Introduction: Extrapancreatic HCC metastasis are associated with a poor prognosis. Nevertheless there are some effective therapies available. Aim of the study was to assess the main sites of extrahepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the clinical evolution and treatment. This was a retrospective single-center study in which patients with HCC confirmed extrahepatic metastasis between January 2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of 64 ± 11 years at the time of metastasis. In 41% of the patients the metastases were present at the time of HCC diagnosis. In patients with subsequent metastasis, the median time until its development was 9 months (IQR 5–16). The diagnosis of metastasis was incidental in 51% of the patients. Computed tomography (CT) was the main diagnostic method (86%) and in 18% of the cases histological confirmation was obtained. Nineteen patients underwent thoracic CT and five performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites were identified, the more frequent were lung (33%) and bone (14%). The MELD score at the time of metastasis was higher than the MELD score at the HCC diagnosis (p = 0.009). Metastasis detection implied changes in HCC therapy in all patients, 41% started sorafenib and 55% were referred for supportive therapy. Seven patients performed metastasis targeted treatment, namely 3 patients underwent radiotherapy. The median overall survival (OS) after metastasis was 4.0 months (95%CI 2.1–5.8 months) and the mortality rate was 81% at 12 months. Patients who underwent metastasis targeted treatment presented a longer OS than those who did not (median 18.5 vs 3.1 months; p = 0.002). In multivariate analysis, MELD score at the time of metastasis (p = 0.004) and metastasis treatment (p = 0.005) were independently associated with OS estimation.

Conclusion: A systematic HCC staging, with thoracic CT and bone scintigraphy, may provide an earlier metastasis detection and enable a targeted treatment with a consequent improvement in survival in this difficult-to-treat population.

P1376 MANAGEMENT OF INTERMEDIATE STAGE HEPATOCELLULAR CARCINOMA
A. Deguchi
Division Of Gastroenterology, Kagawa Rosai Hospital, Marugame-shi, Kagawa/Japan
Contact E-mail Address: akihiro41@me.com

Introduction: According to the Barcelona Clinic Liver Cancer (BCLC) staging system, intermediate stage contains very heterogeneous hepatocellular carcinoma (HCC) patients. Recently, subclassification of intermediate stage on the basis of Milano criteria and up to 7 criteria is proposed. In this study, the effectiveness of determining bed-to-transarterial chemo-embolization (DEB-TACE) in intermediate stage was investigated.

Aims & Methods: 120 patients (M: F=90:30; median age = 76; Child A: B: C = 72:24:4; BCLC stage A: B: C: D = 6:85:23:6) with unresectable HCC who received DEB TACE in our hospital were studied. The objective radiological response was classified according to the modified Response Evaluation Criteria in Solid Tumors (mRECIST) v.1.1 by using dynamic CT at one or two months after therapy. Adverse events were evaluated using NCI CTCAE v. 4.03.

According to Bolondi’s subclassification, the patients of BCLC B stage were divided into four groups (B1: 31; B2: 19; B4: 10). The response rate and tumor factor associated response in these patients group were examined.

Results: The overall response rate and disease control rate in intermediate stage were 36% and 89%, respectively. Considering the subclassification, the response rate in B1 group (61%) was significantly higher than that of B2 + B3 group (29%). Although B2 + B3 group was constituted by the patients who did not satisfy the up to 7 criteria, only in the patients with less than 7 tumors, the response rate (60%) was similar to that of B1 group. Tumor factors associated response and found to be significant on univariate analysis were simple gross classification (single nodular type) and number of tumor. Tumor diameter was not associated with the response.

Conclusion: For the treatment of intermediate stage of HCC, although DEB-TACE is considered to be most effective in B1 group, it is suggested that DEB-TACE is also effective in the patients with less than 7 tumors in B2 + B3 group. In cases with more than 7 tumors, as the response rate is considered to be extremely low, sorafenib and arterial infusion therapy are recommended in B2 + B3 group.

P1377 HEPATOCELLULAR CARCINOMA RECURRENCE RATE IN HCV-INFECTED PATIENTS TREATED WITH DIRECT ANTIVIRAL AGENTS. A SINGLE-CENTER EXPERIENCE
Hepatology Unit, Cardarelli Hospital, Naples/Italy
Contact E-mail Address: raffaellatortora@live.com

Introduction: In the last few years many HCV patients with previous diagnosis of hepatocellular carcinoma (HCC) have been treated with direct antiviral agents (DAAs) for HCV infection. However there are conflicting data on HCC recurrence rate after DAAs therapy.

Aims & Methods: Aim of this study was to prospectively evaluate the rate of HCC recurrence following sustained virological response (SVR) by DAAs. From April 2015 to September 2016 we consecutively enrolled HCV infected patients previously treated for HCC at Liver Unit of Cardarelli Hospital. All patients had a free-disease survival from HCC of at least 6 months before starting antiviral therapy. The efficacy of HCC therapy was evaluated according to mRecist criteria at CT or MRI. Radiological evaluation was carried out within 30 days from the start of therapy. All patients underwent DAAs therapy, selected on an individual basis according to the recommendation issued by the Italian association of the study of the liver.

Results: A total of 71 patients were enrolled. Among them, 42 patients had available data on SVR status and were considered for the analysis. There were 21 males (58.3%) and 15 females. The median age of the patients was 73 years (range: 45–85). The median time until the beginning of therapy (range: 6–18 months). Genotype distribution was as follows: 36 patients infected with genotype 1 (85.7%), 5 with genotype 2 and 1 patients with genotype 3. SVR was achieved in 38/42 patients (90.5%). HCC recurrence was observed in 11/38 patients with SVR (28.9%). The median time for recurrence was 9 months from the start of therapy with a range of 1–13 months; with 2 patients who showed recurrence during therapy. Among the patients who did not achieve SVR, 1/4 showed HCC recurrence after 10 months from end of treatment.

Conclusion: Treatment with DAAs are highly effective with a SVR of about 90% even in patients with advanced liver disease. Nonetheless, in patients with previous history of HCC, the eradication of HCC did not reduce the risk of short and medium-term recurrence.

Introduction: Primary liver cancer is the sixth most common cancer in the world, after cancers of the lung, breast, colorectal, prostate and gastrae[1]. However, the extremely poor prognosis for primary liver cancer makes it the second leading cause of cancer-related death globally (745,000 deaths, 9.1% of the total death)[2]. Histologically, the majority of primary liver cancer is either
P1381 INTERHEPATIC PORTAL HYPERTENSION WITHOUT CIRRHOSIS: EXPERIENCE OF A MORROCCAN UNIVERSITY CENTER (33 CASES)

Introduction: Non-cirrhotic portal hypertension (PNH) is defined as a portal hypertension (PH) without cirrhosis in liver biopsy and without an obstruction of the portal and the hepatic veins.

Aims & Methods: This is a retrospective study conducted on the last 19 years in “Hospi Babat et al. district hospital in Rabat. 33 non-cirrhotic patients with interhepatic portal hypertension were analyzed. We medicalized all medical data of patients with hypertension portal without cirrhosis in liver biopsy and without an obstruction of the portal and the hepatic veins.

Results: 33 patients were included in this study. 22 were women. Mean age was 34 years old (18-70). The PNH has been revealed by a digestive bleeding in 10 cases (30%) and ascites in 7 cases (21.2%). Clinical examination found a splenomegaly in (75.7%). Abdominal ultrasonography combined with Doppler showed signs of PH in all patients and confirmed the absence of obstacle on or above the liver. Upper gastrointestinal endoscopy found esophageal varices in 29 cases (87.9%). Various etiologies were identified: in 21.2% (7 cases), extrahepatic PH was due to liver tumors and in 11.7% (n = 4), the etiology was hepatic tuberculosis. Etiological investigations retained: 3 cases (9%) of primary biliary cirrhosis in pre cirrhotic stage, 6 cases (18.18) of hepatic portal sclerosis, 4 cases (12.12%) of hepatic sarcoidosis, 2 cases (6%) of polycystic liver, one case (3%) of hepatic angiomatous liver, a case chronic hepatitis B, a case of Gaucher disease and one case secondary to hamartoma of the liver. Treatment was indicated according the etiology of PH and its severity (beta blockers, ligations).

Conclusion: Non-cirrhotic interhepatic portal hypertension is mostly asymptomatic and related to a heterogeneous association of diseases with a good prognosis excepted solid and hematological malignancies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Surgical treatment is nowadays the only curative treatment of hydratic cyst of the liver. Surgical approach exposes to many complications especially biliary fistulas. All modalities are described for the treatment of these complications.

Aims & Methods: A retrospective study including 250 patients who underwent a surgical treatment for a hydratic cyst of the liver between 2007 and 2015. The aim of this study is to evaluate the place of conservative management and his benefits and his complications associated with fistulas.

Results: Conservative surgical treatment of hydratic cyst was done in 180 cases and radical surgery in 70 cases. A complication occurs in 66 cases. An external biliary fistula occurs in 45 cases (18%). Management of all this biliary fistulas was conservative or gastroenteric and was associated with fistula. In case of fistula, the treatment was primary endoscopic treatment necessary to heal fistulas. The median hospital stay was 15 days [range 12-60] when biliary fistulas occurred compared to 8 days [6-15] when there is no biliary complications.
P1383 THE EVOLUTION OF ESOPHAGEAL VARICES IN NON CIRRHOTIC PORTAL HYPERTENSION CAUSED BY PORTAL VEIN THROMBOSIS

Introduction: Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by infraportal occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro esophageal varices.

Aims & Methods: The aim of this study is to specify the evolution of esophageal varices and thus risk of rebleeding in patients with PHT by PVT unrelated to cirrhosis. It is a retrospective study from January 2010 to February 2017, including 101 patients followed for PHT by PVT without liver disease in the depart-ment of hepatogastroenterology (medicine C) at Ibn Sina University hospital of Morocco. PVT was diagnosed by abdominal doppler ultrasonography in all patients.

Results: The mean age of patients was 36 ± 15 years with extremes ranging from 11 years to 70 years. The sex ratio M/F was 0.42. Five percent of patients had a splenectomy for undocumented reasons before the diagnosis of PHT. Concerning the etiology, 10.9% (n = 11) were hospitalized for melanoma and 60.4% (n = 61) for hematemesis and melena and 28.7% (n = 29) for non-specific abdominal pain. Clinical examination was normal in 10.9% (n = 11), showed an axasis in 11.9% (n = 12), and signs of PHT such as splenomegaly and collateral abdominal circulation in 95.1% (sludge in 27.7% cases), complete disappearance of the endoscope, and stones in 4 (15.4%) cases with subsequent endoscopic stones removal. In the remaining patients, PVT confirmed complete duct clearance. No adverse events occurred.

Conclusion: In case of CBD complete clearance confirmation using POC is a feasible, quick and safe procedure that can help on clinical decision making (for example obviat-ing the need for possible plastic stent or naso-biliary drainage placement) without substantial increase of time or costs. Our experience, however, is preliminary and mainly aimed to assess the feasibility of the procedure, which could represent the first step for the development of a possible new indication in the setting of difficult biliary stone management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1384 EVALUATION OF COMMON BILE DUCT DUCT CLEARENCE AFTER ENDOSCOPIC MANAGEMENT OF DIFFICULT BILIARY STONES BY DIRECT PERORAL CHOLANGIOSCOPY: PRELIMINARY RESULTS OF A PILOT STUDY
Gastroenterology And Hepatology, Yamaguchi University Graduate School of Medicine, Ube/Japan

Contact E-mail Address: andrea.anderloni@humanitas.it

Introduction: Incomplete stones clearance after endoscopic management of diffi-cult biliary stones poses the risk of complications such as cholangitis. Confirmation of complete stones clearance is normally confirmed fluoroscopi-cally with obvious risk of false negative/false positive results, leading to possible ad-vanced stages or costs. Our experience, however, is preliminary and mainly aimed to assess the feasibility of the procedure, which could represent the first step for the development of a possible new indication in the setting of difficult biliary stone management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1385 LONG-TERM OUTCOMES OF PATIENTS WITH ACUTE CALCULOUS CHOLECYSTITIS AFTER SUCCESSFUL REMOVAL OF GALLBLADDER STONES WITH PERCUTANEOUS TRANSEPHATIC CHOLANGIOSCOPY: A DECADE EXPERIENCE AT A SINGLE TERTIARY CENTER
S. Dong, C.H. Oh, J.R. Moon
Department of Internal Medicine, Kyung Hee University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: gidrdong@hanmail.net

Introduction: Percutaneous cholecystostomy (PCT) has been an alternative treat-ment for acute calculous cholecystitis (ACC) for the patients unsuitable for early cholecystectomy. Lithotripsy with percutaneous transhepatic cholangioscopy (PTCS) after PCT track maturation is particularly considered for those patients with gallbladder (GB) stones who are poor surgical candidate. We examined the long-term outcomes of 171 patients with ACC treated by PTCS.

Aims & Methods: This study was a retrospective observational study of 171 consecutive patients who treated with PTCS for ACC in the period from 1 Jan 2005 to 31 Dec 2015. Outcome measures included the success rates, adverse events, recurrence rate and mortality. All data were collected from patients’ medical records.

Results: PTCS achieved complete clearance of GB stones in 157 patients (91.8%). The complication rate of PTCS was 3.5% (6/171). The adverse events included GB perforation (n = 3, 1.8%), hemorrhage (n = 2, 1.2%), disruption of the percutaneous transhepatic biliary drainage fistula (n = 1, 0.6%), and all of which resolved with conservative treatment. The overall recurrence rate of gallstone diseases was 11.5% during the follow up period. The incidence of recurrent gallstone diseases was significantly higher in those with completely removed GB stones than in those without complete clearance (10.2%, 16/157 vs 21.4%, 43/200). Portal contrast passage was used in 100% of patients to assess CBD clearance.

Conclusion: Gallbladder stone removal with PTCS would be recommended as an effective and safe treatment modality for the patients with acute cholecystitis who are unsuitable for surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.
used for initial bile duct cannulation. Subsequently, sphincterotomy and stone extraction were performed using the combined catheter. The success rate of performing the combined procedure, procedure-related time, adverse events, and the cost of devices were compared with those in 10 patients with BDSs ≤10 mm in size who had undergone endoscopic stone clearance from April 2015 to December 2015 as historical control.

Results: The success rate of selective cannulation and stone clearance did not differ significantly (Stonetome group: 90.9% and 100% vs control group: 100% and 100%, respectively). The median time after bile duct cannulation to complete stone clearance and total procedure time in the Stonetome group were significantly shorter than those in the control group (401.5 s versus 982.5 s, 645.5 s versus 1350s, respectively). In the Stonetome group, delayed bleeding occurred in 1 patient. In the control group, bile duct injury caused by the guidewire occurred in 1 patient. The costs of the used devices did not differ significantly (Stonetome group: SEK78 versus control group: SEK69).

Conclusion: The combined catheter has the same selective cannulation ability as a conventional catheter and a similar capacity to remove BDSs as common retrieval. To therefore, the combined catheter can reduce the procedure time to remove BDSs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1387 ACCURACY OF ASGE CRITERIA IN THE IDENTIFICATION OF PATIENTS WITH SUSPECTED CHOLEDOCHOLITHIASIS

C. Macedo, N. Almeida, D. Gomes, E. Camacho, S. Mendes, L. Tomé, A. M. Ferreira Gastroenterologia, Centro hospitalar e Universitario de Coimbra, Coimbra/Portugal

Contact E-mail Address: claudia.macedo.07@hotmail.com

Introduction: Society for Gastrointestinal Endoscopy (ASGE) emitted, in 2010, guidelines for the clinical orientation of patients with suspected choledocholithiasis (CL), suggesting the direct referral to endoscopic retrograde cholangiography (ERC) in certain groups. However, the ERC is an invasive exam and some studies demonstrated that a significant amount of patients classified with very strong risk of CL did not have alterations in ERC.

Aims & Methods: The aim of this study was to assess the accuracy of the ASGE guidelines in portuguese population. This is a retrospective study that included 212 patients consecutively admitted to the hospital from 2014 to 2016.

Results: Of the 212 patients, 28 (13.2%) had intermediate risk of CL and 184 (86.8%) had high risk, according to the ASGE criteria. These patients were submitted to the following exams/interventions: ERC (154 patients); magnetic resonance cholangiography (50 patients) and endoscopic ultrasound (8 patients). In patients initially classified with high risk of CL, this was confirmed in 119 (64.7%). The same was seen in 10 (35.5%) of the patients with intermediate risk. The ASGE criteria, when applied to this population, demonstrated an accuracy of 64.3% (21.7% sensitivity; 92.3% specificity) in the high-risk group, and an accuracy of 35.5% (78.3% sensitivity; 7.8% specificity) in the intermediate-risk group. Of the patients with intermediate probability, 12 (42.8%) underwent ERC and CL was found only in 4 of these patients. The presence of cholangitis, a common bile duct > 6 mm, a common bile duct stone visualized on transabdominal US and a total bilirubin > 4 mg/dL were strong predictors of CL. The overall ERC complication rate was 13% (20 patients), of whom 8 had no change.

Conclusion: The ASGE guidelines showed a limited diagnostic accuracy in the identification of patients who actually require ERC, conditioning a significant number of unnecessary procedures with subsequent complications associated with it. It is the orientation of these patients, with greater use of less invasive diagnostic techniques such as magnetic resonance cholangiography and endoscopic ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1388 DOES FIBRIN GLUE APPLIED ON THE CHOLANGIOTOMY DURING LAPAROSCOPY COMMON BILE DUCT EXPLORATION REDUCE THE RISK OF BILE LEAKAGE? A RANDOMIZED STUDY

B. Darkahi1, G. Sandblom2, T. Nordén3

1Surgery Department, Enköping/Sweden 2Surgery Department, Uppsala/Sweden

Contact E-mail Address: bahman.darkahi@gmail.com

Introduction: Laparoscopic choledochotomy as a method of extracting common bile duct stones is a technique with many advantages. One problem, however, is bile leakage around the T-tube. To some extent the leakage may be reduced if the incision is sutured around the T-tube, but this technique has some disadvantages. The aim of this study was to investigate whether application of fibrin glue around the tube results in less leakage than suturing.

Aims & Methods: Between 2012 and 2016 a total of 1347 choledectomies were performed in Enköping Hospital. From this group, 42 patients were included in the study and randomized to suturing or fibrin glue for closing the cholangiotomy around the T-tube. Postoperative cholangiography was performed after 7–10 days after surgery. The amount of flow in the abdominal drain and the level of total bilirubin was measured daily. In case the flow ceased, the abdominal drain was extracted three days after surgery.

Results: No significant difference between the groups was seen regarding the flow of the abdominal drain or the T-drain for the first three days or operation time.

Conclusion: Fibrin glue may be an option to seal cholangiostomy around the T-tube, but studies with greater statistical power are needed to confirm this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1389 THE IMPACT OF BARIATRIC SURGERY ON ACUTE CHOLANGITIS MORTALITY AND OTHER OUTCOMES: A NATIONWIDE ANALYSIS

P.T. Kroener1, M. S. Abougergi2, V. Popov3, C. C. Thompson4

1Mt. Sinai St. Luke's/West, New York, United States of America 2Catalyst Medical Consulting, Simpsonville/United States of America/SC 3New York University School of Medicine, New York/United States of America 4Division Of Gastroenterology, Hepatology, And Endoscopy, Brigham and Women's Hospital, Boston/United States of America

Contact E-mail Address: thomas.kroener@gmail.com

Introduction: Rapid weight loss after bariatric surgery (BS) has been associated with the formation of gallstones, and subsequent acute cholecystitis and cholangitis (AC). However, the complex post-surgical anatomy limits the possibility of performing an ERC as part of AC treatment. Therefore, the aim of this study was to assess the impact of bariatric surgery on mortality and resource utilization among patients with AC using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publically available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of AC were included. There were no exclusion criteria. Patients with a past history of BS were identified using the appropriate ICD-9-SCM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization: use of ERCP, cholecystectomy, length of hospital stay (LOS), total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 274,775 patients with AC were included in the study, of which 4,240 (1.7%) had undergone BS. The mean patient age was 51 years and 48% were female. After adjusting for confounders, patients with and without history of bariatric surgery had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 0.87, 95% CI: 0.51–1.49, p = 0.57). As far as resource utilization, patients with bariatric surgery had lower adjusted odds of ERC (aOR: 0.28, 95% CI: 0.09–0.83, p = 0.02), but higher odds of cholecystectomy (aOR: 3.18, 95% CI: 1.00–10.05, p = 0.04). Both patient groups had similar adjusted length of stay (adjusted mean difference: 1.19 days, 95% CI: 0.09–0.83, p = 0.16) total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Conclusion: Bariatric surgery has no impact on inpatient all-cause mortality among patients who develop acute cholangitis, despite its association gallstone acute pancreatitis and limited ERC performance. In addition, bariatric surgery does not affect resource utilization in this patient population as measured by length of stay and total hospitalization charges.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1391 PATHOLOGICAL, CLINICAL AND RADIOLOGICAL CHARACTERISTICS OF NEOPLASTIC AND NONNEOPLASTIC GALLBLADDER POLYPS

S. Z. Wennmacker1, A. Van Dijk2, J. Reassens1, N. Hasami3, J.P. Drenth4, C. J.H.m. Van Laarhoven5, P. De Reuver1, I.D. Nagtegaal2

Amsterdam, Amsterdam/Holland 3Department Of Surgery And Hepatology, Radboud University Nijmegen Medical Centre - Gastroenterology And Hepatology, Radboud University Nij., Nijmegen/Netherlands 4Radboud University Nijmegen Medical Center, Radboud University Nijmegen Medical Center Dept. of Pathology, Nijmegen/Netherlands

Contact E-mail Address: sarah.wennmacker@radboudumc.nl

Introduction: Prevalence of gallbladder polyps in the Netherlands is 943 per 100,000 cholecystectomies. Histopathologically these gallbladder polyps can be divided into neoplastic polyps (with malignant potential) and nonneoplastic polyps (without malignant potential). Although cholecystectomy is only indicated for neoplastic polyps, 47% of polyps after cholecystectomy are nonneoplastic. Further information on the pathological characteristics and subsequent clinical and radiological features could be useful to predict neoplastic or nonneoplastic nature of the gallbladder polyp before surgery.

Aims & Methods: To assess pathological characteristics of neoplastic and nonneoplastic gallbladder polyps and identify preoperative clinical and radiological predictors for neoplastic and nonneoplastic polyps. Data of the Dutch Pathology Registry was used. In this search 2081 histopathologically proven gallbladder polyps (or focal wall thickening ≥5 mm) were identified in patients of ≥18 years undergoing primary cholecystectomy between 2003 and 2013. Of these
polyps 36.3% was neoplastic (adenoma, dysplasia, carcinoma or other malignancies) and 43.7% nonneoplastic (all other types of polyp). Age and sex of the patient, number of polyps, size of the polyp, coincidence with gallstones and presentation as protruding polyp or wall thickening were extracted from the excerpts. Additional clinical and radiological information was collected from patients. Clinical records at three hospitals in the Northeast India (n = 178). The following clinical and radiological predictors were considered: age, gender, ethnicity, BMI, medical history (PSG, Hepatitis, metabolic syndrome, gallbladder disease, Salmonella typhi or Helicobacter pylori infection), family history of gallbladder and cholangiocarcinoma and radiological features (size, number, shape, surface and echogenicity of the polyp). Associations between possible predictors and gallbladder polyps were assessed using univariate and multivariate logistic regression analysis.

Result: Patients with neoplastic polyps were found to be significantly older than patients with nonneoplastic polyps (mean age 65.0 vs 54.2 years, p < 0.001). Neoplastic polyps were significantly larger (mean size 18.1 mm (SD 17.9) vs 7.5 mm (SD 5.9), p < 0.001), more frequently presented as wall thickening (29.2% vs 15.6%, p < 0.001) as a single polyp (38.3% vs 68.0%, p < 0.001). Gallstones were more frequently found in gallbladders with neoplastic polyps (50.1% vs 40.4%, p > 0.001). No preoperative clinical features were predictive for neoplastic or nonneoplastic polyps. Presence of a single polyp on ultrasound was a predictor for neoplastic polyps (OR 6.00 (95%CI 1.32-27.31). Size and type of polyp were often not mentioned in ultrasound report, or different from histopathological confirmation.

Conclusion: Except for age, no clinical characteristics for neoplastic polyps were identified in this cohort. Although pathological characteristics of neoplastic and nonneoplastic polyps are confirmed, identification of these characteristics on preoperative radiological investigations is poor.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1392 METFORMIN INDUCES APOPTOSIS AND MODULATES PROLIFERATION IN THE BILE DUCT CANCER CELLS

Contact E-mail Address: june@hallym.or.kr

Introduction: Metformin has evidence of antineoplastic activity in some cancer cells.

Aims & Methods: This study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by inducing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affect molecular mechanisms involved in the inhibition of cancer cell growth. Human intrahepatic bile duct cancer cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on cell proliferation. Apoptosis was measured by a cell death dye detection enzyme-linked immunosorbsent assay and caspase-3 activity assay. Various protein expressions with or without specific SiRNA transfection were measured by Western blot analysis. The migratory activity of the cancer cells was evaluated by wound healing assay.

Results: 1) Metformin suppressed cell proliferation in bile duct cancer cells by inducing apoptosis. 2) Metformin inhibited mammalian target of rapamycin (mTOR) by activation of AMPKThr172 - tuberous sclerosis complex 2 (TSC2) pathway, and hyperglycemia impaired metformin-induced activation and enhanced phosphorylation of AMPKThr172. 3) Metformin induced expression of key genes of the BER short and long patch pathway. The data also suggests which inturn is due to genetic, expression and epigenetic deregulations in the key genes of the BER short and long patch pathway. Conclusion: The data indicates an important role of oxidative stress in the pathogenesis of bile duct cancer, and the effect was impaired by hyperglycemia. The data are important to be important targets for future development of chemotherapeutic agents.

Disclosure of Interest: All authors have declared no conflicts of interest.

2. Chaiteerakij R1, Yang JD, Harmsen WS, Slettedahl SW, Mettler TA, Fredericksen ZS, Kim WR, Gores GJ, Roberts RO, Olson JE, Therneau TM. The genetic alterations in hOGG1 and XRCC1 gene were highly prevalent in both controls and gallbladder disease cases in NEI population, and was associated with susceptibility and severity of gall bladder anomalies compared to controls, which is significantly lower for CRC in 280 polymorphism in GBC cases compared to controls [OR = 1.986, p = 0.047]. Differential mRNA expression profile clearly showed a sharp down-regulation in hOGG1, APE1, p53 and PARP1 expression in GBC, CL and CS cases compared to controls; and in GBC compared to CL and CS cases. The mRNA expression profile of both short and long patch pathway genes was analyzed as well as bile juice. Each sample was obtained prior to the treatment effect in future, so called “precision medicine” approach based on the biopsy results.
3. Chaiteerakij R1, Yang JD, Harmsen WS, Slettedahl SW, Mettler TA, Fredericksen ZS, Kim WR, Gores GJ, Roberts RO, Olson JE, Therneau TM. The development of non-invasive molecular diagnostics of gallbladder cancer by bile juice-liquid biopsy:

Introduction: Gallbladder cancer (GBCa) is often diagnosed at advanced stage due to the lack of specific symptom,怎么办 diagnose in early stage, because patients with early GBCa has not showed any symptoms and the tissue cannot be obtained easily with anatomical reason. This resulting poor prognosis, because the patients with early GBCa has not showed any symptoms and the tissue cannot be obtained easily with anatomical reason. The genetic alterations in hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in cases compared to controls; and in GBC cases compared to CS cases.

Conclusion: The data indicates an important role of oxidative stress in the pathogenesis of bile duct cancer, and hence holds clinical relevance.

Disclosure of Interest: All authors have declared no conflicts of interest.
treatment. As negative controls, 19 non-GBCa bile juice and 33 non-GBCa tissue samples were used. The mutations of oncogenes in the same way.

Results: The median (range) age was 77 (44–90) years and the male/female ratio was 0.43 (9:21). Six, six, and twelve patients were diagnosed as stage I, II, III, and stage IV, respectively. We set cut-off value at 5% for rare mutation rate based on the results of healthy samples to avoid false positive. Eleven of 20 (55%) tumor tissue samples were positive for mutation. TP53, MET, SMAD4, CTNNB1 and AR were detected in 7/20 (35.0%), 1/20 (5.0%), 1/20 (5.0%), 1/20 (5.0%) and 1/20 (5.0%) respectively. In this study, 14 of 30 (46.7%) patients had both tumor tissue samples and bile juice samples. Eight of 14 (57.1%) tumor tissue samples were positive for mutation. In these eight patients, 7 (87.5%) bile juice samples had the same mutation (TP53, ERBB2/3 were detected in 6/8 (75%), 1/8 (12.5%), respectively). On the other hand, bile juice samples of one of 6 tumor tissue mutation had no mutation. With regard to only bile juice, 14 of 24 (58.3%) bile juice samples with GBCa were positive for mutations. TP53 mutation, ERBB2/3, KRAS were detected in 11/24 (45.8%), 2/24 (8.3%), 1/24 (4.2%), respectively. Bile juice analysis for mutations indicated that bile juice has the ideal positive predictive value (PPV) and negative predictive value (NPV) were 58.3%, 100%, 100% and 65.5%, respectively. None of negative control samples had any mutations.

Conclusion: Mutations in tumor could be detected in bile juice using NGS. Liquid biopsy with bile juice may help us to diagnose GBCa because of high PPV (100%). It may allow us to make new genetic diagnosis of GBCa.

P1395 EFFICACY OF INTRADUCTAL RADIOFREQUENCY ABLATION USING A NOVEL ENDOLUMINAL RADIOFREQUENCY ABLATION CATHETER IN A SWINE MODEL

1Division Of Gastroenterology, Department Of Internal Medicine, The Catholic University of Korea, Uijeongbu; 2Department Of Pathology, The Catholic University of Korea, Uijeongbu; 3St. Mary’s Hospital, Uijeongbu/Korea, Republic of Korea

Contact E-mail Address: hykkim@catholic.ac.kr

Introduction: Intraductal radiofrequency ablation (RFA) is a new endoscopic ablative technique with direct effect to local tumor has been developed to improve the course of self-expandable metal stents (SEMS) in the unresectable malignant biliary obstruction. However, there is the concern for the complication such as bile duct perforation or bleeding because the ideal power setting of RFA has not been clearly revealed still.

Aims & Methods: We aimed to investigate the effects of ablative injury after in vivo intraductal RFA according to the time variation using a novel RFA catheter (ELRA®, STARmed, Goyang, Korea). This novel catheter is a bipolar device and has a temperature sensor within the distal tip, therefore it has a characteristic of target temperature controlled mode. Nine female pigs were divided into three groups according to RFA time variation (60, 90 and 120 seconds) with the same power setting (10 watts) and RFA target temperature (80°C). All pigs underwent endoscopic retrograde cholangiography (ERC) and intraductal RFA. Additional cholangiogram was taken immediately after RFA and then a plastic stent was inserted. All the pigs were humanely sacrificed 24 hours after the intraductal RFA. Necropsy was performed and the common bile duct was examined for histologic analysis.

Results: The ERC and application of the intraductal RFA was successful in 100%, and post-RFA cholangiogram did not show the contrast leakage.

Conclusion: Intraductal RFA has not been clearly revealed still. The predictive model for the probability of neoplasia was fitted from the training set using the logistic regression method equipped with backward elimination with significance: level for removal of P > 0.05 for variable selection. The performance of a fitted prediction model was evaluated by the area under the curve (AUC) of a receiver operating characteristic (ROC) curve. A cutoff value of the fitted risk score was chosen by the Youden Index.

P1397 COMPARISONS OUTCOMES FOR CONTROLLED PHOTODYNAMIC THERAPY IN HIGH GRADE UNRESECTABLE HILAR CHOLANGIOCARCINOMA

E.T. Park, B.C. Yun, S.U. Lee, B.H. Han

Internal Medicine, Kosin University, Gospal Hospital, Busan/Korea, Republic of Korea

Contact E-mail Address: eunpark@hanmail.net

Introduction: Photodynamic therapy (PDT) provide clinical benefit for patients with unresectable biliary malignancy. In this study, we evaluate the efficacies of controlled PDT for unresectable primary and secondary high-grade hilar cholangiocarcinoma (CC).

Aims & Methods: In cases of high-grade unresectable hilar CC (Bismuth type III or IV) and gallbladder (GB) cancer invasion to hilar portion (Group A), we performed controlled PDT. Controlled PDT means malignant stricture dilatation using balloon catheter up to 120 seconds in CC. We performed PDT with straight angled cylindrical diffuser using with gemcitabine-based chemotherapeutics in similar patients (Group B) in terms of clinical parameters and developing complications.

Results: Between July 2010 and June 2015, 26 cases(31) of high grade unresectable hilar CC (Bismuth type III or IV), 5 cases of GB cancer with hilar invasion were enrolled for Group A, 23 cases(26) of high-grade unresectable hilar CC (Bismuth type III or IV), 3 cases of GB cancer with hilar invasion were enrolled for Group B. On three months later, serum bilirubin levels decreased from 7.3 ± 5.2 to 2.4 ± 1.8 mg/dL in group A, 6.9 ± 5.5 to 5.2 ± 3.7 mg/dL in group B (P < 0.05). PDT-induced cholangitis is developed in Group A (3/1, 9.6%) and B (7/26, 26.9%) within seven days (p < 0.001), Progression free survival is superior Group A to Group B that of 14.8 months vs. 8.9 months (P < 0.05).

Conclusion: Controlled PDT with applying cylindrical diffuser promise efficacy for clinical parameters and progression free survival compared with transpyaipal PDT in unresectable high-grade hilar CC and GB cancer. Additionally, diminished post-PDT cholangitis within 7 days affect improving long term progression free survival.

Disclosure of Interest: While many studies have attempted to define the risk factors for neoplastic potential of gallbladder polyp, precise adaption of the risk factors individually in a real treatment strategy of gallbladder polyp remains elusive. Evaluating the probability for neoplastic potential of gallbladder polyp using a combination of several risk factors before surgical resection would be useful in patient consultation.

Aims & Methods: This study was designed to provide the statistical predictive model for neoplastic potential of gallbladder polyps. We collected data of patients confirmed as GBP through cholecystectomy at Samsung Medical Center between January 1997 and March 2015. Those with a definite evidence for malignancy, such as adjacent organ invasion, metastasis on preoperative imaging studies, polyp larger than 15 mm, and absence of proper preoperative ultrasonography imaging, were excluded. A total of 1976 patients were enrolled.

To make and validate the predictive model, we divided the cohort into the modeling group (n = 979) and validation group (n = 997). Clinical information, ultrasonographic findings, and blood tests were retrospectively analyzed. A prediction model for the probability of neoplasia was fitted from the training set using the logistic regression method equipped with backward elimination with significance: level for removal of P > 0.05 for variable selection. The performance of a fitted prediction model was evaluated by the area under the curve (AUC) of a receiver operating characteristic (ROC) curve. A cutoff value of the fitted risk score was chosen by the Youden Index.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Unexplained cholangitis (IAC) associated with IgG4-related disease (IgG4-RD), a multi-organ inflammatory disorder of unknown cause. IAC may present with jaundice, abdominal pain and weight loss; immunosuppression is the preferred treatment. Since the disease presentation may closely mimic that of malignancies of the pancreatobiliary tract and accurate diagnostic tests have only recently been evaluated, misdiagnosis and unnecessary surgery are common. The disease had been consistently reported in literature.

Aims & Methods: Our aim is to assess the incidence of Immunoglobulin G4-associated cholangitis (IAC) in patients resected for presumed perihilar cholangiocarcinoma (PHC).

Results: Between 1984 and 2015, 321 patients underwent liver and bile duct resections for presumed PHC. Of all patients 15% (47/321) were found to have benign disease with still alive were re-evaluated to assess IgG4 serum levels and IgG4/IgG RNA ratio to detect activity of IAC.

Conclusion: Benign hilar disorders mimicking PHC have led to considerable number of liver and bile duct resections during the last three decades. There was evidence of IAC in 45% of these patients. When left untreated, IgG4-RD can reduce misdiagnosis and unnecessary surgery. Novel accurate diagnostic tests for IAC might reduce misdiagnosis and unnecessary surgery.

Introduction: Digital cholangioscopy provides higher-resolution imaging of the pancreatobiliary tract compared to the 1st fiberoptic generation. The impact of a new single-operator digital cholangioscope (d-SOC) in diagnosis and treatment of pancreatobiliary diseases has not been intensely assessed.

Aims & Methods: The aim of this retrospective analysis of prospective case series is to evaluate the outcomes of patients from the Czech and Slovak (n = 321) first generation of d-SOC compared to the 1st fiberoptic generation. The primary outcome was achievement of a complete ductal clearance in patients with difficult biliary strictures (1) and diagnostic accuracy of d-SOC visual diagnosis and biopsies in patients with undetermined biliary strictures; (2) the efficacy of d-SOC directed treatment of difficult lithiasis and (3) to analyze procedure related adverse events (AEs). The diagnostic accuracies were (1) sensitivity (2) specificity for (1) without biopsies (2) achievement of a complete ductal clearance in patients with difficult lithiasis (3) procedure-related AEs.

Results: A total of 150 patients underwent 166 d-SOC procedures (165 cholangioscopies and 1 pancreatoscopy); 81 (48.8%) for diagnostic intents (with biopsy in 66/81 patients (81.5%), and 85 (51.2%) for therapeutic intents (1 patient had pancreaticolithiasis). The most frequent indication for diagnostic d-SOC was undetermined stenosis (n = 59). Reliable views of a target lesion were obtained in all patients. The sensitivity, specificity and diagnostic accuracy of d-SOC for visual diagnosis of malignant lesion was 88.9% (95%CI, 70.9–97.7), 81.2% (65.6–92.3) and 84.6% (73.5–92.4). The number of biopsies obtained per patient was 4 (range 1–13) and the specimen was adequate for histopathological review in 85.5% of patients. The sensitivity and diagnostic accuracy of d-SOC guided biopsies for malignancy were 78.3% (95%CI, 56.3–92.5), 96.4% (81.6–99.9) and 83.3% (70.7–92.1). The diagnostic accuracy of visual inspection was not statistically influenced by the presence of biliary stent (Yates’ χ²=0.9). Of 63 patients attended for d-SOC-guided stone therapy, a complete intraductal clearance was achieved in one session in 37 and in two sessions in further 10 patients, respectively and the overall success rate was 77%. A total of 11 patients (11/166; 6.6%) experienced an adverse event (cholangitis n = 6, pancreatitis n = 3, perforation n = 2), one patient with severe cholangitis died. The incidence of cholangitis was higher among patients who had received prophylactic antibiotics (n = 5) compared to those who had not received it (n = 1). The results of the second analysis were similar. The new generation of d-SOC shows that (1) It provides high diagnostic yield in patients with undetermined biliary stenosis; (2) The SOC directed biopsies have a high diagnostic accuracy; (3) d-SOC guided stone lithotripsy is effective in three quarters of patients and (4) Severe adverse events may occur and prophylactic antibiotics may not be effective in preventing post-d-SOC cholangitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1400 DISTINCT PROGNOSTIC VALUE AND BIOLOGICAL CHARACTERISTICS OF OSTEOPONTIN IN INTRAEPATHEPATIC CHOLANGIOCARCINOMA

K. Zhou1, F. Chen1, C. Zhou1, L. Cheng2, Z. Wang3
1Liver Cancer Institute, Fudan University, Shanghai/China
2Gastroenterology, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: 1421120043@fudan.edu.cn

Introduction: Intrahepatic cholangiocarcinoma (ICC) is famous for its poor prognosis. Deepen the knowledge of the mechanism of ICC contributes to improving the treatment. Osteopontin (OPN) is believed to promote tumorigenesis and metastasis in many kinds of cancers, while its role in ICC is controversial.

Aims & Methods: This study aims to investigate the prognostic value and biological characteristics of OPN in ICC. The expression of OPN was evaluated by qRT-PCR to find the expression ratio to detect activity of ICC. Quantitative PCR was used to investigate the relationship between SPPI and overall survival (OS) in 85 patients. Immunohistochemistry was used for detecting the prognostic value of OPN, as well as the correlation between OPN and clinicopathological characteristics. Stably transfected ICC cell lines which express either higher or lower level of OPN were conducted for lenti virus. Cell-IQ, the live cell imaging and analysis system, was used for proliferation and migration assay. Wound healing assay and Transwell assay was taken to investigate the ability of migration and invasion among transfected cell lines. PCR array was taken to screen the potential oncogenes regulated by OPN.

Results: SPPI is the most highly expressed genes in ICC with fold change of 43.35 according to HTA 2.0. ICC cell lines express higher level of SPPI and OPN than normal live cell line (P < 0.01). SPPI is higher in tumor than adjacent tissues. Patients with higher expression of SPPI in ICC has better OS than those with low expression (P < 0.01). SPPI and OPN are independent prognostic factors. Higher expression of OPN correlates with better differentiation of ICC and less lymph node metastasis. Compared with negative controlled (NC) cells, ICC cell lines expressing more OPN showed accelerated proliferation rate, stronger ability of migration and invasion. Likewise, ICC cells lines expressing less OPN than NC cells proliferated slower, their capability of migration and invasion was inhibited as well. MMP1, MMP10 and CXCR4 were down regulated in ICC cell lines which express either higher or lower level of OPN were conducted for lenti virus. Cell-IQ, the live cell imaging and analysis system, was used for proliferation and migration assay. Wound healing assay and Transwell assay was taken to investigate the ability of migration and invasion among transfected cell lines. PCR array was taken to screen the potential oncogenes regulated by OPN.

Conclusion: High expression of OPN in ICC tumors indicates less aggressive behavior of ICC and better overall survival for patients after resection. OPN is an advantage prognostic factor in ICC. OPN might function as an inhibitory factor of MMP1, MMP10 and CXCR4 to weaken the capability of migration and invasion in ICC cell lines.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: gambitta.pietro@ASST-fatebenefratelli-sacco.it

Introduction: Adenoma of the major duodenal papilla is clinically important because this lesion is premalignant and should be resected completely. Endoscopic papillectomy of ampullary adenomas is a promising alternative to surgical resection, however acute and delayed pancreatitis represent a major complication of this procedure.

Aims & Methods: We evaluated the clinical importance of pancreatic duct drainage after endoscopic papillectomy in order to prevent early (acute pancreatitis) and late (pancreatic duct orifice stenosis) complications of this procedure. Our single-center study with a minimal follow-up of 1 year, includes 19 patients who underwent endoscopic ampullectomy between 2012 and 2016. Careful preoperative evaluation was performed by EUS (100% of patients) and CT/MRI (94%). After a collective evaluation between the surgeon and the endoscopist, patients were candidate for endoscopic ampullectomy. Outcome parameters included ampulla morphology, biophysical accuracy as well as safety, efficacy, recurrence rate, and survival.

Results: Endoscopic resection was successful in 15 patients (79%). Histological resection margins revealed non-specific changes (10.5%), low-grade dysplasia (52.6%), high-grade dysplasia (18.5%) and carcinoma (21%). Biopraphic accuracy was 68.4%. In 4 cases histologic specimen revealed an invasive carcinoma: 2 patients underwent pancreaticoduodenectomy and two were treated conservatively with placement of biliary and pancreatic stents due to the high preoperative risk. After complete endoscopic resection (15 patients), pancreatic stents were placed in 10 cases (66%). In five cases the stents were treated by snare papillectomy and diathermal ablation (APC).

Conclusion: Pancreatic stent placement after endoscopic ampullectomy is mandatory to prevent acute and delayed pancreatitis complications. Preoperative strategy should be accurate by MRI, EUS and ERCP, in order to define the anatomy of the pancreatic duct aiming to improve the success rate of pancreatic stent placement after papillectomy.

Introduction: Early surgery is the standard treatment in patients with resectable periampullary or pancreatic head cancer with jaundice. However, early surgery is not always possible and PBD could be a necessary for patient with jaundice at diagnosis or for those undergoing neoadjuvant treatment. Most studies considered plastic stents for BPD, although SEMS are currently considered superior. A recent RCTS showed that fully covered SEMS are associated with better outcomes compared to plastic stents.

Aims & Methods: Aim compare the rate of endoscopic reintervention (Stent failure of PBD) before surgery and post operative outcome of metal vs plastic. We conducted a bibliographic search using PUBMED, EMBASE including random and non randomized trials. OR using the Manhfeld-Haenszel method was used for dichotomous variables. Weighted mean differences (WMD) were used as the summary statistic for quantitative analysis of continuous variables. Quantitative synthesis was performed using Review Manager version 5.0.

