{2\mu\Delta R^2} \begin{cases} \frac{\pi^2}{3} - \frac{1}{2i^2} & i = j \\ (-1)^{i-j} \frac{8ij}{(i^2 - j^2)^2} & i \neq j \end{cases}$$

$$V_{i,j} = \left[ V_{\Lambda}(R_i) + \frac{\hbar^2}{2\mu} \frac{J(J+1)-\Lambda^2}{R_i^2} \right] \delta_{i,j}$$

The method yields only a discrete set of continuum energies, but in the range spanned by the grid the corresponding unity-normalized wave functions do represent the states of a true continuum.

Solving the relevant radial Schrödinger equation on the grid one obtains a set of discrete energies effectively describing a *confined* molecule, “a molecule in a box”, and the entire spectrum is of the bound–bound type.

$$k(v, T) = w \frac{8\pi^3 v}{3hc} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{3/2} \sum_{J=0}^{J_{\max}} (2J+1) \sum_{v'', v'} \left| \langle \Phi_{v'', J, \Lambda''} | D(R) | \Phi_{v', J, \Lambda'} \rangle \right|^2 \exp(-\frac{E_{v'', J, \Lambda''}}{k_B T}) g(hv - hv_{tr})$$

The matrix elements of the transition dipole moment  $D(R)$  are computed as:

$$\langle \Phi_{v'', J, \Lambda''} | D(R) | \Phi_{v', J, \Lambda'} \rangle = \sum_{i=1}^{N_p} \Phi_{v'', J'', \Lambda''}^*(R_i) D(R_i) \Phi_{v', J', \Lambda'}(R_i)$$

The parameters of the grid are estimated in the following way:

$\Delta R = \frac{2\pi\hbar}{n_B \sqrt{2\mu\varepsilon_{kin}}}$   $n_B$  is the number of grid points per de Broglie wavelength at maximal expected kinetic energy  $\varepsilon_{kin}$ .

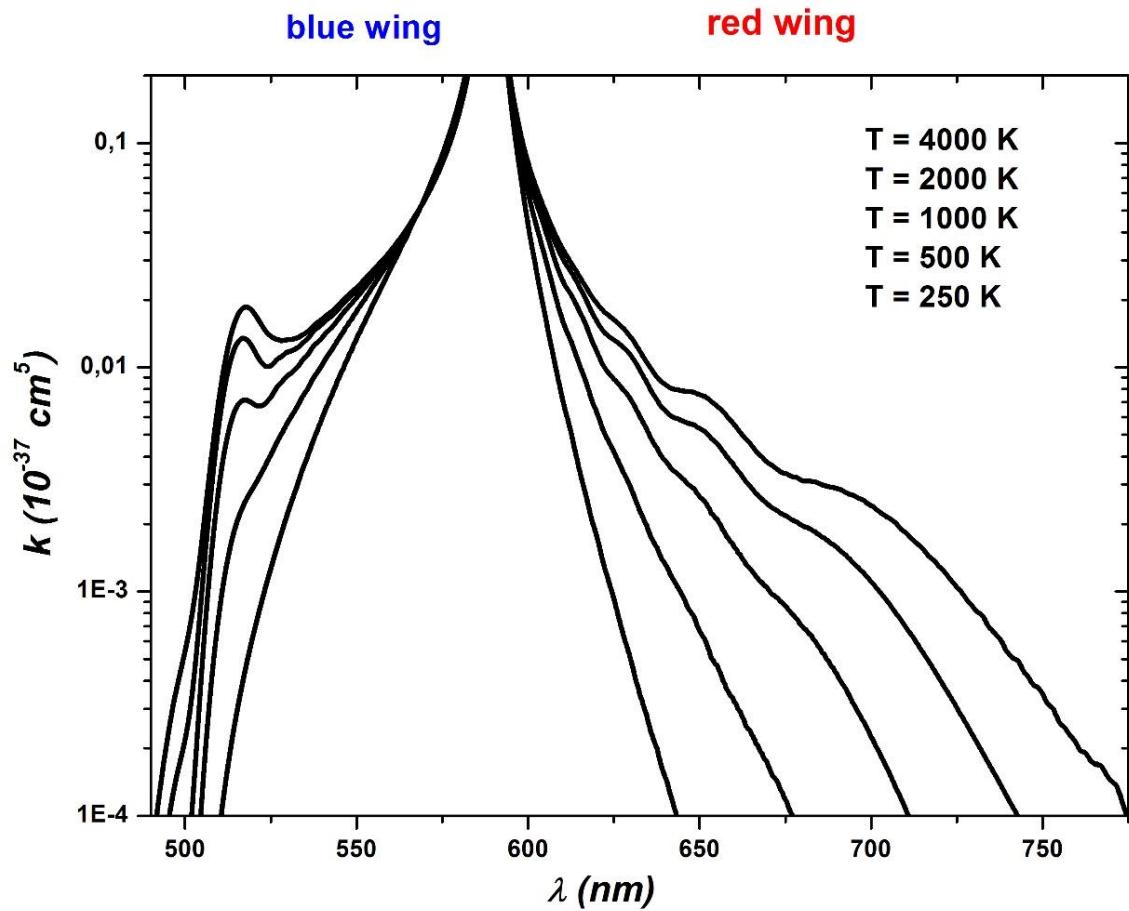

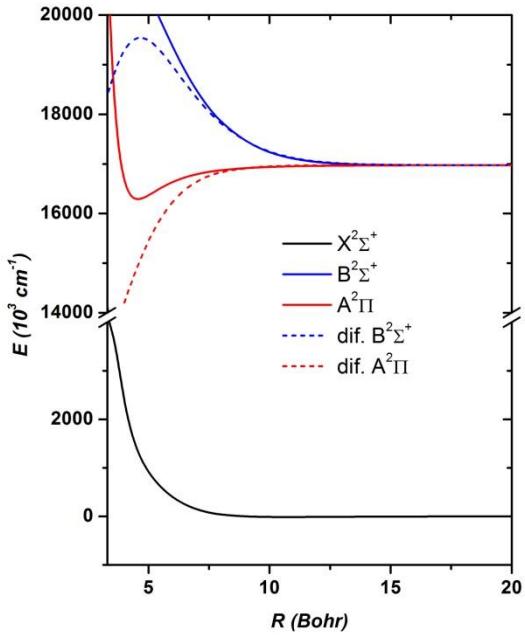

$R_N$  was chosen in order to get closer to the atomic line centre.

$$J_{\max} \approx \frac{R_N}{\hbar} \sqrt{2\mu k_B T}$$

Line profile  $g$  can be approximated with a normalized rectangular instrumental profile:  $1/\Delta(h\nu)$

Fully quantum-mechanical procedure based on the Fourier grid Hamiltonian method, is numerically robust but time consuming.

# Sodium resonance 3s-3p line pressure broadened by helium atoms

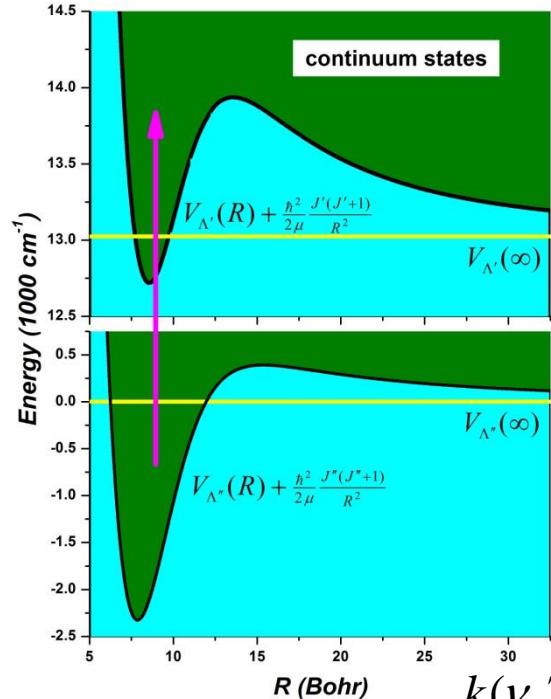

Good agreement with:

C. Zhu, J. F. Babb and A. Dalgarno, Phys.Rev. A:2006

K Alioua , M Bouledroua ,A R Allouche and M Aubert-Frécon, J. Phys. B: 2008

# Semiclassical approximation (SCA)

Introducing a continuous variable  $Y = J(J + 1)$  and change  $\sum_J (2J + 1) \rightarrow \int_0^\infty dY$

Any unity-normalized wave function  $\Phi_\nu$  can be turned into an energy-normalized wave function  $\Psi_\varepsilon = \frac{1}{\sqrt{|\frac{\partial E_\nu, J, \Lambda}{\partial \nu}|}} \Phi_\nu$  and the sum can be changed into the integral

$$\sum_\nu \rightarrow \int_{\varepsilon_{\min}}^\infty \frac{\partial \nu}{\partial \varepsilon} d\varepsilon$$

The absorption coefficient can be written as:

$$k(\nu, T) \approx w \frac{8\pi^3 \nu}{3c} \left( \frac{\hbar^2}{2\pi\mu k_B T} \right)^{3/2} \int_{\varepsilon''_{\min}}^\infty d\varepsilon'' \exp(-\frac{\varepsilon''}{k_B T}) \int_0^\infty dY \left| \langle \Psi_{\varepsilon'', Y, \Lambda''} | D(R) | \Psi_{\varepsilon'' + h\nu, Y, \Lambda'} \rangle \right|^2$$

Using energy-normalized wave functions in the WKB form, and the standard approximations, one obtains:

$$\langle \Psi_{\varepsilon, Y, \Lambda''} | D(R) | \Psi_{\varepsilon + h\nu, Y, \Lambda'} \rangle \approx \frac{\sqrt[4]{2\mu}}{\sqrt{2\pi\hbar}} \sum_i \frac{D(R_i)}{\sqrt[\frac{1}{4}]{\varepsilon - V_{\Lambda''}(R_i, Y)} \sqrt{|\Delta'(R_i)|}} \cos(\varphi(Y, \varepsilon, \nu, R_i) - \sigma_i \frac{\pi}{4})$$

Difference potential:  $\boxed{\Delta(R) = V_{\Lambda'}(R) - V_{\Lambda''}(R)}$     $\Delta'(R) = \frac{d}{dR} \Delta(R)$     $\sigma_i = \text{sgn}[\Delta'(R_i)]$

Summation is over the **Condon points**  $R_i$  satisfying the condition  $\boxed{\Delta(R_i) = h\nu}$ .

Neglecting the rapidly oscillating terms , one obtains **coherent quasi-static** formula of the reduced absorption coefficient :

$$k(\nu, T) = w \frac{32\pi^4 \nu}{3c} \left[ \sum_{i=1}^n \frac{R_i^2 D(R_i)^2}{|\Delta'(R_i)|} \exp\left(-\frac{V_{\Lambda''}(R_i)}{k_B T}\right) + \sum_{i=1}^{n-1} 2 \frac{R_{ii}^2 D(R_i) D(R_{i+1})}{\sqrt{|\Delta'(R_i)| |\Delta'(R_{i+1})|}} \exp\left(-\frac{V_{\Lambda''}(R_{ii})}{k_B T}\right) M_i(\nu, T) \right]$$

Quasi-static formula generally gives a good description of the absorption coefficient, but diverges in difference potential extremes (classical singularity).

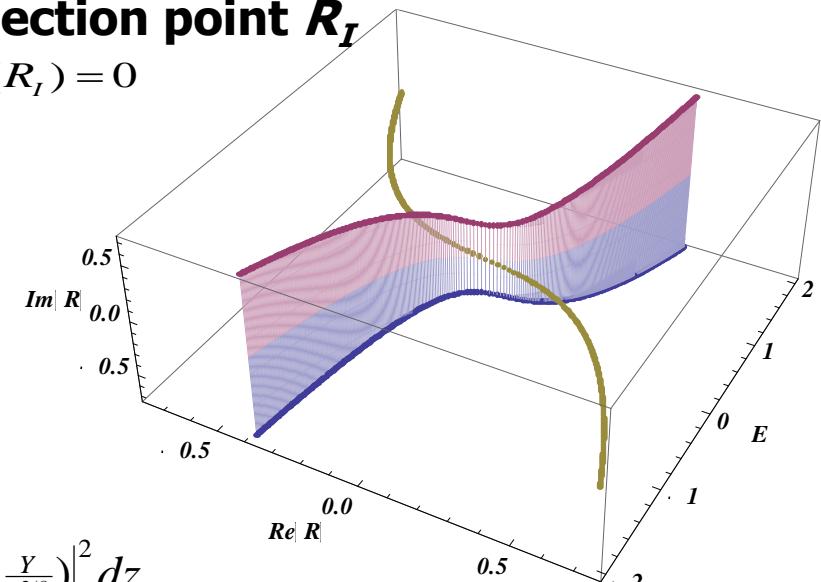

This divergence can be removed by mapping of the semi-classical canonic integral phase, into the characteristic form of the elementary "fold" or "cusp" catastrophe.

### **Elementary profile type:**

1. Difference potential  $\Delta(R)$  is a monotonic function, one real Condon point  $R_1$
  2. Difference potential  $\Delta(R)$  is a monotonic function, one inflection point  $R_{II}$ , one real Condon point  $R_1$  and complex pair of Condon points  $R_{2,3}$
  3. Difference potential  $\Delta(R)$  has extrema , two Condon points  $R_{I,2}$
- If difference potential  $\Delta(R)$  has more extremes, absorption profile can be obtained by combining the elementary profiles.

## 2. Difference potential $\Delta(R)$ has one inflection point $R_I$ transitive Pearcey approximation $\Delta''(R_I) = 0$

$$k(\nu, T) = w \frac{32\pi^4 \nu}{3c} \frac{R_1^2 D(R_1)^2}{|\Delta'(R_1)|} \exp\left(-\frac{V_{\Lambda''}(R_1)}{k_B T}\right) L_c(\nu, T)$$

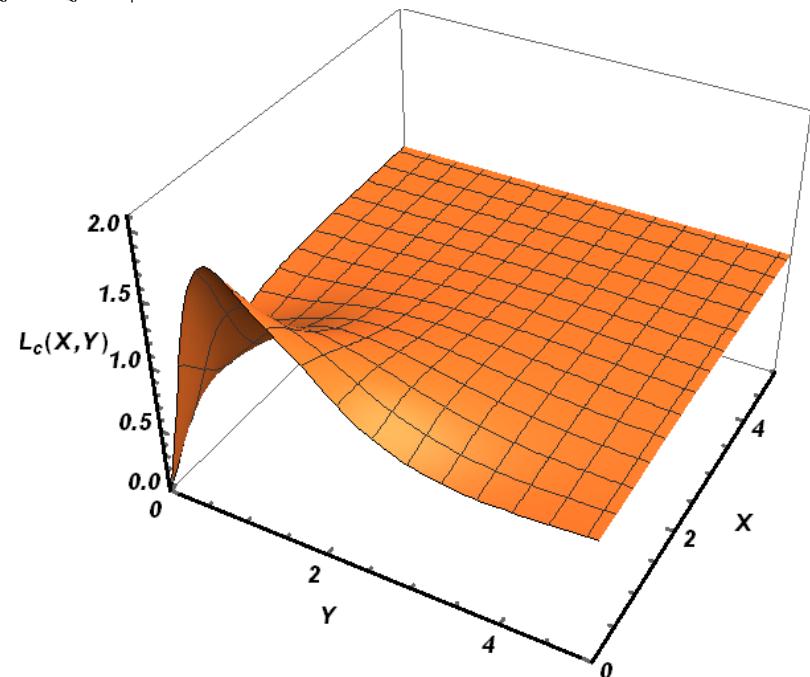

$$L_c(X, Y) = \frac{\left(\sqrt{\frac{8}{27}X^3+Y^2}-Y\right)^{\frac{2}{3}}+\left(\sqrt{\frac{8}{27}X^3+Y^2}+Y\right)^{\frac{2}{3}}-\frac{2}{3}X}{\pi^{3/2}} \int_0^\infty \frac{\exp(-z)}{z^{3/4}} \left|P\left(\frac{X}{z^{1/4}}, \frac{Y}{z^{3/8}}\right)\right|^2 dz$$