Introduction: Cholangiocarcinoma is a neoplasm arising from the intra- or extrahepatic bile duct lining epithelium. Cholangiocarcinoma are presents less than 2% of human malignancies, however, it is the second common primary hepatic malignancy. Till date, many carcinogens have already been identified and the relevant information with regard to these agents is available. One example is the potentially harmful presence of heavy metals that can cause serious health problems. Mental retardation may be exposed to heavy metals as a consequence of their lifetime. The heavy metals in drinking-water pose the greatest threat to public health in this regard. Nile River water is seriously contaminated with heavy metals, pesticides, herbicides and hydrocarbons as a result of increasing discharge of untreated industrial wastes and agricultural irrigation wastewater. Several reports on Dakahlia Province show high levels of heavy metal and organochlorine pesticides in the soil and water in this region. High concentrations of heavy metals, including cadmium, are among the pollutants in the water. Plants and fish grown in this water are also contaminated with heavy metals, which can in turn accumulate in human tissues and animals that feed on these contaminated foods. The serum cadmium levels of residents of Dakahlia Province are almost 10-fold higher than those of residents from cadmium-polluted areas in Cairo and 32 times higher than reference levels for healthy populations in the United States.

Aims & Methods: We aimed to assess serum levels of Heavy metals namely Zink (Zn), lead (Pb), Cobalt (Co), Cadmium (Cd), Chromium (Cr) and Iron (Fe) as a markers of exposure in cholangiocarcinoma patients and healthy control subjects from the same region in Egypt and its correlation with differentiation of cholangiocarcinoma and tumour marker CA-19.9. This study included 45 patients with cholangiocarcinoma (diagnosed after radiological &histopathological examination) and 20 healthy control subject attending Mansoura Surgical Gastroenterology centre. All patients and control were permanent residents of North Delta region and the patients were recruited before receiving chemotherap- or radiotherapy. There were no restrictions based on age, sex, or tumor stage. The serum samples were analyzed for concentrations of zinc, lead, cobalt, cadmium, iron and chromium by the acid digestion method followed by using atomic absorption spectrometry.

Results: The serum levels of Zn, Pb, Co, Cd and Fe were significantly higher in patients having cholangiocarcinoma more than control subjects (P < 0.001). Pressive increase in the median values of serum levels of lead (Pb) was found in well differentiated to moderately differentiated to undifferentiated tumours. (P < 0.05). When correlation was made between the heavy metals and CA-19.9 and the survival of the patients, it was found that Cd only has a positive correlation with CA-19.9 and negative correlation with the survival of the patients (P < 0.5, (P < 0.01) respectively.

Conclusion: The results from this study suggest that cholangiocarcinoma in the Nile Delta region is significantly associated with high serum levels of heavy metals especially Cadmium and lead.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Primary outcome was the rate of endoscopic reintervention before surgery. Secondary outcome was the rate of overall surgical complications, 30 days after surgery, post-operative complications, hospital readmission, overall pancreatic fistula, overall biliary anastomotic leak, overall postoperative mortality. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Three RCTs and five non-RCTs were selected including 909 patients. Of these, 303 patients (33%) were treated with SEMS and 606 (67%) with plastic stents. The rate of endoscopic reinterventions after PBD was significantly lower in the metal stent group in the plastic stent group (p > 0.001). The rate of post operative pancreatic fistula was significantly lower in the metal stent group (OR 0.44 95% CI 0.20–0.96; p = 0.04). The rate of postoperative surgical complications, hospital readmission, overall biliary anastomotic fistula and postoperative mortality did not differ between the two groups.

Conclusion: Metal stents are more effective than plastic and should be preferred for the management of malignant and benign refractory peripancreatic or pancreatic head tumors when early surgery without PBD is not feasible. However, more RCTS are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1404 THE EFFICACY AND SAFETY OF PREOPERATIVE BILIARY DRAINAGE IN PATIENTS WITH OBSTRUCTIVE JAUNDICE: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Tringali, M. Cintolo,1 L. Cristofori,1 E. Foriti,2 F. Pugliese,1 L. Diosoirdi1
1Endoscopy Unit, Niguarda Hospital, Milano/Italy
2Contact E-mail Address: albritt10@gmail.com

Introduction: There is considerd controversy as to whether temporary relief of biliary obstruction prior to major definitive surgery (preoperative biliary drainage) is of any benefit to the patient. A Cochrane meta-analysis revealed a major morbidity with no difference in mortality in the group subjected to PBD. However, the clinical status of patients was heterogeneous between studies.

Aims & Methods: We aimed to investigate the benefits and harms of pre-operative biliary drainage versus no pre-operative biliary drainage (direct surgery) in patients with obstructive jaundice. A computerized medical literature search was performed by using MEDLINE, EMBASE, Cochrane Library, from 1980 to June 2016 aiming at identifying RCTS comparing PBD versus direct surgery. Data from RCTS related to safety and effectiveness of PBD versus no PBD were extracted. A meta-analysis was performed. Odds ratio or mean difference were calculated with 95% cent confidence intervals. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity. Outcomes were mortality and morbidity.

Results: Nine trials including 734 patients with malignant or benign obstructive jaundice comparing PBD (375 patients) with no PBD (359) were included in this review. There was no significant difference in mortality (risk ratio 0.90, 95% CI 0.67 to 1.18; P = 0.42) and in the two groups. Complications were higher in the PBD group (RR 1.41; 95% CI 1.19–1.67; p = 0.008). Serious morbidity was higher in the PBD group than in the direct surgery group (RR 1.66 95% CI 1.04–2.65; p = 0.042). The rate of peritonitis in the PBD group as well (5.1% vs 11.8%, p = 0.041) was higher in the PBD group than in the direct surgery group (RR 1.66 95%CI 1.04–2.65; p = 0.04).

Conclusion: There is currently not sufficient evidence to support or refute the benefit of PBD stay between the two groups: mean difference 4.55 (95% CI 1.28–2.16 p = 0.001). In multivariate analysis, mortality did not differ between the two groups.

Introduction: Exocrine pancreatic insufficiency and exocrine function alterations are characteristics of pancreatitis. They are frequent in diabetes mellitus (DM) patients with a prevalence up to 50%. Although reduced levels of insulin may explain some of the proposed mechanisms of exocrine pancreatitis in chronic DM, the same phenotype is also detected in insulin-independent DM. This highlights the concept that additional factors are likely to contribute to the pathophysiology of acinar cells. We recently discovered that 1-deoxy-sphingolipids (1-deoxy-SLs), the levels of which increase in DM and metabolic syndrome are cytotoxic for beta cells5. Our preliminary results showed that 1-deoxy-SLs are also cytotoxic for acinar cells in vitro. Furthermore, the high level of 1-deoxy-SLs in diabetic animal model aggravated acinar cell damage whereas lowering 1-deoxy-SLs improved cell deterioration.

Aims & Methods: In this research, we investigate molecular and cellular factors that contribute to compromise acinar cell functionality in the context of DM. Based on the endocrine and exocrine pancreas crosstalk, we hypothesize that elevated 1-deoxy-SLs levels affect directly the pancreatic exocrine compartment by compromising pancreatic acinar cells in DM, thus increasing its predisposition to develop exocrine pancreatic diseases. In vitro mouse models with STZ-induced diabetes and cerulein-induced pancreatitis were used in this study. Reduction of 1-deoxy-SLs synthesis was achieved by oral L-serine supplementation. Disease severity was assessed with biochemical and immunohistochemical methods. Molecular mechanisms of 1-deoxy-SL-dependent toxicity were evaluated in vitro on AR42J pancreatic acinar cells and primary acinar cells.
P1407 ROLE OF THROMBOPHILIA IN SPLANCHNIC VENOUS THROMBOSIS IN ACUTE PANCREATITIS

Introduction: Splanchnic venous thrombosis (SVT) is a common vascular complication of acute pancreatitis (AP). There is paucity of data on its frequency, risk factors, outcome, and natural history. Coagulation abnormality has been implicated but not proven as a cause of SVT in AP.

Aims & Methods: We aimed to prospectively study the frequency, risk factors and extent of SVT in patients with AP as well as role of thrombophilia in causation of SVT. Patients with AP presenting to our centre between January 2015 and June 2016 were prospectively evaluated with contrast enhanced computerized tomography (CECT) abdomen for presence of SVT. These patients were subjected to Doppler study done in 7 patients with SVT, spontaneous venous thrombosis on follow-up.

Results: A total of 26 (27.1%) had SVT. Single vessel, two vessels and three vessels were involved in 19 (73.1%), 3(11.5%) and 4(15.4%) patients respectively. Splenic vein, portal vein and superior mesenteric vein involvement were seen in 23(88.5%), 14(53.8%) and 4(15.3%) patients respectively. Necrotizing pancreatitis, CTSI > 6 and Modified CTSI > 6 were found in significantly higher number of patients with SVT than those without SVT(96.2% vs 78.6%, 76.9% vs 47.1% and 67.1% vs 67.1%, respectively). Coagulation analysis was performed in all patients (18 with acute AP and 3 with pseudocyst). Protein C, protein S and AT III deficiency were found in 10(38.4%), 14 (53.8%) and 13(51.0%) patients respectively. β2GPI and lupus anticoagulant were positive in 2 (4.8%) and 1 (11.1%) patients respectively. Anticardiolipin antibody was negative in all the patients. Factor V Leiden mutation analysis was done in 33 patients (14 with SVT and 19 without SVT) of which 2 (6.1%) were positive. There was no correlation between abnormal coagulation results and outcome of AP. Coagulation abnormality did not differ significantly between the patients with and without SVT. Follow-up Doppler study done in 7 patients with SVT, spontaneous resoloution of SVT occurred in 5 (71.4%) within 1 year. None of the patients had varices on follow-up.

Conclusion: SVT in AP is more common in patient with necrotizing pancreatitis and higher CTSI and MCTSI indices suggesting that local inflammation plays a major role in its causation. Thrombophilia in some form is seen in one third of the patients with AP but does not increase the risk of AP.

P1409 EUS-GUIDED PANCREATIC FLUID COLLECTION DRAINAGE WITH LUMEN-APPOSING METAL STENTS OR PLASTIC DOUBLE PIGTAIL STENTS: A MULTI-FACTORIAL ANALYSIS

N. Ge, S. Sun
Dept. Of Endoscopy, Shengjing Hospital, Shenyang/China

Contact E-mail Address: ge_nan2013@163.com

Introduction: We aimed to compare the efficiency of plastic and metal stents for symptomatic pancreatic fluid collection drainage and analyze other main associated factors that affect the outcome of drainage therapy.

Aims & Methods: Rates of technical and clinical success, procedure-related side effects (hemorrhage, stent migration, and cyst rupture), re-interventions, and duration of hospital stay.

Results: There were 52 patients, 40 who underwent plastic stent placement and 12 who underwent lumen-apposing metal stent placement. The total rate of technical success was 100%. The total rate of clinical success was 100%. The total rate of adverse events was 7.7% (4/52). On multiple logistic regression analysis, the use of plastic stents (P < 0.05, Exp B = 12.168) and presence of a large cyst (P < 0.05, Exp B = 1.036) were shown to significantly increase the risk of re-intervention. On multivariate linear regression analysis, etiology of pseudocyst (P < 0.05, B = -8.427; -9.785; -5.514) was associated with prolonged hospital stent, while stent type was not shown to be a factor (P > 0.05).

Conclusion: Both plastic and lumen-apposing metal stents are proven to be highly efficient in pancreatic fluid collection drainage. The lumen-apposing metal stent is superior in preventing complications such as migration and cyst leakage and reducing the rate of re-intervention. Large cyst size is associated with an increased risk of re-intervention and prolonged hospital stay.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The EASY index has been published a protocol of local infusion of antibiotics for the treatment of IPN (Panreatology; 2016;16:719–25).

Aims & Methods: We aim at analysing the efficacy of this step-up approach for the treatment of IPN in clinical practice. This was a retrospective single-centre study of patients admitted with acute pancreatitis (AP) between January 2015 and December 2016. The cases with the diagnosis of pancreatic necrosis (PN) and IPN (defined by positive culture of necrosis and clinical, analytical, and/or radiological data of infection) were identified and evaluated. IPN was treated following a step-up approach defined by 1. intravenous antibiotic therapy, 2. Endoscopic ultrasound (EUS)-guided transmural drainage plus local antibiotic therapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

Results: 694 cases of AP were included (mean age 79.5 ± 18.3, 555 male). CT scan was performed only if clinically indicated. 67 patients (9.6%) had acute necrotizing pancreatitis (APN), and 21 of them IPN (31% of APN). IPN patients were treated with intravenous antibiotics (imipenem [n = 15] and meropenem [n = 6], with good response in 8 (38% of IPN). The remaining 13 cases underwent a EUS guided transmural drainage plus local antibiotic therapy, 3 endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

P1413 WORSE OUTCOMES IN ACUTE PANCREATITIS IN PATIENTS WITH TYPE-2 DIABETES MELLITUS

P. Santos, J.R. Carvalho, S. Fernandes, M. Moura, T. Antunes, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa/Lisbon

Contact E-mail Address: patricia.sants@hotmail.com

Introduction: Predicting severe pancreatitis is important for early aggressive management of patients with acute pancreatitis (AP). Despite the established role of type-2 diabetes mellitus (DM) in the risk of AP, the impact of DM on the clinical outcome in AP has not been fully elucidated.

Aims & Method: Retrospective study including hospital admissions between January 2003 and December 2016 in a single tertiary referral center. Clinical outcomes included organ failure of (OF), persistent OF (>48h) admission to intensive care unit (ICU) and mortality. Variables were analysed by logistic regression (SPSS v23.0). The objective of this study was to assess the risk of mortality and severity in AP among patients with type-2 DM.

Results: A total of 553 patients (58.4% male) with AP were included, median age 80 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.5%). Twenty three percent developed OF (in 43% persistent) and 5.6% died. There were 127 AP patients (23.0%) with type-2 DM. Type-2 DM were not associated with higher Ranson’s score. There was an association between DM and development of OF (OR 3.17, CI95% 18.8–53.7, p < 0.001), persistent OF (OR 45.1, CI95% 18.7–108.9, p < 0.001), ICU admission (OR 12.3, CI95% 2.8–4.1, p < 0.001) and AP severity (OR 17.1, CI95% 6.8–42.8, p < 0.001). At multivariate analysis DM was an independent predictor of OF development and ICU admission.

Conclusion: In our population, Type-2 DM was associated with severity and increased mortality in patients with AP. Our findings provide evidence of the potential role of DM in the management of severe AP.

P1414 ACUTE Pancreatitis IN LIVER TRANSPLANT RECIPIENTS: INCIDENCE AND OUTCOME

P. Macina1, K. Poc2, P. Trunecka3, J. Spick1, T. Hucl1
1Department Of Gastroenterology And Hepatology, Institute For Clinical And Experimental Medicine, Prague/Czech Republic, 2First Faculty Of Medicine, Charles University, Prague/Czech Republic, 3Transplantcentre, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: peter.macina@ikem.cz

Introduction: Acute pancreatitis (AP) is an uncommon but potentially devastating condition that may occur in patients with organ transplantation. Reported incidence ranges from 1.5 to 8% in patients undergoing liver transplantation with significant mortality.

Aims & Methods: The aim of our study was to assess the incidence, potential risk factors and outcome of AP following liver transplantation in our center. We performed a retrospective medical analysis of medical records of all adult patients who underwent liver transplantation in our center between September 1996 and November 2014. The diagnosis of AP was defined by combination of clinical manifestation, finding on imaging methods (CT, USG) and elevation of serum amylnase and lipase. AP was confirmed if it occurred within 1 month after liver transplantation and late (>1 month).

Results: Nine hundred and sixty-seven orthotopic liver transplantations were performed in 578 males and 389 females (mean age 51 years, range 18–74). AP occurred in 18 patients (1.9%, 16 males, 2 females) and resulted in death in 5 patients (28%). According to timing of AP we recognized two clinical presentation—early AP (<1 month after liver transplantation) and late (>1 month). Four patients (22%) developed early AP, which was severe necrotizing with MODS in all cases and resulted in death in 3 of them (75%). Two of them were transplanted for fulminant hepatic failure, one for end-stage liver disease due to chronic hepatitis B infection and one for polycystic liver disease. Two patients were treated by surgical necroctomy and died, the third deceased patient was treated conservatively. In the only surviving patient, a successful EUS-guided drainage of walled of pancreatic necrosis and repeated endoscopic retrograde cholangiopancreatography were performed, and the patient was discharged. The patient was discharged and in good condition within 3 months after the admission and was discharged. However, there were 2 patients who died from acute pancreatitis. One patient developed a pseudocyst. Two patients with late acute pancreatitis had a severe necrotizing form and both died. One patient with cirrhosis of the liver graft, the second patient a chronic rejection of liver graft. AP diagnosed by necrotic pancreatitis which was complicated by retroperitoneal hemorrhage and graft failure. The other patient with necrotizing pancreatitis of unknown etiology developed MODS and eventually died. Male patients (p = 0.01) and patients transplanted for liver cirrhosis resulting from chronic hepatitis B were at a significantly higher risk of AP development (p = 0.03).

Conclusion: The incidence of AP after liver transplant in our center is low. In it necrotizing form which is more frequent early after liver transplant, it carries a significant risk of mortality exceeding 60%. Male patients and those transplanted for end stage liver disease resulting from chronic hepatitis B are more likely to develop post-liver transplantation pancreatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biliary sludge (BS) may be one of the factors, related to development of chronic pancreatitis (CP) via sphincter of Oddi dysfunction. As it was demonstrated by Okazaki K et al. in 1988, patients with biliary sludge have higher sphincter of Oddi (SO) pressure and contraction frequency vs. controls.

Aims & Methods: To assess the frequency of CP signs in patients with BS and to investigate the state of major duodenal papilla (MDP) in patients with idiopathic CP with BS by endoscopic ultrasound (EUS), to evaluate whether antispasmodics can be effective in pain relief at CP, that developed on the background of gallbladder sludge. Protocols of computer tomography, endoscopic and transendoscopical ultrasound studies of over 6000 patients of gastroenterological tertiary clinic were examined. Those who had signs of BS were selected to evaluate the present study. Among at least “mild CP” we found a significant correlation with BS. A total of 30 patients were included. Exclusion criteria were: established etiology of CP and signs of pancreatic neoplasm. Patients, who received ursodeoxycholic acid and drugs that affect smooth muscle contractility for less than 3 month prior to the study were excluded. Thirty consecutive patients (15 m, 15 f, mean age ±SD: 52.8 ± 15.3), who had both BS and CP were summoned for physical examination, quality of life assessment, US-cholecystography and endoscopic pancreatobiliary ultrasound with elastography, calculation of MDP area: SMDP = (MSx + MSp)/(2*2.72) and state of MDP before and after 3 weeks of hyoscymine monotherapy 400 mg tid.

Results: Signs of CP were revealed in 6.3% of BS cases. CP was most common in those who had outpatient-like bile (33.3%) vs. patients with heterogeneous bile with clots -7.7% and hypocholic particles-1.7% (chi-square 38.21, p < 0.0001). Mean SMDP was 14.9 ± 5.2 mm2 (95%CI 10.9–18.9). SMDP was below the normal range (20–25 mm2) in 78% of patients. SMDP had positive correlation to the value of the “bodily pain” according to US-cholecystography (r = 0.042, p = 0.007) and gallbladder contractility coefficient (r = 0.0817, p = 0.007). All patients with higher density of MDP at US- elastography had SMDP lower than the normal range and were attributed to “fibrosis” group. Only 38% of patients with CP and BS had normal MDP at EUS. Perianpillary diverticula were found in 13% of the cases, papillary edema — in 38%, fibrosis — in 13%. MDP changes were associated with higher AP level and larger MPD diameter. Hyoscymine monotherapy resulted in significant improvement in abdominal pain (r = −3.79, p = 0.001) and mean “bodily pain” score of SF-36 questionnaire (r = −3.79, p = 0.001). Dynamics of “bodily pain” score by SF-36 demonstrated significant negative correlation to the post-treatment level of abdominal pain (r = −0.395, p = 0.037) Post-treatment pain level had significant negative correlation with MDP size (r = −0.687, p = 0.002), though no correlation of pre-treatment pain level to MDP features was found, i.e. patients with less MDP size (most of them had decreased elasticity of papilla of Vater, that was considered as indirect marker of fibrosis) had lower hyoscymine efficacy.

Disclosure of Interest: BS may cause MDP changes, resulting in development of obstructive CP. Intensity of pain in biliary CP may be related to sphincter of Oddi dysfunction. Efficacy of antispasmodic therapy in these patients can be predicted by the features of MDP at pancreatobiliary EUS.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic exocrine insufficiency is a late complication of chronic pancreatitis; its clinical onset is characterized by steatorrhea and weight loss, borborygmi, flatulence, abdominal pain and malnutrition. Exocrine and endocrine pancreatic function decreases differently in various diseases (autoimmune, paraudenal, genetic, idiopathic). It has been observed that there has been a recovery of exocrine pancreatic function in autoimmune pancreatitis. In the literature, there are no studies analysing the pancreatic exocrine function over time. The fecal elastase test is a good test procedure to evaluate the exocrine pancreatic function

Aims & Methods: The objective of the retrospective study was to re-evaluate a series of patients with chronic pancreatitis with the aim to evaluate the pancreatic exocrine function over time, in particular, by comparing the exocrine pancreatic function in subgroups of patients with different types chronic pancreatitis. Pancreatic exocrine function was estimated through fecal elastase in 143 patients with at least 2 values each (classified into normal, mild and severe exocrine pancreatic insufficiency), the first one taken at the diagnosis of chronic pancreatitis. Patients undergoing surgical pancreatic resection before the second value of fecal elastase were excluded. Etiology was classified in: biliary pancreatitis/sequale of necrotizing pancreatitis (15), autoimmune (69), paraudenal (15), genetic (17) and idiopathic (27).

Results: The results show a high frequency of severe exocrine pancreatic insufficiency in the moment of diagnosis of chronic pancreatitis (38%) and it appears stable over the years. Autoimmune and paraudenal chronic pancreatitis are correlated with severe exocrine pancreatic insufficiency at diagnosis in a high percentage of cases (51% and 40%), biliary/outcomes of necrotizing pancreatitis and idiopathic pancreatitis in an intermediate (33% and 26%), while genetic in a low percentage (12%).

Conclusion: The exocrine pancreatic function in patients with autoimmune chronic pancreatitis improved in the first five years of the disease, probably due to the efficacy of steroid/immunosuppressive therapy. Pancreatic endocrine function was less compromised at diagnosis, but showed a progressive deterioration in the first five years. Endocrine and exocrine insufficiency were strictly correlated.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1417 "PAINLESS" CHRONIC PANCREATITIS: EPIDEMIOLOGICAL, CLINICAL AND RADIOLOGICAL CHARACTERIZATION

Introduction: The "painless" chronic pancreatitis (P-CP) represents a specific subset of CP characterized by the lack of pancreatic pain. So far, scarcity of data has been reported in the literature about this matter and what differentiates this group of patients from those with chronic pancreatitis associated with pancreatic pain.

Aims & Methods: The aim of the present study is to characterize "painless" CP from the epidemiological, clinical, radiological, functional, and follow-up standpoint, through a comparison with other forms of chronic pancreatitis presenting with pancreatic pain. The Institutional Database of the Gastroenterology Unit of the Verona University was queried, and all chronic pancreatitis cases were retrieved. Patients were clustered based on the presence of “pancreatic-specific pain” into “painless” and “pain-associated” CP. A retrospective case-control analysis was carried out.

Results: Of 678 patients included from March 2006 to March 2016, 436 were considered eligible for the present study. Of these, 368 (84%) were affected by pain-associated CP, while 68 (16%) had “painless” CP. “Painless” patients were older (median age of 38.5±10.8 y/o vs. 42.5±15.3 y/o; p<0.001), less frequently presenting with a history of alcohol consumption (35% vs. 55%; p<0.001), more frequently diabetics (18% vs. 1%; p<0.001), presenting with steatorrhea (16% vs. 2%; p<0.001), and asymptomatic (63% vs. 2%; p<0.001) compared to pain-associated controls. From the radiological standpoint, these cases were more often presenting with calcifications than controls (90% vs. 68%; p<0.001). Moreover, in most of painless cases, the CP cause remained unknown (56%). After a median follow-up of 2.6±2.3 years, the incidence of diabetes was higher in the painless cases than in controls (48% vs. 30%; p<0.006).

Conclusion: The present study represents the first definition of "painless" CP so far reported in the literature. The "painless" CP is a distinct entity from the epidemiologic, clinical, and radiological standpoint when compared to other forms of CP characterized by pancreatic pain.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1418 LONG-TERM OUTCOMES OF A FULLY COVERED SELF-EXPANDABLE METAL STENT WITH ANTIMIGRATION PROPERTIES FOR EU-S-GUIDED PANCREATIC DUCT DRAINAGE

1Department Of Gastroenterology, Novon Eulji Medical Center, Eulji University, Seoul/Korea, Republic of
2Department Of Gastroenterology, University of Ulsan College of Medicine, Asan Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: dongwook.oh1@gmail.com

Introduction: Recently, EU-S-guided pancreatic duct drainage with transmural stenting (EU-S-PD) has been used for patients with painful obstructive pancreatitis in whom endoscopic retrograde pancreatography (ERP) has failed. Although the feasibility and safety of EU-S-PD with a fully covered self-expandable metal stent (FCSEMS) has been assessed, little is known about the long-term outcomes of EU-S-PD with a fully covered self-expandable metal stent (FCSEMS). Removability of an FCSEMS in long-term use and higher cost are the main concerns of EU-S-PD with an FCSEMS compared with EU-PD with a plastic stent.

Aims & Methods: The aim of this study is to evaluate the procedural and long-term outcomes of EU-S-PD with an FCSEMS for patients with painful obstructive pancreatitis who failed ERP. Forty-one consecutive patients with painful obstructive pancreatitis underwent EU-S-PD with an FCSEMS after failed ERP. All patients underwent without sufficient exchange of a previously considered in malignant MPD strictures or complete MPD obstruction in benign pancreatic stricture. Technical and clinical success, adverse events, and stent patency were assessed. An endoscopic examination and CT scan was performed every 6 months to assess stent patency in benign stricture.

Results: 15 patients had malignant MPD obstruction and 26 patients had benign stricture. EU-S-PD was successful in all 41 patients (technical success rate, 100%), and symptoms improved in all patients (clinical success rate, 100%). EU-S-guided pancreaticojejunostomy (n = 39) and pancreatocutaneous (n = 2) were successfully performed. Pain scores improved significantly after FCSEMS placement (P = .01). Early mild-grade adverse events occurred in 5 patients (12.2%), including distal stent fracture (n = 6), stent occlusion (n = 2). These patients were successfully treated endoscopically. No other adverse events related to FCSEMS, including stent migration, pancreatic sepsis, and stent-induced ductal stricture were observed during follow-up periods.
Overall mean stent patency duration was 412 days (range 14–1081) during mean follow-up period of 243.5 days. Median stent patency in all malignant strictures was 95 days (range 14–297). Mean stent patency in benign stricture was 525 days (range 121–1081). No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods. FCSEMS removal and exchange was successful in patients with benign strictures until 3-year placement of an FCSEMS. Prospective randomized trial comparing EUS-PD with FCSEMSs and plastic stents may be warranted for painful obstructive pancreatitis after failed ERP.

ML 228 and inhibited using Echinomycin. PTK and STK analysis of cell lysates displays correlation between phosphorylation and O-glycosylation in hypoxic samples.

Results: Mechanistically we could show, that hypoxia-induced decreased levels of C1GALT1C1 results in reduced T-Synthase activity with subsequent expression of truncated O-glycosylated (Tn antigen). Differential O-GalNAc glyclosylation is inducible using HIF pathway activator ML228 under normoxia and the effect is reversed using 5μM Echinomycin under hypoxia underscoring the role of HIF1α regulated transcription. Interestingly, the pattern of Tn antigen modified proteins are altered from hypoxic samples differing significantly from engineered COSMC-deficient cells, displaying O-GalNAc moieties in addition to O-GlcNAc in cytosolic protein fractions. Further, we could show PTK/AKT/ MAPK signalling is depending on the state of cellular O-glycosylation providing a new rationale for the correlation of PDAC Tn antigen glyctype and cancer cell proliferation.

Conclusion: Our findings point to a novel crosstalk of O-GalNAc and O-GlcNAcylation under hypoxia extending the knowledge base of differential O-GalNAc glyclosylation in pancreatic cancer.

P1424 THE EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER: THE EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER
Y. Zhang, Q. Zhan
Digestive Department, Wuxi People's Hospital, Wuxi/China

Contact E-mail Address: zhangq33@163.com

Introduction: Pancreatic cancer is one of the most common malignant tumors in digestive system. The overall survival rate is less than about 6% of pancreatic cancer. Pancreatic cancer with poor prognosis and survival rate is low, due to the early clinical symptoms is not easy to find, have a high transfer possible, and the operation difficulty, radiotherapy and chemotherapy is not sensitive. Radical surgical resection is the only opportunity to pancreatic cancer patients get longer survival. Therefore, a deeper understanding of the molecular mechanism of pancreatic cancer occurs, explore new effective treatment is imminent.

Aims & Methods: Pancreatic cancer is a highly malignant tumor and fourth leading cause of cancer-related death in the world. The median survival after diagnosis is 2-8 months, and approximately 3-6% of all patients with pancreatic cancer survive 5 years after diagnosis. This is mostly due to the fact that it is diagnosed at a stage when it is either locally advanced or has already metastasized to other organs. Hence, there is a paramount need to understand the molecular mechanisms underlying its initiation, progression and therapy.

The recent discovery of microRNAs (miRNAs) has revealed a novel mechanism of gene regulation and provided new ways for cancer research. MicroRNAs are small non-coding RNA molecules, which regulate the gene expression at post-transcriptional level. It is widely reported that miRNAs can act as oncogene or tumor suppressor genes.

Conclusion: The research on pancreatic cancer is still in its infancy. Further research is needed to understand the detailed mechanism of the role of microRNAs in pancreatic cancer. Therefore, this study investigated the expression of miR-195 in pancreatic cancer and potential mechanisms of its role in tumor progression.

Introduction: Pancreatic cancer (PDAC) is one of the most lethal diseases worldwide, due to its aggressive nature and about 90% of patients die within 5 years of diagnosis, because of early metastasis. The 5-year survival rate of PDAC patients is less than 10%, putting it as the fourth most lethal cancer. Pancreatic cancer presents a challenge for current therapeutic interventions of this disease.

Aims & Methods: We defined the identification of new biomarkers for chemoresistant pancreatic cancer. A secretory survey of chemoresistant PDAC cell lines was performed using SILAC-based mass-spectrometric analyses. Relative differences in protein concentrations among samples were investigated and led to the identification of previously unknown proteins. The impact of RNAi-mediated knockdown of selected genes in proliferating PDAC cells were analyzed using MTT-viability assays. Global protein-expression analyses were performed using Real-Time-PCR and immunohistochemistry using patient-derived PDAC samples.

Results: SILAC-based identification of the Tryptophan degrading enzyme KYNU (KYN), expressed in chemoresistant PDAC cells revealed an overexpressed and secreted form of the KYNU protein, compared to the chemosensitive counterpart. We further identified various stress-related external stimuli (Glicatalbine, IFNg, Hypoxia) as inducers of KYNU expression/secretion. A knockdown approach was linked to substantially lower proliferation of chemoresistant and aggressive PDAC cells. Global expression analyses using a tissue-microarray of PDAC patient samples (n = 368) revealed that high KYNU expression is significantly correlated with a worse outcome in PDAC patients.

Conclusion: The trypotphan degradation pathway member KYNU is overexpressed in a subset of PDAC patients and is linked to substantially increased cancer cell proliferation. Abundant KYNU expression in PDAC patients is linked to a worse clinical outcome. We found that KYNU is a new secreted biomarker of chemoresistant PDAC cells.

Introduction: The progression of pancreatic ductal adenocarcinoma (PDAC) is promoted by its highly abundant tumor stroma. As one of the main components of the tumor stroma human pancreatic stellate cells (hPSCs), precursor cells of pancreatic tumor stromal myofibroblasts (CAF), support PDAC progression by enhancing tumor cell growth, invasion and metastasis [1]. The collagen binding transmembrane receptor integrin α11 (ITGA11) is known to be overexpressed by myofibroblasts [2].

Aims & Methods: The aim of the presented study was to investigate the expression of ITGA11 in human PDAC and to study the role of ITGA11 inCAF regulation. ITGA11 expression was evaluated using immunostaining on human PDAC sections and various other organs. The relationship between ITGA11 expression and cancer markers and tumor marker was evaluated in a stroma rich co-injection model in mice. The biological role of ITGA11 in CAF differentiation was studied in hPSCs and hPSCs activated with TGF-β or conditioned medium from Pan1-c endothelial tumor cells using qRT-PCR, immunostaining, western blot, wound healing, collagen contraction and cell growth assays.

Results: In this study we have for the first time stained ITGA11 in human PDAC specimens. We found that ITGA11 was highly expressed in stromal myofibroblasts of PDAC patients, as shown by co-localization with the myofibroblasts marker alpha smooth muscle actin (α-SMA). Interestingly, there was no expression in healthy human pancreas and various other tissues from human organs. Furthermore, we induced subcutaneous tumors in mice by injecting Pan1-c or Pan1-c+hPSCs and found that ITGA11 was significantly over-expressed in stroma-rich Pan1-c+hPSCs tumors. The quantitative gene and protein expression of ITGA11 in subcutaneous tumors, positively correlated with the expression of the CAF markers α-SMA, Col1a1 and PDGFr. Activation of hPSCs with TGF-β or conditioned medium from Pan1-c resulted in the significant upregulation of ITGA11 and α-SMA. Stable ITGA11 knockdown, mediated by shRNA, significantly inhibited hPSC differentiation, migration potential, contractility and cell growth.

Introduction: The dismal prognosis of pancreatic ductal adenocarcinoma (PDAC) is mainly due to chemoresistance linked to the tumor microenvironment. Recent developments in therapeutic ultrasound (US), particularly US-induced cavitation, could help overcome chemoresistance by breaking microenvironmental barriers and increase cytotoxic drug availability. Three-dimensional (3D) culture in the form of spheroids is a useful model for reproducing multicellular resistance and analyzing the effects of cavitation.

Aims & Methods: The objective of this work was to study the effects of acoustic cavitation on a model of PDAC spheroids and to investigate possible potentialities of chemotherapy by US. CAPAN-2 PDAC cell line-derived spheroids were cultured as previously described by Ivascu et al. Four conditions, i.e. control, chemotherapy by US, control + chemotherapy by US, and US alone were studied. Experiments were carried out to optimize US settings, in order to observe the occurrence of controlled cavitation. Experiments were carried out to optimize US settings, in order to observe the occurrence of controlled cavitation. Comparisons between groups were based on proliferation and growth. Proliferation was evaluated 24 hours after treatment(s) by MTS assay. Growth was assessed by diameter measurement on light microscopy at day 7 and day 10.

Results: Compared to the control group, cell proliferation was decreased in spheroids treated with CT (p < 0.0001), but not with US alone. Proliferation was also further impaired in spheroids treated with CT-US combination compared to those treated with CT alone (p < 0.0001), but this synergistic effect of US and CT did not exceed growth of spheroid, meaning that spheroid diameter did not decrease after US-CT compared to CT alone.

Conclusion: This study shows the feasibility of applying an ultrasonic treatment (acoustic cavitation) in a three-dimensional culture model of PDAC. The combination of US and CT or US ultrasound synergistically reduced cell proliferation. Further analysis of the cytotoxic effects of acoustic cavitation on PDAC spheroids is in progress.

Introduction: Because of the progression of systemic chemotherapy (CT) for locally-advanced pancreatic cancer (LA-PC), chemoradiotherapy (CRT) was selected for limited case. However, very long survival rates were reported in CRT and detection of prognostic factors were warranted. In this analysis, we analyzed the LA-PC cases received CRT compared with CT.

Aims & Methods: Gemcitabine (GEM) and S-1 combination chemoradiotherapy was performed to our previous trial 1 (trial of Japan Pancreas Society 2010). Till March 2016, 30 LA-PC cases received GS-CRT, and the selection criteria were LA-PC with 1) pathological diagnosis, 2) large vessels (CA, SMA, CVA, PV, SV) invasion, 3) allocorphic and concurrency without multiple primary cancer, 4) unexecuted antitumor therapy. The chemotherapy in CRT administration of GEM (200 mg/m²) once a week for 6 weeks, administration of S-1 (80 mg/m²) for 2 weeks a month for 5 days per week for 5.5 weeks, and total dose was 50.4 Gy (Total 28 times). As after treatment, GEM 1000 mg/m² was continued until PD. The patients of CT group were also recruited by the same criteria. One of the regimens among GEM alone, S-1 alone and GEM+S-1 was selected for the primary treatment, and total 26 cases were implemented in more than 2 courses.

Results: Baseline characteristics in CRT and CT group were median age (62, 72.5: p = 0.004), male (20, 12: ns) and tumor location Ph/Pb (17/13, 16/10; ns), respectively. Efficacy was disease control rate (DCR) in 3 months after treatment (90%, 57.7%: p = 0.01), response rate (RR) (26.7%, 0%: p = 0.005) and conversion surgery (10%, 0%: ns). There were significant differences in progression free survival (PFS) (6 months, 5 months: p = 0.002) and overall survival (OS) (13M, 9M: p = 0.0165), respectively. The cases who survived for 18 months and longer were significantly (p = 0.0495) more in CRT (43.3%) than CT group (19.2%). Grade 3/4 adverse events in CRT group were 13 cases of neutropenia (G4-3 cases) and one case of gastrointestinal symptom, and those in CT group, neutropenia was 11 cases (G4-case), interstitial pneumonia (IP) aggravation was one case.

Conclusion: For LA-PC, GS-CRT showed better local tumor control and longer survival, and was considered as good candidate of neo-adjuvant therapy. More than 18 months survivors in LA-PC cases was other benefit of GS-CRT. We should think about good selection criteria of CRT and improve the survival of LA-PC.

P1428 HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) THERAPY FOR UNRESECTABLE PANCREATIC CANCER
Gastroenterology & Hepatology, Tokyo Medical University, Tokyo, Japan

Contact E-mail Address: a-sofuni@ym.hi-ho.ne.jp

Introduction: High-intensity focused ultrasound (HIFU) is expected as a new advanced therapy for unresectable pancreatic cancer (PC). The aim of this study was to detect the limitation of HIFU therapy combined with chemotherapy and to clarify the role of HIFU therapy in the treatment of pancreatic cancer.

Aims & Methods: We have evaluated the therapeutic effect of HIFU therapy in locally advanced and metastatic PC. We treated PC patients by HIFU as optional therapy, as well as systemic chemotherapy, in combination with chemotherapy, and then analyzed survival in the long term.

Results: The therapeutic effect of HIFU therapy was as follows: the rate of complete tumor ablation was 87.9%, the rate of symptom relief effect was 69.4%, and the effectiveness of primary lesion was CR or PR for more than 60% of cases. The treatment of HIFU therapy was very effective in resectable pancreatic tumors, with a response rate of 75.7%.

Conclusion: This study suggested that HIFU therapy has the potential of new method of combination therapy for PC.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis with an overall 5-year survival rate <6%. Surgically resected patients, although undergoing adjuvant therapy, have nevertheless a 5-year survival of <5%. In fact, it has been recently suggested that patients with a tumor of more than 2 cm might harbor micrometastases at diagnosis. In this view, the availability of new highly effective chemotherapy regimens that might be employed in the neoadjuvant setting, the correct evaluation of the T stage of pancreatic cancer plays a key role. The new proposed AJCC Staging System for Pancreatic Adenocarcinoma TNM (8th edition), in fact, differs from the 7th edition mostly for the evaluation of the T, giving high importance to the diameter of the tumor. The new TNM staging system has already been shown to predict survival differences more efficiently compared to previous editions. In this context, an efficient preoperative evaluation of the T is of high importance as it might shift the therapeutic decision from upfront surgery to neoadjuvant chemotherapy, that could improve survival in selected cases. This study aims at evaluating the accuracy of CT scan and EUS in evaluating the T stage of the tumor. We performed a retrospective study in a cohort of surgically resected histopathologically-confirmed PDAC patients at a pancreatic cancer referral center between 2015-2017, who were prospectively included in a dedicated database. Inclusion criteria: a) having both preoperative EUS and CT scan with pancreatic phase evaluation at the centre; b) CT and EUS were performed, at the latest, 30 days apart from each other and from surgical resection; c) no neoadjuvant chemo or radiotherapy was performed. The evaluation of the T by both imaging modalities was compared to the final pathology T re-established based on the new TNM 8th edition, in order to calculate specificity and sensitivity. T-test was used for comparison of categorical variables.

Results: Among the 184 PDAC patients surgically resected between 2015 and 2017 at our center, 30 met inclusion criteria. Of these, 19 (63.3%) were males, with a mean age at resection being 67.8 ± 9.5 years. The tumor was located in the head in 23/30 (76.7%) patients. Mean diameter of the tumor at pathology was 24.9 ± 10.8 mm, mean diameter at EUS was 24.0 ± 8.6 mm (p = 0.74), and mean diameter at CT was 25.9 ± 10.9 mm (p = 0.73). In 4/30 (13.3%) cases CT scan was classified as T1, in 17 cases (56.6%) T2, in 6 cases (20%) T3, and in 3 cases (10%) T4 (p = 0.001). The effectiveness of primary lesions was classified: CR: 8 (26.6%), PR: 8 (26.6%), SD: 8 (26.6%), PD: 6 (20%). The sensitivity and specificity of CT scan versus EUS and CT scan was 86.7% and 76.7%, respectively.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic adenocarcinoma is associated with a 5-6% survival at 5 years and a poor quality of life. In Romania there are few information about the prognostic influence of known risk factors for pancreatic cancer. The purpose of this study was to analyze the possible association with survival.

Aims & Methods: The aim of this study is to evaluate the association between risk factors and the occurrence of pancreatic adenocarcinoma and patients’ survival, which may constitute a theoretical basis for screening. We performed a prospective, multicentric study of patients with suspected pancreatic tumors detected in abdominal ultrasound or CT examination, during January 2015-December 2016, in which were analyzed risk factors and the occurrence of pancreatic adenocarcinoma and patients’ survival.

Results: There were 279 patients with pancreatic adenocarcinoma included in the study. Male patients were 58% from all patients, and the mean age was 63.5 years. Smoking, new-onset diabetes and history of chronic pancreatitis are risk factors for pancreatic adenocarcinoma (p < 0.05). At 5 years more than one-third of patients with pancreatic adenocarcinoma died (median survival = 5 months). It was demonstrated a statistically significant association adjusted for tumor stage between the presence of new-onset diabetes and survival: 5 months vs 3 months with a HR = 3. Other risk factors (alcohol, obesity, sex, genetics, coffee intake, some infections and abdominal surgery, history of chronic pancreatitis) had no prognostic role.

Conclusion: In our study, the risk factors for pancreatic cancer were smoking, having history of chronic pancreatitis and new-onset diabetes, but the only prognostic factor was smoking. The role of sex and alcohol consumption was not confirmed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the 2012 International guidelines on the management of intraductal papillary mucinous neoplasms (IPMN), main-duct IPMN patients with main pancreatic duct (MPD) diameter of ≥10 mm should have surgical resection, whereas surgery is not always mandatory in those with MPD diameter between 5 and 9 mm.

Aims & Methods: The aim of the study was to analyse the prevalence of malignancy (high grade dysplasia or invasive carcinoma) in 20 resected IPMN with MPD diameter between 5 and 9 mm and to identify predictive factors of malignancy. Retrospective analysis of patients with surgically resected IPMN between 2001 and 2016. Demographics, clinical presentation, imaging and histological features were compared between patients with preoperative evidence of MPD diameter between 5–9 mm (Group A) and ≥10 mm (Group B). Malignancy was defined as high-grade dysplasia or invasive carcinoma.

Results: From 122 patients with IPMN submitted to surgery, 66 with MD- or mixed-IPMN entered the final analysis. Mean age was 66 ± 12 years and 48 (72.7%) patients were men. Group A comprised 47 patients and Group B 19. Abdominal pain was present in 23 (34.3%) patients, jaundice in 19 (28.8%), diabetes in 18 (27.3%), pancreatitis in 15 (22.7%) and weight loss in 12 (17.4%). Group A was older (P = 0.043), had a higher incidence of diabetes (P = 0.003), and a lower incidence of weight loss (P = 0.001) than Group B. Overall, malignancy was found in 10 (40%) patients; 8 of them (80%) were in Group A and 2 (10%) in Group B (P = 0.002). The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1432. CLINICAL SIGNIFICANCE OF CHEMOTHERAPY FOR ELDERLY UNRESECTABLE PANCREATIC CANCER PATIENTS

S. Kaino | M. Sen-Yo, S. Shinoda, S. Amano, I. Sakaida
Department Of Gastroenterology & Hepatology, Yamaguchi University Gastroenterology & Hepatology, Ube/Japan

Contact E-mail Address: kaino@ymaguchi-u.ac.jp

Introduction: Pancreatic cancer has poor prognosis despite of improvements in multimodal treatments. As aging of the population advances, it is expected that elderly pancreatic cancer patients increase.

Aims & Methods: The aim of this study was to investigate the clinical significance of chemotherapy for patients with unresectable pancreatic cancer. At our hospital, 96 patients were diagnosed as having unresectable pancreatic cancer between January 2010 and December 2016. In this study, we defined elderly patients as those older than 75 years. We retrospectively examined the safety and efficacy of chemotherapy in patients with unresectable pancreatic cancer. We analyzed and compared the survival periods according to chemotherapies.

Results: Twenty-seven patients were older than 75 years (group A), and 59 were younger than 74 years (group B). We treated 6/10/2/5/4 patients in group A with GEM/S-1-modified FOLFIRINOX (mFOLFIRINOX)/GEM + nabPTX/first line supportive care (BSC)/others, respectively. On the other hand, we treated 12/14/11/13 patients in group B with GEM/S-1/mFOLFIRINOX/ GEM + nabPTX/BSC/others, respectively. Severe adverse events (more severe than grade 3 according to CTCAE v4.0) occurred in 18.2% of the patients in group A and in 33.3% of the patients in group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Introduction: Endoscopic ultrasound-guided biopsy (EUS-biopsy) is considered a reliable, safe, and effective technique for obtaining samples from pancreatic masses with a very high sensitivity and specificity (ranged to 85%–92% and 96–98%, respectively)[1–3]. A new EUS needle (SharkCore FNB needle, Medtronic, Dublin, Ireland) was introduced in order to improve the tissue acquisition.

Aims & Methods: The aim of the present study was to evaluate the presence of a histological sample using Shark Core Needles. This study was an observational multicenter prospective non-randomized clinical trial (NCT02946840). All consecutive patients referred for EUS examination and sampling of solid pancreatic masses underwent EUS-guided biopsy with 25 G Shark Core needles. This needle is an innovative tip geometry with a cutting surface designed to acquire cohesive tissue through both tissue fracturing and tissue snaring. Three needle passes were performed in every mass. At all attempts, a macroscopic on-site quality evaluation (MOSE) was done by endoscopist. If a “worm-like” material was observed at gross visual assessment, it was placed into formalin. If only liquid material was visible, it was smeared between 2 glass slides, fixed with ethanol, and stained with a Papanicolaou-stain for cytological analysis. Endoscopists recorded macroscopic features of the specimens. Pathologists described macroscopic, microscopic, and immunohistochemical features. The primary outcome was the treatment of masses with a diameter of at least 5 mm in greatest axis. All the other specimens (< 5 mm) were defined as micro-fragments. The final diagnosis was based on surgical resection, and clinical/radiological follow up. The secondary outcomes were diagnostic accuracy and procedure-related adverse events.

Results: Study population included 82 patients, enrolled in three centres, between 1st and 3rd quarter 2015 and 2016, with a mean age of 64.0 (SD 13.7, range 21–84) and 57.3% female gender. The mean size of the lesions was 27.6 mm (SD 12.2) and the location was the body and tail in 27 patients (32.9%), neck in 11 (13.4%), head and uncinated process in 44 (53.7%). Three needle passages were performed in all 3 patients who experienced mild bleeding precluding more than one needle passage. At MOSE, endoscopists described presence of “worm-like” material in 192 biopsy samples over 242 (79.3%). In 8 patients only cytological specimens were obtained after 3 needle passes (9.8%). Six cases of mild self-limited bleeding were observed (7.3%). The pathologists described the presence of a core in 80 samples (41.7%), in the other cases, after the specimen preparation, a micro-fragmentation was observed, that didn’t affect the histological evaluation. A final histological diagnosis was reached in 73 patients (90%): 50 pancreatic adenocarcinoma, 16 NET, 5 chronic pancreatitis, 2 pancreatic metastasis from other organs.

Conclusion: The new biopsy needle showed a good overall adequacy and a good rate of histological specimens (both core and micro-fragments) during EUS-guided tissue acquisition of pancreatic masses, with a minimum number of needle passes and no major complications. This ability could allow to avoid the use of rapid on-site evaluation and to perform immunohistochemical, molecular and genetic studies on histological samples.

Disclosure of Interest: All authors have declared no conflicts of interest.
In 399 (86.9%) cases on-site cytopathology support was available, while insufficient information.

Introduction: EUS FNA is accepted as the primary modality for tissue diagnosis of solid pancreatic lesions. The presence of on-site cytopathology for immediate evaluation of aspirated material and need for further evaluation.

Results: In 399 (86.9%) cases on-site cytopathology support was available, while the remaining was unsupported. There were 228 males (57.1%) in the supported group and in 38% (23%, 10%, 3%, 2%) of the unsupported (P = 11.9) respectively. The mean number of passes in the two groups were 2.8 (SD: 1.12) and 1.9 (SD: 1.0) (P < 0.001). The diagnostic yield of the presence of on-site cytopathologist significantly increases the diagnostic yield.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Self-expanding metal stents (SEMS) are increasingly preferred to plastic stents (PS) for preoperative drainage and palliation of biliary obstruction secondary to a stricture in the head of pancreas (HOP). Their use has increased over the last 5–6 years. Endoscopic ultrasound (EUS) with fine needle aspiration or biopsy (FNA or FNB) is commonly utilised to make a tissue diagnosis and to aid in staging in those with borderline resectable tumours. Stents may reduce diagnostic performance of FNA/FNB by reducing the visible mass to puncture. There have been two studies that assessed the impact of stenting on EUS-FNA performance, one found no difference in yield and sensitivity among patients with or without stents and between SEMS and plastic. Whilst a more recent study found accuracy was significantly reduced by the presence of a stent.

Aims & Methods: The aim was to assess whether stents (SEMS or PS) impair diagnostic performance of EUS tissue acquisition, in a retrospective study of all patients with HOP mass undergoing EUS biopsy between January 2010 and June 2016. Stenting information was obtained from the EUS report and images. Biopsies reported as malignant were considered as such, all other reports were considered benign. A definitive diagnosis of cancer was based on positive pathology or imaging signs of progression. A benign diagnosis required negative pathology, stable imaging and symptoms for a year or more. Patients with cystic lesions were excluded.

Results: A total of 1861 patients had EUS-FNA/FNB of which 731 were for HOP lesions, mean age 65 years (410 F), with tissue sensitivity of 72% for all types of needles used. Tissue accuracy was significantly different between the 3 groups (p=0.0001); SEMS 67%, PS 71% and 83% in the unstented group. The difference in accuracy was significant between the unstented group versus SEMS (p=0.0002) and PS (p=0.033) and not significant between PS and SEMS. Stepwise multi-variable analysis revealed significant difference for accurate tissue diagnosis favouring size needle 25G (OR 1.7 [95% CI 1.1–2.7] and tumour size (OR 1.04 [1.02–1.07]) and not affected by presence of stent. SEMS (OR 0.3 [0.2–0.6]) or PS (OR 0.5 [0.3–0.8]). Other needle sizes (19G or 22G), number of passes or types of needle did not significantly affect tissue accuracy.

Conclusion: Our results show a significant adverse impact of both SEMS and PS on tissue accuracy via EUS FNA/FNB. The effect is greatest with SEMS. These lesions, mean age 65 yrs (410 F), with tissue sensitivity of 72% for all types of needles used. Tissue accuracy was significantly different between the 3 groups (p=0.0001); SEMS 67%, PS 71% and 83% in the unstented group. The difference in accuracy was significant between the unstented group versus SEMS (p=0.0002) and PS (p=0.033) and not significant between PS and SEMS. Stepwise multi-variable analysis revealed significant difference for accurate tissue diagnosis favouring size needle 25G (OR 1.7 [95% CI 1.1–2.7] and tumour size (OR 1.04 [1.02–1.07]) and not affected by presence of stent. SEMS (OR 0.3 [0.2–0.6]) or PS (OR 0.5 [0.3–0.8]). Other needle sizes (19G or 22G), number of passes or types of needle did not significantly affect tissue accuracy.

Introduction: Solid-pseudopapillary neoplasm (SPN) is a rare condition, first described by Frantz in 1959. It occurs mostly in young women, and surgical resection is recommended. Its local recurrence rate is less than 10% and usually occurs within 4 years after surgery. Before such a surgery, especially in young people, EUS-FNA (Endoscopic ultrasonography with fine needle aspiration) is discussed to confirm diagnosis but rarely performed due to suspected needle tract contamination by neoplastic cells. The aim of our large multicenter study was to assess the short- and long-term safety of preoperative EUS-FNA in SPN.

Aims & Methods: This study is a multicenter retrospective register of all SPN diagnosed in the last decade in 14 European expert centers (GRAPHE task force). Inclusion criterion was realization of preoperative EUS-FNA followed by surgical resection. Patient and tumor characteristics were collected, as the EUS-FNA technique (number of passes, needle size, trans-gastric or trans-duodenal access). Immediate or late complications of EUS-FNA and recurrence of SPN were then recorded.

Results: During the period study, 49 patients (41 women/8 men) with preoperative EUS-FNA for SPN were recorded. Mean age of patients was 37 ±13y; 14 patients (28%) had resection within 1 year (9/36), caudal in 11% (4/36) and in uncus in 5% (2/36). Mean tumor size measured on EUS was 40 ±22 mm. Needle used was a 25G in 3% (1/37), 22G in 76% (28/37), 20G in 8% (3/37) and 19G in 13.5% (5/37). Transgastric EUS-FNA was performed in 56% (24/43) and trans-gastric in 44% (19/43). Mean number of needle passes was 2.2 ±0.7. EUS-FNA allowed certain preoperative diagnosis of SPN in 74% of cases (35/47), probable diagnosis in 6% (3/47), negative in 4% (2/47) and wrong in 6% (3/47). No acute complication of EUS-FNA was reported. With a mean follow-up of 36 ±12 months, only one local recurrence was noted. In this year 4 old man case, a 19G needle was used (2 trans-gastric passes), and recurrence occurred after 84 months.

Conclusion: In this large multicenter retrospective series, a systematic preoperative EUS-FNA did not seem to modify the SPN recurrence rate. Therefore this study allows to validate this attitude as a possible alternative. The data for the series are incomplete at the date of submission of the abstract. The final data will be completed on the day of presentation.

**PI440** EFFECTS OF IGF2BPS ON GROWTH AND PROLIFERATION OF NEUROENDOCRINE TUMOR CELL LINES

**Aims & Methods:** We aimed to characterize the role of IGF2BPs in neuroendocrine tumor progression and their potential expression pattern in various solid tumors including pancreatic neuroendocrine tumors.

**Results:** The pan-neuroendocrine tumor cell line BON1, knock-down of IGF2BPs resulted in a significant reduction of cell viability. Cell cycle analysis by FACS showed a decreased S phase proportion paralleled by a reduction in the number of phosphorylated mitotic cells. Moreover, knock-down of IGF2BP1 significantly reduced clonogenic growth as assessed by colony formation analyses and led to decreased cell migration as determined by scratch assays. Interestingly, knock-down of IGF2BP1 was insufficient to induce apoptosis, as assessed by PARP and caspase-3 cleavage as well as annexin-V FACS. Rather, si-IGF2BP1 increased the expression of both the anti-apoptotic and pro-survival factors BCL-2 and the cell cycle inhibitor CDKN1B. In contrast, si-IGF2BP1 knock-down of IGF2BP3 rather induced cell viability, whereas si-IGF2BP2 modulation had no impact on cell viability and cell cycle progression indicating opposing effects on the three IGF2BPs on PNEN progression. These in vitro findings were parallelized by distinct expression patterns of IGF2BPs in human and murine PNEN tissues. Elucidation of IGF2BP-modulated RNAs in PNEN cells is ongoing.

**Conclusion:** In summary, our data suggest that IGF2BP1 promotes tumor progression by enhancing cell cycle progression and clonogenic growth, whereas IGF2BP2 and -3 exert no tumor-promoting role in PNEN.

**PI442** EFFECTS OF LOW-DOSES ASPIRIN ON CLINICAL OUTCOME AND DISEASE PROGRESSION IN PATIENTS WITH GASTRO-ENTERO-PANCREATIC NEUROENDOCRINE TUMORS: RESULTS OF A MULTICENTRIC RETROSPECTIVE STUDY

**Aims & Methods:** Aim of the study was to retrospectively evaluate the clinical outcome of GEP NEN patients treated with ASA at three different European referral centres for NENs. All the GEP NEN patients followed up in three European Centres (Fondazione IRCCS Cà Granda Ospedale Policlinico Milano, Italy; Fondazione IRCCS Istituto Tumori Milano, Italy; Mater Misericordiae University Hospital, Dublin, Ireland), from January 2005 and September 2016, were retrospectively enrolled. The possible association between ASA use and disease grading, staging, primary site, overall OS and PFS were evaluated.

**Results:** In the 99 patients included (121 M, median age 64 yrs), the primary neuroendocrine tumor was located at the stomach (35%), pancreas (82%), small bowel (8%), appendix (27%), colon (49) or unknown (6%). Grading was G1 in 51 patients, G2 in 64, G3 in 5 and not available in 28. TNM staging was I in 99 patients, II in 16, III in 32 and IV in 86. No clear impact on OS or PFS was observed in patients taking ASA compared to those not taking it. Interestingly, in small bowel NEN an inverse relation was observed with lower Ki-67 values and less node involvement. Further studies are needed to confirm this observation.

**Conclusion:** According to present data, ASA therapy seems not to have a direct clinical impact on disease progression or survival of NENs, even if it is associated with lower Ki-67 values and less node involvement. Further studies are needed to confirm this observation.

Introduction: Von Hippel-Lindau disease (VHL) is a rare heritable genetic syn- drome that may affect different systems and organs: pancreatic manifestations of the disease are frequent during lifetime of the patients. The key feature is the presence of simple cysts, but serous cystadenomas (SCAs) or neuroendocrine tumors (NETs) can be frequently found as well. The aim of this study is to describe pancreatic manifestations in patients with VHL, considering the peculiarity and rarity of this disease.

Aims & Methods: All patients who referred to the established multi-disciplinary team in our center (Molinette Hospital - Turin) for management and follow-up of VHL disease in the period 2000-2013 were considered. In the study we considered the ones with pancreatic involvement (simple cysts, SCAs or pNETs). We collected data about the patients (demographics and medical history), about the lesions (imaging features, histological and cytological analysis) and about the management.

Results: A total of 5424 patients were identified. There were 1226 patients (22.6%) with tumour size of 2 cm or less. The probability of metastasis increased in a non-linear fashion with increasing tumour size. Univariate analysis showed that tumour size was significantly correlated with survival (P<0.001), no matter surgery was performed or not. However, subgroup analysis suggested this asso- ciation to be linear for patients with localized and regional tumours (P<0.001), but stochastic in patients with distant stages (P=0.703). On multivariate analy- sis, tumour size was an indicator for metastasis (HR=1.010, 95% CI: 1.008-1.012, P=0.001 and size <20 mm was an independent prognostic factor for good survival (HR=1.211, 95% CI: 1.048-1.399, P=0.009 for size of 21-40 mm; HR=1.282, 95% CI: 1.161-1.474, P<0.001 for size >40 mm). For tumours ≤20mm, surgical treatment was associated with significantly improved survival compared with those patients who did not undergo operation (P<0.001).

Conclusion: Tumour size affects the probability of metastasis. Its prognostic impact on survival is restricted to patients with localized and regional disease. For tumours with tumour size ≤20mm, surgical treatment should be considered preferably.

P1445 THE LARGEST FAMILY IN TURKEY WITH MULTIPLE ENDOCRINE NEOPLASIA-TYPE 1 AND A NOVEL MUTATION
A. Çetin1, D. G. Duman2
1Internal Medicine, Marmara University School of Medicine, Istanbul/Turkey
2Gastroenterology, Marmara University Hospital, Istanbul/Turkey

Contact E-mail Address: alicetindr@gmail.com

Introduction: Multiple Endocrine Neoplasia type-1 (MEN-1) occurs usually sporadically but because it is an autosomal dominant disorder it may affect other family members too. The combination of parathyroid and pituitary tumors, and anterior pituitary tumors is characteristic of MEN-1 although it may be accompanied by a substantial number of non-endocrine tumors. The muta- tions in MEN-1 gene result in aberrant expression of MENIN promoter and associated with the transcription of the ACTR1G protein encoded by this gene and is responsible for tumor-suppression under normal circumstances. Herein we present the largest MEN-1 family in Turkey to the best of our knowledge and a newly discovered mutation in MEN-1 that effects this family.

Aims & Methods: The family inherited the specific MEN-1 mutation is originally \( 5 \) einkarhaisar, Giresun and most of the members have moved to Istanbul and Yalova. Consanguineous marriages have been practiced within the family. Familial mapping was constructed and contained fifty-five members. Among them, eleven patients underwent biochemical, radiological and if necessary endosonography and histological testing along with the genetic testing. Additionally, we learnt that 2 members of the family had died of pancreatic malignancy. Diagnostic criteria of familial MEN-1 in-clude: 1 - the presence of at least one MEN-1 associated tumor that are from parathyroid, pituitary, or GEP tract origins, 2 - at least one first-degree relative with one or more of these endocrine tumors and/or 3 - positive genetic testing for abnormal MEN-1 mutation. For our index case, DNA sequencing of the MEN-1 gene performed using Sanger sequen- cing technique at ABI 3500 sytem. For the other family members only the tar- geted mutation analysis is performed.

Results: Among the family members we had peripheral blood DNA from 9 and within these patients tumour tissue DNA from 1 patient. MEND1 gene was used for Sanger sequencing. Our index case was ZK who had hypophys adenoma, parathyroid and pancreas neuroendocrine tumour and the surgery performed. A three nucleotide deletion p.ser560argfs*3(c.1680_1683 del TGAG) was identified. Sevem out of ten members who were analysed tested positive for the mutation. Genetic counseling and information about pre-implantation genetic diagnosis (PGD) was given to all patients who are tested positive for the mutation. All 7 patients had p.ser560argfs*3(c.1680_1683 del TGAG) three nucleotide deletion same with that of index case. Out of 15 patients, MEN-1 diagnosis was confirmed in 11. Tumours detected at patients with MEN-1 diagnosis were: nonfunctional pancreatic neuroendocrine tumour at three, parathyroid adenoma/hyperplasia at 6 patients and hypophysis adenoma
at 4 patients. The mean age of our MEN-1 patients was 51 and the age at diagnosis was 41.8. The mean plasma calcium level was 11.46 ng/dl and there was no history of renal calculi at any of them.

**Conclusion:** The family presented here is the one which had the largest number of affected individuals with genetic and clinical properties of MEN-1 at Turkey. Because the patient presented here is the first with autosomal dominant mutation causing loss of function that is described for the first time. Also at MEN-1 families, counseling to prevent the neoplasia development and to prevent the new family member to be effected with PGD has a pivotal importance. We could point out that awareness is the most important caution for prevention.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Several inflammatory response materials could be used for predictive purposes to assess survival in patients with NETs and to determine their potential use in clinical practice. In this work, we studied the expression of selected proteins in the plasma of NET patients in order to develop a new marker. Aiming to improve the survival of patients with NETs, we analyzed the expression of Plac8 (Placenta-specific 8) in various NETs types. Plac8 introduces a new biomarker for the diagnosis and treatment of NETs. We attempted to develop a novel, non-invasive blood test for the early diagnosis of NETs.

**Aims and Methods:** The object of this study was to determine whether the Plac8, PLR, or thrombocytosis could predict the clinical outcomes in G1-G2 neuroendocrine tumors. We performed a retrospective review of 31 patients with neuroendocrine tumors with ki 67 below 20% diagnosed in Fundeni Clinical Institute between 2011-2017. Data about site of the primary tumor, presence of metastasis, PLR, PLR, thrombocytosis (platelet count > 400) and survival were collected and analyzed.

**Results:** The patients characteristics were: primary tumor location was: 61.29% pancreas, 22.58% gastrointestinal tract, 16.13% unknown, 61.29% had hepatic metastasis, 6.45% had locally advanced tumor. The primary tumor was resected in 35.48% of patients. The overall 2-year survival rate was 77.42%. The Ki-67 index (p < 0.04), PLR (cut off > 300) p < 0.01 have statistical significant impact on survival. Univariate analysis and on multivariate analysis (P < 0.05). Other factors like ki 67 index, metastatic disease, thrombocytosis and NLR have an impact on survival statistical significant on multivariate analysis.

**Conclusion:** This study demonstrates the prognostic role of different variables like Ki-67, PLR and PLT value, thrombocytosis and metastasis. This factors may be integrated in different scoring systems for prognostic that could guide clinicians for a better management in patients with neuroendocrine tumors.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Neuroendocrine pancreatic tumors represent the second prevalent entity of malignant tumors of the pancreas and show an overall mortality of about 60%. At the moment surgical resection is the only option of potentially curative therapy, as with the currently available chemotherapeutic and radiotherapeutic approaches an inhibition of tumor growth but no regression of the tumor can be achieved. Therefore for about 80% of pNET patients there is no curative treatment available. To obtain the identification of novel potential target genes for the development of new therapeutic strategies, primary issues from pNET patients were analyzed. Amongst others Plac8 (Placenta-specific 8) was identified, which is a small protein of unknown function, showing different forms of cellular localization depending on the cell type analyzed, indicating at its ability to fulfill a variety of physiological functions.

**Aims & Methods:** In the course of this study, the function of Plac8 in neuroendocrine pancreatic tumors is to be unveiled to evaluate its value as a potential target for pNET therapy. Therefore primary tumor tissue of about 100 pNET patients were analyzed for Plac8 expression by quantitative realtime PCR and immunohistochemistry. Furthermore established pNET cell lines from human origin where transfected with siRNAs against Plac8 and there proliferative activity and localization were analyzed by chemiluminescent and MTT assay. Changes in these important characteristics of tumor cells were further examined by western blot analysis of key regulators of apoptosis and cell growth.

**Results:** Plac8 is highly expressed in primary human pNET tissue on RNA- as well as on protein level. Functional in vitro analyses show that the siRNA-mediated knockdown of Plac8 not only in human but also in rat cell lines leads to significantly reduced proliferative activity and reduced cell growth. These effects come along with indicative changes in the expression of central regulators of cell cycle while cell cycle pathways seem not to be affected.

**Conclusion:** Overexpression of Plac8 in neuroendocrine tumors of the pancreas promotes the proliferative phenotype of the tumor cells while the inhibition of Plac8 inhibits cell growth and metabolism. Therefore in the future Plac8 could represent a very interesting target for the treatment of pNETs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Since the majority of laryngopharyngeal carcinomas are detected at an advanced stage, most cases are treated with concurrent chemoradiation therapy and radiation therapy. The key to improving the prognosis and quality of life is early detection of the primary cancer and treatment using minimally invasive surgery. We previously reported the good oncologic outcomes with ELPS (Endoscopic laryngopharyngeal superficial laryngectomy) for all cases. However there is no clinical evidence for an additional treatment nor prognosis about the cases conducted endoscopic resection which were diagnosed to be superficial carcinoma with lympho-vascular invasion histopathologically.

**Aims & Methods:** This study aimed to investigate the optimal additional treatment and clinical course for the surferal laryngo-pharyngeal carcinoma with lympho-vascular invasion. We analyzed clinicoopathological data in 9 patients showed Lympho-vascular invasion receiving ELPS between 2007 and 2014.

**Results:** Positive lympho-vascular invasion was found in 9 cases. Detected the tumor depth was SEP in 7 lesions and MP in 2 lesions. Mean alcohol consumption is 9.9 abv packs. Years 5 cases are low activity ALDH2 heterozygotes and have alcohol flushing reaction. Immunohistological findings of 7 cases with lympho-vascular invasion (n=0, v1), 2 cases with vascular invasion(l0, v1), and 2 cases with lympho-vascular invasion,(l1, v1). Two patients underwent an additional chemoradiotherapy without recurrence. Four patients had a cervical lymph node or local recurrence, two of them were salvage ELPS cases after chemoradiotherapy. One other two cases also had distant metastasis and was given palliative treatment, and finally died. The other one underwent surgical salvage and remained alive. One case with lymphatic and vascular invasion had no adjuvant therapy and remained without recurrence. And the other 2 cases had no recurrence but died of other causes. Finally Conclusion: Lympho-vascular invasion is a risk factor for cervical lymph node metastasis, which has a possibility to a very aggressive disease. In those cases, chemoradiotherapy as an additional treatment is recommended as far as possible.If patients already had prior radiotherapy, close follow-up is essential to detect recurrence early. In those cases, chemoradiation or additional surgical resection are also considerable if the general conditions are satisfactory.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The positive lateral margin after endoscopic resection(ER) of early gastric cancer(EGC), additional surgery or endoscopic submucosal dissection(ESD) are recommended. However, the additional surgery often difficult due to advanced age or patient’s comorbid conditions.

**Aims & Methods:** The aims of this study is to investigate of appropriate management in patients with positive lateral margin after ER. We analyzed...
retrospectively 103 patients with positive lateral margin after ER from January 2009 to December 2015, in single tertiary center. Clinicopathological data were retrieved to assess the local recurrence rate, survival rate, procedure related adverse events.

Results: Of the 103 patients, 27 patients (26.4%) underwent early re-treatment within 3 months after initial ER,17 patients in re-do ESD, 10 patients in additional surgery. And 76 patients (73.6%) were observed under close surveillance. Median duration of follow-up period was 45.7 (6-132) months. Recurrence rates of early re-treatment patients (3.7%, n = 27) was lower than surveillance group (18.4%, n = 10, p = 0.05). Five-year survival rates were not significantly different between the two groups, at 100%, 97.4% respectively. In close surveillance periods, 12 patients were confirmed to local recurrence by follow-up biopsy, then delayed re-treatment was performed (7 patients in re-do ESD, 5 patients in surveillance mode). Median duration after initial ER was 27 (27-29) months). Finally, a total of 24 patients were treated with re-ESD, and 17 patients were treated with additional surgery. Among these two groups, there were no significant difference in recurrence rates (8.3% vs. 0%) and five-year survival rates (both 100%). However, adverse events that related to re-treatment was more frequent in additional surgical group (2 ileus, 1 umbilical hernia).

Conclusion: The additional treatment should be recommended for patients with positive lateral margin after initial ER for EGCs. In addition, re-ESD which have a similar efficacy and a better quality of life, compared to additional surgery is a favorable option for control of recurrence or residual EGCs.

P1451 EXPOSURE TO ENDOTHERAPY FOR UPPER GASTROINTESTINAL BLEEDING AT THE POINT OF GASTROSCOPY CERTIFICATION- IS IT SUFFICIENT?
*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/UnitedKingdom

Introduction: Although certification in diagnostic gastroscopy has been established in the UK, there is no formal process for quality assurance (QA) in endotherapy for upper gastrointestinal bleeding (UGIB). Training opportunities are variable, with 11% of final year UK gastroenterologists citing inadequate exposure, despite an expectation to independently manage UGIB upon achieving specialist status. Data on endotherapy exposure during endoscopy training is limited. We aim to assess whether trainees are receiving adequate exposure to endotherapy at the time of gastroscopy certification.

Aims & Methods: Trainees awarded certification in gastroscopy between September 2009–2016 were identified from the national trainee electronic portfolio (JETS). Trainee inputs and formative assessments (direct observation of procedural skills - DOPS) for UGIB therapy, up to their certification date, were analysed. Only trainees with >200 procedures were included, which is the minimum number to allow certification within the UK, thereby excluding those who had submitted baseline information which may have contained therapeutic data. Exposure rates from medical endoscopists (physician and surgical trainees) were compared with non-medical endoscopists (NME).

Results: 885 trainee portfolios were analysed (765 medical and 120 NMEs), with a median procedural count of 276 (IQR 124). The median number of therapeutic entries and DOPS were 4 (IQR 11), and 1 (IQR 3) respectively. Overall rates for endotherapy and DOPS were 2.9% and 0.8% per procedure. When stratified by therapy, the median exposure to each therapy was either 0 or 1, with means displayed in Table 1. 25.2% of trainees had no exposure to any type of endother-

apy (67.5% of NME and 18.6% of medical endoscopists, p < 0.0001). Of medical endoscopists awarded certification, 37.1% had not performed band ligation, 50.7% had not placed a clip, and 54% had not used heater probe. NME had significantly less exposure to each modality of endotherapy considered (overall odds ratio 0.10, p < 0.0001).

Conclusion: Training on endotherapy prior to certification is limited. The current UGIB certification process does not guarantee adequate exposure to endotherapy for UGIB.

P1452 ELECTRONIC CHROMOENDOSCOPY WITH MAGNIFICATION IN THE DETECTION OF DYSPLASIA IN BARRETT’S ESOPHAGUS
C. Carames1, J.C. Carames2, M. Xu1, M. Carames3, M. Gaidhane1, M. Kahaleh1
1Well Cornell Medical College, New York/United States of America
2Santander Hospital, Reynosa/Mexico

Introduction: Barrett’s esophagus (BE) is a known premalignant condition with risk for progression to esophageal adenocarcinoma. Electronic chromendo-
scopy with magnification (ECM) is an evolving imaging technology being inves-
tigated as a novel imaging tool to identify dysplasia in BE to assist with higher yield BE surveillance and improve the diagnostic yield of esophageal biopsies for BE.

Aims & Methods: This is a single-center study to evaluate the efficacy of ECM (Scan by Pentax) in the detection of BE and dysplastic BE in a screening, average risk population with BE in Northeast Mexico. We conducted a retrospective study of 100 consecutive patients (41 males) with known BE (confirmed by pathology) during surveillance upper endoscopy for dysplastic BE between

1. Tanaka S, Toyonaga T, Morita Y. Endoscopic vessel sealing: a novel endo-
scopic precogulation technique for blood vessels during endoscopic submu-
March and September of 2016. All patients underwent EC with iScan. The esophagus was inspected with a ECM capable endoscope (EG-2900-Z) and deliberate biopsies were taken from tissue identified by ECM that suggested BE. All biopsies were confirmed by a GI pathologist. Primary endpoint was the correlation between visual inspection diagnosis of dysplasic BE by ECM versus pathologic diagnosis of BE as the gold standard.

Results: In our cohort 41% were male, with mean age of 47.7 years. Endoscopic diagnoses by ECM were divided into nondysplastic BE (96/100) and suspected dysplastic BE (4/100). On pathology nondysplastic BE was found in 94/100 patients, BE with low-grade dysplasia was found in 4/100 patients. Benign gastric mucosa with no alterations (1/100), and ulcerated esophagitis (1/100). The overall accuracy of endoscopic diagnoses using ECM against pathologic diagnosis was of 98%, with sensitivity of 100% [95% CI (96%–100%)] and positive predictive value of 98% [95% CI (93%–99.7%)].

Conclusion: Endoscopic diagnosis of BE by directed biopsies of esophageal tissue with use of ECM is highly accurate. Future prospective studies are needed to validate our preliminary findings and assess inter-observer variability.

Contact E-mail Address: drtarunbharadwaj@gmail.com

Introduction: Endoscopic full-thickness resection (EFTR) for sub-epithelial lesions (SfELs) of GI tract is less frequently described; possibly due to technical challenges involved in dissection and need for resultant defect closure. Current study describes single-center experience of EFTR for treatment of SETs.

Aims & Methods: Prospective database of patients undergoing EFTR for SETs over 6-years (2011–2017) was abstracted. Patient selection for EFTR-endoscopy, endoscopic ultrasound (EUS) and CT and/or MRI. Inclusion criteria—submucosal lesions, predominantly endophytic component and absence of features of invasive malignancy. Exclusion criteria—patients unfit for general anesthesia or major invasive procedure, unacceptable coagulopathy or high risk features for malignancy. All procedures performed under general anesthesia with endotracheal intubation.

Results: Total N = 18(M:F = 11:7), mean age 53.6(Range 28–78). Presentation—GI bleed (38%), abdominal pain (42%), asymptomatic, incidentally diagnosed (63%). Layer of origin—MP layer (61%), SM (17%), DE (9%), muscularis propria (13%). Size of SET—3.3 cm (range 1–7). Mean procedure time—182 mins (30–545), and mean hospital stay was 4 days. Adverse events—two (11%)—esophageal laceration during specimen retrieval—1 (closed using endoclips), failure—1 (due to undetected large exophytic component—surgical resection). Histopathology with
Aims & Methods: We aimed to evaluate the efficacy of EVL therapy in both primary prophylaxis of variceal bleeding in cirrhosis and to establish the patient’s clinical outcome. This was a retrospective observational cohort study of a total of 444 EVL procedures performed in 250 cirrhotic patients, who were admitted in a gastroenterology department of a tertiary centre, between 2004–2016, to receive EVL as prophylaxis of variceal bleeding. Sessions of ligation were repeated every 2 to 3 weeks in order to reach variceal eradication. The clinical outcome included the recurrence of bleeding (primary endpoint), the eradication success rate of oesophageal varices, EVL-related complications and overall and bleeding-related mortality.

Results: The mean follow-up period for all 250 cirrhotic patients enrolled in the study was 73.2±40.0months, with mean age of 63.9±10.8years and a predominance of male gender (80.4%;n=201). At initial endoscopy, 237 (90%) patients had active or previous symptomatic variceal bleeding severe in 168 (67.2%) cases. EVL was performed as primary prophylaxis in 50.9%(n=226) and secondary prophylaxis in 49.1%(n=218). Varices were obliterated in 209 (83.6%) patients with mean number of EVL procedures necessary to eradicate varices of 1.8±0.95 and a maximum of procedures of 6. Recurrent bleeding occurred in 11.2%(n=28) of cases with a mean time to re-bleeding occurrence of 8.1±14.2months. Major and significant complications were verified in 8.1%(n=36) of patients. The main complications were bleeding related to post-banding ulceration (75.0%(n=27)) and infection (22.2%(n=8)), with mean time between EVL and complication occurrence of 11.1±11.8days (minimum:0;maximum:43). Intra-procedure complications occurred in 11(2.5%) patients with no death, despite of two cases of Sengstaken-Blakemore-Halligan therapy. The overall mortality was 3.4%(n=24), being 0.4%(n=2) related to variceal bleeding. EVL seems to be an efficient, safe and relatively simple therapeutic modality for primary and secondary prophylaxis and serial bleeding in cirrhotic patients. Since the main complications occurs over 1 week after EVL procedure, the majority of patients can be safely treated in an ambulatory setting.

Discussion of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Conclusion:** EVL without laparoscopic assistance is minimally invasive, safe, and effective for treating gastric and duodenal SMTs, which originate from the MP layer and adhere tightly to the serosa. High en blos resection rate could be achieved. However, a larger number of the cases and long-term outcome deserve further research.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1456 THE VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR GASTRIC AND DUODENAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER**

M. Xu1, C. Zhang1, Q. Li1

1Endoscopy Center, Zhongshan Hospital, Shanghai/China

**Introduction:** Given diminishment of quality of life caused by surgery in the stomach and duodenum, a minimally invasive treatment is desirable for gastric and duodenal submucosal tumors (SMTs).

**Aims & Methods:** We aimed to assess the value of endoscopic full-thickness resection (EFTR) technique for gastric and duodenal submucosal tumors (SMTs) originating from the muscularis propria (MP) layer. A total of 276 patients with single gastric SMTs originating from the MP layer were performed EFTR between January, 2010 and February, 2014. The tight adhesion of the tumor to gastric or duodenal serosal layer could be seen in every case from endoscopic ultrasound (EUS) before the procedure. The SMTs oriented endoscopically were performed EFTR using a standard ESD technique without laparoscopic assistance under direct endoscopic view. The defect of gastric and duodenal wall was closed after resection.

**Results:** A total of 276 patients included 94 males and 182 females. Their median age was 57.8 years (range, 30–81 years). Among all the 276 SMTs in our study, 165 located in gastric fundus, 96 located in gastric body, 8 located in the antrum, 1 located in the pylorus, 1 located in duodenal bulb and 1 in duodenal bulb + antrum. The mean size was 1.7 cm (range 0.7-6.0 cm). The success rate of EFTR was 98.9% (273/276). EFTR failed in 3 cases: one case was out of control because of bleeding into enteroceola, two cases required conversion into laparoscopic surgery because of torrential lobulations of the tumor outside the cavity. The median operation time was 65 min (range, 14-210 min). En bloc resection rate was 98.1% (268/273), piecemeal resection rate was 1.9% (5/273). The median length of hospital stays was 4.4 days (range, 1–23 days). Pathological outcomes revealed that the SMTs were classified 137 (47.8%) fibrous tumors, 57 (21.3%) leiomyomas, 13 (4.7%) schwannomas, 8 (2.9%) calcifying fibrous tumors, 7 (2.5%) glomus tumors, 5 (1.8%) displaced pancreas, and 3 (1.1%) fibromatosas. The procedure-related complications were as follows. Different degrees of postoperative gastric or duodenal ulcer occurred in 168 (60.9%) cases, among which 24 (8.7%) cases showed cases required analgesics. Pneumoperitoneum occurred in all the patients and was treated successfully with peritoneoscopic decompression. Seroperitoneum occurred in 15 (5.4%) cases, localized peritonitis occurred in 3 (1.1%) cases, and digestive tract leakage occurred in 1 (0.4%) case. All the cases with above complications recovered spontaneously or after conservative treatments. No massive bleeding or abdominal abscess was found after EFTR. None of the 273 cases developed procedure-related death. No tumor residual or recurrence was found during the follow-up period ranging 5–55 months.

**Conclusion:** EVL without laparoscopic assistance is minimally invasive, safe, and effective for treating gastric and duodenal SMTs, which originate from the MP layer and adhere tightly to the serosa. High en blos resection rate could be achieved. However, a larger number of the cases and long-term outcome deserve further research.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1457 BLUE LIGHT IMAGING AND LINKED COLOR IMAGING FOR DETECTION AND CHARACTERIZATION OF CHRONIC GASTRITIS**

J. Weigt1, A. Link1, A. Canbay1, P. Malfertheiner1

1Gastroenterology, Hepatology & Infectious Diseases, Medizin. Universität Magdeburg Gastroenterologie und Hepatologie, Magdeburg/Germany

**Contact E-mail Address:** jochenweigt@gmx.de

**Introduction:** Current standard in the characterization of gastric mucosal changes is the use of virtual chromoendoscopy with magnification to visualize the pit pattern and vascular changes. The most recent development in light emitting technology is the so called Multi Light Illumination, that composes light out of 4 coloured LED. Blue Light Imaging (BLI) is composed of a continuous spectrum with peaks at 410 and 430 nm to enhance surface and vascular structures. Linked Color Imaging (LCI) uses BLI light together with post processing that realocates colour tones resulting in a high contrast of different red tones. Until now only few data exist about the use of BLI and LCI in chronic gastritis (CG).

**Aims & Methods:** We aimed to analyse the use of LCI and BLI in detecting and characterizing of chronic gastritis and premalignant conditions of the stomach. In total 217 consecutive patients (149 male; mean age 65 years) were enrolled. All patients had undergone standard upper GI endoscopy under conscious sedation. In all cases an endoscope equipped with zoom (Fujifilm EG-760Z) was used. Endoscopic classification was based on the following parameters: normal gastric mucosa was defined as mucosa with visible superficial capillary network (SCN) without any focal lesions; atrophy (AG) was defined by whitening of the mucosa with visible deeper vascular architecture in white light, BLI and LCI; intestinal metaplasia (IM) was diagnosed if mucosa had visibilised indented surface with whitening in LCI or white light or light blue crest sign in BLI; CG was diagnosed in case of loss of SCN or focal lesions not matching the definition of other focal lesions or cancer. Biopsies were sampled according to the updated Sydney classification system and in addition of every visible focal lesion. After endoscopy a prediction of histology was made by the endoscopist.

**Results:** We investigated 24 patients (15 female, 9 male, age 65 yrs (25-87yrs)). H. pylori was detected by histology or urease test in 7 patients. 3 patients showed normal gastric mucosa, 13 patients presented IM or AG either in the antrum or the corpus. According to MAPS criteria 7 patients had extensive disease with premalignant conditions in both, antrum and corpus. The concordance of endoscopic classification and histology was 79.1% (19/24) in the antrum and corpus each. Despite the inconcordance of histology and endoscopic diagnosis in 5 cases the intervals for surveillance according to MAPS guidelines would have been correctly respected with the use of endoscopic assessment in all cases.

**Conclusion:** LCI and BLI are accurate in detection and characterization of changes in gastric mucosa with an acceptable concordance to histology. These new imaging modalities are a step towards precise endoscopic diagnosis of gastric mucosal changes and have the potential to reduce the number of unnecessary histologic investigations and offer the possibility for more appropriate endoscopic diagnosis.

**Disclosure of Interest:** J. Weigt: Research and presenter for Fujifilm. All other authors have declared no conflicts of interest.
P1458 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR RELATIVE INDICATION GROUP OF EARLY ESOPHAGEAL SQUAMOUS CARCINOMA (ESESC) IN AGED PATIENTS
Z. Qi1, Y. Zhong1, P. Zhou1
1Endoscopy Center, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: poem001@qq.com

Introduction: According to the Japanese Esophageal Society Guidelines, Early Esophageal Squamous Cell Carcinoma (ESESC) involving the muscularis mucosae or <200 μm invasion of the submucosa, and circumferential extent of >2/3 were relative indications (RI) for ESD. Additional treatment (AT, including esophagectomy or chemoradiotherapy) may be needed for ESESC. But in aged RI patients, most will refuse AT due to higher rates of debilitating symptom in China.

Aims & Methods: The aim of this study was conducted to evaluate the long-term outcomes of aged RI patients without AT after ESD.

Results: Between January 2008 and December 2013, a total of 158 aged ESESC patients were included in the present retrospective study. Prognosis outcomes were analyzed.

Results: 89 patients included in absolute indication (AI) group and 69 in RI group. The baseline characteristics were balanced between the two groups. During the follow-up time (median 56 (1-108) months), short-term adverse events (4.3% vs. 1.1%, p = 0.319) and postoperative stricture rate (31.8% vs. 21.3%, p = 0.134) were higher in RI group than in AI group. 5-year recurrence-free survival rate (85.8% vs. 87.2%, p = 0.561), metastasis-free survival rate (100% vs. 98.6%, p = 0.437), overall survival rate (96.6% vs. 90.0%, p = 0.613) and cause-specific survival rate (98.9% vs. 98.5%, p = 0.264) for AI group and RI group were comparable.

Conclusion: Aged RI ESESC patients without AT (esophagectomy or chemoradiotherapy) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1459 RETROSPECTIVE ANALYSIS ON SUSPICION OF FOREIGN BODY INGESTION AND FOOD IMPACTION ON GASTROENTEROLOGY EMERGENCIES
J.T. Correira De Sousa1, D. Libanio1, P. Lago1, R. Marcíos-Pinto1, I. Pedroto1
1Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: joao.correia.de.sousa@gmail.com

Introduction: Suspicion of foreign body (FB) and food impaction (FI) are one of the most common motives for endoscopic emergency. This retrospective study reviewed 288 cases of suspicion on FB/FI, by the frequency of endoscopic alterations, predictive factors to presence, types of FB found, and therapeutic approach.

Aims & Methods: Unicentric retrospective cohort study of endoscopies performed during one year of gastroenterology emergency setting.

Results: In 2015, 288 endoscopies were performed on suspicion of FB/FI (22% of total endoscopies), n = 1309, of them 69.1% (n = 199) were performed during the night. Patients’ median age was 58 years, and 52.8% were women. The presence of FB/FI was confirmed in 71.2% (n = 205); of them 61.5% (n = 126) were complete FB/FI. The most frequently found foreign bodies were meat bones 18% (n = 37) and fish bones 14.6% (n = 30). Most FB/FI were found on the proximal esophagus (56.1%, n = 115). Endoscopic removal was performed on 129 cases (63.4%), endoscopic mobilization in 54 (26.3%), and in 22 endoscopic removal wasn’t achieved (10, where referred of otolaryngology; 2 for surgery and 10 were deferred to endoscopy with sedation, in operating room). Endoscopy under sedation was performed in 20 cases (9.7%). About ¼ had associated comorbidities, the most common were esophageal ring in 22 (10.7%) and benign stenosis in 17 (8.3%) patients. Major complications were rare: 1 perforation (0.3%) and 3 deep esophageal lacerations (1.5%). Age (≥55years), presence of comorbidities, and previous episodes were associated with presence of FB/FI on Endoscopy (Odds Ratio 2.01, 3.39 and 4.63 respectively).