$$P(x, y) = \int_{-\infty}^{\infty} e^{i(u^4 + xu^2 + yu)} du \quad \text{Pearcey integral}$$

$$X(T) = |\Delta'(R_I)| \sqrt{\frac{3}{|\Delta'''(R_I)|}} \left(\frac{2\mu}{\hbar^2 k_B T}\right)^{1/4}$$

$$Y(\nu, T) = |\Delta(R_I) - h\nu| \sqrt{\frac{3}{|\Delta'''(R_I)|}} \left(\frac{2\mu}{\hbar^2 k_B T}\right)^{3/8}$$

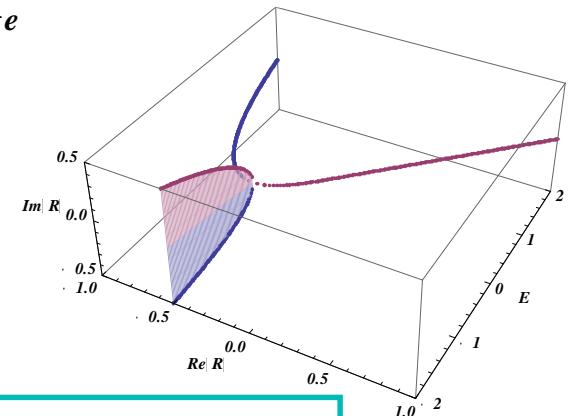

If  $Y(\nu, T) > 5$  or  $X(T) > 5$ , what is the most common case,  $L_c(\nu, T) \rightarrow 1$

### 3. Difference potential $\Delta(R)$ has extrema in point $R_e$

J.N.L. Connor, R.A. Marcus, *J. Chem. Phys.* 1971  
 K.M. Sando, J.C. Wormhoudt, *Phys. Rev. A* 1973  
 J. Szudy, W.E. Baylis, *JQSRT* 1975  
 P.A. Vicharelli, C.B. Collins, *SLS* 1983  
 R. Beuc and V. Horvatic: *J. Phys. B*: 1992  
 R. Beuc, B. Horvatić, M. Movre, *J. Phys. B*, 2010

$$\Delta''(R_e) = 0$$

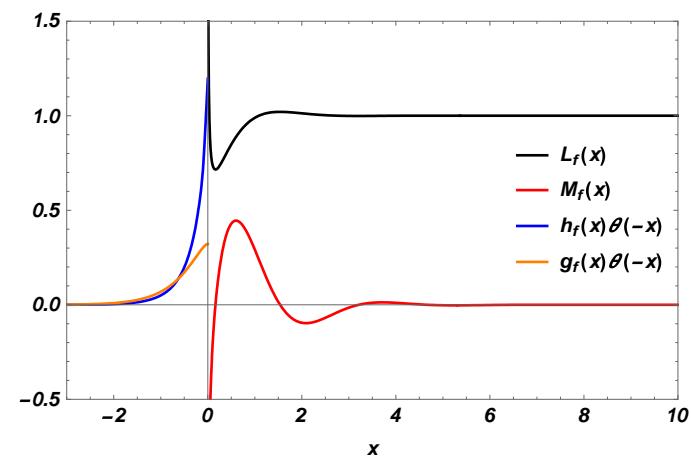

### uniform Airy approximation

$$k(\nu, T) = w^{\frac{32\pi^4 \nu}{3c}} \left\{ \left[ \frac{R_1^2 D(R_1)^2}{|\Delta'(R_1)|} \exp\left(-\frac{V_{\Lambda''}(R_1)}{k_B T}\right) + \frac{R_2^2 D(R_2)^2}{|\Delta'(R_2)|} \exp\left(-\frac{V_{\Lambda''}(R_2)}{k_B T}\right) \right] L_f(\zeta) \right. \\ \left. + 2 \frac{R_1^2 D(R_1) D(R_2)}{\sqrt{|\Delta'(R_1)| |\Delta'(R_2)|}} \exp\left(-\frac{V_{\Lambda''}(R_1)}{k_B T}\right) M_f(\zeta) \right. \\ \left. + \left( \frac{8m}{\hbar^2 k_B T} \right)^{\frac{1}{6}} \frac{R_e^2}{|\Delta''(R_e)|^{2/3}} e^{-\frac{V(R_e)}{k_B T}} \left[ D(R_e)^2 h(\zeta) + \left( \frac{\hbar^2 k_B T}{8m} \right)^{\frac{1}{3}} \frac{4[D'(R_e) - D(R_e) \frac{\Delta'''(R_e)}{6\Delta''(R_e)}]^2}{|\Delta''(R_e)|^{\frac{2}{3}}} g(\zeta) \right] \right\}$$

$$L_c(\zeta) = \sqrt{\zeta} h(\zeta) + \frac{1}{\sqrt{\zeta}} g(\zeta) \quad M_c(\zeta) = \sqrt{\zeta} h(\zeta) - \frac{1}{\sqrt{\zeta}} g(\zeta)$$

$$h(\zeta) = \sqrt{\pi} \int_0^\infty \frac{Ai\left[-\frac{\zeta}{x^{1/3}}\right]^2}{x^{2/3}} e^{-x} dx \quad g(\zeta) = \sqrt{\pi} \int_0^\infty \frac{Ai'\left[-\frac{\zeta}{x^{1/3}}\right]^2}{x^{1/3}} e^{-x} dx$$

$$\zeta = \zeta(\nu, T) \approx \left( \frac{4\pi^2 h \mu}{k_B T |\Delta''(R_e)|} \right)^{\frac{1}{3}} \sigma(\nu_e - \nu)$$

The standard semiclassical approximation does not give the rovibrational structure of the molecular bands, neglects the effects of turning points, but agrees perfectly with the averaged-out quantum-mechanical spectra. Also, the semiclassical theory can give a physical interpretation of the results obtained by fully quantum-mechanical calculations (W. H. Miller).