Conclusion: Endoscopy is frequently preformed for suspicion of FB/FI in our emergency setting. Presence is confirmed in the majority of the cases. Predictive factors for presence were identified. Most FB/FI were removed with success low complication rates. This data favor the endoscopic approach on suspicion of FB/FI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1460 LEARNING CURVE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS; LOW-VOLUME SINGLE-CENTER EXPERIENCE
S.T. Kim1, T.H. Kim, S. Na
1Internal Medicine, Jeju National University Hospital, Jeju/Korea, Republic of

Contact E-mail Address: panzervor@paran.com

Introduction: Endoscopic submucosal dissection (ESD) has become a standard therapy for early gastric neoplasia. There is no consensus yet about the number of experiences required for performing ESD alone.

Aims & Methods: We aimed to investigate the learning curve of ESD performed by a single beginner endoscopist focusing on developing the performance of dissection, shortening the procedure time, and preventing complications.

Methods: Records of 120 consecutive ESD procedures performed by a single beginner endoscopist with an ESD knife from March 2012 to February 2016 were collected. For analysis of the learning curve, total procedures were divided into four periods, each comprising 30 sequential ESD. The parameters assessed were the en-bloc resection rate, complete resection rate, procedure time, and related complications.

Results: In the procedure time according to the number of experiences, the procedure time decreased from 30 experience. However, there was no statistical difference from the first (63.5±54.0) to the second quarter (44.7±31.4, p = 0.19), to the third quarter (40.7±27.8, p = 0.08), and to the fourth quarter (40.8±23.1, p = 0.09). There was no procedure that exceeded 100 minutes from the first quarter. There were a total of seven perforations, four of which were in the first quarter, two in the second, and one in the third. In the procedure time according to the location of the lesions, upper third lesion (92.0±43.7) showed longer procedure time than middle (46.6±40.2, p < 0.01) and lower third (39.5±27.5, p < 0.01) with statistically significant difference. In addition, the fibrotic lesions, regardless of size and location, all took a very long time, more than 100 minutes.

Conclusion: It needs accumulate experience with the help of a professional expert up to 30 cases, and to the more advanced level, about 90 procedures are needed. And, the location of the lesion is the important factor in determining the difficulty of the procedure. Therefore, it is best to avoid the upper third lesion as far as possible until experience 90 cases or at least 30 procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1461 COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCARISPORIPA
C.B. Ryu1, M.S. Lee1, J.Y. Bae2
1Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon/Korea, Republic of
2Department Of Internal Medicine, Seoul Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: ryuchbe@gmail.com

Introduction: Endoscopic resection for gastric subepithelial tumors (SETs) originated from the muscarisporiopsis (GSET-PM) has offered less invasive alternatives to surgical resection. The aims of this study were to compare endoscopic submucosal dissection (ESD) with surgical resection for the removal of GSET-PM.

Aims & Methods: This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5 cm and showed an endoluminal growth pattern according to endoscopic ultrasound (EUS) finding.

Results: ESD group were more likely to have upper portion (10/17, 58.8%) and surgery group were more likely to have mid portion (41/76, 53.8%) (p = 0.039). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm, p = 0.037) and higher endoluminal ratio (58.5 ± 9.1% vs 45.8 ± 15.4%, p = 0.002). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52/76, 68.4%) (p < 0.001). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, p < 0.001). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontrolled bleeding) and 1 showed perforation was completely resected with endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group (p = 0.006), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two groups.

Conclusion: ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: The aim of this study was to compare CA-EGD to SVE for complete examination of the MDP. CA-EGD allowed a better overview of the papilla and overall satisfaction of the evaluators. For secondary outcomes, measures were image quality of mucosal pattern, ability to obtain an overview after image processing, by three blinded multicenter-experts. Our primary outcome was complete examination of the papilla and overall satisfaction of the evaluators. For secondary outcomes, a score was given from 1 to 10 (1=poor, 10=excellent).

Results: A total of 62 patients were randomized and completed the study. Complete examination of MDP was achieved in 59 patients using CA-EGD compared to 60 patients using SVE (95 vs. 97%, p = 1.0). CA-EGD had mean scores of 8.7±1.3, 7.1±0.86 and 7.9±1 regarding mucosal pattern, overview and overall satisfaction, respectively, versus 5.3±1.6 (p < 0.001), 8.3±0.9 (p < 0.001) and 7.6±0.6 with SVE (p = 0.01).

Conclusion: CA-EGD is non-inferior to SVE for complete examination of MDP. CA-EGD had significantly higher scores than SVE regarding the image quality and overall satisfaction, while SVE had a better overview. CA-EGD is a safe and effective method for examination of MDP and can replace the SVE for diagnostic indications.

Hereditary Diffuse Gastric Cancer: Early Diagnosis and Endoscopic Therapy

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: 19 patients underwent EA, with a mean age of 63.5 ± 17.7 years and a successful resection in the tumor of 17.4 ± 7.8 mm. The male to female ratio was 0.7. "En bloc" resection was done in most cases 15/19 (78.9%). Bleeding occurred in 6 cases (31.6%) and two patients (10.5%) developed acute pancreatitis. One patient died due to severe bleeding. The average days of hospitalization after endoscopic ampullectomy were 5.7 with a range from 2 to 25 days. Adenocarcinoma was described in the final histopathological result in 4/19 cases (21.1%). One year follow-up noted a recurrence rate of 15.8% (3/19 cases).

Conclusion: In conclusion, endoscopic ampullectomy is a difficult procedure with an increased risk of complications but performed by experienced endoscopists is safe and surgical interventions can be avoided.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: This is the largest UK case series of POEM for achalasia including the first successful UK POEM procedure for DES. At our institute, POEM was performed successfully in a potentially more challenging cohort where 52.9% had prior endoscopic/surgical treatment with substantial morbidity. Our results are in line with international consortia and ASGE findings that POEM is a safe and efficacious procedure for the treatment of achalasia and oesophageal spastic disorders for both short term and sustained symptomatic benefit.

(continued)

Conclusion: The purpose of this study was to evaluate the feasibility of L-ESD and the quality of the resected specimen obtained by L-ESD in living porcine compared with C-ESD. We performed ESD for a total of 144 sessional lesions in three porcine stomachs (C-ESD: 7 lesions; C-ESD: 7 lesions) under general anesthesia. En-bloc resection rate, procedure time, adverse events, and the quality of the resected specimen were evaluated. To evaluate the smoothness of the cutting surface in the resected specimens, we compared the length of the resected side of the submucosa (LRS) with the length of the muscularis mucosa (LMM). Results: The en-bloc resection rate was 100% in both groups. Although the mean L-ESD procedure time was 23.3 ± 10.8 minutes, and was significantly longer than that of the C-ESD group (9.4 ± 6.6 minutes; p < 0.005), there was no uncontrollable bleeding or perforation in either group. The mean ratio of LRS to LMM was 107 ± 33% in the L-ESD group, and was significantly lower than that of the C-ESD group (138 ± 28%)(p < 0.005).

Conclusion: ESD using CO2 laser might be a feasible and effective method for the treatment of early gastrointestinal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Probe-based confocal laser endomicroscopy (pCLE) provides real-time microscopic visualization with 100-fold magnification, allowing endoscopic access to the histological evaluation of gastrointestinal lesions. pCLE may thereby be helpful in guidance of endoscopic therapy. However, histopathological assessment still remains a gold standard for histological diagnosis so far, while pCLE-based diagnosis has not been generally accepted yet. Therefore, more studies assessing diagnostic accuracy of pCLE are warranted.

Aims & Methods: The aim of this study was to compare diagnostic accuracy of pCLE with standard biopsies in the diagnosis of macroscopically visible esophageal and gastric lesions.

Results: We examined 45 lesions (38 esophageal, 7 gastric) in 41 patients. Definitive diagnoses revealed 28 malignant lesions (21x adenocarcinoma (AC), 7x squamous carcinoma (SCC) and 1 benign lesion. In summary, pCLE diagnosis was definitive in 34 (75.5%) and incorrect in 11 (24.5%) (11/45) while diagnosis based on biopsy was correct in 75% (33/44) and incorrect in 25% (11/45) when diagnosis was based on biopsy. The sensitivity of pCLE for the correct histological diagnosis was 82% (62/76), specificity (Sp) 65% (17/26), positive predictive value (PPV) 90% (22/24) and negative predictive value (NPV) 72% (53/74).

Conclusion: pCLE provides satisfactory diagnostic accuracy comparable with standard biopsies in malignant esophageal and gastric lesions in particular.

Disclosure of Interest: All authors have declared no conflicts of interest.
(12.5%) had esophageal cancer, 207 patients (78.1%) had stage IV disease. At the time of inclusion, 138 patients (52%) had grade 3 dysphagia and the mean body mass index (BMI) was 20.9 Kg/m². All the patients underwent anti-biotic prophylaxis previous to the procedure. There was an increase on BMI to 23.8 Kg/m² at 6 months follow up. Eight patients (3.8%) had immediate complications after the procedure (bleeding from the PEG tract; 6; anesthetic complications - 2). The overall complication rate at the first month of follow up was 14.4%, at the third month 20.5% and at the sixth month 11.7%. The overall peri-PEG infection rate was 14%, and was the main complication at the first month of follow up. The development of hyper-granulation tissue was the most frequent complication at the third month of follow-up. Buried bumper syndrome occurred in 10 patients (3.7%). None of the patients had tumor seeding at the gastrostomy site. Overall mortality was 26.4%, none of the deaths attributable to PEG tube insertion.

Conclusion: PEG placement is a safe and effective technique in cancer patients. The rate of major complications and tube site infection were similar to the results found in literature for non-cancer patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Probe-based confocal laser endomicroscopy (pCLE) has been developed to overcome limitations of the current endoscopic sampling techniques. pCLE allows detailed examination of cellular structures and may examine larger areas compared to standard biopsy. Patients after endoscopic treatment of Barrett’s esophagus (BE)-related neoplasia (BORN) should undergo endoscopic surveillance with biopsies to detect persistence or recurrence of intestinal metaplasia (IM) or neoplasia (N).

Aims & Methods: The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN. A single-center, prospective, controlled and pathologist-blinded (still ongoing) study in patients undergoing surveillance after endoscopic treatment of BORN. pCLE images were obtained from the neo-Z-line (a few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present). BE was defined in pCLE as columnar-lined epithelium with dark mucin in goblet cells, a villiform pattern, and regular-shaped capillaries in the mucosa. The dysplastic BE was characterized by black cells with irregular borders and shapes, high dark contrast to the surrounding tissue, and irregular leaking capillaries in the mucosa.

Results: We examined 29 patients, from these 14 patients (48%) had the initial diagnosis of low-grade intraepithelial neoplasia (LGIN), 7 patients (24%) had high-grade intraepithelial neoplasia (HGIN) and 8 patients (28%) had an early adenocarcinoma (EAC). Persistent/recurrent IM was detected at the level of neo-Z-line in 10 patients (34.5%) by both standard biopsies and pCLE. pCLE but not biopsies detected persistent/recurrent IM in 2 patients (6.7%), another 2 patients had IM present in biopsies but not in pCLE. pCLE diagnosed one patient with recurrent LGIN in a macroscopic visible tongue arising from neo-Z-line, which was not confirmed in biopsies. Sensitivity and specificity of pCLE detection of persistent/recurrent IM was 83.3% (95% CI 51.6-97.9) and 80.4% (95% CI 66.9-98.7), respectively, with positive predictive value 83.3% (95% CI 51.6-95.0) and negative predictive value 89.5% (95% CI 70.4-96.8). Agreement of pCLE and histopathological findings was 86%.

Conclusion: pCLE seems to be comparable with standard biopsies in detection of persistent/recurrent IM after endoscopic treatment of BORN. Nevertheless, these results need to be confirmed in a larger cohort of patients. Supported by a grant from Ministry of Health of the Czech Republic, No. 16-27548A.

Disclosure of Interest: All authors have declared no conflicts of interest.
**Conclusion:** In FI patients, the location of the symptoms has a better correlation with the endoscopic findings compared with FII patients. The esophagohioido-
inscopy is safe and effective in patients with FI and FII.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

---

**Aims & Methods:** 33 patients (13 male; mean age 45, range 17–80) underwent a total of 294 endoscopic procedures over 2 years. Treatments were either 100 IU units of Botox injected into 4 quadrants of the pylorus or pneumatic dilation (PD) incrementally up to 16–20 mm (Hercules; Cook Medical). Patients with gastric malignancy, previous pyloric surgery or no documented follow-up were excluded. High-dose-therapeutic responses were assessed at first follow-up post-proce-
dure and graded as ‘good’, ‘partial’ or ‘none/poor’. Patients were grouped according to type of therapy and indication.

**Results:** There were no immediate or late complications observed. 31 procedures were performed for gastroparesis with a mean post-procedure follow-up of 11 weeks. Overall, a partial or good response was observed in 81% (25/31). Specific treatment with Botox alone (18 procedures) or as part of combination therapy (10 procedures) led to a good or partial response in 86% (24/28) compared to 33% (1/3) who had PD alone (p = 0.03). 14 procedures were performed in the post-surgical group with a mean post-procedure follow-up of 10 weeks. Overall, a partial or good response was observed in 93% (13/14); treatment with Botox alone or as part of combination therapy led to a good or partial response in 100% (10/10) compared to 75% (3/4) who had dilation alone (p = 0.1). 6 therapies were performed without a defined indication, 2 patients (33%) had a partial or good response, both of which had combination therapy.

**Conclusion:** Pyloric intervention with Botos, PD or combination therapy are safe and effective treatment options for patients with gastroparesis or delayed gastric emptying following gastrosopic transposition. Subjective treatment without a clear indication shows little improvement.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
factor for delayed bleeding. Given that the majority of delayed complications occurred than 5 post-procedure, a standardised 5 day inpatient stay would prove futile in our cohort.

Introduction: The management and the predictive factors of response to endoscopic dilation of refractory benign oesophageal strictures remains controversial.

Aims & Methods: To evaluate the prevalence and factors predicting response to treatment of benign refractory oesophageal strictures with scheduled endoscopic dilatations

Retrospective analysis of 75 patients submitted to scheduled endoscopic dilatation of benign oesophageal strictures between October 2010 and November 2016. Strictures were classified as refractory when ≥5 endoscopic dilations were needed with at least one dilation achieving ≥15 mm of diameter during the course of management of the oesophageal strictures.

Results: The study sample included 42 (56%) male patients and the mean age was 55 ± 18 years. Dysphagia scale at baseline was: solids (1)–17 (22.7%), semi-solids (2)–23 (30.7%), liquids (3)–23 (30.7%) and complete (4)–12 (16%). Body mass index (BMI) at baseline was 22 ± 5 Kg/m². The aetiology of the benign strictures was: surgical–31 (41.3%), peptic–15 (20%), caustic–10 (13.3%), radiotherapy–10 (13.3%) and others–9 (12%). The location of the oesophageal stricture was as follows: proximal third–34 (43.5%), middle third–12 (16%), distal third–27 (36%) and multiple locations–2 (2.7%). The type of stricture: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilation over a median period of 19 weeks (1–229). Dilations were done with Savary-Gilliard dilators–35 (46.7%), TTS-balloons–24 (32%) or both–16 (21.3%). The mean diameter of dilation achieved was 15.7 ± 2.2 and a dilation diameter of ≥15 mm was achieved in 36 (74.6%) patients. Local injection of corticosteroids have been shown to improve outcome. Local corticosteroids were associated with improved clinical outcomes in patients undergoing endoscopic dilation of benign oesophageal strictures. In our study sample with multiple aetiologies of benign oesophageal strictures, only the maximum dilation diameter and local injection of corticosteroids (OR: 7.22, 95%CI: 0.021–0.55, p = 0.007) were strongly associated with improved dysphagia scores.

Conclusion: In our study sample with multiple aetiologies of benign oesophageal strictures, only the maximum dilation diameter and local injection of corticosteroids were associated with improved clinical outcomes in patients undergoing endoscopic dilation of benign oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1489 LOCAL CORTICOSTEROIDS IMPROVE EARLY CLINICAL OUTCOMES IN PATIENTS UNDERGOING ENDOSCOPIC DILATION OF BENIGN OESOPHAGEAL STRICTURES
M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa

Introduction: Localised corticosteroids have been shown to improve outcomes in patients undergoing endoscopic dilation of peptic strictures.

Aims & Methods: To evaluate factors predicting early clinical response to endoscopic dilation of benign oesophageal strictures. Retrospective analysis of 75 cases submitted to scheduled endoscopic dilatations between October 2010 and November 2016. Clinical improvement was defined as dysphagia score ≤1, IBM SPSS®/21 was used for statistical analysis.

Results: The study sample involved 42 (56%) male patients and the mean age was 54 ± 18 years. Dysphagia scale at baseline was: solids (1)–17 (22.7%), semi-solids (2)–23 (30.7%), liquids (3)–23 (30.7%) and complete (4)–12 (16%). Body mass index at baseline was 22 ± 5 Kg/m². Stricture aetiology: surgical–31 (41.3%), peptic–15 (20%), caustic–10 (13.3%), radiotherapy–10 (13.3%) and others–9 (12%). The location of the oesophageal stricture was as follows: proximal third–34 (43.5%), middle third–12 (16%), distal third–27 (36%) and multiple locations–2 (2.7%). The type of stricture: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilations achieved a median period of 19 weeks (1–229). Dilations were performed with Savary-Gilliard dilators–35 (46.7%), TTS-balloons–24 (32%) or both–16 (21.3%). The mean dilation diameter of achieved was 15.7 ± 2.2 and a dilation diameter of ≥15 mm was achieved in 36 (74.6%) patients. Local corticosteroids were associated with the need for local corticoid injection (p = 0.001) and higher dilatation diameter (p < 0.001). Refractory strictures were significantly associated with the need for local corticoid injection (OR 9.76, 95%CI 0.035–0.46, p = 0.02) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local corticosteroids during scheduled endoscopic dilations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1488 EFFICIENCY AND SAFETY OF ENDOCUTSCOPIC PAPILLECTOMY FOR TREATMENT OF DUODENAL PAPILLA TUMORS
Y. Chu1, M. Xu1, P. Zhou1, C. Zhang1
1 Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: xu.meidong@zs-hospital.sh.cn
Introduction: A duodenal papilla tumor is an uncommon neoplasm in the upper gastrointestinal tract. In the early stage, patients often have no complaints and the tumors are usually occasional found during gastroduodenoscopy examination. Endoscopic papillotomy can be achieved with curative resection for benign adenoma and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillotomy on duodenal papilla tumors.

Aims & Methods: From June 2009 to November 2016, the information of patients who received endoscopic papillotomy was recorded, which included basic characteristics and clinical outcomes, such as recurrence rate, bleeding, pancreatitis. Clinical outcomes (totally 40 cases) received endoscopic papillotomy. The procedure was completed with gastroscopy in 32 cases and duodenoscopy in 8 case. Endoscopic mucosal resection (EMR), endoscopic piecemeal mucosal resection (EPMR) and endoscopic submucosal dissection (ESD) was performed in 21, 17 and 2 cases respectively. None of the lesions invaded the submucosal layer.

bbling (n = 1). Surgery was performed in 10 patients (13.3%) (refractory strictures) and post dilation perforation (n = 3). Improvement of dysphagia symptoms was only associated with the maximum dilation diameter (p = 0.026) and local injection of corticoids (p < 0.001) as confirmed by binary logistic regression wherein both maximum dilation diameter (OR: 4.92, 95%CI 1.05–20.4, p = 0.027) and topical injection of corticosteroids (OR: 7.22, 95%CI: 0.021–0.55, p = 0.007) were strongly associated with improved dysphagia scores.

Conclusion: We aimed to analyse trends in endoscopic e-certification, and assess for differences between trainees in gastroenterology (GI), surgical (GS) and non-medical endoscopy experts (NME).
PANCREATIC STENTS AND BILIARY STENTS WERE INSERTED IN 9 AND 12 PATIENTS RESPECTIVELY. IN GENERAL, 5% (2/40) AND 12.5% (5/40) CASES HAD INTRAOPERATIVE AND POSTOPERATIVE BLEEDING RESPECTIVELY. 20% (8/40) CASES suffered from pancreatitis, of which mild, moderate and severe happened in 3, 4 and 1 cases. Six patients had tumor recurrence. AND 3 patients received repeat endoscopic papillotomy, two received pancreatic-codonemectomy and one received no other treatments with close follow-up. Two patients died from failures of treatment for papillary tumors and one patient died due to other unrelated cause.

**Characteristics and adverse events of endoscopic papillary in cases**

**Sex**
- Male Female: 29 8

**Age (years, mean ± SD)**
- 55.1 ± 10.0

**Endoscope type**
- Gastroscope: 32 8

**Gastroscopy Endoscopy**
- Duodenoscope: 32 8

**Resection method**
- EMR EPMR ESD: 21 17 2

**Pathological results**
- LGD, HGSD, Tis, Tim, Tsm, Non-tumor: 12, 24, 0, 2, 0, 2

**Tumor sizes (cm)**
- Longer diameter: 2.02 ± 0.88, 1.50 ± 0.69

**Biliary Stent**
- Yes, No: 12, 28

**Pancreatic stent**
- Yes, No: 9, 31

**Hospital stays (days, mean ± SD)**
- 6.7 ± 13.4

**Follow-up time (months, mean ± SD)**
- 36.6 ± 28

**Adverse events**
- Intraoperative bleeding: 5% (2)

**Postoperative bleeding**
- 12.5% (5)

**Perforation**
- 2.5% (1)

**Cholangitis**
- 0

**Pancreatitis, Mild, Moderate, Severe**
- 20% (8), 7.5% (3), 10% (4), 2.5% (1)

**Recurrence**
- 16.2% (6)

**Surgery**
- 7.9% (3)

**Mortality**
- 7.9% (3)

**Conclusion:** Endoscopic papillotomy is proved to be efficient in treating papilla tumors without submucosal invasion. However, adverse events like pancreatitis and bleeding should be taken seriously and managed properly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1482** CHANGES IN SCORING OF DIRECT OBSERVATION OF PROCEDURAL SKILLS (DOPS) FORMS IN ENDOSCOPY TRAINING AND THEIR IMPACT ON COMPETENCE ASSESSMENT

**K. Siau**1, P. Dunckley1, A. Nevill1, J. Anderson1, I. Beales1, R. Broughton1, M. Feeney1, A. Haycock1, N. Hawkes1, B. Mckaig1, S. Thomas-Gibson1, R. Valori1, C. Wells1, G. Johnson1

1JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

2Faculty Of Education, Health And Wellbeing, University of Wolverhampton, Walsall/United Kingdom

Contact E-mail Address: keith@siau.org

**Introduction:** DOPS are validated tools for assessing competence in endoscopy. Previously, DOPS were scored on a 4-point competence-based scale, with scores of 3 and 4 signifying competence. In July 2016, the DOPS rating scale changed to a supervision-based scale that has been shown to be more reliable,1,2 with 4 ratings from maximal supervision, up to competent without supervision. We aimed to assess whether changes to the rating scale have affected distribution of scores and hence demonstrate validity.

**Aims & Methods:** We used the UK trainee endoscopy database (JETS) to collect DOPS scores for gastroscopy (n = 1934), sigmoidoscopy (n = 517), colonoscopy (n = 2296) and polypectomy (n = 370) in the 6-months before July 2016 (old DOPS) and in the 6-months after (new DOPS) for trainees at early stages of training. All trainees were included for analysis. To allow the new DOPS rating scale to be aligned to a 4-point scale, DOPS scores of 3 or 4 on old DOPS, and scores on the new and old DOPS were considered using the Mann-Whitney U-test.

**Overall, there were variations in distributions of all scores (p < 0.001) between forms (Figure 1). Compared to new DOPS, scores of 1 were underutilised on old DOPS (6.6% vs. 3.0%, p < 0.001). Frequencies of low scores (pooled scores of 1-2) were similar for gastroscopy (p = 0.33) and sigmoidoscopy (p = 0.34), but not for colonoscopy (new 11.9% vs. old 13.9%, p < 0.001) and polypectomy (new 6.8% vs. 19.9%, p < 0.001). Trainees on old DOPS were more likely to be rated as competent (score 3 or 4) compared to new DOPS (86.4% vs. 55.8%, p < 0.001). On subgroup analysis, this was evident for gastroscopy (86.3% vs. 49.1%, p < 0.001), colonoscopy (86.1% vs. 58.2%, p < 0.001), sigmoidoscopy (90.6% vs. 62.0%, p < 0.001), but not polypectomy (80.1% vs. 67.9%, p = 0.12).

**Conclusion:** Endoscopists are assessing a greater range of scores using a new DOPS rating scale based on degree of supervision, in two cohorts of trainees matched for experience. This indicates better construct validity with the new rating scale. Further work is underway to determine the reliability of the new DOPS to inform summative assessment and certification for UK endoscopy trainees.

Introduction: Acute perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: We aimed to assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used in closing acute perforations in animal models. Medical literature (Cochrane library, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 46 studies on animal models were identified. 15 studies, including 4 randomized controlled trials, met our inclusion criteria (acute, less than 2 hours, iatrogenic, no fistulas or leaks, clear documentation of the method of closure, and technical and clinical success and 5 cases or more of endoscopic closure per study), were analysed. A total of 214 endoscopic closures were attempted in these studies. The overall technical success rate was 94.8% (n = 201/214, 95% CI: 92%-97.6%), clinical success was 92.3% (n = 195/214, 95% CI: 88.5%-95.8%), and complication rate was 4.2% (n = 6/214, 95% CI: 1.6%-6.8%). Technical success for endoclamp closure was 84.9% (95% CI: 71.4%-93.6%), and clinical success was 83.2% (95% CI: 69.5%-92.5%), and complication rate was 4.2% (95% CI: 1.9%-6.9%). Technical success for endoclip closure was 84.9% (95% CI: 71.4%-93.6%), and clinical success was 83.2% (95% CI: 69.5%-92.5%), and complication rate was 4.2% (95% CI: 1.9%-6.9%). Technical success for endosuturing (endoscopic suturing device) was 97% (95% CI: 98%-99.9%), clinical success was 97% (95% CI: 88%-99.7%), and complication rate was 1.7% (95% CI: 0.6%-8.3%). Technical success for endosponge was 97% (95% CI: 90%-99%), and complication rate was 1.6% (95% CI: 0.1%-2.8%). Technical success for endoclip perforation closure was 97% (95% CI: 98%-99.7%), clinical success was 94.8% (95% CI: 89.9%-99.3%), and complication rate was 1.9% (95% CI: 0.6%-7.1%).

Conclusion: Our study suggests that endoscopic closure is a suitable treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.

Introduction: Bowel cleaning has a critical role to increase the quality and effectiveness of colonoscopy. International guidelines recommend the use of split-dose regimens of PEG solutions. However, the adoption of split-dose regimens in clinical practice remains sub-optimal, in particular in early morning.

Aims & Methods: We aimed to compare the efficacy of bowel preparation using an asymmetric split-dose regimen (approximately 25% of the dose is given on the day of the procedure and 75% of the dose is given on the day before) with the standard split-dose regimen in patients undergoing screening colonoscopy. We prospectively enrolled consecutive outpatients undergoing screening colonoscopy. All subjects received a split-dose preparation with a 2L PEG-citrate-simethicone plus Bisacodyl. Patients were randomly assigned to: group A, asymmetric split dose regimen (1.5 L of PEG + bisacodyl the day before and 0.5 L 3 hours before colonoscopy); group B, symmetric split dose regimen (1 L of PEG + bisacodyl the day before and 1 L 4 hours before colonoscopy). Bowel preparation was evaluated using the Boston Bowel Preparation Scale (BBPS) score. The primary endpoints were the proportion of adequate bowel cleaning (BBPS = 2) in both groups. Moreover, all patients filled in a nurse-administered questionnaire assessing compliance, tolerability and safety of bowel preparation. The threshold for statistical significance in this study was p < 0.05 and a 10% margin was used to demonstrate non-inferiority of asymmetric vs. symmetric split-dose regimen.

Results: 179 patients were enrolled (mean age 60 ± 8 years, males 56%), 88 in group A and 91 in group B. Split-dose was taken by 76/88 and by 77/91 patients in group A and B, respectively (85.2% vs 88.5%, p = 0.831). Failure of ceased preparation occurred in 2 patients for each group. In the ITT analysis, adenoma detection rate [32/76 (42.1%) vs 35/77 (45.4%); p = 0.745] and scores of each colon segment. The full amount of product and adjunctive fluids were taken by 68/76 (89.4) and 71/77 (92.2%) (p = 0.158) in group A and B, respectively. Tolerability and occurrence of adverse events were similar in the two groups.

Conclusion: An asymmetric (morning-dose) split-dose preparation with a low volume formulation with additional Bisacodyl is not inferior to the standard split-dose regimen in achieving an adequate bowel cleansing in patients undergoing screening colonoscopy. A lower amount of preparation in the morning allow to the patients to wake up later; this regimen could be thus preferred by patients undergoing colonoscopy early in the morning. Further study are needed to determine the efficacy and tolerability of the asymmetric preparation for colonoscopy scheduled in early morning.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is a technique with remarkably greater difficulty than upper gastrointestinal ESD because of unstable maneuvers and inherited anatomic variability in the colon. Thus, aiming at reducing these restrictions, we have used single balloon (SB) overtube to assist colorectal ESD in cases considered to have difficult operability. In this study, we evaluate the usefulness of a single balloon overtube to assist colorectal ESD.
Aims & Methods: The study included 35 patients with 39 colorectal lesions who underwent ESD (group SB) or endoscopy nurse alone in (1) 5.5% and a second physician in (1) 5.5% of the institutions, with either nurse anaesthesiologist or an anaesthesiologist in (5) 27.8%, a designated anaesthesiologist was in charge of sedation in (7) 38.9% of the institutions. General anaesthesia was used in (4) 22.2%, while conscious sedation was used in (3) 16.7%. In (3) 16.7% of institutions deep sedation, conscious sedation or general anaesthesia was used according to the cases and clinician decision. A third physician was independently for eligibility by two reviewers (S.B. and M.S.). Any Disagreements were resolved by consulting a third reviewer (A.P.).

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: 18 eligible original articles, of which (5/18) 27.8% agreed for eligibility by two reviewers (S.B. and M.S.). Any Disagreements were resolved by consulting a third reviewer (A.P.). All articles were examined independently for eligibility by two reviewers (S.B. and M.S.). Any Disagreements were resolved by consulting a third reviewer (A.P.).

Results: This review resulted in 18 eligible original articles, of which (5/18) 27.8% agreed for eligibility by two reviewers (S.B. and M.S.). domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD), and Teamwork and Decision-making (T&DM). Each MARS domains was represented by 10 items and is assessed on a 7-point scoring scale - endoscopists should score > 90 in each domain (80-90 = need for improvement, < 80 = suboptimal performance). CIR and PDR measures are routinely calculated for all endoscopists using the HICCS Electronic Reporting System with manual validation of this data. Feedback is presented on a quarterly basis to practitioners—endoscopists are expected to achieve 90% CIR and 20% PDR. Correlation of these factors with practitioners ENTS scores were measured using the Pearson test.

**Results:** 9 endoscopists with known variability in standard colonoscopy KPIs consented to an assessment of ENTS using the MARS tool. Their ENTS scores were correlated with existing KPIs for each colonoscopy (Oct 2016-May 2017). A positive correlation was found between ENTS domains and CIR (COMM 0.58, SITA 0.66, LEAD 0.66; JDM 0.75) and PDR (COMM 0.49; SITA 0.55; LEAD 0.50; JDM 0.60). Three endoscopists were identified as having sub-optimal scores in all of the ENTS domains (operators 5, 7, 9). Taking into account important KPI thresholds 2 out of 3 (33%) of these endoscopists identified were not meeting CIR targets (c.f. 66% of ENTS competent group) and one (33%) did not meet PDR targets (c.f. 0% in ENTS competent group).

Colonoscopy as a screening tool is a practical way to measure of ENTS performance designed as a 360 degree feedback and identifies areas for development within independently practitioners that are not currently highlighted by standard colonoscopy KPI measures. There is some correlation with current KPI feedback panels but using a specific validated ENTS assessment tool augments current assessment panels. Both CIR and PDR primarily depend on the colonoscopists' individual skills rather than the team elements required for polypectomy or EMR and these more complex tasks may show stronger correlation with MARS ENTS evaluation.

**Introduction and Rationale:**

Colorectal cancer (CRC) is the third most common cancer diagnosed in men and second most common cancer in women, affecting 1,361,000 people worldwide each year. CRC is a slow growing tumour that most commonly develops from polyps which form in the inner lining of the colon or rectum. The identification and removal of polyps whilst still in a pre-cancerous state has been shown to be effective in reducing mortality from CRC. Current clinical practice relies on white light (WL) colonoscopy for detecting colorectal polyps, but this is associated with a detection "miss-rate" of up to 26% for small (<10 mm) polyps and 2% for large polyps (van Rijn et al., 2006). Missed lesions (false negative results) puts patients at an unnecessary risk of late stage detection, when management has higher costs and worse clinical outcomes. Recent technological developments have resulted in more accurate technologies for polyp detection and this will be used to inform the design of future clinical studies. EMI-137 has the potential to be cost-effective for patients participating in the UK National Bowel Cancer Screening Programme. The value of information analyses have highlighted the key parameters for which further evidence is required, and this will be used to inform the design of future clinical studies.

Aims & Methods: We identified all DOPS submitted between July 2016 and Feb 2017 from the UK endoscopy trainee database (JETS) and acquired data on trainees, procedures and scores. We collated scores for each of the 4 assessable domains (pro-procedural, procedural, post-procedural and ENTS) into overall ENTS competency (defined as all items scoring competent) varied across procedures (p < 0.001): ERCP 39.8%, EUS 44.1%, gastroscopy 59.6%, colonoscopy 62.3%, Polypectomy 71.1%, gastrointestinal bleed (71.5%), sigmoidoscopy 72.4% and polypectomy 73.2%. Scores by individual ENTS components are displayed in Table 1. Of DOPS awarded overall competency, 5.9% (240/4077) lacked full competence in ENTS (p < 0.10 across modalities). Across trainee specialties and endoscopic modalities, competence was greatest for ‘communication and teamwork’ (77.1% overall), but least with ‘judgement and decision making’ (68.3%). Statistical analysis was performed using chi2 and regression modelling.

Results: 3601 DOPS were prospectively collected, with ENTS assessed in 99.3%. Competency rates of individual ENTS items are summarised in Table 1. Rates of overall ENTS competency (defined as all items scoring competent) varied across procedures (p < 0.001): ERCP 39.8%, EUS 44.1%, gastroscopy 59.6%, colonoscopy 62.3%, Polypectomy 71.1%, gastrointestinal bleed (71.5%), sigmoidoscopy 72.4% and polypectomy 73.2%. Scores by individual ENTS components are displayed in Table 1. Of DOPS awarded overall competency, 5.9% (240/4077) lacked full competence in ENTS (p < 0.10 across modalities). Across trainee specialties and endoscopic modalities, competence was greatest for ‘communication and teamwork’ (77.1% overall), but least with ‘judgement and decision making’ (68.3%). PI1494 STUDY OF ULCERATIVE COLITIS COMPLICATED BY PRIMARY SCLEROSING CHOLANGITIS

S. Murasugi, A. Ito, H. Kambayashi, M. Yonezawa, T. Ohmori, K. Tokushige

Contact E-mail Address: murashun0305@yahoo.co.jp

Introduction: Primary sclerosing cholangitis (PSC) is often associated with autoimmune diseases, and approximately 70% of PSC patients in Europe/United States and 32% in Japan also have ulcerative colitis (UC). The complication of PSC is confirmed in about 5% of UC patients, the clinical features of UC associated with PSC differ from those of UC without PSC.

Aims & Methods: We investigated the clinical and colonoscopic features of colitis associated with PSC. We retrospectively examined the clinical features, including the clinical course and colonoscopic findings, of 25 colitis patients with PSC attending our hospital between 2000 and 2017.

Results: The male-female ratio was 12:13 and the age at diagnosis of PSC was 49 ± 15 years. PSC was the initial diagnosis in 12 patients (48%), while colitis was the first to be diagnosed in 4 patients (16%), and both diseases were found concurrently in 9 patients (36%). Among the 21 patients with the diagnosis of PSC, 7 patients (33%) had the symptoms of PSC and the latter was recognized by screening. There were 12 patients with UC (52%) and 11 patients with nonspecific colitis (48%). Among the 24 patients in whom the disease extent was assessed, 22 had pancolitis, 1 had left-sided colitis, and 1 had proctitis. Inflammation predominantly affected the right colon in 20/22 patients with pancolitis and also involved the terminal ileum in 9 patients (45%). The Mayo score for colonoscopic evaluation of UC was 1 in 16 patients (64%), 2 in 8 patients (32%), and 3 in 1 patient (4%). There were no rectal lesions in 10 patients (40%). Liver biopsy was performed in 17 patients, and Ludwig’s stage was Stage I in 1 patient (6%), Stage II in 12 patients (71%), Stage III in 3 patients (18%), Stage IV in 1 patient (6%). Ludwig’s stage did not correlate with the Mayo score. All patients with PSC and enterocolitis received oral ursodeoxycholic acid (UDCA), including 13 patients with UDCA only (52%), 2 patients with combination of salazosulfapyridine (SASP) (8%) in combination with 5-aminosalicylic acid (5-ASA) (20%), 2 patients in combination with prednisolone (PSL) (8%), 1 patient with the combination of SASP + PSL (4%), and 2 patients with 5-ASA + PSL (8%). The UDCA dose was 400 mg in 2 patients (8%), 600 mg in 15 patients (60%), and 900 mg in 9 (32%).

Conclusion: In colitis patients with PSC, there was no clear association between colonoscopic disease activity and the severity of PSC. There was no sex difference and the age at diagnosis of PSC showed a bimodal distribution (30s and 60s). Prednisolone was very frequent and predominantly affected the right colon, but disease activity was low. Rectal lesions were mild or absent. About half of the patients had inflammation of the terminal ileum.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Unadjusted ENTS scores by endoscopic modality.
Introduction: The development of Endoscopic Non-Technical Skills (ENTS) is associated with improved performance and high quality endoscopic outcomes. Whilst ENTS domains have been incorporated into Joint Advisory Group (JAG) Direct Observation of Procedural Skills (DOPS) forms, used as training tools, knowledge of ENTS domains amongst independent practitioners varies. To improve performance in this area of practice requires validated measurement tools and specific feedback against which improvement can be measured. We have previously developed a validated 360-degree multi-assessor rating scale (MARS tool) based on experienced endoscopy assistant ratings for ENTS providing data on 4 main domains of ENTS—each comprising 10 related but independent practice points. Providing an optimised feedback format for this data is likely to maximise the potential benefits of measuring ENTS performance.

Aims & Methods: We aimed to provide an optimised format for performance enhancing feedback in the ENTS domains and basis for specific auditable outcomes and performance indicators. Local colonoscopists gave consent to application of the ENTS questionnaire. The validated MARS tool assesses 4 ENTS domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Judgement & Decision-making (J&DM). Each MARS domain in the administered questionnaire was represented by 10 items and is assessed on a 7-point scoring scale. We sought to develop 1) a format to illustrate an individual’s overall performance in each of the 4 main ENTS domains in comparison to other operators and 2) a detailed domain breakdown highlighting areas of underperformance 3) Collate feedback on the presentation formats.

Results: 9 endoscopists consented to an assessment of ENTS using the MARS tool. The MARS questionnaires were administered during January 2017–relating to the prior 3 months clinical practice. Acceptable performance thresholds were set as >90% good-excellent ratings in each domain. Need for improvement was defined as 80–90% good-excellent ratings (i.e. 10–20% average or poor ratings) and sub-optimal performance as 80% or less good-excellent ratings (i.e. >20% average-poor ratings). Good intra- and inter-rater reliability was demonstrated defined as 80–90% good-excellent ratings (i.e. 10–20% average or poor ratings).

Conclusion: Failed prior attempts at resection or heavy manipulation of lesions reduces the chance of achieving en bloc resection and increases the risk of complications and recurrence. Nevertheless, specialist management in a dedicated setting improves results in safe and successful organ preserving endoscopic treatment of these extremely challenging lesions in over 95% of cases with few significant complications.

Disclosure of Interest: All authors have declared no conflicts of interest.
and O2 have relatively dark xenon light sources and maximum optical magnifi-
cation at 110 times, respectively. Therefore, the differences in visualization of mucosal blood flow in the small and large bowel among the groups were considered to be attributable to differences in instrument efficiency.

**Conclusion:** Our results show that magnifying observation with BILI is superior to that with endo-illumination. However, the more invasive tumor is, the more presence of submucosal fibrosis, the percentage of adenoma, intramucosal cancer, SM-1(>30 mm), and SM-2(>100 mm) cancer with fibrosis were 32.31%, 66.67%, 87.5%, and 90% (P < 0.00). Additionally, the fibrosis rate for tumors ≤3 cm and >3 cm were 44.12% and 58.97% (P < 0.002). When biopsies were performed two or more times on a same lesion, it showed significant difference comparing to patients who only underwent biopsy just once. (OR 4.98, 1.20–20.51, 95% CI, P = 0.026)

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P5101 ADVANCED NEOPLASIA YIELD IN NEOPHILATES UNDERGOING COLONSCOPY AFTER SCREENING FLEXIBLE SIGMOIDOSCOPY: DOES THE DISTAL COLON PATHOLOGY PREDICTS THE YIELD IN PROXIMAL COLON?**

**Contact E-mail Address:** r.rameshshanker@nhs.net

**Introduction:** Current patients undergoing a screening flexible sigmoidoscopy (Bowel Scope examination) at the age of 35 are referred for colonoscopy if the following polyp criteria are met: polyp >1 cm, villous histology, high grade dysplasia, 3 or more adenomas or ≥20 hyperplastic polyps (HP).

**Aims & Methods:** Objective is to assess the proportion of patients who had an advanced adenoma (size >1 cm, villous or high grade dysplasia on histology) in the proximal colon when referred for a colonoscopy after a screening flexible sigmoidoscopy. A retrospective cross-sectional study of patients who underwent Bowel Scope screening between July 2013 - July 2016 at St Mark’s Bowel Cancer Screening (BCS) Centre was performed. Epidemiological, procedural and polyp data were retrieved from the on endoscopy and Bowel Cancer Screening database.

**Results:** 960 patients had a screening flexible sigmoidoscopy in the time period. Descending colon was reached in 82% of patients. Advanced adenomas were detected in 351 (35.2%) patients. 520 (52.5%) patients had a colonoscopy following screening flexible sigmoidoscopy as per the BCS protocol. Median age was 55 years (male: female ratio 2:1). Caecal intubation was achieved in 98% (510/520) of cases. At least one adenoma or a sessile serrated adenoma/polyp (SSA/P) was detected, proximal to the extent of flexible sigmoidoscopy examination, in 45% (236/520) of patients (Table 1). The incidence of advanced adenoma in the distal colon was an indication for colonoscopy in 351/520 patients (68%). Of these, 52 (14.8%) had a synchronous proximal colonic advanced adenoma and 20 (5.7%) had a synchronous SSA/P. Only 5 (1.4%) patients had an advanced lesion. A pattern of only SSA/P in the proximal colon. Presence of distal advanced adenoma was associated with proximal advanced adenoma (p = 0.0006). However, there was no association between presence of distal advanced adenoma and proximal SSA/P (P = 0.47) or advanced SSA/P (P = 0.4).

**Conclusion:** Distal colonic advanced adenomas are a marker of synchronous proximal colonic adenomas and sessile serrated polyps. When colonoscopies were performed for other indications (non-adenomatous polyp > 1 cm, multiple distal HP polyps) the yield in the proximal colon was significantly smaller. These “soft” indications for colonscopy accounted for a significant additional workload that appears unjustified.

**P1502 LEARNING CURVE FOR OPTICAL DIAGNOSIS OF COLORECTAL POLYPS USING CUMULATIVE SUM ANALYSIS**

R. Rameshshanker, A. Wilson, S. Thomas-Gibson, N. Kamperidis, N. O’Shea, B.P. Saunders
Wolfox Endoscopy Unit, St Mark’s Hospital, Harrow, London, United Kingdom

**Contact E-mail Address:** r.rameshshanker@nhs.net

**Introduction:** Optical diagnosis for diminutive and small colorectal polyps is an attractive option to reduce costs and streamline patient care. The American Society of Gastrointestinal Endoscopy Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) established a 90% diagnostic threshold for real time endoscopic assessment of the histology of diminutive colorectal polyps. For adoption of optical diagnosis in clinical practice, colonoscopists must be trained and show on-going competence. The learning curve for trainees to achieve the competency has not been fully explored.

**Aims & Methods:** Aim is to evaluate the minimum number of polyps to achieve and maintain the optical diagnostic thresholds per PIVI standards using an upward CUSUM plot. Four trainees without previous experience in optical diagnosis at our institution participated in this prospective study.