# Semiquantum approximation (SQA)

Using standard semiclassical approximations, we calculated integral :

$$\int_{\varepsilon_{\min}}^{\infty} d\varepsilon \exp\left(-\frac{\varepsilon}{k_B T}\right) \left| \langle \Psi_{\varepsilon, 0, \Lambda''} | RD(R) | \Psi_{\varepsilon+h\nu, 0, \Lambda'} \rangle \right|^2$$

By comparison with the semi-classical form of reduced absorption coefficient, we get expression:

$$k(\nu, T) \approx w \frac{32\pi^4 \nu}{3c} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{1/2} \int_{\varepsilon_{\min}}^{\infty} d\varepsilon'' \exp\left(-\frac{\varepsilon''}{k_B T}\right) \left| \langle \Psi_{\varepsilon'', 0, \Lambda''} | RD(R) | \Psi_{\varepsilon''+h\nu, 0, \Lambda'} \rangle \right|^2$$

Turning energy-normalized wave functions to unity-normalized wave functions one obtains

$$k(\nu, T) \approx w \frac{32\pi^4 \nu}{3c} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{1/2} \int_0^{\infty} dv'' \int_0^{\infty} dv' \exp\left(-\frac{E_{v'', 0, \Lambda''}}{k_B T}\right) \left| \langle \Phi_{v'', 0, \Lambda''} | RD(R) | \Phi_{v', 0, \Lambda'} \rangle \right|^2 \delta(h\nu - h\nu_{tr})$$

One can approximate the integrals by sums

and obtain a quantum-like ("quasiquantum" or "[semiquantum](#)") expression.

$$k(\nu, T) \approx w \frac{32\pi^4 \nu}{3c} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{1/2} \sum_{v'', v'} \exp\left(-\frac{E_{v'', \Lambda''}}{k_B T}\right) \left| \langle \Phi_{v'', 0, \Lambda''} | RD(R) | \Phi_{v', 0, \Lambda'} \rangle \right|^2 g(h\nu - h\nu_{tr})$$

In order to evaluate this relation, one needs to know the vibrational energies and the corresponding wave functions for  $J = 0$  only.

Semiquantum approximation gives good results if the distance between the vibrational transitions  $h\nu_{tr} = E_{v', \Lambda'} - E_{v'', \Lambda''}$  is comparable or less than the width of the instrumental profile  $g$ .

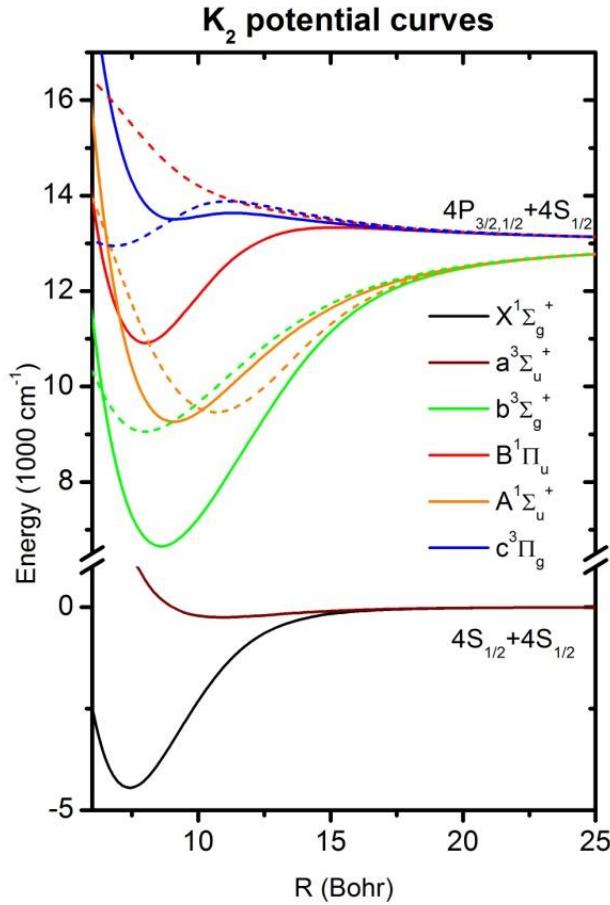

The semiquantum spectrum was collected in bins of the size  $\Delta h\nu = 10 \text{ cm}^{-1}$  and smoothed out with a simple unity-normalized triangular profile having a width of  $50 \text{ cm}^{-1}$ .

The semiquantum approximation is in very good agreement with fully quantum calculations, while its computer time consumption can be lower by four orders of magnitude.

A disadvantage of this method is an unsatisfactory description of the discrete structure of molecular bands.

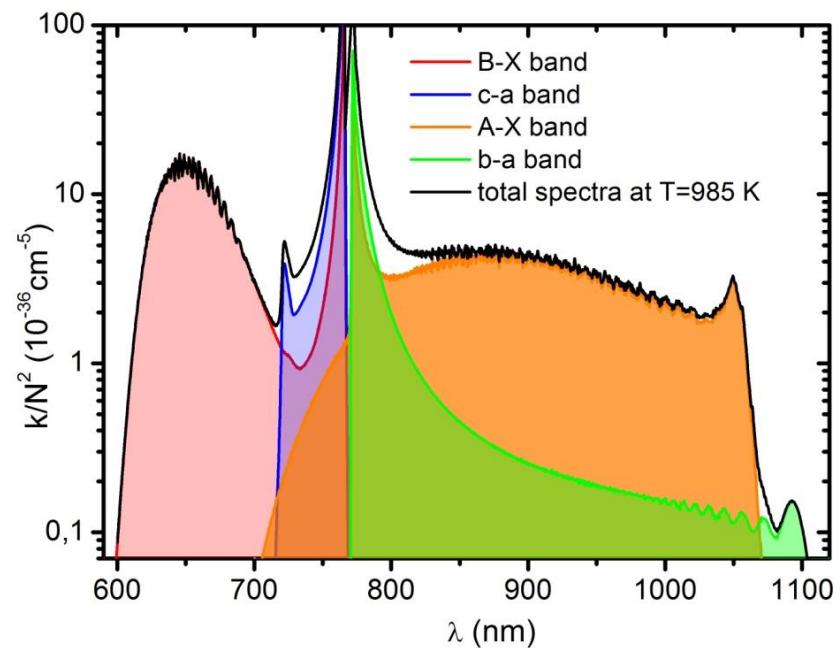

However, even the low-resolution absorption spectroscopy may serve as a valuable tool for checking the accuracy of molecular electronic structure calculations, and for gas temperature and number density diagnostics .

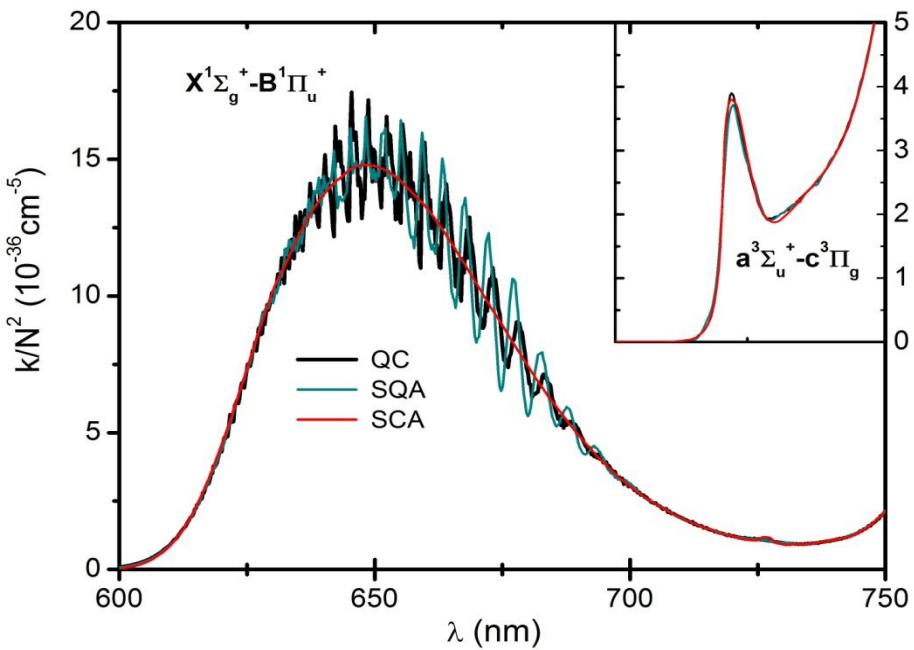

# Absorption spectra of potassium molecule

The quantum-mechanical calculation  
for temperature  $T = 985$  K.