**Results:** A total of 708 polyp observations were performed by trainees during the study period. Total number of adenomas, hyperplastic polyps and sessile serrated adenomas/polyps (SSA/P) were 364, 214 and 52 respectively. Trainees OD performance was plotted on a upward CUSUM plot. Four trainees without previous experience in optical diagnosis were carried out, including a consecutive cohort of 56 patients who underwent EFTR for colorectal SMTs originating from the MP layer. A prospective study was carried out, including a consecutive cohort of 56 patients who underwent EFTR for colorectal SMTs originating from the MP layer between January 2008 and September 2014 in our center. Among these, 21 lesions were located in the colon, 9 located in the intraperitoneal rectum and 26 located in the extraperitoneal rectum. The tight adhesion of the lesion to the serosal layer was identified before EFTR in all cases. EFTR was performed using a standard ESD technique under direct endoscopic view. The defect of colorectal wall was closed after resection in all cases. Complete resection rate, complications and lesion recurrence were evaluated.

**Results:** Successful EFTR was performed in 54 (96.4%) patients. The other 2 patients were transferred to suffer laparoscopic right hemicolectomy and EFTR combining laparoscopic operation respectively, because the lesions involved the external organs and were too difficult to get en bloc resection endoscopically. The endoscopic resection rate and complete resection rate were both 96.4% (54/56). Among 54 cases, 52 of these lesions were performed with EFTR without laparoscopic assistance, while 2 needed laparoscopic assistance to get the defect closed after resection. The median operation time was 45 min (range, 20–130 min). The median maximum diameter of resected tumors was 1.5 cm (range, 0.5–5.0 cm). Accurate histopathologic results were acquired from all the resected lesions, including 18 leiomyomas, 11 gastrointestinal stromal tumors (GISTs), 8 fibrous tumors, 5 schwannomas, 11 granulomas, 2 displaced endometrium, and 1 hamartoma. Three patients had local peritumors and two patients developed postoperative bleeding. All of them recovered after receiving conservative treatments. No single case developed diffuse peritumors. No lesion residual or recurrence was found during the follow-up period ranging 2–54 months.

**Conclusion:** EFTR appears to be a safe, feasible, and effective procedure for providing accurate histopathologic evaluations, as well as a curative treatment for colorectal SMTs originating from the MP layer. However, it should be performed by the very experienced endoscopists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1503 THE CLINICAL VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR COLORECTAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA: A PROSPECTIVE SINGLE-CENTER STUDY**

M. Xu, C. Zhang, Q. Li
Endoscopy Center, Zhongshan Hospital, Shanghai, China

**Contact E-mail Address:** xumeidong@aliyun.com

**Introduction:** Given diminishing quality of life caused by colectomy and resection, a minimally invasive treatment is desirable for colorectal submucosal tumors (SMTs).

**Aims & Methods:** The aim of the current study was to evaluate the clinical efficacy, safety and feasibility of endoscopic full-thickness resection (EFTR) for colorectal SMTs originating from the MP layer. A prospective study was carried out, including a consecutive cohort of 56 patients who underwent EFTR for colorectal SMTs originating from the MP layer between January 2008 and September 2014 in our center. Among these, 21 lesions were located in the colon, 9 located in the intraperitoneal rectum and 26 located in the extraperitoneal rectum. The tight adhesion of the lesion to the serosal layer was identified before EFTR in all cases. EFTR was performed using a standard ESD technique under direct endoscopic view. The defect of colorectal wall was closed after resection in all cases. Complete resection rate, complications and lesion recurrence were evaluated.

**Results:** Successful EFTR was performed in 54 (96.4%) patients. The other 2 patients were transferred to suffer laparoscopic right hemicolectomy and EFTR combining laparoscopic operation respectively, because the lesions involved the external organs and were too difficult to get en bloc resection endoscopically. The endoscopic resection rate and complete resection rate were both 96.4% (54/56). Among 54 cases, 52 of these lesions were performed with EFTR without laparoscopic assistance, while 2 needed laparoscopic assistance to get the defect closed after resection. The median operation time was 45 min (range, 20–130 min). The median maximum diameter of resected tumors was 1.5 cm (range, 0.5–5.0 cm). Accurate histopathologic results were acquired from all the resected lesions, including 18 leiomyomas, 11 gastrointestinal stromal tumors (GISTs), 8 fibrous tumors, 5 schwannomas, 11 granulomas, 2 displaced endometrium, and 1 hamartoma. Three patients had local peritumors and two patients developed postoperative bleeding. All of them recovered after receiving conservative treatments. No single case developed diffuse peritumors. No lesion residual or recurrence was found during the follow-up period ranging 2–54 months.

**Conclusion:** EFTR appears to be a safe, feasible, and effective procedure for providing accurate histopathologic evaluations, as well as a curative treatment for colorectal SMTs originating from the MP layer. However, it should be performed by the very experienced endoscopists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1504 COLONIC ESD BY UTILIZING SHORT DOUBLE BALLOON ENDOSCOPE—HOW TO TREAT DIFFICULT CASES IN COLONIC ESD**

S. Katsuki, T. Fujita, K. Takamashi, E. Waga
Center Of Gastroenterology, Otaru EkiSaikai Hospital Center of Gastroenterology, Otaru, Japan

**Contact E-mail Address:** sinichi-katuki@otaru-eki-saikai.jp

**Introduction:** Colon ESD has been becoming a standard treatment in the world. However, sometimes it is hard to remove the colon tumor during ESD. When we found it is difficult to detach the colorectal neoplasm in ESD, we should consider the following three points: if we don’t have enough experience and skill, we should take the training more. If there are lots of vessels and fibrosis in the submucosal layer, it is necessary to choose adequate tools. And if patients have complicated colon, suitable endoscope need to be selected. In such cases we always use DBE.

**Aims & Methods:** We evaluated the outcomes of colonic ESD by using DBE (DBE-ESD). Short DBE we used were EC450B1, EN530BI and ES60BT (Fujifilm Co., Tokyo, Japan). We've performed DBE-ESD on 211 lesions in 184 patients. We analyzed the lesions located in the proximal colon, and the following items were examined: arrival time, procedure time, rate of negative margin, perforation rate, length of hospital stay and recurrence rate in the 5th-year after the ESD.

**Results:** There were 159 lesions located in the proximal colons. The median arrival time to the lesion was 7.9 min, operation time 51.1 min, negative rate of horizontal margin 99.4%, vertical margin 99.4%, perforation rate 0%, median length of hospital stay 3.1 days, and recurrence rate in patients with more than 5 year follow-up 0%.

**Conclusion:** Because the balloons and the overtube retained the scope at stable position, we were able to get good working space. Therefore, DBE should be one option for difficult cases in ESD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1505 WITHDRAWAL TIME MONITORING AND FULL-SPECTRUM ENDOSCOPY IMPROVE ADENOMA DETECTION RATE

G. De Nucci1, P. Andreozzi2, C. Bezzo3, R. Reati1, D. Morganti1, D. Redaelli1, E. Mandelli1, B. Omazza1, I. Arena1, S. Saibeni1, G. Manes1

Contact E-mail Address: gernumadenuzzi@gmail.com

Introduction: Adenoma detection rate (ADR) is a quality indicator of screening colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscopy (FUSE) have been suggested to increase the ADR since allow an accurate evaluation of the hidden areas of the colon.

Aims & Methods: We aimed to evaluate whether monitoring of WT alone or in combination with the use of FUSE would be able to increase the ADR. In a prospective non-randomized observational study, consecutive outpatients, aged 18-85 yr, undergoing colonoscopy with different indications were enrolled. In phase 1, endoscopists performed 660 colonoscopies either with standard forward-viewing endoscope (SFVE) (n = 330) or with FUSE (n = 330) without a dedicated WT protocol. In this phase, colonoscopy WT were measured without the endoscopists' knowledge of being monitored. In phase 2, endoscopists were informed of being monitored and performed further 660 colonoscopies either with SFVE (n = 330) or with FUSE (n = 330).

Results: No differences were observed among the four arms in terms of demographic, clinical features, and dedications to colonic WT. Colonoscopy WT was lower in phase 1 arms compared to phase 2 arms (SFVE: 267 ± 96 vs. 387 ± 65, p = 0.001; FUSE: 293 ± 112 vs. 430 ± 93, p = 0.001). When endoscopists were aware of being monitored and used full-spectrum endoscope we observed a higher ADR [phase 1 SFVE: 27.3% (90) phase 1 FUSE: 33.0% (109) phase 2 SFVE: 33.6% (111) phase 2 FUSE: 41.8% (138); p = 0.001] and adenoma per colonoscopy (APC) [phase 1 SFVE 0.43 ± 0.85 phase 1 FUSE 0.58 ± 1.08 phase 2 SFVE 0.64 ± 1.24 phase 2 FUSE 0.71 ± 1.08; p = 0.004]. The detection rate of adenoma located proximally to the splenic flexure was higher in phase 2 arms (phase 1 SFVE 11.2% vs. phase SFVE 16.4%; p = 0.056; phase 1 FUSE 12.7% vs. phase 2 FUSE 18.9%; p = 0.033), whereas adenoma located distally to the splenic flexure was higher in the FUSE arms compared to SFVE arms, but these differences were not significant (Phase 1 SFVE 20.0% vs. Phase 1 FUSE 24.8%, p = 0.081; Phase 2 SFVE 21.8% vs. Phase 2 FUSE 27.0%, p = 0.147).

Conclusion: Unmonitored endoscopists have a sub-optimal WT, which increases when they are aware of being monitored and used full-spectrum endoscope combined with WT monitoring results in increase of adenoma detection rate. In particular, monitoring WT increases the detection of adenoma in proximal colon, whereas the use of FUSE seems to increase the detection of adenomas in distal colon.

P1506 HIGH LEVELS OF ‘PRESUMED POLYP MISS RATE’ AT 1 AND 3 YEARS FOLLOWING INDEX SCREENING COLONOSCOPY: NO ROOM FOR IMPROVEMENT

Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Introduction: Polypectomy with polypectomy is considered the optimal method of bowel cancer prevention. Despite improvements in colonoscopy training and technology, it remains as an imperfect tool and the adenoma miss rates vary when they are aware to be monitored. Use of full spectrum scopes combined with WT technology, it remains as an imperfect tool and the adenoma miss rates vary.

Aims & Methods: Data from 25,407 patients undergoing healthy check up assessing periodontal disease according to periodontosis-risk classes (PRC 0-healthy gingiva, PRC 1 - tarter or plaque, PRC 2 - redness or swelling) and screening colonoscopy between 2009 and 2012 in Austria were included. Colonoscopy outcomes were compared between patients with and without signs of periodontal disease using multivariate models adjusting for age, sex, smoking, alcohol consumption, diabetes and BMI.

Results: In multivariate adjusted models, patients with periodontal disease had similar odds for the detection of colorectal polyps as those without signs of periodontal disease [adjOR 1.070; 95% CI: 0.918; 1.247]. Regarding the prevalence of adenomas, patients with periodontal disease, likewise, had similar odds as those with healthy periodontal tissue [adjOR 1.010; 95% CI: 0.840; 1.213]. Similarly, those with periodontal disease had comparable odds for colorectal adenomas as those without signs of periodontal disease [1.055 (0.785; 1.418)].

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Our study highlights that there is likely to be a significant miss rate for adenomas and SSA/Ps even after careful index colonoscopy. Miss rate was higher when multiple polyps are seen at the index examination. This finding appears to justify the current BSG (British Society of Gastroenterology) guidelines for an early, 1 year colonoscopy when multiple polyps are seen. The presumed polyp miss rate at 1 & 3 years may be justified as a new quality metric within screening programmes.

NON-POLYPOID LESIONS IN INFLAMMATORY BOWEL DISEASE: The King’s Institute of Therapeutic Endoscopy (KITE) is a tertiary centre for endoscopic assessment and resection of large challenging colorectal polyps. Here we present the largest single-centre case series of large non-polypoid resections associated with colitis.

Aims & Methods: Adults with confirmed colitis (ulcerative colitis extending beyond the rectosigmoid junction and crohn’s colitis affecting at least the left colon) with lesions at least 20 mm in size within the colitis segment were included. Data including demographics, clinical history, lesion characteristics, method of resection and post-resection surveillance were collected prospectively in patients from January 2011 to November 2016. Resection techniques included endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) and hybrid ESD. Surveillance of resection site with magnification chromoendoscopy (mCE) was performed at 3 months with pan colonic mCE at 1-year post resection and annually thereafter.

Results: Thirty-lesions satisfied the inclusion criteria in 13 patients. Patient demographics and clinical data are provided in table 1. Mean lesion size was 47.3 +/- 22.4 (20-90) mm. All lesions were non-polypoid with distinct margins and no ulceration. High-frequency mini-probe ultrasound confirmed intramural lesions in 5 cases where pit/vascular pattern was distorted due to inflammation. En bloc resection was achieved in 6 cases. 69% lesions were deeply scarred of which 66% had experienced prior instrumentation. Resection of a single lesion was segmentally extended due to intense fibrosis. Macroscopic evidence of complete resection was confirmed histopathologically in 6/6 of resected lesions. Complete excision was confirmed in all en bloc resections. A single case of small perforation and another with delayed minor bleeding were both managed endoscopically. Mortality/hospital admission within 30 days post resection was 0%. Median follow up was 28 months (12-35) with no recurrence. Alternative site dysplasia was detected in 2 patients. All lesions were sub 20 mm and resected endoscopically. Two patients were referred for colectomy due to a concomitant diagnosis of neuroendocrine tumour and the second with alternate site advanced dysplasia.

P1509 RESEARCH ON APPLICATION OF TRANSDURAL TUBE DECOMPRESSION FOR PREVENTION OF COMPLICATIONS IN COLORECTAL MUCOSAL LESIONS AFTER ESD

L. Bing, Z. Qi, Y. Zhong  
Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, Shanghai, China

Contact E-mail Address: 13356423348@126.com

Introduction: Endoscopic submucosal dissection (ESD) has been widely used in the miniminally invasive treatment of early colorectal mucosa and submucosal lesions. This technique has made it possible to resect even large mucosal or submucosal lesions en bloc, and the recurrence rate is lower. However, due to the thinner colorectal wall and more abundant blood vessels, postoperative complications after ESD is higher in this site. As a result, how to prevent complications related to ESD for colorectal lesions has raised widespread concern. In recent years, more and more researchers placed transanal tube for patients with colorectal cancer resection or intestinal obstruction to promote the early discharge of the gas and liquid in the intestine. The efficacy of this method to reduce incidence of complications and to promote recovery of intestinal function have been verified by a number of studies. Based on this, we applied transanal tube to some patients with colorectal ESD, hoping to provide new ideas for the prevention and treatment of complications.

Aims & Methods: We aimed to evaluate transanal tube for prevention of complications in colorectal mucosal lesions after endoscopic submucosal dissection (ESD). Data of 61 patients with colorectal mucosal lesions undergoing ESD from January to December 2016 were reviewed. All patients were followed up and we analyzed the incidence rate of complications after ESD within one month.

Results: The median age of 61 patients was 61(32 - 83) years. 21 of all lesions were located at right-half colon, 9 at left-half colon and 31 at rectum. The mean diameter of the lesions was 3.26 ± 2.27 (0.8-12) cm. There were not intraoperative complications including serious bleeding and perforation. Delayed bleeding on the eighth post-ESD day was detected in 1 (1.6%) patient who was cured by transfusion. 3(4.9%) patients suffered post-ESD electrocoagulation syndrome and perforation did not present in all cases. In this group with transanal tube for decompression, the rates of perforation, delayed bleeding and post-ESD electrocoagulation syndrome were all lower than others which was 1.4% ~ 8.5%, 0.5% ~ 9.5% and 12.1% ~ 40.2% respectively in literature reports.

Conclusion: The application of transanal tube in colorectal mucosal lesions after ESD could effectively reduce the incidences of complications. However, we should do more research to know whether transanal tube need to be placed routinely after ESD or not.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1510 OUTCOMES FOLLOWING UNDERWATER ENDOCOPIC MUCOSAL RESECTION OF > 10MM COLONIC POLYPS: A PROSPECTIVE DUAL-CENTRE STUDY
K. Siau1, A. Yusuf2, N. Suzuki1, S. Ishag4
1Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: Underwater endoscopic mucosal resection (UEMR) is an alternative to traditional EMR for the resection of colonic polyps. With this technique, water insufflation is used in place of air or CO2, and submucosal lifting is usually not required, as water-immersed submucosa cushions itself from the muscularis propria.2,3 Theoretically, this reduces the risk of diathermy-induced injury,4 and allows for more complete resection margins.3,4

Aims & Methods: In this prospective dual-centre study, we aim to evaluate the safety and efficacy of UEMR for clinically significant (> 10 mm) colonic polyps. Studies of outcomes included: 1) completeness of UEMR, 2) intraprocedural and 30-day complication rates, 3) percentage requiring submucosal lift, and 4) rates and predictors of polyp recurrence. Procedures were performed by two screening endoscopists accepting tertiary referrals at St. Mark’s Hospital, London, and Russell’s Hall Hospital, Dudley, UK. Recurrence was defined as the presence of any polyp tissue at the resection site. Endoscopy records were examined and correlated with history. Univariate analyses were performed using Pearson’s chi2 to identify predictors of measured outcomes.

Results: Between June 2014 and March 2017, and A total of 85 patients (median age 69.5 years, interquartile range [IQR] 11, 50.6%) underwent UEMR of 97 colonic polyps (median size 25 mm, IQR 25 mm, range 10–160 mm). 13 (13.4%) were recurrences following previous conventional EMR. Polyps were predominantly left sided (66%) with flat (63.5%) or sessile (35.4%) morphology. 43.8% of polyps were removed en bloc, whilst argon plasma coagulation (APC) was used in 13.7%. Histology comprised of: low-grade dysplasia (80.2%), high-grade dysplasia (12.5%), adenocarcinoma (3.1%) and non-adenomatous sessile serrated polyp (4.2%). Overall, resection at index UEMR was deemed endoscopically complete in 97.9%. Submucosal lift was required in 27.8% and positively correlated with polyp size >30 mm (OR 3.58, 95% CI 1.37–9.38, p=0.01), but not morphology (flat vs. sessile, p=0.099). The 30-day complication rate was 4.1% (n=4), consisting of 2% requiring submucosal lift, and 4% delayed rebleeding (n=2; average diameters: 35 mm) and delayed rebleeding (n=2; average diameter: 57.5 mm), with haemostasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n=59) who attended for repeat endoscopy post-UEMR, the rate of recurrence or residual polyp was 14.8% (9/62) at 4 months and 13.59 (22.0%) within 1 year. Significant predictors of post-UEMR recurrence included: piecemeal vs. en bloc resection (OR 5.50, 95% CI 1.10–27.6, p=0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p=0.04), but not polyp size, site, morphology or dysplasia status, use of submucosal lift, APC, patient age, or study centre.

Conclusion: UEMR is a safe alternative to conventional EMR for the management of clinically significant colonic polyps. However, our post-UEMR recurrence rate of 22.0% appears higher than other studies,2,3 but may be skewed by the tertiary referral nature of our institution. Although randomized trials are awaited, we suggest that those performing UEMR should attempt en bloc resection where possible, and consider wider resection margins for recurrent polyps.

P1511 WATER-AIDED COLONOSCOPY - RESEARCH FOCUS IN THE PAST DECADE AND CURRENT CLINICAL PRACTICE
F. W. Leung
Medicine, Seguedela Ambulatory Care Center, VAGLAHS; David Geffen School of Medicine at UCLA, North Hills/United States of America/CA
Contact E-mail Address: felixleung@socal.rr.com

Introduction: Water-aided techniques have forged a paradigm shift in endoscopic diagnosis and therapy. The inauguration (10/22/2014) of the International WATERS with memberships worldwide attested to participants’ commitment to advance clinical, educational and research missions. To aid planning of future work in each of these areas, a descriptive study of water-aided colonoscopy was performed.

Aims & Methods: The aims of this study were two-folds. Study 1: To assess the frequency and trends of water-aided colonoscopy in the past decade. Study 2: To obtain a cross-sectional snapshot of current clinical practice. Study 1: Studies registered at Clinicaltrials.gov were searched for using the search term "water colonoscopy". Study 2: Members of International WATERS voluntarily participated in a survey to assess the proportion of patients with different modes of sedation, respondents selected yes (1) or no (0) responses to each of 16 questions related to their practice of water-aided colonoscopy.

Results: Study 1: In the past decade, 48 trials of water-aided colonoscopy were registered at Clinicaltrials.gov. They aimed at evaluation of insertion pain in unsedated, minimally sedated, or on demand sedation patients; assessment of efficacy in difficult colonoscopy; study of the impact on adenoma detection; and underwater mucosal resection or polypectomy. Study 2: Questionnaire responses are summarized in Table 1. Respondents: n = 23. Water-aided colonoscopy is used in patients sedated with propofol, minimal sedation on demand sedation (3–16%); but more commonly in patients with moderate or no sedation (30–34%). During insertion 95.5% use infusion of water and only 36.4% leave the air/CO2 pump on. 42.9% and 33.3% record volumes infused and suctioned upon arrival to the cecum. 52.4% remove almost all infused water during insertion. 71.4% and 59.1% performed polypectomy (<20 mm and >20 mm, respectively) underwater during withdrawal.

Table 1A: % of respondent’s patients

Conclusion: The variable modes of application amongst respondents who profess to use water-aided colonoscopy reflect the versatility and strength of the paradigm-changing approach, which is easily adaptable to meet the diverse needs of individual colonoscopists. Standardization based on results of randomized controlled trials appears to be prudent to permit further assessment of water-aided colonoscopy in clinical, educational and research settings.

Introduction: Endoscopic submucosal dissection (ESD) is a suitable technique used for the endoscopic management of selected early gastrointestinal neoplasms (EGN).

Aims & Methods: This is a prospective study of patients with EGN eligible for ESD in three tertiary hospitals. The main goal was to evaluate initial therapeutic results and learning curve of ESD. Initial Technical success rates, procedure speed, en-bloc & ROX resection, RO, speed and complications rates were prospectively evaluated. The results of the learning curve were analyzed by chronological order of blos of cases. Perforation was established as any disruption of the muscular layer, regardless of size or identification of peritoneal fat. Time of procedure was considered from initial submucosal injection to final detachment of the specimen.

Results: ESD was attempted in 183 lesions from January 2012 to April 2017. Majority of procedures were performed at Puerta de Hierro University Hospital (160/87.4%). Mean age was 67 (SD 10.6) years, with male proportion 55.23%. Most common location was colorectal (77.6%), followed by gastric (12.8%) and esophageal (9.4%). Success was observed in 96.2% of patients with en-bloc and R0 resection of 93.9% and 92.3%, respectively. Mean lesion size was 46.5 mm (range 8–130) with a mean speed of 9.01 min/cm2 (range 1–209). Perforation was
The main complication (48 (26.2%) events), requiring surgery in 5 (10.4%) cases. Perforation was statistically less frequent than other complications (p = 0.05) and LST morphology (p = 0.05). Most frequent location of perforation was transverse colon (OR 88.3; SE 137), followed by descending colon (OR 13.5; SE 19.4) and splenic flexure (OR 6.3; SE 11.8). Perforation was more common in LST-NG lesions vs LST-G (OR 19.3; SE = 15.6). Perforation rates were not statistically associated with the presence of severe submucosal fibrosis compared to absence of fibrosis (0.8 SE 0.6 vs 1 SE 1.0; p = 0.9). Post-ESD complications were observed in 15 (8.2%) patients (delayed perforation(7), bleeding(4), esophagus rupture syndrome(1), severe esophageal stricture(1), haemopteritus(1) and splenic rupture(1)). Six cases (40%) were managed with surgery. Results from the learning curve progression according to consequent chronological blocks of 50 cases (33 last bloc) are summarized in table 1. Initial success increased from 94% to 100%; speed of ESD decreased after the first 50 cases (15.5 cm²/min), up to 6.7 and 6.5 cm²/min in the last 2 blocs. A high perforation rate in the first period (32%) was reduced to 18-30.3% in the following periods. Endoscopic treatment was successful in most cases of perforation (86%). Surgery was required for severe complications, incomplete ESD and/or perforation (n, %) (16 cases, 8.7%).

Conclusion: On clinical ESD, high rates of success and en-bloc and R0 resection can be achieved along the learning curve. Perforation is the most common complication and is still a challenge for Western countries. However, increasing experience reflects a high success in endoscopic management of perforation.

Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Little is known about the risk of stenosis and outcomes following endoscopic resection of lesions in the colorectum which leave extensive mucosal defects. A limited number of studies suggest significant stenosis rates, although reports on outcomes and suggested management are conflicting. We determined the risk of stenosis and outcomes of endoscopic resection of colorectal lesions leaving mucosal defects ≥75% of the circumference.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. Resection technique included EMR, ESD and hybrid techniques involving ESD. Patients were grouped according to circumferential extent of the mucosal defect after resection. Surveillance colonoscopy was performed at 3 and 12 months. Clinicopathological characteristics and outcomes were compared between groups.

Results: 435 colorectal lesions ≥2 cm were resected using EMR (n = 342), ESD (n = 45) or hybrid techniques (n = 48). Circumferential extent of the resulting mucosal defect was ≥75% in 41 patients. 8 lesions were fully circumferential: 1 caecal lesion and the rest in the recto-sigmoid and rectum. 3 of these circumferential lesions contained deeply invasive adenocarcinoma and 1 benign lesion ultimately required surgery. The 41 lesions with a mucosal defect ≥75% of the circumference had a mean size of 100.5 mm vs 49.0 mm for other lesions (p < 0.001). These patients had significantly more complications (16.7% vs 4.7%, p < 0.001), including a higher rate of perforation (8.3% vs 2.3%, p = 0.02), although none required surgery, and a significantly higher rate of recurrence (44.8% vs 9.2%, p < 0.001). 79% of patients without cancer were free from recurrence and had avoided surgery at last follow-up compared to 97% of patients with mucosal defects <75% (p < 0.001). Stenosis occurred in 7 patients: 4 lesions extensively involving the rectum and recto-sigmoid and 2 lesions involving the sigmoid colon extending to the rectosigmoid. Of these involved a mucosal defect of only 50% of the circumference and 3 were fully circumferential. 1 patient had a symptomatic anorectal stenosis requiring dilatation under anaesthesia, 1 patient was asymptomatic but underwent early dilatation after the first surveillance endoscopy at 3 months. The remaining patient was asymptomatic and managed expectantly. In all these latter cases spontaneous improvement in the stricture was noted at the subsequent surveillance colonoscopy.

Conclusion: The majority of patients with these extensive complex lesions can successfully be treated with endoscopic resection and avoid surgery. However, these patients have a significantly greater risk of complications and recurrence and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

P1515 RISK OF HIGH-GRADE DYSPLASIA AND SUBMUCOSAL INVASION IN DIFFERENT MORPHOLOGICAL SUB-TYPES OF LARGE COLORECTAL NEOPLASTIC LESIONS RESEDCTED AT A UK TERTIARY REFERRAL UNIT
A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji

Introduction: The majority of patients with colorectal neoplasia will require endoscopic resection. Risk stratification and selection in western practice should be improved to reduce the incidence of prior heavy manipulation and guide appropriate referral.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Although it is well recognised that the risk of invasive carcinoma in apparent benign colorectal lesions differs according to morphology, the incidence of invasive cancer varies between studies and there is limited data from large western series to inform practice. The importance of appropriate resection techniques, including the use of ESD, is increasingly recognised in western practice. It is therefore imperative that the risk of submucosal invasion is assessed as accurately as possible to prevent inappropriate attempts at resection. We determined the risk of submucosal invasion and high-grade dysplasia (HGDi) in different morphological sub-types of large colorectal lesions subjected to endoscopic resection.

Aims & Methods: Colorectal lesions ≥2 cm subjected to endoscopic resection were included. Lesions were assessed with magnification chromoendoscopy. Clinicopathological data recorded included morphological type according to Paris classification, sub-types of laterally spreading tumours (LST), degree of dysplasia, presence of submucosal invasion and outcomes following resection.

Results: 435 colorectal lesions ≥2 cm were resected. Mean lesion size was 55.2 mm (range 20 mm–160 mm). The frequency of and the incidence of high-grade dysplasia (HGD) in different morphological sub-types are shown in Table 1. The incidence of high-grade dysplasia (8.6%) and invasive adenocarcinoma (1.2%) was very low in LST granular homogenous lesions.

Conclusion: In our study, a withdrawal time exceeding seven minutes was significantly associated with the number of polyps detected in colonscope. Further studies may be helpful to confirm these results ideally by comparing these parameters in the same patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1517 OUTCOMES OF ENDOSCOPIC RESECTION OF RECURRENT COLORECTAL LESIONS TREATED AT A UK TERTIARY REFERRAL CENTRE

A. Emmanel, S. Gulati, M. Burt, B. Hayee, A. Hajj

Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-Mail Address: aemmaneul@nhs.net

Introduction: Endoscopic resection of large colorectal lesions, especially by piecemeal EMR, carries a significant risk of recurrence. Although several series examine the outcomes and risk of recurrence following endoscopic resection, few focus on the outcomes of patients being treated for recurrence after initial expert resection, and these mostly focus on one technique to deal with recurrence. We evaluated the outcomes after recurrence of colorectal lesions after apparent successful endoscopic resection in a specialised UK tertiary institution employing a range of resection techniques.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonoscopy ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Outcomes were evaluated for patients treated for recurrent lesions.

Results: Of 396 colorectal lesions ≥2 cm initially resected, recurrence occurred in 48 patients. 36% of these patients had already had a mean of 1.6 previous failed attempts at resection prior to referral to our institution, and 66% had had either a failed attempt at resection or extensive sampling involving ≥6 biopsies or tattoo placed under the lesion. 69% of patients were successfully treated with further endoscopic resection and avoided surgery. 27 recurrent lesions larger than 20 mm were treated with endoscopic resection, with a mean lesion size of 48.3 mm (± 19.3). Techniques used were EMR (n = 16), ESD (n = 2), Hybrid ESD and EMR (n = 9). The remaining lesions < 2 cm were resected using EMR. A mean of 1.4 ± 0.75 procedures were required to achieve successful endoscopic treat- ment of recurrence. 23 patients who were ultimately successfully treated with endoscopic resection, 1 required a single further endoscopic resection after recurrence, 8 patients required 2 or more further resections. 8 patients required surgery, 3 as a result of developing invasive adenocarcinoma with the recurrence. There were no perforations as a result of endoscopic resection of recurrent lesions managed conservatively.

Conclusion: These data demonstrate the challenges of an advanced endoscopic resection service in much of western practice where patients with recurrent lesions represent a particularly complex cohort, most of whom have already had extensive prior manipulation or attempts at resection. Familiarity with a range of resection techniques and appropriate equipment is essential to successfully treat recurrent lesions in this group with endoscopic resection, which can be achieved in the majority of patients without significant morbidity.

Introduction: Self-expandable metallic stent (SEMS) is widely used to treat malignant colorectal obstruction. However, most reports about SEMS insertion have concentrated on right colon, and very tough to insert SEMS on the left colon, especially distal ascending colon.

Aims & Methods: This study aimed to (1) investigate the effectiveness of new insertion technique with SEMS for right-sided colonic obstruction and (2) compare safety and technical success of SEMS insertion. The data from ten patients who underwent SEMS with a new technique for malignant obstruction of ascending colon in our hospital were analyzed retrospectively. Initially, we tried to insert with the straight type guiding tube and wire for obstructed area of ascending colon under CO2 insufflation. It was difficult to start cannulation more than 20 minutes manipulation. For difficult cannulation, we change to curved type guiding tube (CleverCut2V/CleverCut3V Double and Triple Lumen sphincterotomes). All cases were difficult cannulation and change to curved type. The mean time of SEMS insertion was 11.6 minutes (range 3–21 minutes). Only 2 patients required pre-cannulation with distal colonoscopy. All patients were extubated and discharged with stent inserted in colon. The clinical success, complications, and technical difficulties were analyzed. We compared the results between SEMS insertion and decompression tube placement in right and left-sided colorectal obstructions.

Results: Cannulation time with a curved type guiding tube decreased of all cases (20 min vs 8.5 min). For ascending colon, the technical and clinical success rate of SEMS insertion with new technique significantly 100% (10/10). There was no
compilation (0.10). Concerning SEMS insertion, the technical difficulty and safety of SEMS insertion were similar between right- and left-sided colorectal obstructions. Conclusion: A new technique of curved type guiding tube with SEMS insertion for right-sided colon, especially distal ascending colon is significantly more effective than straight type guiding tube, and this procedure was safer and less technically challenging than expected. SEMS insertion should be considered for treating right-sided malignant colonic obstruction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic full-thickness resection (EFTR) in the colon using the FTRD kit is a recent technique that allows en-bloc resection of colonic lesions that are poor candidates for resection by endoscopic mucosal resection (EMR). It does not require the injection of a solution into the submucosa and allows an en-bloc resection of colonic lesions up to approximately 30 mm. We present results of the initial experience in 3 centers of Catalonia.

Aims & Methods: We retrospectively analyzed the clinical, endoscopic and anatomic features of all cases of EFTR performed in 3 centers in Catalonia using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany) during the period between June 2015 and January 2017. All patients underwent the procedure under deep sedation with propofol, all patients were duly informed of the technique and potential complications derived from the procedure, obtaining written informed consent prior to the procedure. All EFTR resections in the colon were performed using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany), grasping and pulling the lesion inside the cap, deploying the OTSC and resecting the tip over the OTSC with the preloaded snare. Clinical assessment was performed before and after procedures with a complete blood test before procedure. Blood test was not routinely used after procedures. Demographic, clinical, endoscopic and histologic data were collected from each patient, and analyzed with Stata 14.2.

Results: 16 endoscopic full-thickness resections of the colon were performed. The mean age of the patients was 69 years (53–79), with men being 88%. The indications were recurrent/residual lesions with non lifting sign (75%) and untreated lesions with non lifting sign (25%). The locations were juxtavalvular (n = 2), ileocecval (n = 3), sigmoid, stump or anastomosis (n = 2). The mean diameter of the resected samples was 20.8 mm (13–33 mm). The histology of the lesions was adenoma with low grade dysplasia (50%), adenoma with high grade dysplasia (25%), sessile serrated polyp without dysplasia (6%) and three lesions were adenocarcinoma with deep submucosal invasion (19%). There were no clinically relevant complications or emergency surgery. 1 patient had mild self-limited hemorrhage, 6 patients had mild abdominopelvic pain (38%) and 3 patients developed postpolypectomy syndrome (19%).

Conclusion: Endoscopic full-thickness resection is a safe and feasible technique for selected cases in colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lynch syndrome (LS) is an autosomal-dominant disease, with increased risk of colorectal cancer (CRC), hence annual surveillance colonoscopy is recommended. do not recommend one over the other.

Aims & Methods: We aimed to compare the diagnostic yield (DY) of different endoscopic modalities for detection of colorectal neoplasia in patients with LS by performing a meta-analysis of existing literature. We searched PubMed for prospective studies. For each modality, we performed comparative total per-adeno-noma analysis and sub-analyses for flat lesions and location (right/left colon).

Results: Meta-analysis was performed using pooled rate ratios (RR) with fixed effects model within each subgroup. The low heterogeneity within each subgroup was confirmed. Conclusion: A new technique of curved type guiding tube with SEMS insertion for right-sided colon, especially distal ascending colon is significantly more effective than straight type guiding tube, and this procedure was safer and less technically challenging than expected. SEMS insertion should be considered for treating right-sided malignant colonic obstruction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic mucosal resection (EMR) has been shown to be useful in the removal of large colorectal adenomas. These lesions are often resected by using a piecemeal technique, which is a risk of recurrence in 10% to 30% of cases. Recently, hot avulsion technique (HA) has shown promising results in the resection of residual fragments of large colorectal adenomas, with lower recurrence rate.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of HA at index EMR and at EMR local recurrence. We did a retrospective study based on all the HA performed between June 2015 and February 2017. The endoscopic characteristics, complications and recurrence rate after the initial HA were evaluated.

Results: 33 HA were performed among 29 patients (16 men and 13 women) with an average age of 69 years. The average follow up time was 11 months. HA was used to remove residual adenomatous tissue at 17 index EMR (mean size of the lesion 30 mm) and to remove recurrent fibrotic adenomatous tissue at EMR scar in 12 cases (mean size of recurrence tissue 14 mm). HA was successful in removing residual/recurrent adenomatous tissue in all patients. There were no immediate or long term adverse events. Comparing the two groups, local recurrence after initial HA recurred in one case at the index EMR group (1/17) and in 2 cases at the local EMR group recurrence (2/12). The overall recurrence rate in patients with a minimum 6 months follow up was 15% (3/20). Conclusion: HA is a safe and effective technique to eradicate both residual tissue in large colorectal adenomas and recurrent fibrotic adenomatous tissue at EMR site, with low recurrence rate.

Introduction: Quality of bowel preparation and adenoma detection rate (ADR) are routinely assessed in screening colonoscopy. However, data on patient experience are scarce.

Aims & Methods: This prospective non-interventional study compared bowel preparation quality according to the Harefield Scale, performance quality measures and patients satisfaction in screening colonoscopies performed within an Austrian quality assurance program.

Results: Colonoscopies performed by 20 endoscopists were included in this study. 53.0% of screened individuals were women. Because of the unequal patient count using Citoflex® (CF, n = 261), Prepcore® (PP, n = 2678), Klean-Prep® (KP, n = 804) and Moviprep® (MP, n = 1252), PC and CF were grouped into a joint group (LV). Age and gender adjusted success rates and ADR per purgative were 97.0% and 23.3% for LV, 97.5% and 32.5% for KP and 93.5% and 26.0% for MP. Women had higher success rates than men (p = 0.073) and success rate decreased with patients' age (p = 0.008). The compliance regarding consumption of the entire volume was best with LV (89.2%, KP 87.6%, MP 87.3%), which had a significant effect on success rate (p = 0.027). 93.5% of patients in the LV group would use the same purgative again compared to 68.4% in the KP and 73.2% in the MP group.

Conclusion: All investigated purgatives met the required quality standards of ≥90% rate of adequate bowel preparation according to the current ESGE guidelines. Success rates were higher in women and younger patients. Although only <90% of patients consumed the whole volume, the majority of patients would use the same purgative again.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference: 107.614 examinations from 288 endoscopists were analysed between 2012 and 2017 within the Austrian certificate of screening colonoscopy. For comparison two different categories were included: excellent, good, fair, unsatisfactory, poor only in the right colon. Data are shown as Mean and SD.

Results: 8578 surveillance colonoscopies (43.88% female, mean age 66.67) and 9927 screening colonoscopies (51.04% female, mean age 62.31) were included. Within screening colonoscopy 37.59% (SD = 31.50) were excellent prepared vs. 34.60% (SD = 33.98) within surveillance colonoscopy, good 47.43% (SD = 27.28) vs. 45.61% (SD = 31.28), fair 11.39% (SD = 11.58) vs. 14.39% (SD = 21.69), poor 2.38% (SD = 3.06) vs. 3.68% (SD = 9.75), unsatisfactory 0.77% (SD = 1.20) vs. 0.89% (SD = 3.69), poor only in the right colon 0.69% (SD = 1.81) vs. 0.39% (SD = 1.22). Calculations revealed no significant differences among screening and surveillance colonoscopies relating the following categories: excellent (p = 0.4357), good (p = 0.5911), unsatisfactory (p = 0.6262) and poor (p = 0.4357) and poor only in the right colon (p = 0.4357). Bowel preparation varies significantly between screening and surveillance in groups of fair (p = 0.0454) and poor (p = 0.0497).

Bowel preparation influences the adenoma detection rate (ADR). Mean ADR in excellent preparation was 22.16% (SD = 16.36%), in good 25.41% (SD = 17.30%), in fair 24.63% (SD = 19.44), in poor 19.94% (SD = 25.57), in unsatisfactory 12.08% (SD = 22.77) and in poor only in the right colon 24.22% (SD = 30.89%). Adequate rate in screening colonoscopy was 96.22% (SD = 3.98%) vs. 95.07% (SD = 10.45%) in surveillance colonoscopy. Rates correspond to ESGE guidelines and do not differ significantly from other work (p = 0.1265).

Conclusion: Data showed distinct differences between fair and poor, whereas there were more fair and more poor prepared patients at the surveillance colonoscopy, than at the screening colonoscopy. Age of patients at surveillance colonoscopy was higher, hence D-H, Fredrik improved enlightenment. ADR in excellent, good and fair bowel preparation was adequate. In poor, unsatisfactory was low and ADR at poor only in the right colon is high due to low count (N = 374).

Disclosure of Interest: All authors have declared no conflicts of interest.
A total of 4949 patients were included in the study, of whom 2103 had (PEG-ES) bowel preparation (n = 20.13%) patients were excluded from further analysis for the following reasons:

**Contrast:**
- Evaluation for this procedure has consistently been debated1,2,3.
- The optimum bowel preparation for this procedure has consistently been debated1,2,3.

**Aims & Methods:** The aim of this study was to determine the impact of endoscopic surveillance on CRC prevention in patients after surgery. We did a retrospective single center study on findings of follow up endoscopies and determination of the cumulative risk of adenomas and prevalence of high risk adenomas (HRA) (villose histology, high-grade dysplasia and ≥10 mm) and CRC.

**Results:**
- 30 patients submitted to IRA were included (50% women), with a mean age of 43 years, 2 patients with attenuated phenotype. Nine patients had adenocarcinoma in the resected colon. Six patients started chemoprophylaxis after surgery (sulindac-4; celecoxib -1). The median time to adenoma appearance was 5 years (95% CI 3.4-6.6) and to HRA/CRR 12 years (95% CI 5.2-18.8), with a decreased median time to both adenomas and HRA/CRR in patients under chemoprophylaxis. The cumulative risk of adenomas was 20% at 1 year after surgery, 34.1% at 3 years and 57.4% at 5 years. During the follow up period, 1284 patients had CRC developed in 17 patients (56.7%) HRA–12 patients (40%); intramuscosal carcinoma–2 patients (6.7%); invasive adenocarcinoma–3 patients (10%). None of the patients died with CRC. The cumulative risk of HRA/CRR was 21.8% at 5 years, 46.1% at 10 years and 66.3% at 15 years. All the patients with HRA/CRR had rectal involvement prior to surgery (p = 0.008) and a higher number of adenomas resect in the rectal remnant (p = 0.017).

**Conclusion:** The FAP endoscopic surveillance program allowed detection of HRA/CRR in a high percentage of patients. Based on these results, an intensive endoscopic surveillance program should be suggested but endoscopic surveillance intervals widen in the first 5 years after surgery.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P5127 BOWEL PREPARATION FOR FLEXIBLE SIGMOIDOSCOPY: COMPARISON OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION (PEG-ES) AND PHOSPHATE ENEMA IN 4949 PATIENTS AT 16 UK HOSPITALS**

A. Yusof, S. Paranahewa, A. Jeevagan, P. Mayhead

Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom

Contact E-mail Address: abdyus12@nhs.net

**Introduction:** Flexible sigmoidoscopy is increasingly used to examine the left side of the bowel for diagnostic and surveillance purposes, and is now part of the UK bowel cancer screening programme. It is crucial to achieve adequate bowel cleansing in order to optimise the diagnostic yield of the test, and also to minimise the number of repeat procedures. However, the optimum bowel preparation for this procedure has consistently been debated1,2,3.

**Aims & Methods:** Both phosphate enema and (PEG-ES) are commonly used for bowel preparation in flexible sigmoidoscopy at both hospitals participating in this study. We therefore wanted to compare the outcomes for these two methods. We retrospectively reviewed all the patients who underwent flexible sigmoidoscopy from January 2014 to December 2016 using each hospital's electronic endoscopy reporting system. We analysed their demographics, type of bowel preparation used in each case, and the quality of their individually achieved bowel preparation, subjectively graded as “Excellent, Adequate or Inadequate” by the endoscopist performing the procedure. A chi-squared test was used to calculate p-values.

**Results:**
- In total 6196 patients underwent flexible sigmoidoscopy during the study period (males 2885 (46.5%), mean age 62.80 years, range 16–101 years). 1247 (20.13%) patients were excluded from further analysis for the following reasons: No bowel preparation (n = 451), non-compliance of the quality of the bowel preparation (n = 657), and non-PEG-ES oral preparation used (n = 139).
- A total of 4949 patients were included in the study, of whom 2103 had (PEG-ES) bowel preparation (n = 657), and non-PEG-ES oral preparation used (n = 139).
- A total of 4949 patients were included in the study, of whom 2103 had (PEG-ES) oral preparation used (n = 139).
- A total of 4949 patients were included in the study, of whom 2103 had (PEG-ES) oral preparation used (n = 139).

**Conclusion:** Our large retrospective study showed that oral preparation with (PEG-ES) gave significantly better results than phosphate enema, which gave acceptable results in only 67.5% of the patients. As a result of this study, PEG-ES is now the preferred option at our hospitals, if there is no contraindication for this. Disclosure of Interest: All authors have declared no conflicts of interest.