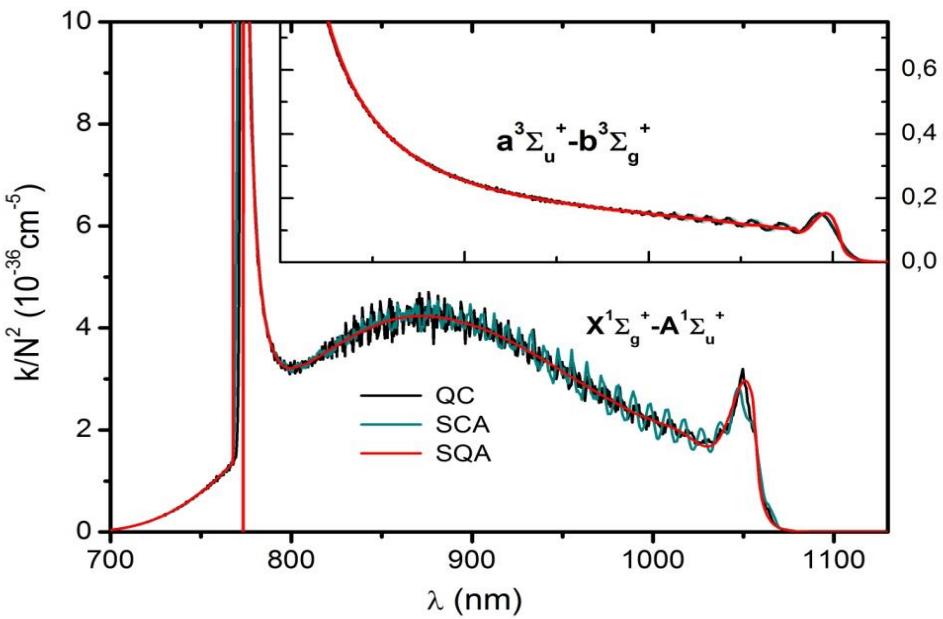

R. Beuc, M. Movre, B. Horvatić, Eur. Phys. J. D, 2014  
 In the theoretical simulation we used *ab initio* potential energy functions and the relevant transition dipole moments [L. Yan, W. Meyer, unpublished results], experimentally determined potential functions for the singlet transitions [C. Amiot, J. Mol. Spectrosc. (1991) and C. Amiot, J. Vergès, C.E. Fellows, J. Chem. Phys. (1995)], and the long-range calculation [M. Marinescu, A. Dalgarno, Phys. Rev. A (1995)].

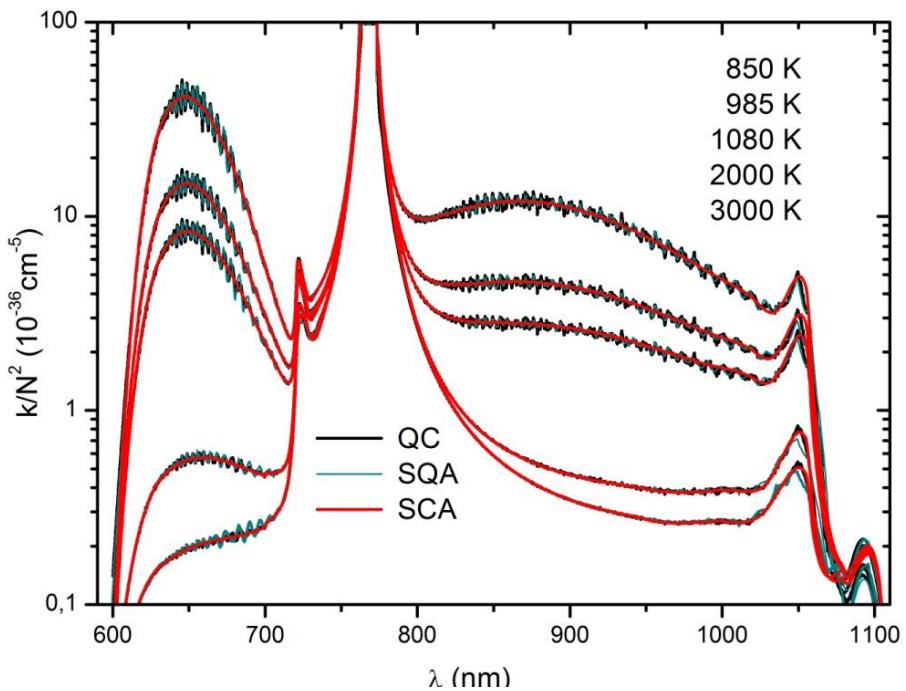

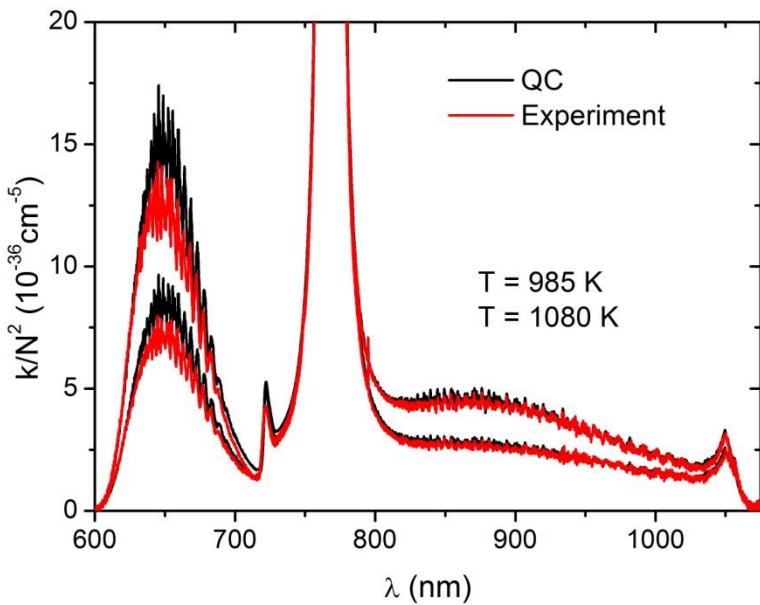

Comparison of QC, SQA and SCA for vapor temperature  $T = 985 \text{ K}$ .

For the calculation of the absorption spectrum of the  $B-X$  transition, the computer time was:  
 3000 s for the QC  
 0.2 s for the SQA and SCA.

Comparison of QC, **SQA** and **SCA** for a range of temperatures.

We compare **experiment** [C. Vadla, R. Beuc, V. Horvatic, M. Movre, A. Quentmeier, K. Niemax, Eur. Phys. J. D, 2006] and **QC** for two experimental temperatures. A slight increase in the simulated  $B-X$  band intensity may be attributed to the uncertainty in the *ab initio* transition dipole moments.