P1529 ENDOSCOPIC REMOVAL OF HIGH-RISK COLORECTAL ADENOMAS: SAFE AND EFFECTIVE?

M. Rutka1, K. Farkas1, A. Fabian1, R. Bot1, A. Balint1, A. Milasins1, Z. Szepes1, T. Molnar1
1 First Department Of Internal Medicine, University Of Szeged, Szeged/Hungary

Contact E-mail Address: rutka.marianna@gmail.com

Introduction: The incidence and mortality of colorectal cancer (CRC) can be decreased through the removal of precancerous adenomas. Endoscopic removal of polyps over 2 cm is considered a high-risk procedure both for complications and malignant transformation.

Aims & Methods: The aim of this study was to evaluate the outcome and complication rate after endoscopic removal of polyps over 2 cm. In this retrospective study clinical and demographic data of patients undergoing polypectomy due to colorectal adenomas over 2 cm between 2012 and 2017 were collected. Data on endoscopic procedures, complications of polypectomy and histological assessments of the removed polyp were obtained.

Results: Data of 100 patients (male/female: 58/42) was analyzed in the study. Full removal of the 106 removed polyps proved to be pedunculated, 21 were sessile and 34 flat. Six patients had more than one large polyp (>2 cm). The locations of the removed polyps were rectum in 33, sigmoid colon in 38, coecum in 12 and other parts of the colon in 23 patients. In 65 cases, polyps were excised with endoscopic mucosa resection (EMR) or hybrid endoscopic submucosal dissection (ESD). In 41 cases snare was used to remove the polyps in one or more pieces. Based on histological findings 54 (50.9%) polyps were shown to be low-grade adenomas, 34 (32.07%) high-grade adenomas, 1 (0.9%) polyp was hyperplastic, and 17 (16.03%) proved to be malignant among which complete endoscopic removal was achieved in 9 patients (52.9%). Additional smaller polyps were found in 39 patients and a synchronous cancer in 7. During polypectomies 91 hemoclips were deployed to close suspected perforation (8 cases) to cease bleeding within a mean of 4 days after the first examination. Hemoclip insertion was needed in 5 cases and epinephrine injection in 1 case. The bleeding stopped spontaneously in 2 cases. Second-look colonoscopy was required in 8 cases due to bleeding within a mean of 4 days after the first examination. Hemoclip insertion was needed in 5 cases and epinephrine injection in 1 case. The bleeding stopped spontaneously in 2 cases. Surgical intervention was not needed in any case.

Conclusion: Malignant transformation was revealed in 16% of the polyps over the size of 2 cm. Complete endoscopic removal of these polyps was successfully performed in half of the patients. Endoscopic removal of high-risk polyps is safe in experienced hand.

P1530 WHAT IMPROVED AND WHAT REMAINS TO BE ACHIEVED IN ORDER TO COMPLY WITH THE NEW RECOMMENDATIONS OF POLYPECTOMY BY THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY

1Gastroenterology, CHVNG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimepeixeiro@gmail.com

Introduction: The choice of polypectomy technique differs according to regional preferences and availability. This year, in order to standardize the approach to this techniques, the European Society of Gastrointestinal Endoscopy (ESGE) published recommendations for colorectal polypectomy and endoscopic mucosal resection (EMR).1

Aims & Methods: We aimed to evaluate the recent years evolution of the adherence to the recommendations of colorectal polypectomy and EMR at a tertiary center. We conducted a univariate analysis of polypectomy and mucosectomy techniques performed consecutively between January and June of 2011 and 2016 at a tertiary center. According to the recommendations, the excision of sessile and flat polyps is considered adequate when performed with cold biopsy forceps or cold snare for polyps ≤3 mm, cold snare if 4-9 mm, or hot snare if 10-19 mm and EMR if ≥20 mm. Polypectomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps <20 mm, always in association with any prophylactic therapy when polyp size ≥20 mm.

Results: We included 1721 endoscopic procedures of polypectomy and EMR, considering 796 patients (64.5% male; mean age: 64.2 ± 11.0 years). 1381 (80.2%) sessile polyps, 153 (8.9%) flat lesions and 187 (20.9%) pedunculated polyps were identified, with a mean size of 7.9 ± 7.0 mm. Regarding sessile and flat polyps, one of the recommended excision techniques was performed in: 84.6% (n=270) of ≤3 mm polyps (75.7% in 2011 vs. 95.8% in 2016; p < 0.001); 22.2% (n=109) of 4–5 mm polyps (12.5% vs. 36.5%; p < 0.001); 13.4% (n=59) of 6–9 mm polyps (5.4% vs. 23.8%; p < 0.001); 100% (n=206) of 10–19 mm polyps; and 100% (n=88) of ≥20 mm lesions. For pedunculated polyps, the excision technique was adequate in: 99.3% (n=134) of polyps of size <20 mm (100% vs. 97.6%; p > 0.05) and in 84.6% (n=44) of those ≥20 mm (82.6% vs. 86.2%; p > 0.05). Overall, 52.3% (n=900) of endoscopic procedures of polypectomy or EMR were performed as recommended; 42.7% (n=410) in 2011 vs. 64.5% (n=490) in 2016; p < 0.001.

Conclusion: Even before publication of the European recommendations, there has already been an increase in the proportion of polypectomies performed adequately in the different groups of lesions. There is still a need to adjust clinical practice in some subgroups, especially in polyps of size 4–9 mm, in order to strictly comply with the recommendations.

Introduction: Endoscopic resection of superficial neoplasms at the perineal rectum is difficult due to pain sensitivity, narrowness of the anal canal, presence of internal rectal plexus, whereas that of at the ileocecal valve (ICV) due to the variable morphology of the ICV itself and ileal involvement.

Aims & Methods: Aim was to assess the feasibility and outcomes of ESD in these locations. Prospectively collected database in a single nonacademic center. From 2010 to 11.2016, all consecutive patients scheduled to ESD for a superficial neoplasm in the perineal rectum (distal margin <30 mm from the dentate line) and at the ICV were compared to those in the pelvic rectum and in the cecum and ascending colon, respectively. ESD was performed with the standard technique. Follow-up was scheduled at 3 and 6 months within the first year and then yearly. Biopsies were taken from the scar of the resection site if a residual tissue was detected.

Results: A total 16 neoplasms at IVC were compared to 110 neoplasms in the cecum and ascending colon; 30 neoplasms in the perineal rectum were compared to 58 cases in the pelvic rectum (Table). Features of neoplasms in the perineal and pelvic rectum were no different as well as neoplasms at the IVC and cecum and ascending colon. ESD en bloc rates were lower in the perineal rectum and at the IVC, but no significant differences were found with the respective control groups (P = 0.490 and 0.404, respectively). ESD R0 rate was significantly lower at the IVC (P = 0.021). Adverse events were not different, although 3 perforations occurred in the cecum and ascending colon. During follow-up (median 16 months; range 24-84): residual tissue was diagnosed at the IVC in 2 (13%) cases, in the cecum and ascending colon in 2 (2%) cases (P = 0.078); in the perineal rectum in 4 (13%) cases and pelvic rectum in 2 (3%).

Conclusion: The ESD of neoplasms at the IVC and perineal rectum is feasible and effective. The complete resection rate is low due to the challenging anatomy of
that precludes conducting a mucosal incision far from tumor margins. A careful endoscopic follow-up is mandatory to detect residual neoplasms.

P1532 SELF-EXPANDABLE METAL STENT IN THE OCCLUSIVE COLORECTAL CANCER AS PALLIATIVE TREATMENT
T. Gago, A. Antunes, A.M. Vaz, P. Queiros, J. Roseira, A. C. Cunha, A. Ramos, H. Guerreiro
Serviço De Gastroenterologia De Faro, Centro Hospitalar do Algarve, Faro/Portugal

Contact E-mail Address: taniagago@gmail.com

Introduction: Colorectal cancer (CRC) is one of the most common malignancies in the industrialized world, with associated oncologic disease being relatively common. Endoscopic placement of self-expandable metallic stent (SEMS) is the first-line palliative treatment for malignant bowel obstruction.

Aims & Methods: Evaluate the outcome of endoscopic SEMS placement in CRC obstruction. Retrospective analysis of patients CRC submitted to endoscopic placement of SEMS from 2009 to 2016 in the Gastroenterology Department of Centro Hospitalar do Algarve. Statistical analysis was performed with SPSS version 22.

Results: The study included 23 patients with CRC obstruction, who were submitted to endoscopic SEMS placement, with a mean age of 75.2±13.47 years. The stents were placed with a palliative purpose in 69.6% of cases (n=16) and a transitory procedure before surgery in 30.4% of cases (n=7). Technical and clinical success was found in 91.3% of the patients, without any recorded death during the procedure. In patients whose goal was palliative treatment (75% men and 25% women) they had a mean age of 81.6±9.28 years. In 43.8% of the patients the tumor was located in the rectum, 31.6% in the sigmoid region and 25% in the recto-sigmoid transition. Being the majority (75%) well differentiated. There was a need for dilatation in 31.3%, most of the stents were uncovered (56.3%), 25% of the patients had complications. After stent placement about 25% of the patients did chemotheraphy. There was a 75% mortality rate (37.5% died by 6 months and 37.5% died by 12 months of follow-up). The use of chemotheraphy after SEMS placement influenced the complications associated with the procedure (p<0.05) but none of the other variables had a statistically significant influence on early death (up to 6 months).

Conclusion: SMES is an effective and safe palliative option for unresectable tumors, although the use of chemotheraphy after the placement of prosthess may have an influence on the appearance of complications. Malignant colon obstruction of the colon can be treated effectively with the use of endoscopic techiniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1533 RISK FACTORS FOR ADENOMA RECURRENCE AFTER ENDOCOPIC MUCOSAL RESECTION OF LARGE COLORECTAL POLYPS
J. Pinho, D. Martins, P. Sousa, R. Araújo, A. Castanheira, E. Cancela, R. Cardoso, P. Ministro, A. Silva
Gastroenterologia, Centro Hospitalar Tondela/Viseu, Viseu/Portugal

Contact E-mail Address: julianapinhop18@gmail.com

Introduction: Endoscopic mucosal resection (EMR) has been shown to be a safe and effective technique for removal of large colorectal adenomas. However, local adenoma recurrence remains a significant limitation, with prior published data describing recurrence rates of 10% to 30% post EMR.

Aims & Methods: This study aimed to evaluate the outcomes of EMR for large colorectal adenomas and identify the risk factors for adenoma recurrence. We did a retrospective analysis of the cancer registry in the management between June and December 2016. Resected lesions larger than 20 mm in diameter with at least 3 months follow up were included. Patients referred for surgery were excluded.

Results: During the study period, 201 colorectal lesions ≥20 mm in size were resected using EMR with associated adenoma sizes ≥10 mm. Mean lesion size was 35 mm and 137 (68.2%) were located in the rectum and left colon. 66 lesions (32.8%) were larger than 40 mm in diameter. Piecemeal resection was performed in 171 lesions (85.1%). Local adenoma recurrence occurred in 44 cases (21.9%) after a mean time of follow up of 7.6 months, and the majority was managed with polypectomy or new EMR. The cumulative risk of adenoma recurrence was 7.5% at 3 months, 15.5% at 6 months and 17.1% at 12 months. In the multivariate analysis, the variables associated with a high risk of recurrence were lesions ≥40 mm in size (p<0.0001) and intra-procedural bleeding (p=0.020). The recurrence rate was higher in the patients treated with argon plasma coagulation (p=0.046).

Conclusion: After EMR of large colorectal adenomas, local recurrence rate was 21.9%. The risk factors for adenoma recurrence include lesions ≥40 mm and intra-procedural bleeding. Argon plasma coagulation was not associated with lower recurrence rate.

P1534 THE INFLUENCE OF THE REAL FOLLOW-UP TIMES DURING A COLORECTAL CANCER SCREENING PROGRAM IN DAILY PRACTICE
1Gastroenterology Department, Cliniques Universitaires Saint-Luc, Brussels/Belgium
2Gastroenterology, Morales Meseguer Hospital, Murcia/Spain
3Hospital Morales Meseguer, Murcia/Spain

Contact E-mail Address: kikemurcia@gmail.com

Introduction: European colorectal screening guidelines have modified the follow-up interval times based on baseline colonoscopy findings in recent years. In addition, the waiting list and individual conditions may modify the real follow-up times and this could impact in advanced adenoma detection rate in follow-up and patients outcome.

Aims & Methods: The aim of the present study was to comparatively analyse the risk of advanced lesions (advanced adenoma, invasive cancer) in high-risk patients included in a colorectal cancer screening program with different real follow-up times. One-thousand one-hundred and sixty-six patients (mean age 60.66±5.86 years, 69.1% men) who underwent a baseline colonoscopy with ≥3 adenomas and/or ≥10 mm between 2007–2012 were included. A Kaplan-Meier regression and a comparative subgroup analysis by Long-Rank test were carried out to determine the impact of early and late examinations. An adjustment for baseline covariates (high-grade dysplasia, villous component) by Cox analysis was also performed.

Results: The real follow-up times in ≥3 adenomas (n=853, 73.18%) and ≥lade- noma ≥10 mm (n=779, 66.81%) were 38.54±11.57 and 38.66±11.68 months respectively. The risk of advanced lesions were 0.26%, 1.46%, 2.83%, 9.09% and 10.38% (p=121 advanced lesions) in 12, 24, 36, 48 and ≥60months respectively. The most important increase was at 3–4 years (0.52%/month). The proportion of advanced lesions within 1–2 adenomas subgroups at 48 months was 5.43% and 10.43% (p<0.001), with no differences in small adenomas ≤<10 mm (p=0.478).

Conclusion: The risk of advanced lesions in high-risk patients increased significantly at 36–60 months after baseline colonoscopy, being more important in ≥3 adenomas subgroup. There were no differences for 1–3 years interval.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1535 CLINICAL OUTCOME OF ENDOCOPIC SUBMUCOSAL DISSECTION OF MALIGNANT NON-PEDUNCULATED COLORECTAL LESIONS

Introduction: Conventional endoscopic resection, such as snare polypectomy and endoscopic mucosa resection (EMR) of benign polyps in colon and rectum reduces colorectal cancer (CRC) incidence and mortality but the role of endoscopic resection of colorectal Egregement of patients with early CRC (i.e. submucosa and invasion) remain elusive. Large sessile and flat lesions are difficult to remove en bloc with EMR, resulting in a high level of tumor recurrence. Thus, endoscopic resection of large (>2 cm) sessile and flat malignant lesion with snare or EMR is not recommended in men and topical submucosal dissection (ESD) results in high en bloc resection rates of large (≥2 cm) benign lesions resulting in low numbers of recurrences. However, there is limited data in the literature on the potential role of ESD in the treatment of patients with early CRC. In the present study, we present our results on performing ESD in patients with large sessile and flat malignant lesion in the colon and rectum in a large European center.

Aims & Methods: Our aim was to investigate the potential role of ESD in treatment of early colorectal cancer. We retrospectively reviewed medical records of
254 patients that underwent colorectal ESD at the endoscopy unit at Skane University Hospital, Sweden between 2012 and 2016. Indications for ESD were flat and sessile lesions larger than 20 mm in diameter with low or high grade dysplasia (251 cases). Moreover, three patients with known colorectal adenocarcinoma underwent ESD due to significant comorbidity excluding surgery. In all, we identified and included 29 cases of histologically verified submucosal invasive CRC in this study.

Results: This study included 29 patients with median age of 69 years (range 44-89 years). Median tumour size was 40 mm, ranging from 20 - 70 mm. Tumours were either flat (Paris classification Ha, 6 cases), sessile (Paris classification 1s, 19 cases) or a combination of flat and sessile (4 cases). Half of the lesions were located in the rectum and half in the colon. En bloc resection was achieved in 24 cases (83%), piecemeal resection in 4 cases (14%) and ESD was incomplete in one case (3.4%). Median time to complete the procedure was 89 min (Range 594 min). Macroscopic complete resection was obtained in 26 cases (90%). R0 resection was found in 20 specimen (69%), R1 in 3 cases (10%) and R1 was found in 5 cases (17%). Lymphovascular involvement was seen in 6 cases (21%) whereas lymph node involvement was seen in 2 cases (7%). In total four patients were diagnosed with cancer in the resected sigmoid segment revealed T3N0. No acute significant bleeding occurred during the procedure. One patient sought emergency care 12 days after the procedure with rectal bleeding, no colonoscopy was performed to determine the site of bleeding. Five patients underwent additional surgery since the pathological report stated that the resection was R1. Tumour residue was only found in one of the five resected specimens. 18 patients have undergone endoscopic follow up, to this date without any sign of recurrence. Two patients await surgery and therefore no follow up could be performed.

Conclusion: We herein present our findings on performing ESD on 29 patients with early CRC. Our results indicate that colorectal ESD is a safe and effective treatment in meticulously chosen patients even with malignant lesions. Further studies with a larger number of cases are needed.

Disclosure of Interest: All authors have declared no conflict of interest.

P1536 ENDOCOSPIC SUBMUCOSAL DISSECTION (ESD) VS HYBRID DISSECTION TO WHICH TECHNIQUE TO FAVOR IN LARGE COLORECTAL LESIONS?

M. Guillaumot, S. Leblanc, H. Soliman, B. Brieau, M. Barret, R. Coriat, F. Prat, S. Chausside
Gastroenterology, Cochin Hospital, Paris/France

Contact E-mail Address: marie-anne.guillaumot@aphp.fr

Introduction: Large colorectal lesions (>20 mm) can be removed endoscopically by endoscopic mucosal resection (EMR), often in a piecemeal fashion resulting in low en bloc and radical (R0)-resection rates. In this indication, submucosal dissection (ESD) allows en bloc resection whatever the size, but still remains technically difficult and time consuming. A hybrid endoscopic technique has been developed, called simplified or hybrid dissection. The aim of our study was to evaluate the outcomes of complications of endoscopic resection performed by hybrid technique compared to classical endoscopic submucosal dissection.

Aims & Methods: Our study was carried out from January 2013 to June 2016 from a prospective database. The 40 lesions removed by hybrid technique were compared to the 103 lesions of the hybrid dissection group, which were performed as follow: submucosal injection around the lesion of macromolecules, circumferential mucosal incision and submucosal dissection using the tip of a single-strand snare by endoscopist mode, central submucosal injection of the lesion and final resection with the single-strand snare, if possible in en-bloc. Patient characteristics, tumor location and size, dissection characteristics, "block" resection rate, R0 resection rate (healthy margins), procedure and hospitalization time, and complications were identified and compared with the so-called "classical" ESD technique.

Results: Lesions were more frequently located in the colon (vs rectum) in the hybrid dissection group compared to the ESD group (72.5% versus 28.5%, p < 0.001). Lesion size were type Ac according to Paris classification in 10% of the hybrid dissection group and 13.1% in the ESD group (p = 0.8). The mean size of the lesions was lower in the hybrid dissection group than in the ESD group (32.4 mm ± 13 mm compared to 54.4 mm ± 26.7 mm, p = 0.001). An en bloc resection was performed in 52.5% and 84.4% in the hybrid dissection and ESD group, respectively (p < 0.001). The procedure time (including general anesthesia time) was lower in the hybrid dissection group compared to the ESD group (105 min ± 62 min vs 191 min ± 73 min, p < 0.001, respectively). The hospitalization time was lower in the hybrid dissection group than in the ESD group (1.1 days ± 1.13 days vs 2.5 days ± 1.8 days, p = 0.001). R0 resection rates were lower in the hybrid dissection group than in the ESD group (47.5% and 61% respectively, p = 0.001). Hybrid dissection was performed for adenocarcinoma, adenoma with high grade dysplasia and patient with low grade dysplasia in 12.5%, 42.5% and 40%, respectively. The rate of adenocarcinoma was lower compared to the ESD group (12.5% versus 30.8%, p = 0.009). In the hybrid dissection group, the rate of perforation was lower than the ESD group (5%). There was no significant difference in the rate of bleeding (1.8% in the hybrid dissection group and 2.5% in the ESD group). In case of complication, there was no need of surgical treatment in the hybrid dissection group, but was needed in one patient in the ESD group.

Conclusion: Hybrid dissection is less effective in terms of en bloc resection of large colorectal tumors. Classical endoscopic submucosal resection should be preferred, especially in case of suspected adenocarcinoma despite longer procedure and hospitalisation time.

Contact E-mail Address: d.caroli@libero.it

Introduction: Since its introduction in 1968, Endoscopic retrograde cholangiopancreato-gramy (ERCP) has become a routine endoscopic procedure used to diagnose and to treat conditions associated to the pancreatobiliary system. It is nevertheless associated to the highest risk of complications of all routine endoscopic procedures. It is important to have a thorough understanding of the potential complications and the adverse events that may be associated to ERCP procedures so that these may be managed appropriately should they occur. The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

Aims & Methods: Utilizing an anonymous database of hospital discharge records referring to the period between 2007 and 2015, a retrospective study was carried out to examine the complications associated to ERCP. All of the elective hospitalizations for gallstones in the bile duct during which the procedure was carried out within two days of being hospitalized were examined. Hospitalizations for neoplasms were not considered. The study considered the onset of complications or death as outcome indicators as well as the patients status at the time of hospitalization. All hospitalizations were divided and no differences linked to their characteristics. The stratification of complications according to the type of hospital (rural vs urban) did not show any significant differences.

Conclusion: Study findings uncovered that pancreatitis was the most common post-procedural ERCP complication in the patients studied; the total complication rate was in line with that reported in the literature. That result and the fact that no correlation was found between the type and percent of complications and the type of hospital can be attributed to the effective regional hospital organization characterized by a capillary network of specialists capable of performing complex endoscopic procedures throughout the region limiting the need of transfer patients from one hospital to another.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1538 EFFECT OF OBESITY, DYSLIPIDEMIA AND DIABETES MELLITUS ON THE RISK OF POST-ERCPC PANCREATITIS

Gastroenterology, Habib Thameur Hospital, Tunis/Tunisia

Contact E-mail Address: hajer.hassine@gmail.com

Introduction: Risk factors for post-endoscopic retrograde cholangiopancreato-gramy pancreatitis (PEP) have been widely investigated. Nevertheless, studies focusing in metabolic conditions especially obesity, dyslipidemia and diabetes mellitus (DM) are still limited in number.

Aims & Methods: The aim of our study was to evaluate the effect of these factors on the frequency of PEP. We retrospectively analyzed all ERCP performed over a 12 months period [January 2015 - December 2015] and carried out at the gastroenterology unit of our hospital. All patients were evaluated prospectively for the frequency of PEP based on the consensus criteria.

The patients with obesity (Body mass index BMI ≥ 30 kg/m²), dyslipidemia (triglyceride > 2 g/L or LDL-cholesterol ≥ 1.6 g/L) and DM (history of DM or fasting glucose level
**P1539** PLACE OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN THE MANAGEMENT OF HEPATIC HYDATID DISEASE

**Gastroenterology, Habib Thameur University Hospital, Tunis/Tunisia**

**Contact E-mail Address:** hajer.hassine@gmail.com

**Introduction:** Hepatic hydatid disease (HHD) is a major endemic health problem in certain areas of the world such as Tunisia. Intrabiliary rupture of a hepatic hydatid cyst is a common complication ranging between 3 and 17%. Furthermore, biliary stenage is the most frequent postoperative complication following surgery for hydatid cysts of liver. Both conditions require percutaneous biliary drainage. One patient presented post ERCP pancreatitis (1.5%).

**Aims & Methods:** The aim of this study was to assess the results of ERCP in patients presenting with HHD. We retrospectively analyzed the results and complications of all ERCP performed for HHD whether before or after surgical treatment over a 10 years period (January 2007 - December 2016) and carried out at the gastroenterology unit of our hospital.

**Results:** Sixty seven procedures were included (mean age 40.4 years [15-82] and sex ratio male/female [31:36]). Of the 67 procedures, 58 (86.6%) were performed in patients who had undergone previous surgery. The indications of the ERCP were persistent external biliary fistula in 77.6%, obstructive obstruction or cholangitis due to residual materials within bile duct in 20.7% and secondary biliary strictures in 1.7%. In patients who had not undergone previous surgery (13.4%), the indications of the ERCP were cholangitis due to intra-biliary rupture of hydatid cyst in 44.4% associated with acute pancreatitis in 55.6%. The cannulation of the papilla was impossible in 6 cases (8.9%) and the endoscopic sphincterotomy (ES) could not be performed. When papilla cannulation was obtained, per endoscopic cholangiographic findings were: dilation of the biliary tract (21.3%) with filling defects of varying size and shapes (52.3%), leakage of contrast medium into the cavity (41%) and juxta ductal stenoses (3.3%). ES was then performed in all cases with satisfactory results. Thus, hydatid membranes (36%) or daughter cysts (1.6%) encountered in bile ducts have been emptied out in 93.4% by biliary occlusion balloon and/or Dormia basket. Nevertheless, two patients required biliary stenting due to the bile duct stricture, and two others required nasobiliary drainage. One patient presented post ERCP pancreatitis (1.5%).

**Conclusion:** ERCP is a safe and effective way to manage biliary complications of HHD. In most patients, ES is the most efficient treatment of postoperative external biliary fistulas, jaundice and accompanying cholangitis. In some cases, biliary stenting or nasobiliary drainage may be required.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1540** QUALITY INDICATORS AND POST OPERATIVE OUTCOME OF ERCP PERFORMED IN A LOW RESOURCE SETTING; CAN QUALITY INDICATORS FROM DEVELOPED SETTIMGES BE ADOPTED?

I. Kongmala Liyanage¹, E. Thulagala¹, S. Kulatunga¹, R. Perits¹, N. Nawarathne¹

¹Gastroenterology And Hepatology Unit, National Hospital of Sri Lanka

Colombo/Sri Lanka

**Contact E-mail Address:** Isurujith@gmail.com

**Introduction:** Endoscopic Retrograde Cholangiopancreatography (ERCP) is a complex and invasive procedure. Quality control and monitoring for complications is an important part of ensuring patient safety. Gastroenterology and Hepatology unit of the National Hospital of Sri Lanka performs the most number and variety of ERCP procedures in Sri Lanka. Although facilities are limited, detailed patient records and logs were maintained since commencement of ERCP procedures in this unit.

**Aims & Methods:** A retrospective analysis was carried out on quality indicators and complications of the ERCP procedures performed in this unit since 2006. Data from written records were entered into an electronic database and analysis was done using STATA version 13. Quality indicators and standards published by the American Society of Gastrointestinal Endoscopy and American College of Gastroenterology in 2015 were used.

**Results:** A total of 3780 ERCP procedures were performed. Females consisted of 54% of the patients (n = 2041). Mean age in years was 57.6 (SD = 8.4). Male patients were older with a mean age of 61.2 years whereas the mean age of females was 54.6 years (p < 0.05). Cholelithiasis was the commonest indication (85%) and 68% out of these patients had active cholangitis at the time of the procedure. Chronic pancreatitis, benign and malignant strictures requiring stenting, postoperative bile duct damage the other common indications. Data were not made available on 19 out of the 24 quality indicators. A total of 15 quality standards were met (7/9 pre procedure, 4/5 intra procedure and 4/10 post procedure).

Major prevalent major complications were Post ERCP Pancreatitis (PEP) and post ERCP Cholangitis (PCE) complicating 2.22% and 4.78% procedures respectively. Mortality was less than 0.1% (n = 3). Cardiovascular complications and complications of anesthesia were seen in 16 patients (0.41%) resulting in one mortality. These were significantly associated with older age and the total number of medical comorbidities the patients had (p < 0.05). Deficiency practices were noted mostly in the role of these conditions in larger prospective studies since the expanded prevalence of metabolic syndrome in general population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

---

**P1541** USE OF MICROCATHETERS IN ECHOENDOSCOPY-GUIDED BILIOPANCREATIC RENDEZ-VOUS–INITIAL EXPERIENCE

Endoscopy Unit, Biliary And Pancreatic Diseases Unit, Complejo Hospitalario de Navarra, Pamplona/Spain

**Contact E-mail Address:** jdsalpinto@gmail.com

**Introduction:** EUS-guided biliary or pancreatic rendezvous is a technically demanding procedure, and the intraduodenal manipulation of the guidewire remains the most challenging step. Passing the guidewire through the needle may cause its fragmentation on the sharp metallic bevel. We have described the method of using a microcatheter for EUS-guided rendezvous, which allows easier handling and exchange of the guidewire, while avoiding both the risk of fragmentation and the need of injection of contrast to achieve a complete ductogram. 

**Aims & Methods:** We aimed to evaluate the early experience of the microcatheter method in EUS-guided rendezvous procedures in the biliary and pancreatic ducts. During EUS-guided biliary or pancreatic rendezvous, initial puncture of the duct of interest was attempted with a 19G needle without stilet to...
Previously flushed with contrast. A 0.025” guidewire was then inserted through the needle, followed by duodenal advancement antegrade to the papilla. If further manipulation was necessary to enter the duodenum, movements were performed with caution in order to avoid fragmentation of the guidewire. Whenever the passage through the papilla was not achieved or the guidewire movements were hazardous, we performed a microcatheter technique. After removing the needle, leaving the guidewire in situ, a 3F, 150 cm long microcath- eter was inserted over the guidewire into the duct. Then, manipulation of the guidewire, guidewire exchange and contrast injection were performed according to the discretion of the endoscopist. We reviewed the cases of EUS-guided pancreatic or biliary rendezvous performed in our unit using microcatheters from September 2015 to March 2017. Technical success was considered when the rendezvous could be completed.

Results: Nine patients presented with previous unsuccessful manipulation of the guidewire with the needle during EUS-guided biliary or pancreatic rendezvous underwent a microcatheter-guided attempt on the same procedure. Pancreatic rendezvous was attempted in 3 cases (2 chronic pancreatitis, 2 pancreas divisum and 1 pancreatic cancer) and biliary rendezvous in the other 4 (3 biliary stenosis and 1 ampul- loma). Technical success was achieved in 7 patients (78%) with the microcatheter technique. Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepatico-gastrostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stent insertion. There were no adverse events after the procedure, irrespective of technical success.

Conclusion: In our series, using a microcatheter for the indractural manipulation of the guidewire increases the EUS-guided rendezvous technical success without increasing the complication rate, irrespective of technical success.

Introduction: Confocal endomicroscopy is an endoscopic imaging technique permitting the microscopic analysis of the digestive mucosa in real time (oesophagus, stomach, duodenum, colon, biliary tract and pancreas) due to injection of fluorescein which is an intravenous contrast. The aim of this national observational study under the guard of SFED is to evaluate the practice of confocal endomicroscopy in France, specifically its indication, histologic correlation, therapeutic benefits depending on the operator and complications.

Aims & Methods: We executed a multicentric observational prospective study from September 2013 to February 2015. Collection of data was based on a structured data collection sheet. All patients were treated on performing confocal endomicroscopy. The intravenous injection of fluorescein was given either in bolus or in a perfusion method at a dilution of 1 or 10%. Demographic, clinical, endoscopic and endomicroscopic data were collected. For each act the correlation between the confocal endomicroscopy and histology and the outcome of the ECM depending on the operator was reported.

Results: In total 399 procedures of confocal endomicroscopy were done on 399 patients (median age was 39 +/- 14.5, males were 52%) and these were performed in 12 centers. The main indications were: diagnosis and monitoring of Barrett esophagus 28% (111/399), surveillance of gastritis 4% (16/399), characterization of polyp and searching for dysplasia in IBD patients 17% (68/399), undefined biliary stenosis 11% (42/399), pancreatic cysts 30% (123/ 399), undefined rare cases (lymphodes characterization, pancreas polyp, cholestasis with inflammation, GIST, celiac disease, control post mucosectomy of gastric and duodenal polyp) 10% (39/399). The quality of imaging was good in 83% of cases (331/ 399), average in 16% (64/399) and poor in 1% (6/399). The correlation with histology was measured by using Cohen’s kappao coefficient. The results were respectively k = 0.9, 0.78, 0.82, 0.7, 0.94, 0.93 for Barrett’s esophagus, gastritis, IBD, colorectal polyps, undefined biliary stenosis and pancreatic cysts. The outcome of the procedure according to the operator was beneficial for three main indications: Barrett’s esophagus, small intestinal polyp and uncertain pancreatic cysts (100% of cases), and undefined biliary stenosis (90% of cases and especially for real time therapeutic decision). One major side effect was seen during the study, which was an anaphylactic choc after a bolus injection of 2.5cc of fluorescein in a 69y old patient who didn’t have any previous history of allergies. This patient was hospitalized for surveillance for three days.

Conclusion: In conclusion, confocal endomicroscopy is an in vivo microscopic examination that is easily performed throughout the digestive tube with a good histologic correlation especially for Barrett’s esophagus, undefined biliary stenosis and pancreatic cysts. Its importance in the management of patients remains to be evaluated with the advent of new endoscopic magnification techniques.

Introduction: Biliary tract complications (BTC) are the leading problem in patients after orthotopic liver transplantation (LT). The present study analysed the results and predictors of treatment outcomes in patients with biliary stenoses undergoing endoscopic retrograde cholangiopancreatography (ERCP) and/or percutaneous cholangiodrainage (PTCD) at the University Medical Centre Hamburg-Eppendorf.

Aims & Methods: All adult patients who received ERCP or PTCD for BTC after LT between 2009 and 2015 were retrospectively analysed. Remission of BTC was defined as no need of intervention for at least 12 months. To identify predictors of endoscopic treatment outcome in patients with biliary stenoses, a multivariate logistic regression analysis was performed after univariate variable selection. Laboratory parameters that were significant in the multivariate analysis, were dichotomised stepwise according to the most informative cut-off predicting outcome. Furthermore, endoscopic techniques were analysed in both the ERCP- and PTCD-subgroup.

Results: Of 144 patients with BTC after LT, 116 were diagnosed with biliary stenoses. Among these, 86 received ERCP, 17 PTCD and 13 both techniques. Long-term remission was achieved in 55 patients (47% overall; 53% in ERCP alone and 30% when PTCD was applied). Patients with non-anastomotic strictures (NAS) (odds ratio [OR] 0.25, 95% confidence interval [CI] 0.1-0.57; p = 0.001), requirement of PTCD (OR 0.30, 95% CI 0.10-0.79; p = 0.018) and higher pre-interventional serum-bilirubin levels (OR 0.88, 95% CI 0.76-0.98; p = 0.037) were less likely to achieve remission. The most informative bilirubin cut-off to predict the outcome was 5 mg/dl. This cut-off maintained a significant association with outcome in the multivariable model (OR 0.30, 95% CI 0.08-0.95; p = 0.049). In the ERCP-subgroup, dilatation with a higher maximal balloon-dia- meter was associated with a favourable outcome (p = 0.043).

Conclusion: Both ERCP and PTCD can provide long-term benefit in patients with BTC after LT. However, patients with NAS and requirement of PTCD had less favourable outcomes. The pre-interventional bilirubin level could be a valuable parameter to identify patients at risk of treatment failure. Larger ERCP balloon dilatation techniques.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) represents a crucial procedure in the management of biliopancreatic pathology. However, its performance in patients with surgically modified gastro-enteric-biliary anatomy (SMGA) is a challenging issue.

Aims & Methods: We aimed to evaluate the efficacy of this advanced endoscopic technique in patients with SMGA. This was a retrospective observational cohort study of all patients with surgical modification of biliopancreatic access undergone ERCP, between 01/2002 and 02/2017. Demographic variables, indications, the breakdown of surgical procedures and technical success rate were evaluated as well as potential predictive factors of therapeutic efficacy rate. Compared patients with successful technique(G1) and therapeutic failure by ERCP...
P1548 ASSOCIATION BETWEEN PREDICTIVE FACTORS AND RADIATION EXPOSURE DURING ENDOSCOPIC RETROGRADE CHOLANGIPANCREATOGRAPHY
S. Dong, C.H. Oh, J.R. Moon
Kyung Hee University College of Medicine Dept. of Internal Medicine, Seoul/Korea, Republic of

Contact E-mail Address: gidrdong@hanmail.net

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) relies on the use of ionizing radiation in the form of fluoroscopy. Because use of fluoroscopy has positive relationship with radiation exposure, it makes a risk of the development of cancer and other radiation toxicity. The increasing exposure of patients and endoscopists to radiation is concerning.

Aims & Methods: The aim of our study was to evaluate of predictive factors of radiation exposure to the patients and endoscopists during ERCP. We measured the radiation exposure of patients and endoscopists during procedure as determined by radiation dose in dose area product (DAP), absorbed dose (AD) and fluoroscopy time. And we correlated them with age, sex, body mass index, diagnosis, duration of procedure, procedure name and procedure complexity.

Results: As a result of analysis of the 892 ERCPs performed during 4 years, the mean duration of fluoroscopy time was 5.52 mins (95% CI, 5.15–5.93). Mean radiation duration were as follows: CBD stones (n= 511, 5.76 mins); malignant stenosis of bile duct (n = 189, 5.78 mins); pancreatic disease (n = 95, 5.28 mins); benign stenosis of bile duct (n = 51, 5.52 mins); and peripapillary stenosis (n = 138, 5.26 mins). Multivariate analysis revealed that prolonged duration of fluoroscopy time was related with specific factors of patient included age, BMI, diagnosis and procedure complexity (all p < 0.05). Among the parameters, procedure complexity was the most significant relation with radiation dose. In addition, we compared the following three procedure by procedure duration; two more procedures performed during ERCP and mechanical lithotripsy (all p < 0.05).

Conclusion: ERCPs are associated with significantly higher radiation exposure to patients and endoscopists to the specific procedure type. Increased radiation exposure is the aware of increased dose of radiation required when performing ERCP in patients with increased BMI, old age, and who need two more ERCP procedure.

Introduction: Double-balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography or DBE-ERCP allows access to the biliary ducts of patients with surgically altered upper gastrointestinal anatomy. We studied the feasibility and efficacy of DBE-ERCP at our institution.

Aims & Methods: This is a retrospective study of all patients with surgically altered GI anatomy who underwent DBE-ERCP at our institution between February 2011 and March 2017. The primary endpoint was the global success rate of DBE-ERCP. The secondary endpoints were (1) the success rate of enteroscopy defined as reaching the desired postsurgical anatomic target, (2) the diagnostic success rate defined as successful cannulation of the native papilla or
anastomosis, and (3) the therapeutic success rate. We used a 2.2 m DBE with a 2.1 cm 2.2 mm of operating channel (EN-450 75, or EN580TU Fujinon inc Saitama Japan).

Results: A total of 12 patients (sex ratio 1/1) with a mean age of 65 [47–82] underwent 14 DBE-ERCP. 7 patients had Roux-en-Y gastro-jejunostomy with a bile-jejunostomy, 4 patients had Roux-en-Y with a native papilla, and 1 patient had a Billroth II gastric bypass. Enteroscopy success rate was 93% (13/ 14 procedures). The diagnostic success rate was 85% (11/13 procedures) with 4/5 of native papillae. Therapeutic interventions including sphincterotomy (n = 4), biliary stone extraction (n = 4) and biliary dilation (n = 2) were needed in 8/11 procedures and their success rate was 100%. The global success rate of DBE- ERCP was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superficial intestinal lacerations without perforation (complication rate 7%).

Conclusion: DBE-ERCP in patients with surgically altered upper GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of the technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Transpancreatic Sphincterotomy (TPS) involves wire-guided can-
nulation of the main pancreatic duct (MPD) followed by standard pull-type
spingertome cutting towards the main channel. Typically a MPD stent inser-
tion should follow TPS to prevent post-ERCP pancreatitis (PEP). ESGE [1] recommends that in patients with a small papilla that is difficult to cannulate, TPS should be considered if additional wire-guided MPD cannulation succeeds. A previous study had suggested that TPS might be as effective as double guide wire (DGW) technique in achieving biliary cannulation in difficult cases and has a lower risk of pancreatitis [1].

Aims & Methods: The main objective of this study was to review the practice, complications and outcomes of TPS in University of North Tees hospital (district general hospital in the north-east of UK). All ERCP procedures between January 2014 and October 2016 were reviewed. Endoscopy reports, blood results and discharge letters were used for data collection.

Results: 1365 ERCP procedures were performed in the study period. Overall CBD cannulation rate was 91.3%, 105/1365 (7.7%) wire guided TPS procedures were required. Mean age in the TPS group was 67 years (range 18-91) 65/105 (61%) male and 41/105 (39%) females. 3 senior consultants and a senior endo-
copic fellow performed TPS. TPS was used as the initial strategy in the event of MPD cannulation and without using alternative methods such as DGW.

Choledocholithiasis was the most common ERCP indication in TPS group (58/ 105). Other indications include pancreatic cancer, biliary stricture, choIanocarcinoma and bile leak post cholecystectomy. CBD cannulation was achieved in 96/ 105 (90.5%) of cases - 81/105 (77.1%) during the first ERCP and 15/105 (14.2%) at second ERCP [where CBD cannulation was achieved at second attempt, TPS had been done at the first ERCP]. In 9/105 patients CBD cannulation was not achieved. 8/105 (7.6%) had a complication. 6/105 (5.7%) patients had PEP - 5/6 had a prophylactic MPD stent. 1/105 had a post sphincterotomy bleed which was controlled with endoscopic therapy. 1/105 had a perforation and a subsequent long hospital stay. There were no procedure-related deaths.

Conclusion: This study demonstrates that TPS is a safe and effective way of gaining CBD access. Our data suggests that experienced operators in a DGH setting can safely carry out TPS. Our study is the second largest cohort in the literature and the largest cohort in the UK. We would suggest early adoption of TPS if wire access to the pancreatic duct is achieved, this will likely reduce complication rate as a result of less engagement with the papilla and overall reduced time at CBD cannulation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
was performed using SPSS version 20.0. A P-value of less than 0.05 was considered statistically significant.

**Results:** We included 1976 patients who presented choledocholithiasis and underwent different endoscopic extraction techniques. Mean diameter of stones (extracted using only the basket (Group A) was 6.8 mm with a mean CBD diameter of 14.3 mm (mean CBD diameter) for patients treated eventually by surgery (P < 0.001). Only 3.2% of cases had to be referred to surgery. Stones removed using only a retrieval balloon (Group B) was for a mean stone diameter of 7.6 mm with a mean CBD diameter of 13.3 mm. By associating the basket with a retrieval balloon (Group 4) we obtained a 100% success rate of endoscopic removal for a mean stone diameter of 9.6 mm with a mean CBD diameter of 12.9 mm. We also analyzed the parameters of patients who underwent endoscopic extraction by using a retrieval balloon combined with balloon dilator (Group 5). The success rate in this group was 90% for a mean stone diameter of 14.8 mm with a mean CBD diameter of 12.4 mm. In Group 6 we included cases which required combined techniques (n = 3). We observed a mean stone diameter of 9.4 mm with a mean CBD diameter of 13.8 mm in patients solved endoscopically, compared to those referred to surgery who had a mean stone diameter of 14.2 mm with a mean CBD diameter of 14.3 mm (P < 0.001). In this group the success rate was 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean stone diameter of 13.6 mm and a mean CBD diameter of 14.3 mm (P < 0.001).

**Conclusion:** The most successful endoscopic method to remove large stones >15 mm was balloon dilator combined with retrieval balloon. Intermediate sized stones (<7 mm) were successfully removed by using retrieval balloon or lithotriptor or a combination of basket with retrieval balloon ± balloon dilator. Most CBD stones <7 mm were successfully removed by using basket. In conclusion, any diameter >7 mm will most probably require more elaborate techniques.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Diclofenac and indomethacin are the most studied drugs for preventing post-ERCP pancreatitis (PEP), but their use is controversial.

**Aims & Methods:** Our aim was to evaluate all trials published in full text and studied efficacy of diclofenac or indomethacin prospective controlled with placebo or non-treatment for the prevention of PEP in adult patients undergoing ERCP. Systematic search of databases (PubMed, Scopus, Web of Science, Cochrane Database) was performed. Relevant data were published from inception to 30 June 2016.

**Results:** Our meta-analysis of 4741 patients from 17 trials showed that diclofenac or indomethacin significantly decreased the risk ratio (RR) of PEP to 0.60 (95% CI 0.46–0.78, P < 0.001). Only 3.2% of cases had to be referred to surgery. Stones removed using only a retrieval balloon (Group B) was for a mean stone diameter of 7.6 mm with a mean CBD diameter of 13.3 mm. By associating the basket with a retrieval balloon (Group 4) we obtained a 100% success rate of endoscopic removal for a mean stone diameter of 9.6 mm with a mean CBD diameter of 12.9 mm. We also analyzed the parameters of patients who underwent endoscopic extraction by using a retrieval balloon combined with balloon dilator (Group 5). The success rate in this group was 90% for a mean stone diameter of 14.8 mm with a mean CBD diameter of 12.4 mm. In Group 6 we included cases which required combined techniques (n = 3). We observed a mean stone diameter of 9.4 mm with a mean CBD diameter of 13.8 mm in patients solved endoscopically, compared to those referred to surgery who had a mean stone diameter of 14.2 mm with a mean CBD diameter of 14.3 mm (P < 0.001). In this group the success rate was 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean stone diameter of 13.6 mm and a mean CBD diameter of 14.3 mm (P < 0.001).