# Cesium emission and absorption spectra

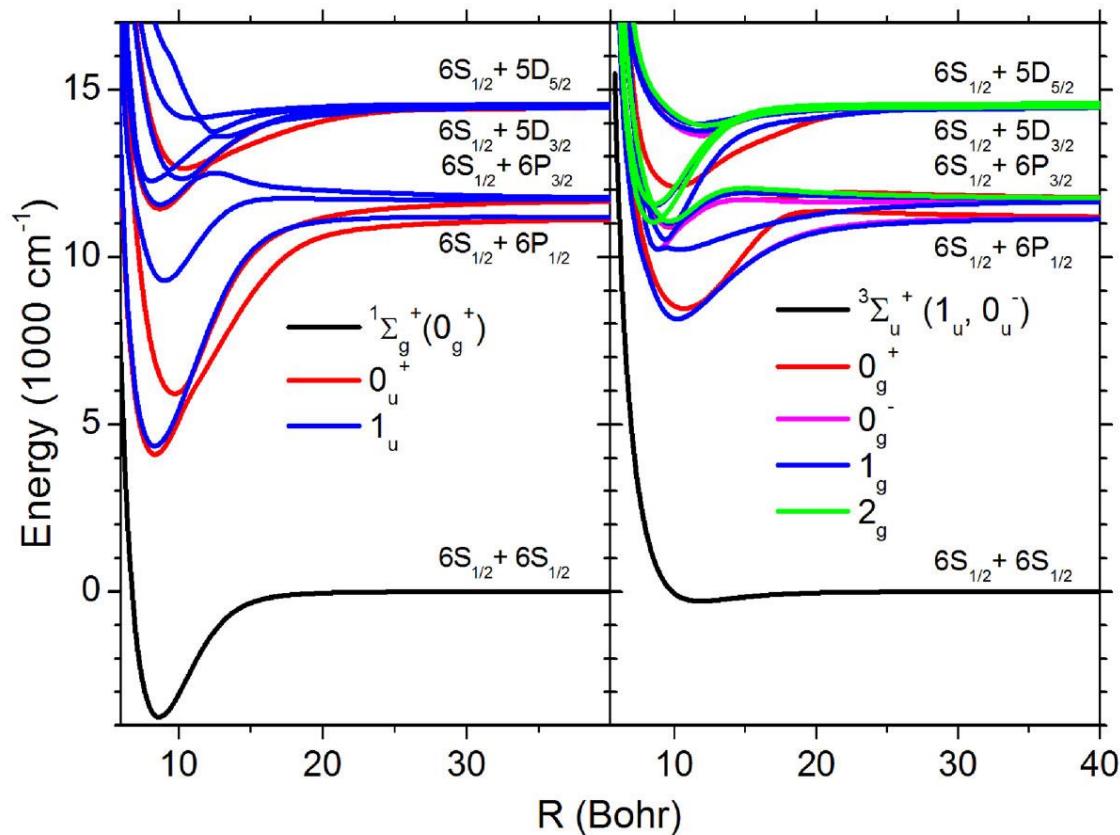

B. Horvatić, R. Beuc, M. Movre, Eur. Phys. J. D, 2015

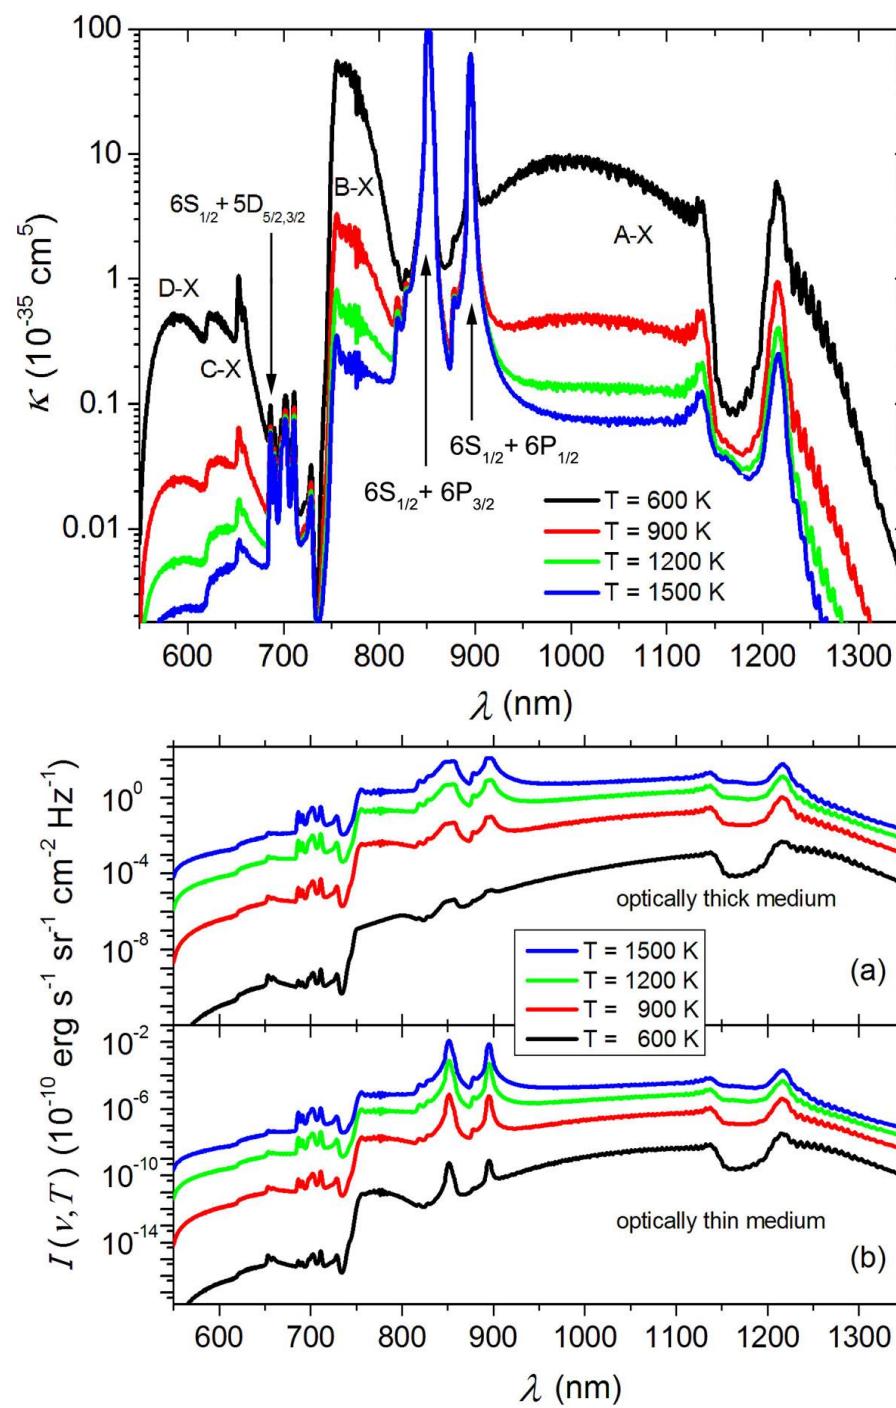

A recent *ab initio* [A. R. Allouche, M. Aubert-Frécon, J. Chem. Phys. 2012] calculation of  $\text{Cs}_2$  electronic potential curves and electronic transition dipole moments provided us with an input for the numerical simulation of  $\text{Cs}_2$  spectra.

We investigated the red and near-infrared (600 – 1300 nm) absorption and emission spectrum of a cesium vapor for temperatures within the range 600 – 1500 K using SQA.

11 singlet and 19 triplet electronic transitions  $\Lambda'' \rightarrow \Lambda'$  contribute to the absorption spectrum.

The computing time was 6 – 60 seconds , depending on the temperature.

Absorption spectra for a range of temperatures.