**Conclusion:** The most successful endoscopic method to remove large stones >15 mm was balloon dilator combined with retrieval balloon. **P1555 RECTAL DICLOFENAC AND PANCREATITIS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY**

L. Del Olmo Martinez1, B. Velayos2, M. Ruíz-Rrebollo2

1Gastroenterology, Hospital Clínico, Valladolid/Spain

2Hospital Clínico Universitario, Valladolid/Spain

**Contact E-mail Address:** ldolom@yahoo.es

**Introduction:** Rectal diclofenac or indomethacin reduces the risk of pancreatitis after endoscopic retrograde cholangiopancreatography (ERCP). Most studies of its efficacy included high-risk cohorts and excluded low-risk patients. We investigated the potential of rectal diclofenac to prevent post-ERCP pancreatitis (PEP) in a variety of patients.

**Aims & Methods:** A cohort of 1534 ERCPs performed at the Hospital Clínico de Valladolid between 2009 and July 2016 was collected. The median age of the patients was 75 years old (between 12 and 102 years). 54% were male and 45.9% female. There were 93 procedures in which cannulation of the desired pathway was not achieved but the papilla had been manipulated so they are patients who were not included in the study. A total of 25 ERCPs (1.64%) were successfully performed but not treated with diclofenac or indomethacin. The endoscopic retrograde cholangiopancreatography pancreatitis depends on difficulties of cannulation. Results from a randomized study with sequential binary intubation. *J Clin Gastroenterol* 2015

---

**Results:** Two groups were similar in age, sex, suspicion of Oddi sphincter dysfunction, recurrent acute pancreatitis, chronic pancreatitis, cannulation time, use of cut-off, previous PEP, dilation without sphincterotomy. There were differences in the number of sphincterotomies in which it was greater in the Diclofenac group (p=0.004). There was also a greater number of Wirsung cannula in the group treated with Diclofenac (p=0.004). There were a total of 47 PEP (3.1%), being 78.3% mild and 21.7% moderate pancreatitis. Taken as a whole the patients had no difference in the number of PEP between the two groups, since in those treated with Diclofenac there was 3.4% and in the non-treated patients 2.8%. Taking into account only patients with de novo sphincterotomy, there was no difference between the number of PEP between the two groups being 4.4% in those treated with Diclofenac versus 4% in the untreated patients. In those patients who were cannulated Wirsung, an incidence of PEP of 8.2% was observed in the group treated with Diclofenac, compared to 0% in the placebo group (p=0.006). There were no differences between those treated with Wirsung’s prosthesis and those not treated in both groups. There was no PEP in patients treated with pancreatic prosthesis.

There was a higher incidence of PEP in women in both groups and a trend towards greater number of PEP among those treated with Diclofenac, although without statistical significance. There was also a greater number of PEP in patients under 40 years of age treated with Diclofenac compared to those not treated with 14.3% versus 7.1% (p=0.024). No differences were found between the groups treated and not treated with Diclofenac when crossing with sphincter dysfunction of Oddi, previous PEP, number and sizes of choledocholithiasis and sizes with the appearance of PEP.
Conclusion: In this retrospective cohort study of patients undergoing ERCP that included low-risk patients, rectal diclofenac was not associated with a significant decrease in the absolute rate of pancreatitis. In our study, diclofenac decreases the impact of PEP in those patients who are cannulated the pancreas.

P1555 A PILOT STUDY OF PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY FOR COMPUTER-AIDED DIAGNOSIS OF BILE DUCT CANCER USING THE DEEP LEARNING TECHNOLOGY

K. Furukawa1, N. Yokoyama2, H. Hashidate3
1Dept. Of Gastroenterology, Niigata General Hospital Dept of Gastroenterology, Niigata/Japan
2Niigata City General Hospital Dept. of Digestive Surgery, Niigata/Japan
3Pathology, Niigata City General Hospital, Niigata/Japan

Contact E-mail Address: furukawa@hosp.niigata.niigata.jp

Introduction: The confocal laser endomicroscopy (CLE) is of two types, an endoscope-based CLE (eCLE), which is integrated in the tip of the endoscope, and a probe-based CLE (pCLE), which goes through the accessory channel of the endoscope. The biliary tract, which cannot be reached by using eCLE, is observable with pCLE by using cholangiopercopy. pCLE has the advantage of obtaining a magnification image that is like taking a biopsy tissue specimen but noninvasively, without the interference of bleeding and mucous secretion. However, it is sometimes difficult because only few gastroenterologists can achieve the required level of diagnostic accuracy.

Aims & Methods: We developed a computer-aided diagnosis (CAD) system based on pCLE imaging using deep learning technology. The purpose of this study was to determine the usefulness of this CAD system for the diagnosis of bile duct cancer. We prepared the classifier of the extracted features of the bile duct cancer pCLE images by using the deep learning framework presented by Kyocera communication system Co. Ltd. Japan. The pCLE images by Cellvisio (Mauna Kea Technologies, France) were obtained through the SpyGlass DS (Boston Scientific Corporation, USA) imaging system. pCLE images were compared with histological examination results from the surgical specimen and biopsy using SpyBiTE (Boston Scientific Corporation, USA). Learning sets were constructed by using 49 images of normal area and 23 images of cancer lesion. The test sets of the pCLE images were constructed using 6 images of normal area and 14 images of cancer lesion separately from the learning set.

Results: The accuracy, sensitivity for cancer diagnosis, specificity, negative-predictive value, positive-predictive value of our CAD system by test set were 72.0%, 93.0%, 98.6%, and 100%, respectively. The false-negative diagnostic errors reduced the sensitivity and negative-predictive value. The images of 6 false-negative diagnoses, indicating a 1.0 probability, did not show signs of cancer at all. A constant diagnosis was possible while being extremely small lesions. The specificity and positive-predictive value were good, and the pCLE image was thought to have a characteristic suitable for CAD by using deep learning technology. However, many false-negative diagnoses with a probability 1.0 may have occurred owing to deflection and the lack of learning sets. To improve the accuracy, the learning set of set of adenocarcinoma was expanded.

Conclusion: Automation diagnosis of bile duct cancer can be achieved by using the deep learning technology of pCLE imaging. Our CAD system will be improved with the appropriate learning sets.

P1556 COMPARISON OF EUS-GUIDED FINE NEEDLE BIOPSY TECHNIQUES FOR CORE TISSUE ACQUISITION AND DIAGNOSTIC PERFORMANCES IN PANCREATIC SOLID LESIONS

C. Cho1, S.J. Yeo1, A.N. Soo2, H.I. Bac1
1Internal Medicine, Kyungpook National University Medical Center, Daegu/Korea, Republic of
2Pathology, Kyungpook National University Medical Center, Daegu/Korea, Republic of

Contact E-mail Address: cmcho@ku.ac.kr

Introduction: Acquisition of core tissue in endoscopic ultrasound-guided tissue sampling (EUS-TS) is necessary for histologic diagnosis and immunohistochemical staining in the diagnosis of some solid mass lesions. Although recent studies revealed the superiority of core biopsy needle in the specimen adequacy, core recovery still remains that which EUS-TS technique would result in better acquisition of core tissue and diagnostic accuracy.

Aims & Methods: The aim of our study was to evaluate EUS-TS techniques with a ProCore needle using suction and slow pull suction for solid pancreatic lesions with the intention of obviating any unnecessary cytoreductive potential. Patients who referred to EUS-TS for pancreatic mass were enrolled. We performed EUS-guided fine needle biopsy (EUS-FNB) using a ProCore needle (Cook Medical, Limerick, Ireland) with two needle passes and applied each pass of different techniques (suction or slow pull suction) which were randomly allocated. EUS-TS specimens were evaluated by one experienced cytopathologist who was blinded to applied techniques. The acquisition of core tissue and diagnostic performances were compared between two techniques.

Results: From Aug. 2014 to Dec. 2016, 94 patients with pancreatic mass were enrolled and 12 patients were excluded due to no final diagnosis (n = 5), cystic lesion (n = 5) and loss of follow up after EUS-TS (n = 2). Finally, 82 patients (48 males; median age, 63 years) with 164 needle passes were included without technical failure and procedure-related adverse events. The median size of the lesions was 37 mm (range, 11 to 144 mm). There were 61 pancreatic and 14 benign lesions. Overall core tissue acquisition and diagnostic accuracy was 84.8% (139/164) and 73.2% (120/164), respectively. There was no significant difference between suction and slow pull suction in the acquisition of core tissue (85.4% vs. 84.1%, p = 1.000) and diagnostic accuracy (72.0% vs. 74.4%, p = 0.860).

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including variable lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

Introduction: Gallbladder drainage, performed by EUS-guided positioning of specially designed fully covered metal stents, may be considered a valid option in patients with cholecystitis unfit for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Aims & Methods: Our aim was to evaluate the feasibility and clinical impact of EUS-guided drainage with NAGI-stent in patients with acute cholecystitis unfit for surgery. Sixteen consecutive patients (9 males; mean age: 84 years; with diagnosis acute cholecystitis according to Tokyo guidelines criteria, not suitable for surgical approach, were conservative treated and drained with EUS-guided short flared stents positioning. The procedure was performed in 2 tertiary endoscopy units by 4 experienced endoscopists (≥ 500 EUS-FNB performed yearly), by using the NAGI-stent. Each attempt to access the gallbladder was firstly performed from the transduodenal position and resulted successful in 13 (81%) patients, whilst a transgastric approach was preferred in the remaining 3 patients. Two different approaches were performed for the EUS-guided gallbladder puncture: a) a 0.035-inch wire was advanced through a 19G-needle into the gallbladder and dilation of the access was achieved with a 1 Fr cystoenterostome; b) a 0.035-inch wire was advanced through a 10 Fr cystoenterostome directly into the gallbladder after access. At the end of the procedure, a fully covered metallic stent, 12-16 mm of diameter and 20-30 mm of length with bilateral anchor flanges (NAGI-stent) was advanced on the wire by using the fluoroscopy guide. Technical success, clinical success, adverse events, and long-term outcome were assessed.

Results: Technical success was achieved in all cases, clinical success was observed in 15 (95%) patients, whilst in 1 case the procedure failed due to stones impaction into the stent but it resolved with a new stent positioning. Symptomatic relief occurred in all patients, 1 day after the procedure in 12 (75%) cases and 2 days later in remaining 4 (25%) patients. A bleeding episode occurred in 2 (12.5%) patients, in one case such complication was intra-procedural and it was successfully stopped during the same endoscopic session, in the other case it was a delayed adverse events requiring arterial embolization but the patient died 10 days later. At follow-up, two patients died due to myocardial infarction at 2 and 6 months, one for acute renal failure after 6 months, two for pancreatic cancer at 7 months and one for cholangiocarcinoma after 5 months. In the remaining patients no cholecystitis recurrence or biliary obstruction were observed at median follow-up of 112 days (range 49–180 days).

Conclusion: Our data showed that EUS-guided gallbladder drainage with NAGI-stent is a feasible and successful option in patients with cholecystitis unfit for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is considered the gold standard method for assessment solid pancreatic masses. The needles for aspiration currently available are 19G, 22G and 25G and there is no concrete evidence to prove the benefit of one against another.

Aims & Methods: We aimed to compare the efficiency in the diagnosis of solid pancreatic lesions through the EUS-FNA with 25G and 22G needles. Studies were analyzed from five databases (Medline, Scopus, Cochrane, LILACS and CINAHL), without year or language restriction, using an extensive search strategy. Only randomized trials comparing 22G and 25G needles were included. Two independent reviewers went through the literature search and the results were analyzed by fixed and random effects. The diagnostic characteristics were calculated for a 95% confidence interval.

Results: 504 studies were found in the search, of which 21 were read and then finally 10 randomized controlled studies were selected to be included in the analysis. Thus, a total of 462 patients were evaluated (233: 25G needle; 222: 22G needle). The sensitivity of the 25G needle was 93% (CI: 89–96%; 22G: 90%), and for the 22G needle was 91% (CI: 85–94%; 22G: 92%). The specificity of the 25G needle was 96% (CI: 84–99%; 22G: 94%). The positive likelihood ratio of the 25G needle was 4.57 (CI: 2.08–10.03, 22G: 4.26 (CI: 0.43–41.88, 22G: 94%). The post-test probability of the 25G needle in the study population was 96% and for the 22G needle was 91.30%. The area under the sROC curve of the 25G needle was 0.9705 and for the 22G needle 0.9795, also showing no statistically significant correlation between them (p = 0.497).

Conclusion: Based on randomized studies, this systematic review and meta-analysis did not demonstrate a significant statistical difference between the 22G and 25G needles used during EUS-FNA in the diagnosis of solid pancreatic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: All 3 cadavers underwent successful EUS-guided injection of the hydrogel. Cadaver 1 received a total injection volume of 9.5cc with creation of peri-pancreatic space for the course of the tumor. Cadaver 2 received a total injection volume of 27cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 11.77 mm in maximal diameter. Cadaver 2 received a total injection volume of 27cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 11.77 mm in maximal diameter. Cadaver 2 received a total injection volume of 27cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 11.77 mm in maximal diameter. The hydrogel was clearly visualized during EUS with hyperchogenic echogenicity and on post-procedure CT images without any artifacts in all cases.

Conclusion: EUS-guided delivery of hydrogel is feasible and results in an increase in the peri-pancreatic space in a cadaveric model. The hydrogel is clearly visualized on EUS and CT without significant artifacts. Further studies are warranted to evaluate feasibility, effectiveness and safety in a clinical model.

Introduction: There are few published studies about the use of a novel radio-frequency (RF) system (EUSRA RF needle; VIVA RF generator; STARmed Co Ltd, Korea). With poor standardization of the procedure in terms of ablation powers and ablation times, it results in great heterogeneity of the results.

Aims & Methods: To standardize the radiofrequency ablation (RFA) procedure using this system performing ex-vivo tests on porcine liver in order to find the best ablation power and ablation time to produce the maximum size of coagulative necrosis at histological examination. The system consists in a radiofrequency generator delivering electric energy, a 19 Gauge needle (150 cm in length with a 10 mm monopolar electrode), a peristaltic pump (to perfuse the needle with chilled saline solution, maximizing the ablation volume without tissue charring), an isolating plate and a pedal to deliver RFA. Liver samples were treated at different powers: 10, 20, 30 and 40 Watts (W); each ablation power was applied for a duration of 1, 3, 5, 7 and 15 minutes, according to Fibonacci escalation dose scheme, used in phase I studies. We studied the macroscopically: the size (millimeters) of the globular treated area and the size of the coagulative necrosis; microscopically on an ex-vivo section of the porcine pancreas. We perform a retrospective review of all EUS cases for pancreatic neoplasms showing a clear correlation (phi 0.24). The system can produce larger zones of mild cellular alterations at lower ablation powers (10 W), increasing with the increase of ablation times, which is better for future in-vivo animal studies in order to assess the evolution of these zones (evolving into fibrosis? necrosis? recovering?).

Introduction: Malignant associated thromboembolic disease (TED) has a complex multifactorial pathogenesis. Tumor cells activate platelets and express procoagulant factors including tissue factor and thrombin; in addition, normal host tissues may express procoagulant activity in response to the tumor. Thrombotic risk varies substantially according to cancer location and pancreatic cancer is one of the leading causes. The clinical spectrum includes migratory superficial thrombophlebitis, arterial thrombosis, deep venous thrombosis, portal vein thrombosis and disseminated intravascular coagulation (DIC) resulting in the role of endoscopic ultrasound (EUS) diagnosing TED in pancreatic cancer patients.

Aims & Methods: We perform a retrospective review of all EUS cases for pancreatic cancer in two centers and assess all TED events diagnosed.

Results: In a period of 6 months, a total of 55 EUS for pancreatic neoplasms were performed in two centers. TED was present in 5 patients (9%): 3 were male and the mean age was 70 (range, 46–81). In 1 patient the EUS indication was a large abdominal mass whose origin was not clear, in the remaining 4 the indication was the pancreatic neoplasm. In all of them was performed EUS with fine-needle aspiration (FNA). EUS identified an intraperitoneal embolism (PE) and an inferior vena cava thrombosis (IVCT) with right atrial extension: 2 (3.6%) had recently been diagnosed by computed tomography (CT) but 3 (5.4%) were not previously known. In all these, CT confirmed diagnosis.

Conclusion: To the best of our knowledge, this is the first case series of EUS-based TED diagnosis in pancreatic cancer patients. This series underlines importance of a systematic, station approach EUS technique, namely in the mediastinal lymph nodes regardless the clinical indication. TED is a common complication of pancreatic cancer and has major therapeutic and prognostic implications.

Introduction: Cholecodolithiasis is the most common cause of biliary pain, leading to hospitalisation and gallbladder surgery. Patients affected by cholecodolithiasis presents an incidence of cholecodolithiasis ranging from 8% to 20%. When the suspicion of cholecodolithias is confirmed, stones should be removed by ERCP, but this operative measure is associated with high rates of adverse events as post-ERCP pancreatitis, bleeding or perforation. A correct diagnosis of cholecodolithiasis, before ERCP, is mandatory to decrease the operative risk and health care costs. Endoscopic ultrasound (EUS) has a high sensitivity and specificity in the diagnosis of CBD stones and could substitute other imaging modalities as CT-scan or MRCP, when indicated.

Aims & Methods: The aim of our study was to assess the role of early EUS (<48 hours), in patients undergoing US in emergency room for suspected biliary colic. We retrospectively evaluated all the patients arrived at first aid for suspected biliary colic (i.e. right upper quadrant pain and/or epigastric region, associated with an elevation in serum ALT, AST, GGT, ALP, or total bilirubin, but in absence of amylase or lipase elevation). All patients, irrespective of the finding at admission, were performed an EUS within 48 hours since admission. Data are presented as proportions with 95%-CI and mean±standard deviation (SD). Correlation between categorical variables was evaluated by computing the “phi” coefficient. We computed the number needed to misdiagnose, i.e. the number of patients who need to be tested in order for one to be misdiagnosed by the test, as 1/(1-diagnostic accuracy). All the analyses were run with R (Statistical Software) and with a 5% significance level.

Results: Overall, from January 2016 to December 2016, 88 patients (56% female; mean age 64 ± 17 years) were admitted to our hospital for suspected biliary colic. We retrospectively evaluated all the patients arrived at first aid for suspected biliary colic. All the analyses were run with R (Statistical Software) and with a 5% significance level. Further, we documented common bile duct (CBD) stones in 58 (65%) patients, CBD sludge in 4 (5%) subjects, whereas no cholecodolithiasis was found in 26 (30%) patients. At EUS examination CBD stones were found in 70 (80%) patients. Comparing US to EUS, we found false negative results in 16 (18%) cases and false positive findings (i.e. identifying CBD stones not documented by EUS) in 8 (9%) patients. The two diagnostic procedures showed little correlation (phi=0.289). The number of...
patients needed to be tested by US in order to provide an incorrect diagnosis was 3.7 (95% CI: 2.6–5.5).

Conclusion: US performed in the emergency room has a low diagnostic performance compared to EUS, but remains a first-step approach in patients with right upper quadrant pain and/or in epigastric region, associated with an elevation in liver enzymes. Based on the results of our study, EUS performed within 48 hours from the admission allows an immediate correct endoscopic treatment with significant sparing of unnecessary operative procedures, reducing possible related complications and costs.

P1567 BILIOPANCREATIC RADIOFREQUENCY ABLATION: COMPARISON OF THE THREE CURRENTLY AVAILABLE DEVICES IN A PIG MODEL

M. Barret1, S. Leblanc1, B. Bordaçahar1, A. Rouquette2, S. Chaussade1, F. Prat1
1Gastroenterology, Cochin Hospital, Paris,France
2Pathology, Cochin Hospital, Paris,France

Contact E-mail Address: maximilien.barret@aphp.fr

Introduction: Three devices are currently available to perform radiofrequency ablation (RFA) of biliopancreatic lesions. Data from animal models are scarce.

Aims & Methods: Radiofrequency ablation was performed in four live pigs on the common bile duct and the liver parenchyma using an endobiliary probe (endHBP), on the liver and pancreatic parenchyma using an RFA catheter through an echoendoscope and biopsy needle (EUS-RFA) and using a needle-knife to perform RFA (RFA) of biliopancreatic lesions. Data from animal models are scarce.

Results: In the common bile duct, the depth of ablation ranged from 215 mm (Power = 15 W, Time = 120 s) to 330 ± 43 mm (Power = 10 W, Time = 30 s), suggesting that power is the most important parameter in this location. Conversely, depth of ablation in the liver parenchyma using the endHBP probe ranged from 947 ± 237 mm (Power = 10 W, Time = 30 s) to 1960 ± 20 mm (Power = 10W, Time = 180 s), suggesting that time is the most important parameter for RFA in the liver. The EUS RFA probe in the liver parenchyma showed a tissue necrosis increasing with the power setting used, ranging from 1903 ± 451 mm (Power = 8 W, Time = 120 s) to 2457 ± 104 mm (Power = 12W, Time = 120 s). This was not observed in the pancreatic parenchyma, where tissue damage ranged from 3108 ± 373 mm (Power = 8, Time = 120s) to 2305 ± 78 mm (Power = 12, Time = 120s). The EUSRFA ablation of the liver parenchyma resulted in tissue damage from 1573 ± 245 mm (Power = 30w, Time = 11 s) to 1545 ± 120 mm (Power = 70 W, Time = 9 s). In the pancreas, ablation depth ranged from 3616 ± 475 mm (Power = 30s, Time = 15s) to 3805 ± 446 mm (Power = 70 s, Time = 30 s).

Conclusion: Power and time of ablation have different effects on the extent of tissue necrosis in the common bile duct, the hepatic and pancreatic parenchyma, depending on the type of catheter used to perform RFA. As indications for hepatic and pancreatic ablation tend to expand, specific ablation protocols should be developed for each tumor location and device.

4SOLID PANCREATIC NEOPLASMS CONTRAST ENHANCED GUIDED FINE NEEDLE ASPIRATION IN SOLID PANCREATIC NEOPLASMS

Contact E-mail Address: andraseicean@gmail.com

Introduction: The preoperative differentiation of the solid pancreatic neoplasms by endoscopic ultrasound fine needle aspiration (EUS-FNA) remains around 90% and different needles or techniques of sampling has been used for improving the results. Data about the progress in diagnosis when the contrast harmonic enhanced (CH-EUS-FNA) is used are scarcely.

Aims & Methods: We aimed to assess the role of contrast-enhanced EUS-FNA compared to standard EUS-FNA in diagnosing the solid pancreatic neoplasms. Methods: Patients from one tertiary medical center with visible solid pancreatic mass on CT scan were included. EUS-FNA(one pass) and CH-EUS-FNA (one pass) were performed randomly in each patient by using a standard 22G needles, an Olympus-Aloka equipment and Sonovue as contrast agent. Core histology was assessed separately for each pass by the same pathologist blinded from the randomization process. The final diagnosis was based on the results of EUS-FNA and surgery, or the findings after 9 months’ follow-up.

Results: The final diagnosis of 40 patients included was adenocarcinoma (n = 36), neuroendocrine tumors (n = 2), chronic pancreatitis (n = 2). The lesions were located in the head of the pancreas (60%), body (32%) and tail (8%). The diagnostic sensitivity and specificity based on core histology was 89% and 94% in the CH-EUS-FNA passes and 86% and 91% in the EUS-FNA passes and the diagnostic value was significantly better in the CH-EUS-FNA group (p = 0.0046, t-test). The visual core size was not significant for the true-positive diagnosis of malignancy.

Conclusion: In a randomized control trial, CH-EUS-FNA improved significantly the diagnostic rate of solid pancreatic neoplasms over standard EUS-FNA. These techniques are complementary, not competitive, and they can be performed in the same session, resulting the increasing of the diagnostic rate with a minimum of passes.

P1570 EARLY CAPSULE ENDOSCOPY PROVIDES BETTER BLEEDING LOCALIZATION VALUE IN PATIENTS PRESENTING WITH NON-HEMATEMESIS GASTROINTESTINAL BLEEDING WHEN COMPARED TO CLINICAL SYMPTOMS ALONE

S. Jawaid1, N. Marya2, A. Foley1, C. Marshall1, K. Bhattacharya1, D. Cave1
1University of Massachusetts Medical Center, Worcester/United States of America
2UCLA, Los Angeles/United States of America

Contact E-mail Address: sjawaid@gmail.com

Introduction: Traditionally, clinical symptoms such as melena were used as strong predictors for an upper GI bleeding source with primary evaluation with an EGD (esophagogastroduodenoscopy). Little consideration was given to the small bowel. It has been known for decades that melena can originate from the nose to the right colon and hematocrit can originate from the proximal gut to the rectum. Thus, current endoscopic approaches have limited localization value and diagnostic yields. We hypothesize capsule endoscopy (CCE) provides better localization of bleeding when compared to clinical symptoms alone.

Methods & Study: We compared the efficacy of localizing the source of bleed in early CCE versus SOC (standard of care) tests chosen based on clinical symptoms alone. This was a prospective single center randomized trial of 73 consecutive patients presenting to the University of Massachusetts Medical Center with NHGB (melena, hematochezia/anemia, or guaiac-positive stools/anemia). Exclusion criteria included presence of pacemaker, dementia, non-English speaking, hemodynamically significant bleeding. Patients were randomized to SOC arm versus early capsule (EC) deployment. The EC group received a primary diagnostic procedure based on clinical symptoms that was dictated by the gastroenterologist on service, who was at liberty to choose the procedure sequence as they felt appropriate.

Results: Out of 73 enrolled, 71 were included. 2 patients from the initial included group were excluded (one due to technical capsule failure and one was transferred from an outside hospital). Baseline characteristics were similar and depicted in Table 1. The EC group (n = 34) had localization of presumed source of bleeding in 21 (62%) of patients at the time of the first diagnostic procedure compared to 48.4% (n = 16) in the SOC group (p = 0.02). Active bleeding or stigmata of recent bleeding at the time of the first procedure was seen in 64.7% (n = 22) of patients in the EC groups compared to only 30% (n = 6) in the SOC group (p = 0.003). However, when melena was the only bleeding symptom in the SOC (n = 26) group, EGD was the most commonly chosen primary diagnostic procedure (n = 23), but was only diagnostic 52% of the time. After complete diagnostic evaluation in the SOC group, patients presenting with gastrointestinal symptoms more often than the other diagnostic approach, since it examines much more of the GI tract than EGD and COL alone. Detection of the anatomic site of bleeding allows for better therapeutic decisions.

P1571 MUCOSAL HEALING RATES INDUCED BY ADALIMUMAB IN ISOLATED SMALL BOWEL CROHN'S DISEASE: PROSPECTIVE EVALUATION BY CAPSULE ENDOSCOPY

E. Gal1, I. Ben-Bassat1, Z. Levi1, G. M. Fraser1, Y. Sniir1, H. Yanai1, I. Dotan2, I. Avni-Biron1
1Gastroenterology, Rabin Medical Center, Petach Tikva/Israel
2Division Of Gastroenterology, Rabin Medical Center, Petach Tikva/Israel

Contact E-mail Address: eyal.gal83@gmail.com

Introduction: Detecting mucosal barrier healing (MH) of isolated small bowel Crohn’s Disease (CD) induced by anti-tumor necrosis factor alpha agents are scarce.

Aims & Methods: 1) To evaluate MH rates by capsule endoscopy (CE) in patients with isolated SB inflammation treated with adalimumab (ADA). 2) To correlate MH with clinical and biological indices of remission. This was a prospective observational, single center study. CD patients with isolated (per CE) active (CDAI > 220) SB disease, who were recommended ADA therapy by their treating physician were consecutively recruited; first CE was performed prior to commencing ADA, and the second -14-week after starting ADA. All enrolles underwent a patency capsule study to confirm patency. Disease severity was assessed by the capsule endoscopy Crohn’s Disease activity index (CECDAI) score. MH was defined as CECDAI score <3.

Results: Out of 31 patients screened, 24 were eligible, and 22 completed the study (as two patients developed an allergic reaction to ADA and were withdrawn). Females: 12 (54.5%), median disease duration: 3 years (IQR 1–7), biological evaluation: 13 patients (61%) had lesions on the SOC exam. In our study, we confirmed MH was detected in 8/22 patients (36.4%), CDAI < 150 in 11/22 patients (50%), normal- ization of CRP in 7/22 patients (31.8%), and normalization of fecal calprotectin in 8/22 patients (36.4%). Inflammatory indices significantly decreased within 14 weeks of ADA treatment compared with baseline: median CECDAI 5 (1–16) vs 10 (5–20), p = 0.001; median CDAI 150.8 (109.8–211.5) vs 256 (240.5–232.0), p < 0.001; median CRP 0.14 (0.07–0.5) vs 1.1 (0.2–1.5) mg/dl, p = 0.002; median fecal calprotectin- 83 (80–139) vs 126 (61.5–266.5), pg/gram, p = 0.014. MH detected by CE did not correlate with normalization of either CDAI <150, CECDAI <3, or fecal calprotectin lower than 250.

Conclusion: ADA induced MH in 36% of CD patients with isolated active SB disease. MH did not correlate with either clinical or biological remission. Thus, further evaluation should be performed after 52 weeks of maintenance therapy.

Introduction: Capsule endoscopy (CE) is widely used to investigate the small bowel (SB). However, patients with non-bleeding gastrointestinal (GI) disease (IBD) are considered to be at higher risk for capsule retention. The ESGE recommends using dedicated cross-sectional imaging to assess SB patency in patients with known Crohn’s Disease (CD) prior to CE. Evidence suggests that a combination of SB MRI with faecal calprotectin (FC) may potentially together may be more effective in assessing SB inflammation compared to an individual modality alone. We aimed to assess the effectiveness of this approach.

Aims & Methods: Retrospective, multicentre study; consecutive patients who had undergone both SB MRI and CE within 6 months of each other were included.

Results: Out of 540 screened, 282 underwent both CE and SB MRI at 4 centres in the United Kingdom, Israel and Portugal. Indications included suspected SB inflammation (n = 81), IBD reassessment (n = 21). Overall, there were 3 incomplete CEs, but no case of SB capsule retention. Of 82 SB MRIs, 4 patients had evidence of SB obstruction, 10 had SB thickening and/or inflammation, 3 had other findings (SB pneumatisos, polyps). 64/82 cases were normal and 1 study had poor quality, precluding any conclusion. Of the 4 cases with SB inflammation on MRI, 2 had SB inflammation on CE. Of the 10 patients with SB thickening and/or inflammation seen on MRI, 6 had corresponding CE findings; in particular, there were 2 cases with strictures on CE and 4 cases with mucosal inflammatory changes. 64 patients had normal SB MRI and 35 (54.7%) had a normal CE. 18/64 (28.1%) patients had mucosal inflammatory changes on CE; 2 of them had strictures which were eventually traversed by the capsule. 10 patients had other non-inflammation findings on CE. Of 18 patients with normal SB MRI, 10 had a raised FC (> 150 μg/g). 5 had borderline FC levels (50–100 μg/g). None of the patients in this group had normal FC levels; the mean FC was 637.5 ± 844.4 μg/g. In the group of patients with both normal SB MRI and CE, 16/35 had raised FC, 7 patients had borderline FC levels. The overall mean FC for the 5 patients with normal SB MRI was 266 ± 229 μg/g. The mean FC between patients with SB inflammation seen on CE and patients with normal SB MRI and CE was significantly different (p = 0.04).

Conclusion: A significant proportion (28.1%) of patients with normal SB MRI to investigate possible SB inflammation had CE findings showing SB inflammation, including 2 patients with strictures. However, no retention occurred in this group. Raised FC was significantly associated with CE findings despite normal SB MRI.

Contact E-mail Address: sabina.beg@nhs.net

Introduction: The interpretation of small bowel capsule endoscopy (SBCE) requires a high level of concentration. An abnormality may be present on just a few of the many thousands of images presented for interpretation. It is
unidentified whether fatigue affects the accuracy of SBCE reporting and how many SBCE can be read in one session.

Aims & Methods: Thirty-two participants (16 experienced SBCE readers and 16 novices) were invited to participate in this study. Each participant was asked to read 6 pre-selected SBCE studies consecutively. These studies were presented in a random order. All readings took place using the single view mode, readers were able to choose the frames per second viewed from a range of speeds. Fatigue was measured subjectively using a Likert scale and objectively using a computer-based psychomotor vigilance test. These measures were performed at prior to commencing the study and after every second capsule read. Accuracy in lesion detection was determined by comparison with a gold standard reading derived from the non-consecutive readings of two expert capsule readers. Accuracy was plotted against the order in which SBCE studies were read. The aim of this study was to determine whether fatigue influences accuracy of SBCE interpretation and how many cases can be read before accuracy declines.

Results: In keeping with existing literature, high intra-observer variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices. As progressive SBCE studies were read the mean speed increased for both experts and novices, with a mean reduction of 10 minutes between the first and the last study read. This was associated with faster reading speeds selected in progressive studies read. Where accuracy was analysed with respect to the reading speed chosen, a negative correlation between increasing speed and accuracy was demonstrated, with 31% of lesions detected when read at 6–10 frames per second, compared to 15% when using the 22–28 speed. There was no significant change in accuracy with progressive capsule read when the group was analyzed as a whole. The accuracy of experienced readers declined after just one study read, from 38% to 27% and plateaued thereafter. Novice readers demonstrated no significant change in accuracy with the time points used tend towards improvement, perhaps indicating skills acquisition during the study.

Conclusion: The accuracy of SBCE reporting declines after one study reporting in a given period of time by expert SBCE readers. The optimal time interval between readings needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

Contact E-mail Address: husseyma@tcd.ie

Introduction: Rates of incomplete colonoscopies (IC) range from 2–19%, requiring repeat procedures or radiological imaging which can often lead to diagnostic delays as well as increased inconvenience for the patient. Same-day CCE may allow one to avoid both ineffective and cost-effective mode of colonoscopy post IC.

Aims & Methods: We aimed to determine the feasibility of same-day CCE post incomplete colonoscopy. A prospective pilot study was performed without a contraindication to CCE with an IC for reasons other than poor bowel prep was offered the test following an appropriate recovery time of 1-hour post IC. Informed consent was obtained from all subjects. Upon ingestion of the capsule, the recording of IV methoclopramide was given to overcome the antimotility effects of fentanyl given during routine colonoscopy. Standard booster protocol for CCE was administered. Patient demographics, procedure indication, the number of cases can be read in one session, and patient satisfaction were recorded.

Results: To date, 40 same-day CCE have been completed. The mean age was 57 yrs (22–83 yrs) and 65% (26) were female. Indications for OC were; altered bowel habit 33% (n = 13), Iron deficiency anaemia 30% (n = 12), Inflammatory bowel Disease Assessment 15% (n = 6), PR bleeding 5% (n = 2), abdominal pain 5% (n = 2), poly surveillance 5% (n = 2), positive family history of CRC 5% (n = 2) and abnormal imaging 2% (n = 1). OC were incomplete due to excessive looping 40% (n = 16), patient intolerance 30% (n = 12) and severe diverticular disease 30% (n = 12). The mean sedation used during OC was 5 mg midazolam (range 3–10 mg) and 75 mcg of fentanyl (range 50–100 mcg). In all 84% (n = 34) of CCE were complete, however full colonic views were obtained in 94% (n = 37). Mean colonic passage time was 222 minutes and overall image quality was deemed to be excellent in 16% (n = 6), good in 31% (n = 12), adequate in 44% (n = 18) and poor in 9% (n = 4) of participants. Overall final scores were normal 25% (n = 10), polyps 38% (n = 15), inflammation 22% (n = 9), diverticular disease 25% (n = 10), adenoma 30% (n = 11), and diverticulitis 5% (n = 1). Amongst the patients who had polyps, 8 required polypectomy and the remaining 7 were put on a surveillance programme. Based on the CCE findings, 4 of the IB patients required treatment escalation. In terms of adverse events one patient reported abdominal pain during colonoscopy and one patient retained the capsule due to an inflammatory stricture.

Conclusion: CCE would appear to be feasible in the majority of patients and significantly detects colonic pathology.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI575 DEDICATED DIFFUSION WEIGHTED MR IMAGING FOR STAGING PERITONEAL METASTASES IN COLON CANCER: AN ACCURATE PREOPERATIVE SELECTION TOOL FOR CYTORDERUCTION SURGERY (CRS/HIPEC) CANDIDATES

I. Jansen1, D.M. Lambert2, S. Chandrasegaram-Shannuganathan1, N. Kook2, G.L. Beets1, R. Gh. Beets-Tan1, A. Aalbers2, M. Lahaye1
1Radiology, The Netherlands Cancer Institute, Amsterdam/Netherlands
2Surgery, The Netherlands Cancer Institute, Amsterdam/Netherlands

Contact E-mail Address: M.Lahaye@nki.nl

Introduction: Peritoneal carcinomatosis (PC) is a well-known mechanism of spread; it is the second-most frequent cause of death in colorectal cancer patients. However, the prognosis of PC patients has dramatically improved in recent years. Novel imaging techniques like preoperative accuracy of cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS-HIPEC). 5-year survival rates of up to 50% are reported after CRS-HIPEC. Despite this survival gain, CRS-HIPEC has a considerable morbidity rate of up to 21%2. Obviously, patients with a limited life expectancy need to avoid pointless and costly aggressive surgical procedures. Hence, recognizing patients with a maximum risk-to-benefit ratio for the procedure is imperative. To select patients who could benefit from CRS-HIPEC the Peritoneal Cancer Index (PCI) is used. The PCI combines the size/portion of peritoneal tumours found out at surgery in 13 abdominal regions. Each of the 13 regions is scored for implant size on a scale of 0–3 (0 = no visible tumour implants; 1 = implants < 0.50 cm; 2 = 0.50–5.0 cm; 3 = > 5.0 cm). The PCI is the sum of the lesion scores from all 13 areas, and thus can vary between 0–39. The PCI is widely validated and is a quantitative prognostic indicator for long-term outcome. However, with this surgical staging procedure it is not always feasible to inspect all relevant peritoneal regions because of adhesions and/or tumour. So, there is a desperate need for a non-invasive imaging tool that could select those patients who will benefit from CRS-HIPEC. However, currently there is no validated imaging tool that can accurately predict the PCI.

Aims & Methods: Therefore, the aim of this study was to estimate the PCI preoperatively with diffusion weighted MRI (DW-MRI) and compare this with the PCI found at surgery to assess whether DW-MRI can be used to select CRS/HIPEC candidates. In this ongoing study twenty-four consecutively enrolled patients (April 2016–April 2017) with histologically proven peritoneal carcinomatosis from colorectal origin were included. Patients were excluded for exploratory laparoscopy and/or CRS/HIPEC and underwent preoperative dedicated DW-MRI (scanning time 30 min).

Two independent researchers prospectively determined the PCI on DW-MRI. Patients were categorized as low-risk (PCI 0–21) versus high-risk (PCI 22–39); in our center considered operable versus non-operable. Reference standard was PCI found at surgery. Furthermore, the both readers evaluated whether a R1 resection could be achieved on a 5-point scale combining PCI and other risk factors for an incomplete surgery, like invasion in hepatic hilum, mesenteric vessels, extensive pelvic invasion of liver metastases. Sensitivity and specificity of the test were calculated and receiver operating characteristic (ROC) curves were constructed. The area-under-the-curve (AUC) was calculated for each reader. Quadratic weighted kappa was used to evaluate the interobserver agreement.

Results: At surgery the mean PCI was 13.8 (range 0–34). For reader 1 the mean PCI was 13.8 (range 0–34). For reader 2 the mean PCI was 13.8 (range 0–34). For both readers evaluation the PCI was considered operable versus non-operable. Both readers categorized 23 out of 24 patients correctly (accuracy 96%) when compared to surgical findings. Both readers underestimated the same patient. The sensitivity and specificity for selecting patients with a PCI ≤ 22 was for both readers 100% and 75%, respectively. The interobserver agreement was perfect (k = 1.0). The AUC for predicting overall operability was 0.99 for reader 1 and 0.95 for reader 2.

Conclusion: These data suggest that DW-MRI is a robust and highly accurate tool to noninvasive selection of colorectal cancer patients who could benefit from CRS-HIPEC. Interestingly, no overstaging occurred with DW-MRI; this means that DW-MRI did not deprive patients from potential curative surgery. In addition, due to the lack of large studies concerning this subject, our ‘pilot study’ is one of the largest DW-MRI study in PC.

cases to obtain an automatic histological classification of colonic polyps. Our automatic histology prediction system is based on the segmentation of textural elements from polyp surface and their correlation with Kudo’s pit pattern classification. Textural elements are identified as bright regions in polyp surface and there are characterized according to their shape to tubular and circular: a high presence of tubular patterns is associated to an adenomatous histology whereas the absence of prominent tubular structures is associated to non-adenomatous. Taking this into account, we characterized segmented bright regions using a tubularity metric (Tub) designed to obtain low values for circular shapes and high values for tubular shapes of the ROIs. We tested our method in high definition (HD) white light polyp images which were obtained with a colonoscope Olympus C1F-H190 at Hospital Clinic in Barcelona. Neither conventional nor virtual chromoendoscopy were used. These images were selected to show as much variability in polyp appearance as possible. We used the mean of all Tub values for an image to classify it into two classes: Adenoma and Non-Adenoma. A ROC curve was constructed to select the optimal threshold value of Tub. Then, we compared the histology prediction provided by our system and the actual histology obtained after lesion removal.

Results: 51 polyp images were analyzed: 38 (74.5%) adenoma and 13 (25.5%) non-adenoma. Mean size of polyps was 14 ± 13 (range 1–40) and had the following morphology based on Paris classification: 5 (8.8%) 0-Ip, 27 (52.9%) 0-IIa and 16 (37.3%) 0-IIa. Mean Tub values were different for adenoma compared to Non-adenoma (19.5 ± 6.5 vs 14.1 ± 6.3; p = 0.013). An optimal threshold value of Tub = 13.14 to separate adenoma vs. non-adenoma was selected from the operating point of the ROC curve. With this value, our method was able to provide accurate histological diagnosis in 44 out of 51 images (86.3%) (table) with a Sensitivity, Specificity, PPV and NPV for the diagnosis of adenoma of 95%, 61%, 88% and 80%, respectively. On the other hand, processing of a single HD image took 2.7 seconds making feasible its use in the endoscopy room.

Conclusion: A computer vision system based on bright regions in the image has a high accuracy for on-line prediction of polyp histology during colonoscopy. Though the use of shape characterization is promising, the inclusion of other polyp characteristics (i.e. shape, color, vessels, . . .) as well as enlarging the validation database could improve the robustness of our methodology.

threshold of wall thickness for fibrosis was > 6.3 mm (specificity 100% and sensi-
tivity 89.6%). The cut-off value of ADC value was < 1.1 × 10⁻⁵ mm²/s⁻¹ with a sensitivity of 71.79% and specificity of 94.44% (AUC = 0.83).

Conclusion: The DWI sequence with ADC value can identify fibrosis in intestinal wall of COC and it is not always using the use of contrast medium.

### P1580 MOLECULAR IMAGING OF c-MET IN THE CLINICAL MANAGEMENT OF GASTROINTESTINAL CANCERS

N. Mcdonald, C. Portal, I. Wilson
Edinburgh Molecular Imaging, Edinburgh/United Kingdom

Contact E-mail Address: i.wilson@edinimage.com

Introduction: The primary indication for c-Met targeted optical imaging agent EMI-137 is enhanced endoscopic detection of lesions during colorectal cancer screening, including flat lesions that are difficult to detect by normal white light endoscopy. We have evaluated the potential benefit of EMI-137 and analogues beyond colorectal cancer screening since c-Met is up-regulated in many other cancers.

Aims & Methods: We have synthesised analogues of EMI-137 where the fluores-
cent reporter was replaced by a radiosonde chelating moiety for PET imaging. The use of this agent alongside EMI-137 could enable the PET localization of the lesions prior to surgery guided by fluorescent signals. Through a systematic analysis of scientific literature databases, and the Human Protein Atlas, we have identified more than 13 different types of solid cancer that are amenable to PET imaging for which there is evidence for c-Met as a target. We believe that imaging of c-Met with EMI-137 in these indications has the potential to positively impact critical problems in the existing patient care path and reduce morbidity, mortality, and healthcare costs. We have assessed: 1) the healthcare problem, the impact on patient care path, and the likelihood of adoption by clinicians 2) the hardware landscape; whether imaging hardware required is commercially available or is being developed, and feedback from clinicians in the US and EU 3) our confidence in c-Met as a valid imaging target to address the healthcare problem.