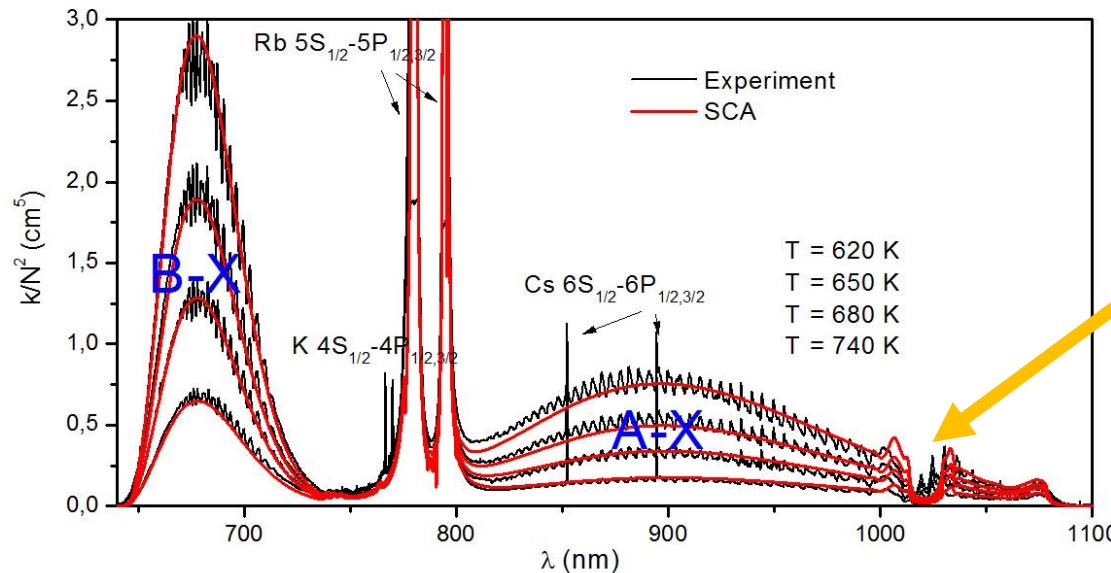

In the LTE approximation, the spectral radiance of a uniform emitting layer (thickness  $L$ , atomic number density  $N$ ) is:

$$I(\nu, T) = \frac{2hv^3}{c^2} \frac{1 - e^{-N^2 L k(\nu, T)[1 - \exp(-hv/k_B T)]}}{e^{hv/k_B T} - 1}$$

- (a) optically thick medium  
 $\kappa N^2 L \gg 1$ ,  $N^2 L = 3 \cdot 10^{34} \text{ cm}^{-5}$
- (b) optically thin medium  
 $\kappa N^2 L \ll 1$ ,  $N^2 L = 10^{29} \text{ cm}^{-5}$

# Absorption spectra of rubidium dimer

R. Beuc, M. Movre, V. Horvatic, C. Vadla, O. Dulieu and M. Aymar , Phys.Rev. A, 2007

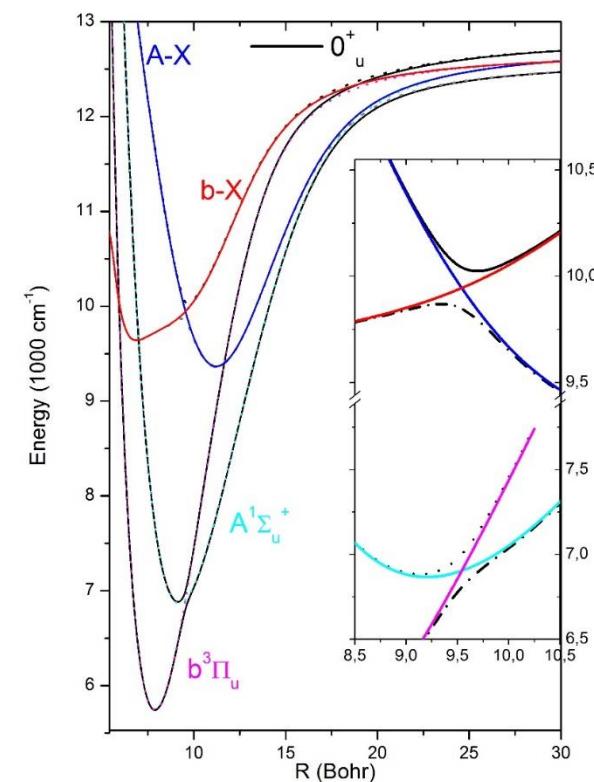

A-X absorption band is formed by a transition from ground  $0^+_g(X^1\Sigma_g^+)$  state to excited states  $0^+_{u^-}(A^1\Sigma_u^+)$  and  $0^+_{u^-}(b^1\Pi_u)$  coupled by spin-orbit interaction  $V_{SO}(R)$ .

In the framework of FGH method, energies and wave functions for coupled states can be determined by diagonalization of  $2N \times 2N$  matrix  $H$

$$H = \begin{pmatrix} T & 0 \\ 0 & T \end{pmatrix} + \begin{pmatrix} V_A & V_{so} \\ V_{so} & V_b \end{pmatrix} \quad T_{i,j} = \frac{\hbar^2}{2\mu\Delta R^2} \begin{cases} \frac{\pi^2}{3} - \frac{1}{2i^2} & i = j \\ (-1)^{i-j} \frac{8ij}{(i^2 - j^2)^2} & i \neq j \end{cases}$$

$$(V_{A,b})_{i,j} = \left[ V_{A,b}(R_i) + \frac{\hbar^2}{2\mu} \frac{J(J+1)}{R_i^2} \right] \delta_{i,j} \quad (V_{so})_{i,j} = V_{so}(R_i) \delta_{i,j}$$

If the dominant contribution to the spectrum consists of bound-bound transitions, and if the distance between the **rotational** lines is less than the width of the instrumental profile, the absorption coefficient can be determined using the **vibrational band continuum approximation (VBCA)**; [R.W. Patch, W.L. Shackelford, S.S. Penner. JQSRT, 1962, L.K. Lam, A. Gallagher, and M.M. Hessel, J.Chem.Phys. 1977].

$$k_{b,b}(\nu, T) = w \frac{8\pi^3 \nu}{3c} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{3/2} \sum_{v'', v'}^{bound} \exp\left(-\frac{E_{v'', \Lambda''}}{k_B T}\right) \frac{\left| \langle \Phi_{v'', 0, \Lambda''} | D(R) | \Phi_{v', 0, \Lambda'} \rangle \right|^2}{|B_{v'} - B_{v''}|} \exp\left(-\frac{B_\nu (E_{v', v''} - h\nu)}{(B_{v'} - B_{v''}) k_B T}\right)$$

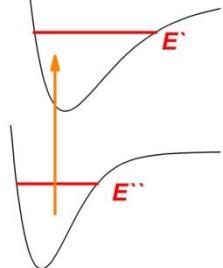

VBCA gives good results, if the dominant contribution comes from the transition between the lowest vib-rotational states, where following conditions are satisfied

$$\left| \langle \Phi_{v'', J, \Lambda''} | D(R) | \Phi_{v', J, \Lambda'} \rangle \right| \approx \left| \langle \Phi_{v'', 0, \Lambda''} | D(R) | \Phi_{v', 0, \Lambda'} \rangle \right| \quad E_{v, J, \Lambda} \approx E_{v, \Lambda} + B_\nu J(J+1)$$

# Hybrid approximation

Using good properties of SQA and VBCA, we introduced a **hybrid approximation** (HA) of the reduced absorption coefficient:

$$k(v, T) = w \frac{8\pi^3 v}{3c} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{3/2} \sum_{v'', v'}^{V'', V'} \exp\left(-\frac{E_{v'', \Lambda''}}{k_B T}\right) \frac{\left| \langle \Phi_{v'', 0, \Lambda''} | D(R) | \Phi_{v', 0, \Lambda'} \rangle \right|^2}{|B_{v'} - B_{v''}|} \exp\left(-\frac{B_v(E_{v', v''} - h\nu)}{(B_{v'} - B_{v''})k_B T}\right) G(E'', E'', v'', v', v) + \\ + w \frac{32\pi^4 v}{3c} \left( \frac{h^2}{2\pi\mu k_B T} \right)^{1/2} \sum_{v'', v''} \exp\left(-\frac{E(E'', E', v'', v')}{k_B T}\right) \left| \langle \Phi_{v'', 0, \Lambda''} | RD(R) | \Phi_{v', 0, \Lambda'} \rangle \right|^2 g(h\nu - h\nu_{tr})$$

$$G(E'', E'', v'', v', v) = \theta\left(\frac{h\nu - E_{v', v''}}{B_{v'} - B_{v''}}\right) \theta\left(\min\left[\frac{E'' - E_{v'', \Lambda''}}{B_{v''}}, \frac{E' - E_{v', \Lambda'}}{B_{v'}}\right] - \frac{h\nu - E_{v', v''}}{B_{v'} - B_{v''}}\right)$$

$$E(E'', E'', v'', v') = E_{v'', \Lambda''} \left[ 1 - \theta(E'' - E_{v'', \Lambda''}) \theta(E' - E_{v', \Lambda'}) \right] \\ + \min\left[E'', E' - E_{v', \Lambda'} + E_{v'', \Lambda''}\right] \theta(E'' - E_{v'', \Lambda''}) \theta(E' - E_{v', \Lambda'})$$

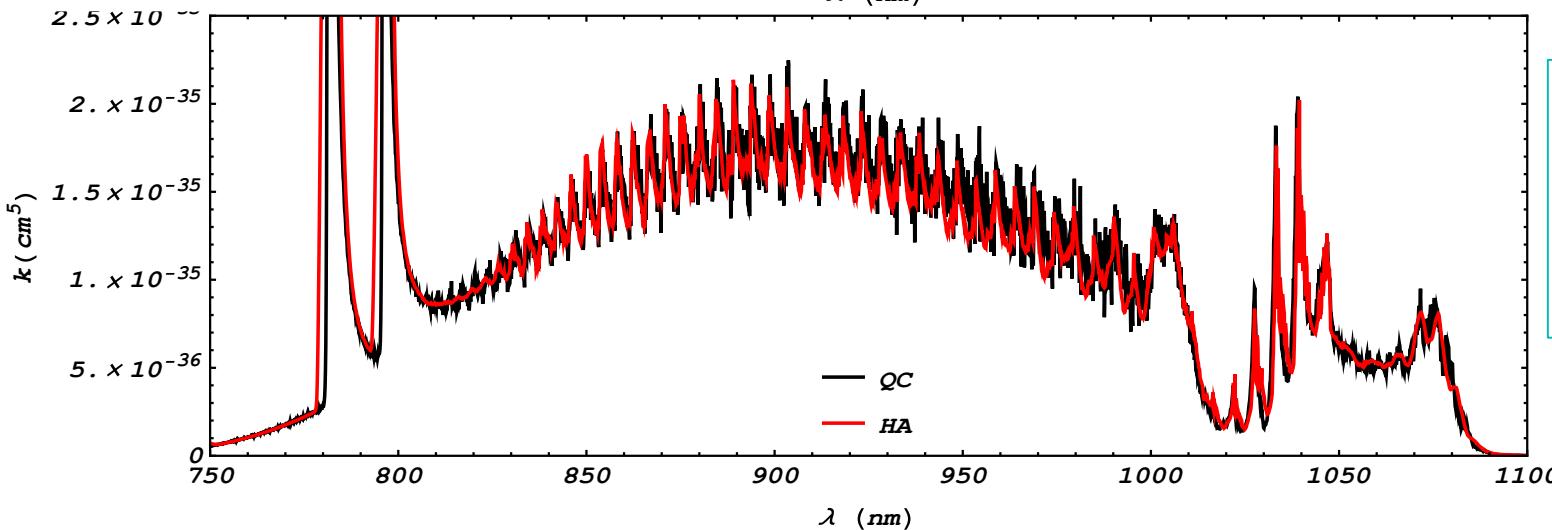

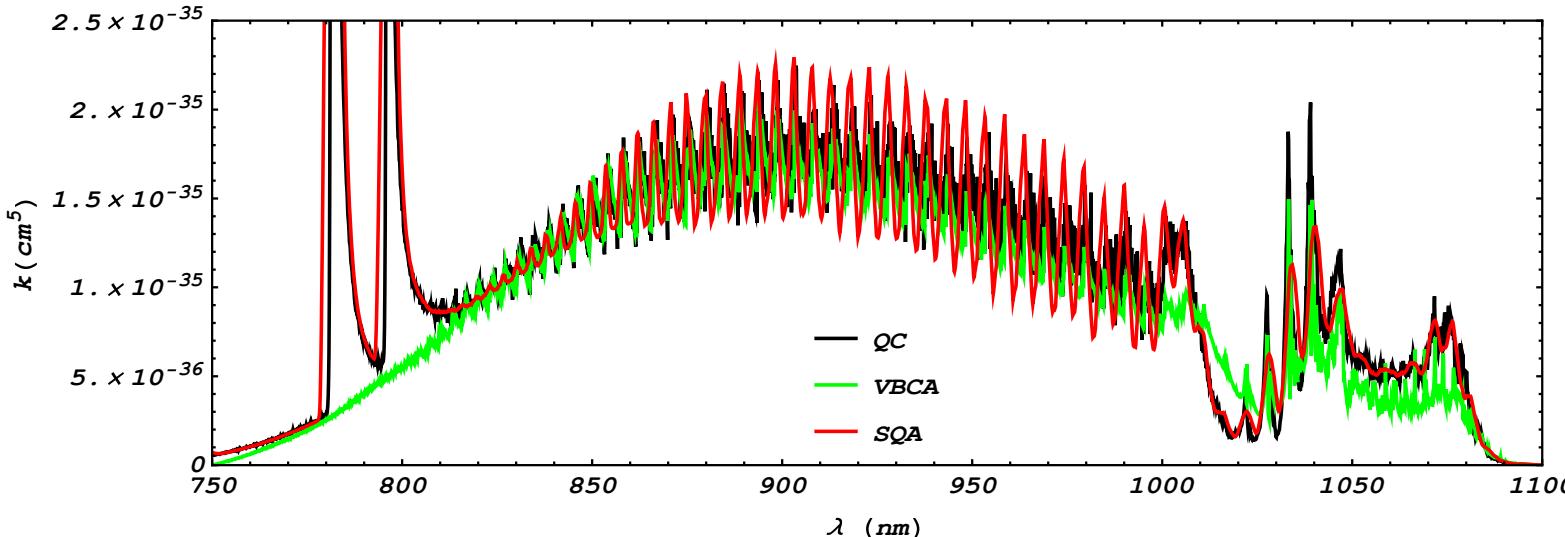

The first contribution to  $k(v, T)$  is the VBCA of transitions for which  $E'' \geq E_{v'', J, \Lambda''}$  and  $E' \geq E_{v', J, \Lambda'}$ , and the second contribution is the SQA of all other transitions.

$$E'' = E_{0, \Lambda''} + x \frac{B_{v''=0}^2}{D_{v''=0}} \quad E' = E_{0, \Lambda'} + x \frac{B_{v'=0}^2}{D_{v'=0}}$$

$$E'' \geq E_{v'', J, \Lambda''} \quad E_{v'', J, \Lambda''} = E_{v'', \Lambda''} + B_{v''} J(J+1) \quad \Phi_{v'', J, \Lambda''} \approx \Phi_{v'', 0, \Lambda''}$$

$$E' \geq E_{v', J, \Lambda'} \quad E_{v', J, \Lambda'} = E_{v', \Lambda'} + B_{v'} J(J+1) \quad \Phi_{v', J, \Lambda'} \approx \Phi_{v', 0, \Lambda'}$$

# Theoretical simulations of rubidium A-X band at a temperature of 740 K.

Comp. time:  
QC=2618 s  
VBCA=126 s  
HA=16 s  
SQA=0.3 s

The hybrid approximation improves the description of the molecular bands structure at a cost of an acceptable increase of the computer time.

# Thank you for your attention