Results: We have identified a number of promising applications within Digestive Oncology; gastric cancer, locally-advanced rectal cancer, and bile duct cancer surgery are all life-threatening indications with urgent healthcare problems that could be improved by utilising imaging of c-Met with EMI-137. Compatible imaging systems are commercially available for these indications. There is also strong evidence for c-Met as a biomarker in stratification in Barrett’s oesophagus (BO), a potentially precancerous lesion with the risk of progression to oesopha-
gal cancer. Progression rates are low and overall survival rates in BO patients are similar to the general population. However, due to the poor prognosis of oesophageal cancer, patients with BO lesions are managed by regular endoscopic surveillance and biopsy. This means that there is arguably a disproportionate healthcare burden related to the level of risk.

Conclusion: Gastric cancer, locally advanced rectal cancer, and bile duct cancer surgery all have strong evidence for c-Met as a valid target, and the healthcare problems are clear and widely recognized, with EMI-137 having the potential to help improve high intensive procedures in serious, life-threatening conditions. An imaging agent that enabled more accurate risk stratification of BO patients would lead to a change in patient management, with the potential to remove unnecessary biopsy and to reduce the frequency of surveillance.

### P1581 HOMEMADE FIXATION OF FULLY-COVERED SELF-EXPANDING METAL STENT

Endoscopy, ICESP Sao Paulo Dept. of Endoscopy, Sao Paulo/Brazil

Contact E-mail Address: kpennacchi@yahoo.com.br

Introduction: Esophageal self-expandable metal stents are currently used as an alternative for surgical treatment in esophageal neoplasia, benign strictures, fis-
tulas and anastomotic leaks. Migration is a common complication after stent placement and have higher rates when fully covered stents are employed. Covered stents prevent tumor ingrowth and can be removed easily, they can be used in the closure of fistulas and leaks. External fixation of the stent with Shim’s technique seems to be efficient in preventing stent migration, but has a high cost and it is not always available. Fixation by clipping or sutures has similar limitations. We developed a homemade technique for external fixation of the stent using dental floss to prevent dental stent to prevent stent migration. We present the results of this technique in a small cohort.

Aims & Methods: The present study enrolled sixteen patients with esophageal malignancies, anastomotic leaks, esophageal fistulas and extrinsic compres-
sion. The stents used in these patients were five partially covered and ten fully covered. We developed a homemade technique using dental floss for external fixation of the stent which prevent stent migration. We pull stripes of dental floss into the stent mesh and using a method similar to exchange of a nasobiliary drainage catheter, the dental floss is drawn out through the nose, tied a knot into it and its loose end is fixed to the patient’s earlobe.

Results: Upper gastrointestinal endoscopy was performed after two weeks and the proximal uncovered flange of the stent was evaluated. If it was embedding the esophageal mucosa and did not separate from the esophagus with air insuf-
flation, the external fixation was removed. Otherwise, the fixation was kept for another 2–4 weeks when a new endoscopic evaluation was performed. Patients were evaluated 15–30 days after stent placement. In cases of migration of the entire length of the stent into the stomach, the patient received a new stent and the same fixation method was employed. In cases of stents partially migrated through the cardia, the same stent was repositioned and fixed with dental floss stents as previously described.

Conclusion: According to the results we believe this homemade technique using dental floss for external fixation of stents is a simple and cheap method that can be applied and used to prevent stent migration.

Disclosure of Interest: All authors have declared no conflicts of interest.

### P1582 CLINICAL OUTCOME WHEN USING SELF EXPANDING METAL STENT IN OBSTRUCTIVE BRONCHOESOPHAGEAL CANCER IN 248 PATIENTS WITH 7 YEARS EXPERIENCE IN A TERTIARY CENTER

M. Shafazand, T. Radomski, L. Alkcin, N. Papachrysos
Gastroenterology, Sahlgrenska University Hospital, Gothenburg/Sweden

Contact E-mail Address: mortzer.shafazand@vregion.se

Introduction: The reported incidence of colorectal cancer in Sweden in 2014 was 60-65/100,000 inhabitants and caused 25–30 deaths/100,000 [1]. Of all colorectal cancer, approximately 15–20% debutes with acute obstructive symptoms. Solid malignancy in these conditions (open surgery) have been shown to lead to mortality risk up to 20% and morbidity risk of 45–50%, followed by increased need for intensive care and more infections and stoma complications. Self-expanding Metal Stent (SEMS) for relieving malignant eosophageal obstruction is a treatment alternative for non-curative cases or for bridging the patient for later surgery. Studies have shown [2]clinical success of SEMS at 90%. An article from 2007 concludes that SEMS in acute colon obstruction has better results regarding sickness and side effects compared with acute open surgery and chemotherapy.

Aims & Methods: Our compilation covers the years 2010–16, when 248 SEMS interventions (53% men, 47% women, age 28–97) were performed at SU/Ostra Hospital. In 78% of cases, the obstruction was located below the left ilexare. In 80%, SEMS was made for palliative purposes.

Results: Technically, SEMS succeeded in 98% of cases and had clinical success in 90% of cases (absence in need of emergency surgery). Complications (colony perforation) occurred in 6% of the cases. Mortality within 30 days was 11% and within 90 days 22%. There were no 90-day deaths. There was no treatment failure with regard to 90-day mortality for the indication was palliative vs. bridging. 29 resp. 3%. Based on the clinical outcomes "success" vs "failure", the 90-day mortality rate was 19 resp. 55%.

Conclusion: Our interpretation is that SEMS is an effective method of acceptable safety regarding complications in acute malignant colon obstruction. The method is suitable for both intended intestinal relief for palliative purposes, as well as awaiting later curative measure (bridge to surgery).

Disclosure of Interest: All authors have declared no conflicts of interest.

### P1583 ENDOSCOPIC TREATMENT OF ESOPHAGEAL FISTULAS

D. Bucur1, D. Opreanu2, G. Constantinescu2, M. Ilie2, V. Sandru2, D. Tabacu1
1Gastroenterology, Clinical Emergency Hospital Bucharest, Bucharest/Romania
2Dept. Of Gastroenterology, Clinical Emergency Hospital Bucharest, Bucharest/Romania

Contact E-mail Address: bucur.denis@gmail.com

Introduction: Tracheoesophageal fistulas are severe complications which com-
monly occur secondary to malignant tumors of the esophagus. Other causes include mediastinal or respiratory tract tumors, surgery, radiotherapy and trauma. Without treatment they often lead to pulmonary and gastroenterological complications, such as pneumonia, acute respiratory distress syndrome and poor nutrition. The purpose of this study was to assess the efficacy of endoscopic treat-
ment performed in our clinic for esophageal fistulas.

Aims & Methods: We performed a retrospective study on 43 patients admitted in our clinic between January 2015 and April 2017 for esophageal fistulas.

Results: The average age of the patients included in the study was 24 years old. The causes leading to the tracheoesophageal fistulas were the following: esophage-
al malignancy in 18 cases (41.8%), surgery in 8 cases (18.6%), respiratory tract malignancy in 6 cases (14%), gastric sleeve in 5 cases (14%), radiotherapy in 3 cases (7%) and trauma in 2 cases (4.6%). In every case, the treatment of choice was placement of fully-covered metallic stents. A number of 16 patients needed reintervention, with a mean of 2 reinterventions per patient. Regarding recurrent fistulas, endoclips were used in one case (2.3%), additional stenting in 11 cases

References:
Per patient, range 1–69 treatments) were performed in 135 patients (female 131/135 (97%) patients with a mean of 30.1 months (0 to 103).

OF SYMPTOMATIC ENTERIC STRICTURES IN CROHN’S DISEASE

Introduction:

Endoscopic treatment of enteric strictures in patients with Crohn’s disease (CD) is well established; however, long-term outcome is unknown.

Aims & Methods: All patients with CD, who had undergone endoscopic therapy of symptomatic strictures at Robert Bosch-Hospital Stuttgart from 2008–2017, were included in this retrospective cohort study. A follow-up was available for 131/135 (97%) patients with a mean of 30.1 months (0 to 103).

Results: A total of 452 endoscopic interventions (mean 3.4 per patient, median 2 per patient, range 1–69 treatments) were performed in 135 patients (female n = 67/male n = 68, mean age 47.5 years, BMI: 22.8 ± 4.98 kg/m², duration of illness: median 25.1 months). In 165 cases, the dominant stricture was located in the ileocecum, in 105 in the colon, esophagus (90), duodenum (54), upper intestine (26), lower intestine (11) or stomach (1). In 166 and 286 cases, there was an anastomotic and non-anastomotic stricture present, respectively. Treatment consisted of hydrostatic balloon dilatation (n = 447); bougienage (4), and ESEM (1). Dilatation was performed to a mean of 14 mm (SD: 2.4, range 7 to 24 mm). In seven cases complications occurred after endoscopic treatment (bleeding: n = 5; infection: n = 1); perforation: n = 1) which resulted in an extension of the hospital stay (n = 5), antibiotic therapy (1) and surgery (1). Immediate clinical success was observed in 438 of 452 of cases (96.9%). A follow-up.

Conclusion: Endoscopic dilation is effective and safe. Repetitive dilation is feasible with a significant reduction of clinical symptoms, and surgery was required in about 30% of patients at long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: c.clisby83@gmail.com

Introduction: Palliative stenting is now established as a major treatment for dysphagia resulting from incurable oesophageal neoplasms. Palliative oesophageal stenting is associated with multiple possible complications after oesophageal stent insertion; most of these present with increasing dysphagia; however pain, bleeding, and reflux are also common. Although data on rates of various complications are available, there are no agreed standards to audit performance against, nor any requirement to do so. As this is a palliative procedure, success in symptom control is paramount; if this is not being achieved, then the appropriateness of the procedure must be questioned. As with any invasive procedure, complication rates are affected by multiple variables: technical, length and site of stricture, operator experience, patient co-morbidities and performance status. As a result of these variables, stated complication rates also vary. Only one study reported a rate of dysphagia (29%); migration occurred in 5–15% of cases, tumour ingrowth/overgrowth 5–20%, and food bolus obstruction in 5–15%. Quoted median survival ranged from 61–104 days, with a 30-day mortality of 20–28%.

Aims & Methods: Our aim was to scrutinise the efficacy and the safety of our palliative oesophageal stenting work. A retrospective study of all patients undergoing oesophageal stent insertion at our unit, between 01.01.2012 and 01.04.2016 was undertaken, looking for evidence of complications, repeat interventions, and for survival statistics after stent insertion. Patients who had undergone stent insertion for reasons other than oesophageal malignancy were excluded.

Introduction: Endoscopic dilation is an effective treatment in oesophageal strictures, but recurrences may require frequent and repeated dilations in the long term. Several trials have been conducted to determine the efficacy of intralesional steroid injection in the treatment of benign refractory oesophageal strictures, since the first pediatric case series was published in 1969. However, a meta-analysis has not been carried out yet.

Aims & Methods: The aim of the analysis is to summarise the results and establish evidence in support or against the complementary treatment. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). Two reviewers conducted a comprehensive search on databases from inception to February 2016, to identify trials, comparing the efficacy of dilation combined with intralesional steroid injection. A meta-analysis was conducted on the data using the random-effects method by DerSimonian and Laird, because of the high level of the heterogeneity.

References

Results: Between 01.01.2012 and 01.04.2016, 152 patients were inserted in 125 patients in palliative oesophageal cancer patient; 104 patients had stent inserted once, 16 patients had twice, 4 patients had 3 times and 1 patient had 4 stent insertions. 69.6% were male and the median age at death was 79 years (SD 10.94). The reported histology for the 125 patients revealed, 85 (68%) adenocarcinoma, 35 (28%) squamous cell carcinoma, 5 (4%) lung cancer causing external compression of the oesophagus, 2 (1.6%) mesothelioma, 1 (0.8%) externally compressing spindle cell sarcoma, 1 (0.8%) metastatic adenocarcinoma from the colon, 1 (0.8%) externally compressing signet ring adenocarcinoma. Of these stent insertions 52 (34.2%) were documented to have going or recurrent dysphagia after the procedure, of which the causes were: tumour over- or ingrowth in 9 (5.9%); stent migration in 15 (9.9%); distal obstruction due to gastric folds 2 (1.3%), dysfunction of the anti-reflux valve in 3 (2.0%); and food bolus obstruction in 9 (6.0%). The indication for stent insertion was 2 (1.3%) benign obstruction and stent disintegration in 1 (0.7%) case. In 13 (8.6%) cases cause for dysphagia was not found or not investigated. 100 (65.8%) stent insertions resulted in complete resolution of the dysphagia. Repeat endoscopy was necessary in 34 (27.2%) patients, who had 98 repeat gastroscopies in total, to deal with minor complications of the stent insertion or to investigate dysphagia. In total there were 13 (8.7%) significant complications caused by the stent insertion of which 7 (4.6%) were bleeding, 2 (1.3%) were tracheo-oesophageal fistula formations, 1 (0.7%) was delayed perforation, 1 (0.7%) was a too short stent, 1 (0.7%) was a disintegrating stent and 1 (0.7%) was a compression of the bronchi. Median survival of the 125 patients after stent insertion was 96 days (SD 128) and 30-day mortality was 11.2% (14 patients). It is important to note that with retrospective data analysis, some data is not available, due to variations in recording at the time and a reliance on the patient to report symptoms to a clinician. Currently 2 patients are still alive.

Conclusion: Palliative stenting at this centre continues to be an effective treatment for patients with dysphagia from oesophageal cancer. On the whole, outcomes from stenting at this unit compare favourably with published data in terms of dysphagia, other complications, and mortality. Steps to improve post-procedure monitoring in the form of a “stent registry” with prospective collection of data by telephone or face-to-face follow-up could be useful in future service development.

Disclosure of Interest: All authors have declared no conflicts of interest.
available in many centers and have revolutionized the management of iatrogenic bowel vascular injuries. Aims & Methods: Evaluate the role of intervention radiology procedures to manage different post-cholecystectomy complications focused on the novel techniques to improve the final outcome. From June 2014 to June 2016, 30 patients presenting complications after cholecystectomy were referred to interventional radiology unit in our university hospital. They were 9 males and 21 females (age range: 18–66 years). Patients presented with biliary leaks (n = 12), benign biliary strictures with intrahepatic biliary dilations (n = 21), postoperative hernia (n = 2) and bleeding related to hepatic artery pseudo-aneurysm (n = 1). Different types of interventional procedures were performed, including: Percutaneous trans-hepatic drainage (PTD) (n = 16), surgical dilatation of benign stricture with increasing caliber dilators over 6 months followed by metallic stent procedures after catheter withdrawal (n = 6), biliary stenting with plastic stent (n = 2). Insertion of pigtail catheter (n = 15), preoperative progressive pneumo-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias before their surgical repair (n = 1), and selective embolization of bleeding hepatic artery pseudo-aneurysm (n = 1) using tissue adhesive (n-Butyl 2 Cyaanoacrylate).

Results: All percutaneous procedures were technically successful. No recorded early or late complications. After manometric studies, all managed cases with biliary strictures did not show any clinical evidence of restenosis during 6 months follow-up. Overall, 14 out of 30 patients (46.7%) were only managed by different interventional radiology procedures. Second step surgical repair was needed for 13 patients (43.3%) and endoscopic managed for 3 patients (10%) with biliary leaks.

Conclusion: Minimally invasive interventions were valuable techniques in the management of different post-cholecystectomy complications. In fully equipped centers, expert multidisciplinary teams would achieve high cure rates for iatrogenic biliary injuries.

P1590 WHAT IS THE ROLE OF ANGIOGRAPHY IN ACUTE COLONIC AND SMALL BOWEL BLEEDING?

R. Vale Rodrigues1, P. Amaro1, M. Ferreira1, M. Barros1, P. Donato1, L. Tomé3
1Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra; Portugal

Contact E-mail Address: rita.vale.rodrigues@gmail.com

Introduction: Angiography is a diagnostic and therapeutic modality that is widely available for upper gastrointestinal bleeding but is used less frequently when the source of bleeding is placed distally to the Treitz angle.

Aims & Methods: To assess the usefulness of angiography in the diagnosis of colonial and small bowel bleeding and to determine the efficacy and complications of therapeutic procedures. Retrospective study; we included all patients with colonial and small bowel bleeding that were submitted to arteriography with or without embolization, admitted to the gastroenterology department of a tertiary hospital between February 2006 and November 2016. Statistics: Chi-square/ Fisher exact test, T-student.

Results: We reviewed 216 patients. Mâle evaluated, 63.6% male, mean age = 75 years (29–95). Angiography was done for: bleeding recurrence (36.2%), hemodynamic instability (33.3%), both (27.3%) or failure to endoscopic hemostasis (3%).

Conclusion: The role of angiography in the diagnosis of acute colonic and small bowel bleeding is still controversial but may offer therapeutic options in selected cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1592 PROPENSITY SCORE ANALYSIS OF 18-FDG PET/CT ENHANCED STAGING IN PATIENTS UNDERGOING SURGERY FOR OESOPHAGEAL CANCER

N. Patel1, K. Fokoy2, D. Chan1, C. Brown1, A. Powell1, T. Abdelrahman1, P. Fielding2, A. Roberts2, W. Lewis1
1General Surgery, University Hospital Wales, Cardiff/United Kingdom, 2Radiology, University Hospital Wales, Cardiff/United Kingdom

Contact E-mail Address: neilrimara@hotmail.com

Introduction: PET/CT has become an integral part of the staging pathway for oesophageal cancer and is usually performed before, during and after surgery.

Aims & Methods: Consecutively 120 patients undergoing oesophagectomy for cancer [median age 63 (31–80) yr., 395 male, 75 neoadjuvant therapy]; 60 did not proceed to surgery and were excluded. Postoperative morbidity and mortality occurred in 83 (69%; CD 3 in 27, 22.5%) and 4 (3.3%) patients respectively. ROC curve analysis showed oxygen uptake (peak V02) gave an area under the ROC of 0.66 (95% CI 0.55 to 0.77, p = 0.005); anaerobic threshold (AT) gave an area under the ROC of 0.62 (95% CI 0.51 to 0.74, p = 0.048) and optimum cut-off of 10.5ml/kg/min (sensitivity 60%, specificity 44%). Multivariable analysis revealed peak V02 to be the only independent factor to predict morbidity severity CD > 3 (OR 0.85, 95% CI 0.75–0.97, p = 0.018). Cumulative survival was associated with operative MSS (Chi2 4.892, DF 1, p = 0.027) but not with PET variables.

Conclusion: PET/CT is a significant predictor of morbidity after oesophagectomy with peak V02 the most important factor.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1593 PREDICTION OF LYMPH NODE METASTASIS FOR SUPERFICIAL ESOPHAGEAL CANCER WITH USING RANDOM FOREST ANALYSIS

M. Takeuchi1, H. Kawakubo1, K. Fukuda1, R. Nakamura1, K. Suda1, N. Wada1, Y. Kitagawa1
1Department Of Surgery, Keio University School of Medicine, Tokyo/Japan

Contact E-mail Address: masaty871222@gmail.com

Introduction: Although surgical techniques and perioperative management for oesophageal cancer has been developed, it cannot be still safe to be performed oesophagectomy. Therefore, endoscopic submucosal dissection (ESD) for the superficial cancer has been increased. We also need to consider the risk of lymph node metastasis before treatment in each patient and the aim of this study is to predict lymph node metastasis for superficial esophageal cancer.

Aims & Methods: Predictive models can help to identify patients who are likely to develop lymph node metastases. This study is to predict lymph node metastasis for superficial esophageal cancer.
Aims & Methods: Seventy patients who were diagnosed as clinical T1a-MM, T1b-SM1 or T1b-SM2 and underwent esophagectomy at the Keio University, Tokyo, Japan between July 2000 and June 2016 were enrolled in this study. Patients who underwent esophagectomy as additional resections after ESD were included. We used random forest analysis to predict lymph node metastasis. Results: There were 62 men and 8 women in this study. The mean age of all patients was 62.8 ± 8.2 years. The main location of the tumor was in the middle thoracic esophagus (Upper: Middle; Lower; 13: 39: 18, respectively). 14 patients had lymph node metastasis in pathological findings; 2 patients (25%) were diagnosed as clinical T1a-MM, 2 patients (6.6%) were clinical T1b-SM1 and 10 patients (31.3%) were T1b-SM2. Random forest technique (2000 trees) resulted in an estimate of error rate of 25.7%. Lymph node metastasis was most associated with the factor of pathological T (relative importance 100%) followed by lymph node (98.9%) and T factor (95.9%). However, there were 3-6 months between the two fillings. The mean differences of the COPE-NVI scales were not statistically significant.

Conclusion: In our series, patients used Positive Attitude to manage everyday life (COPE-NVI scales). However, in order to improve them to positive attitude, some modifications are necessary. Disclosure of Interest: All authors have declared no conflicts of interest.

Comparison of manual counting to the computed methods showed mostly excellent accuracy of the obtained results using intraclass correlation with reliability analysis (ICC) and coefficient B with linear regression (B):

<table>
<thead>
<tr>
<th>mCRC</th>
<th>OvCa</th>
<th>HCC</th>
<th>PCa</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZC</td>
<td>ICC  = 0.926, B = 0.368 ICC &lt; 0.978, B = 0.968 ICC &lt; 0.869, B = 0.621 ICC = 0.601, B = 1.20</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ISCC</td>
<td>ICC = 0.973, B = 0.851 ICC &lt; 0.992, B = 1.030 ICC = 0.990, B = 1.606 ICC = 0.934, B = 0.914</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IACCC</td>
<td>ICC = 0.896, B = 0.945 ICC &lt; 0.990, B = 0.606 ICC = 0.955, B = 0.723 ICC = 0.932, B = 1.32</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Results: Quantification results from 2 blinded observers for reliable detection of hot spots were 0.949 in mCRC, 0.843 in OvCa, 0.805 in HCC and 0.957 in PCa. The ICC for the ratio of CD8+C in 1 hot spot compared to the average from 3 hot spots was consistent in all groups. The absolute cell count in 1 vs 3 hot spots was consistent in all groups. EORTC C30 functional scales are: PE2 (physical functioning), RF (role functioning), EF (emotional functioning), CF (cognitive functioning) and SF (social functioning). EORTC-C30 and COPE-NVI questionnaires. Thirty-two patients completed the questionnaires after surgery. Mean COPE-NVI scales were: SS = 22.3 (SD 9.5), AS = 23.2 (SD 4.8), PA = 30.8 (SD 7.9), P0 = 22.5 (SD 8.8), TO = 22.1 (SD 5.0). Overall, mean C30-QLQ was 72.9 (SD 16.3). Mean C30 functional scales were: PE2 = 80.8 (SD 16.6), RF = 85.0 (SD 20.7), EF = 81.5 (SD 17.0), CF = 87.4 (SD 14.0) and SF = 90.0 (SD 14.0). Avoidance Strategies score was negatively correlated with Social Function (rho = -0.60, p = 0.004). The remaining correlations between COPE-NVI scales, C30-QLQ and C30 functional scales were statistically not significant.

Conclusion: In our series, patients used Positive Attitude to manage everyday life (COPE-NVI scales). However, in order to improve them to positive attitude, some modifications are necessary. Disclosure of Interest: All authors have declared no conflicts of interest.
P1598 LIVER RESECTION IN OBSESE PATIENTS WITH HEPATOCELLULAR CARCINOMA

Hepato-biliary-pancreatic Surgery, Hyogo College of Medicine, Hyogo, Japan
Contact E-mail Address: iwarnam43387@gmail.com

Introduction: Obese disease has been recognized as a risk factor for hepatocellular carcinoma (HCC). On the other hand, there are few reports concerning liver resection (LR) in obese patients.

Aims & Methods: We performed curative LR in 471 patients with HCC between 2001 and 2015. In this study, we defined an obesity as no less than 25 of body mass index (BMI). We compared clinicopathological findings, operation details, and surgical outcomes of the obese and non-obese patients. Furthermore, we assessed the safety and the benefit of laparoscopic partial hepatectomy and left lateral segmentectomy in the obese patients.

Results: Among 471 patients, 123 patients (26.1%) were defined as obese. Among them, 20 patients (4.2%) showed no less than 30 of BMI. Diabetes, hypertension, and hyperlipidemia were significantly more common, and the patients with hepatic steatosis were positively associated in the obese patients group than in the non-obese patients group (p < 0.05). The two groups showed no differences in the liver function tests except the indocyanine green retention rate at 15 minutes. There were no significant differences between the two patients group in the number of tumors, diameter of tumor, prevalence of cirrhosis, frequency of portal invasion, the operative procedure, operative duration, blood loss, incidence of postoperative complications, postoperative hospital stay, and in-hospital mortality (3.3% vs. 1.4%). No significant difference was found in relapse-free survival rate, or overall survival rate between the two groups, too. Thirteen patients underwent laparoscopic surgery, and 34 patients had open surgery. The two groups showed no difference in the background, including BMI. However the operation time (265 min. vs. 397.5 min) and the postoperative hospital stay (14 days vs. 18 days) were significantly shorter, and the blood loss (50 ml vs. 600 ml) was less in the laparoscopic surgery group than in the open surgery group (p < 0.05).

Conclusion: Liver resection in the obese patients with HCC was safe, and laparoscopic liver resection might be more useful for reducing the surgical stress and reducing the hospital stay.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1599 TIMING OF ELECTIVE CHOLECYSTECTOMY AFTER ACUTE CHOLECYSTITIS - A POPULATION-BASED STUDY

A. Popowicz, G. Sandblom
Department Of Clinical Science, Intervention And Technology, Karolinska Institute, Stockholm/Sweden
Contact E-mail Address: agnieszka.popowicz@ki.se

Introduction: Acute cholecystectomy as treatment of acute cholecystitis is standard of care. However, many patients are still treated conservatively and undergo elective cholecystectomy 2 weeks following the primary admittance is postulated as a good timing for an elective surgery but there are no studies on the optimal timing for delayed cholecystectomy.

Aims & Methods: The aim of our study was to determine when it is most advantageous to perform a delayed surgery with respect to acute cholecystitis. All patients treated for acute cholecystitis in Sweden during the years of 2006 and 2013 were identified through the Swedish Inpatient Register. This cohort was cross-linked with the Swedish register for gallstone surgery. Cox regression was used for survival analysis. The impact of time from admission to surgery with regards to operative time, percentage of procedures completed with minimally invasive technique, peri and postoperative complications and bile duct injury or bile leakage was analysed with a multivariate logistic regression model.

Results: The years 2006 to 2013, 31091 patients were treated for acute cholecystitis in Sweden. After exclusion of patients that did not perform surgery, were not registered in GalRiks and that patients that were treated with acute cholecystectomy 5352 patients were identified that underwent planned surgery. In multivariate linear regression analysis with adjustment for gender and age the risk for peri- and postoperative complications, bile duct injuries and bile leakage and amount procedures not completed with minimally invasive technique decreases with time from the last hospitalization to surgery. All p-values < 0.05.

Conclusion: For those patients undergoing elective cholecystectomy after an acute cholecystitis the safety increases if surgery is performed later than 30 days after discharge.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1600 MIXED REALITY SURGERY USING CT-BASED PATIENT-SPECIFIC IMMOVABLE 3D HOMOLOGS ENHANCED SPATIAL AWARENESS IN HEPATO-PANCREATO-BILIARY AND GASTROINTESTINAL SURGERY

M. Sugimoto
Graduate School Of Health Welfare Science, International University of Health Welfare, Tokyo/Japan
Contact E-mail Address: sugimotomakat@mac.com

Introduction: We developed a CT-based patient-specific holographic surgical simulation navigation system of immovable mixed reality (MR).

Aims & Methods: The aim of this study is to identify its benefit of simulating, analyzing and evaluating operative surgical treatment options in gastrointestinal and hepato-pancreato-biliary surgery. We used our original immersive MR application using HoloLens, that is a pair of MR smartglasses built-in high-magnification display. By reconstituting the patient-specific 3D surface polygons of each organ out of the patient’s MDCT images, MR anatomy was displayed on the grasses three-dimensionally during actual surgery. Based on the pair of MR smartglasses by satellite tracking. The gesture controlled manipulation by surgeons’ hands with surgical groves was useful for intraoperative anatomical references of tumors and vascular position under sterilized environment. It allowed the user to manipulate the spatial attributes of the virtual and real anatomies, which can enhance spatial awareness. The use of our systems reduced the length of the operation and discussion time.

MR navigation assistance could support complex procedures with the help of pre- and intraoperative imaging with better visualisation of the surgical anatomy and spatial awareness with visualisation of surgical instruments in relation to anatomical landmarks.

Conclusion: We report illustrative benefits of the immersive MR in surgical planning, simulation, education, and image-guided navigation. This could overcome the limitations of the conventional image-guided surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1602 EFFICACY OF DOUBLE PIGTAIL STENT FOR POST OSEO-GASTRIC SURGICAL LEAKS NON LINKED TO BARIATRIC SURGERY: A PILOT BI-CENTRE RETROSPECTIVE STUDY

J. Jacques1, L. Pagnon1, A. Taibi2, R. Legros1, T. Tabouret1, T. Barrioz3, M. Wangermez2, S. Durand-Fontanier2, S. Bouvier2, M. Mathonnet2, D. Valleix2, A. Le -Sidaner2, H. Lepetit1, V. Loustaud-Ratti1, D. Sautereau1
1H. Lucua Chambéry-entérologie, CHU Lignomèges, Lignomèges/FR, Lignomèges/France
2Digestive Surgery, CHU Lignomèges, Lignomèges/France
3Dept. De Endoscopic Digestive, CHU Poitiers, Poitiers/France

Contact E-mail Address: la.pagnon@gmail.com

Introduction: Post-surgical leaks are the first complication after non-bariatric oeso-gastric surgery in terms of frequency and morbidity. Anastomotic fistulae change the prognosis of the operated patient increasing the length of stay, increasing costs, increasing mortality and increasing risks of oncological recurrence. Surgery is still a possibility of treatment in particular in case of severe sepsis but the role of endoscopy or even of a new armamentarium of endotherapy dedicated to such complications. In cases of post laparoscopic sleeve gastrectomy leaks, a shift is ongoing between closure or diversion methods (Ovesco, clips, covered self expandable metal stents (SEMS)) and internal drainage (double pig tail stents). Two large studies have just reported a high efficiency and a low complication rate with internal drainage with double pig tail stents for post sleeve gastrectomy leaks. No data are available for such an endoscopic internal drainage in fistulas of the upper digestive tract non-linked to bariatric surgery. Here we report the results of a pilot bi-centre retrospective study.

Aims & Methods: A retrospective study of all upper digestive tract leaks non linked to bariatric surgery and treated by double pig-tail stent (DPTS) in two
Introduction: Abdominal compartment syndrome (ACS) is serious complication of big number of surgical interventions. According the data of the World Society of the Abdominal Compartment Syndrome (WSACS), rate of mortality without treatment is more than 90%, after treatment from 25% to 75% [1]. Patients with ruptured abdominal aortic aneurysms (rAAA) are the group of high risk regarding complication. Rate of incidence ACS at these patients is between 8% to 25%[2]. According to data of various authors, from one third to one half of them have died [3]. One of the main cause of this is the absence of good monitoring of intraabdominal pressure in this group of patients[4]. Currently, we have on one effective way of treatment: decompressive laparatomy [5]. But prophylaxis becomes more important point, if we take to attention mortality after start the develop of abdominal compartment.

Aims & Methods: We aimed to investigate the impact of implantation polypropylene mesh during all three years of follow-up on occurrence of ACS. We aimed to investigate the impact of implantation polypropylene mesh for other deseases, related with ACS and it severity. We aimed to investigate the impact of implantation polypropylene mesh for other deseases, related with it complication and mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1604 ESSENTIAL PERCUTANEOUS DRAINAGE (EPD) OF PERITONEAL COLLECTIONS AND ABSCESES SECONDARY TO BARIATRIC SURGERY LEAKS: THE PARADIGM SHIFT OF SEEING PERITONEUM AS AN ORGAN AMENABLE FOR FLEXIBLE PERITONEAL collections are dreaded complications. Laparoscopic or open surgery and percutaneous CT drainage are the current indications. Endoscopic management of pancreatic collections is a rationale for Endoscopic Peroral Drainage (EPD) approach in cases of BS leaks with abdominal collections.

Aims & Methods: The aim of this study is to evaluate utility and safety of EPD to treat peritoneal collections and abscesses secondary to BS leaks. Methods: This retrospective study included 65 consecutive patients from 2007 to 2015 at a single center (40 Sleeve gastrectomy, 25 gastric bypass) after 5 to 21 days from tertiary centers has been performed. DPTS are traced by the pharmacies of our two hospitals and all cases of DPTS were analysed thanks to the database of the pharmacies of our two hospitals since May 2014 (first DPTS used for non bar- iatric upper digestive tract fistula) or 10 french DPTS have been used according to the size of the fistula and the choice of the physician. Technical success was defined as the possibility to place the DPTS within the fistula. Clinical success was a composite endpoint combining clinical amelioration of the patient and healing of the fistula allowing the removal of the DPTS.

Results: 17 patients have been treated by DPTS from May 2014 to March 2017 for an upper digestive tract leaks non linked to bariatric surgery. Fistulas were linked to a levis-sanyt surgery in 8 patients (47%), total gastrectomy in 4 (23.5%), boerhaave syndrome in 2 (11.8%), endoscopic perforation in 2 (11.8%) and aortic surgery in 1 (5.9%). An infected collection was present in 16 patients (94%) and 11 (64.7%) suffer from a clinical sepsis. The mean delay between surgery and the diagnostic of fistula was 10 days and the delay of the diagnosis of fistula and the endoscopic drainage by DPTS was 16.4 days. DPTS were used alone in first intention in 11 cases (64.7%), in first intention in combination with a SEMS in 11.7% and in second intention after failure of a SEMS in 3 (11.7%). All patients had a technical success and 15 patients (88.8%) had a clinical success. The mean delay for refeeding after DPTS was 17 days. The mean ablation time of the DPTS was 73 days. 3 patients presented a complication (1 stenosis, 1 bleeding and 1 migration).

Conclusion: Endoscopic internal drainage using DPTS seems to be an interesting therapeutic option for upper digestive tract leaks non linked to bariatric surgery. DPTS are effective, safe, cheap and could replace SEMS not always well toler- ated and with a high rate of migration. Prospective multicenter studies are needed.
surgery. Patients presented heart rate over 120 bpm. Images from CT showed left side of the abdomen free from abdominal content. An Upper GI series was performed to localize the leak opening and enter to peritoneal cavity. Either 9.8 or 5.8 mm diameter gastroscopy were used. In 10 patients with orifices smaller than 5.8 mm balloon dilatation of the leak opening allowed peritoneal access. The technique of AL was performed in 100 (to 700ml). Sample was taken for bacterial cultures. The cavity was flushed and suctioned out with sterile saline solution (200 ml to 1000 ml). In cases of inadequate location surgical drains catheters were repositioned or replaced using endoscopic forces and snare. Failure in accomplishing lateral anastomosis after 3 attempts when the catheter was performed advancing with endoscopes through the leak all the way down to the skin. Once the tip of the endoscope was outside the peritoneum the latex drains were removed. Catheters were snared or grasped and pulled back into the peritoneum leaving the proximal end close to the fistula opening. Nineteen patients without surgical drainage systems one laparoscopic port was localized inside peritoneum and re-opened under endoscopic vision to allow drainage catheters placement. In 8 patients peritoneal adhesions were endoscopically liberated with endoscopic forces or knives to facilitate peritoneal navigation.

Results: Heart rate returned to normal within 24 hours and leukocytosis improved after 72 hours. In 50% of patients heart rate returned to normal immediately. Average time for the whole procedure was 45 minutes. Abdominal catheters were removed between 7 and 18 days once full resolution of the drainage was achieved. Twenty patients were discharged within the first 24 hours. The rest were discharged between 3 and 8 days. Partially covered SEMS were placed for 6 to 8 weeks leading to complete closure of leaks. There were no adverse events related.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1605 CLINICAL ASSESSMENT OF THE FAILING TO REVERSE A DIVERTING ILEOSTOMY
A. Sobolewska-Wlodarczyk1, M. Wlodarczyk2, J. Wlodarczyk1, P. Siwiński1, J. Kazimierczyk1, A. Duki1, Ł. Drzik1
1Department Of Biochemistry; 2Department Of Gastroenterology, Medical University of Lodz; Lodz; Poland

Introduction: A diverting loop ileostomy with procedure of intestinal resections and colorectal anastomosis decreases morbidity from anastomotic leaks and may even reduce the risk of anastomotic leak as shown in recent studies. Reversal of a temporary ileostomy is considered a simple surgical procedure presenting with a low morbidity and mortality rates. However, ileostomy reversal may be associated with number of complications requiring reoperation, with anastomotic leak (AL) being most critical often leading to failure in restoration of digestive tract continuity.

Aims & Methods: The study aimed at evaluating the results of reversal of ileostomy in patients primarily operated on for colorectal cancer and inflammatory conditions. We assessed the frequency of failure following the surgical procedure of diverting loop ileostomy closure. The study was conducted at a tertiary referral center. 147 adult patients (89 men, mean age 50.5y ± 16.7y and 58 women, mean age 49.3y ± 16.9y) were enrolled to this study. All included patients underwent surgical closure of a temporary loop ileostomy at the Department of General and Colorectal Surgery, Lodz, Poland, between 2004 and 2014. The study was collected in a retrospective manner basing on hospital records. The analyzed parameters included length of hospitalization, gender, age, BMI, concomitant conditions, American Society of Anesthesiologists classification score (ASA) and the character of postoperative complications. Statistical analysis was used to evaluate the correlation between the variables and postoperative complications.

Results: AL as a postoperative complication with the need to create a new ostomy occurred in 15 patients (10.2%). Higher values of BMI and older age have been noted compared to noncomplicated surgeries (27.54 vs. 23.36 vs. 23.02 ± 3.96; p < 0.001; 54.53 ± 12.3 vs. 50.25 ± 15.95; p = 0.029 respectively). There was no significant correlation between patients’ gender and the incidence of AL (p = 0.087). The number of prior surgical procedures and ASA scale positively correlated with the prevalence of AL (p = 0.038; p = 0.003 respectively). There were no significant difference between patient with colorectal cancer and inflammatory conditions (p = 0.534). The average time interval from prior surgery to reversal of the stoma and AL occurrence were not related and did not reveal statistical significance (8.5 ± 4.41 vs. 7.24 ± 4.47; p = 0.25). Univariate logistic regression demonstrated that a BMI levels, patients’ age and average time interval from prior surgery to reversal procedure were significantly associated with number of complications requiring reoperation, with anastomotic leak (AL) being most critical often leading to failure in restoration of digestive tract continuity.

Conclusion: Postoperative complications is still a major issue related with failure of intestinal continuity restoration in patients undergoing loop ileostomy closure. Patients with elevated BMI, older age and shorter average time interval from prior surgery to reversal procedure present higher risk of failure in restoration of digestive tract continuity and the incidence rate was similar in patients operated primarily on for inflammatory conditions and colorectal cancer.

Introduction: The impact of body composition on the outcomes following pancreateicoduodenectomy is still unclear.

Aims & Methods: The aim of this study was to analyze the association between body composition the postoperative complications and 90-day mortality in patients undergoing bilipancreatic cancer surgery. Retrospective study of patients with pancreatic, ampullary or bile duct carcinoma that underwent surgery between March 2012 and October 2016. Body composition (skeletal muscle mass, body fat area, subcutaneous fat area and muscle radiation attenuation) was assessed in diagnostic or staging computed tomography (CT), in axial images at the level of the 3rd lumbar vertebra. Postoperative complications were recorded according to Clavien-Dindo classification and categorized as minor (grade I–IIIa) or major (grade IIIb–V).

Results: Fifty-nine patients were analyzed and 11 were excluded due to unavailable CT scan at our institution. Forty-eight were included, 28 were men, with a mean age of 70.5 ± 8.5 years. The incidence of major complications was 25% and 90-day mortality was 8.3%. On simple logistic regression of factors associated with major complications skeletal muscle area (OR 0.97, 95% CI 0.94–1.00, P = 0.09) and index (OR 0.91, 95% CI 0.81–1.00, P = 0.09) showed a trend for a protective effect. On multivariate logistic regression skeletal muscle area and radiation attenuation index were protective factors (OR 0.89, 95% CI 0.79–0.99, P = 0.05) and longer surgery (OR 1.01, 95% CI 0.99–1.03, P = 0.07) was associated with higher incidence of major complications. The receiver-operator characteristic (ROC) curve showed an acceptable power of discrimination of major complications using a model with skeletal muscle index and surgery duration as independent variables (area under the curve 0.736). On simple logistic regression surgery duration (OR 1.02, 95% CI 1.00–1.06, P = 0.05), visceral fat area (OR 1.02, 95% CI 1.00–1.04, P = 0.02) and AL level (OR 1.05, 95% CI 1.02–1.08, P = 0.04) were associated with higher 90-day mortality whereas muscle radiation attenuation had a protective effect (OR 0.88, 95% CI 0.76–0.99, P = 0.05).

Conclusion: These results suggest that low values of skeletal muscle and muscle radiation attenuation and high visceral fat area as well as high values of visceral fat and low skeletal muscle are associated with worse clinical outcomes following bilipancreatic cancer surgery.

P1607 GASTROSCHISIS: A 16-YEAR STUDY
A.M. Bradeanu1, L. Balanescu2, I. Nenciu3

Contact Email Address: anamariabrad@yahoo.com
Introduction: Gastrostomias is a ventral body wall defect tract which protrude mainly large and small intestines. The disease’s clinical course and prognosis is strongly related on both surgical techniques, severity of the defect, accompanying anomalies and complications.

Aims & Methods: We performed a retrospective study based on the analysis of patients records admitted to our hospital Neonatal Intensive Care Unit between January 2000 and December 2016. The aims of this study were to evaluate defect’s incidence, management and outcome of patients with gastrostomias in our institution.

Results: During the period 2000-2016 the overall incidence of gastrostomias in our NICU was 3.23% (140 cases out of 4,327). The abdominal wall gestational age was 35.5 weeks and the average birth weight was 2270 g. The abdominal wall defect was identified in antenatal period only in 15.4% of cases. Also, 23 patients (16.4%) presented other associated anomalies: 12 cases with urogenital anomalies, 5 cases with cardiac defects, 2 cases with neural tube defects. Surgical techniques performed for abdominal defect closure were: primary closure in 35 cases (25%), staged closure in 12 cases (8.57%), Gross technique in 44 cases (31.4%) and manual reduction and closure (Bianchi procedure) in 49 cases (35%). The average period of digestive pause was 12.9 days and the mean length of stay in NICU was 30.4 days. Patients were also ventilated for a average period of 4.6 days. The most frequent complication was late-onset sepsis (37.8%); also 26 neonates (18.5%) underwent surgical revision. The average mortality in our group was 33% but it constantly decreased over the years (from 84% in 2000 to 11% in 2016). Sepsis, prematurity, low birth weight and associated defects were identified as major risk factors for the unfavorable neonatal outcome.

Conclusion: The management of neonates with gastrostomias depends on several factors including the status of herniated organs, the size of abdominal cavity, the presence of other associated congenital anomalies and last but not least on the resources and experience of the neonatal interdisciplinary team. Significant changes occurred in the management of gastrostomias in our Unit and as consequence, the outcome of patients with gastrostomias has dramatically improved during the studied period.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1608 ASSESSING THE EFFECT OF ETHNICITY ON URINARY METABOLIC PROFILES IN INFLAMMATORY BOWEL DISEASE

1Gastroenterology, Imperial College Healthcare NHS Trust, London/United Kingdom
2Division Of Digestive Diseases, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom
3Division Of Computational And Systems Medicine, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: l.hicks@imperial.ac.uk

Introduction: Urinary metabolic profiling has been shown to distinguish patients with inflammatory bowel disease (IBD) from healthy controls (HC), and also separate ulcerative colitis (UC) from Crohn’s disease (CD) in Caucasian (Cau) cohorts (1). Diet and lifestyle also have an effect on metabolic profiles (2), and these differ in patients from different ethnic backgrounds. Moreover, clinical phenotype varies between Caucasians and South Asians (SA)(3), however discriminatory metabolites have not been studied in different ethnic populations. The aim of this study was to compare the urinary metabolic profiles of IBD patients and healthy controls from Caucasian and South Asian backgrounds.

Aims & Methods: Samples from 405 IBD patients (283 Caucasian and 122 South Asian) and 137 healthy controls (98 Caucasian and 48 South Asian) were analysed by UPLC-QTOF MS. Clinical and dietary data were collected. Orthogonal partial least squares discriminant analysis (OPLS-DA) was performed to examine whether there were differences in metabolic data between Cau and SA. R2 (variance), Q2 (quality assessment) and p values (validity) for each model were described.

P1609 EFFECTS OF ACUTE CHANGES IN FERMENTABLE FIBRE INTAKE ON REGIONAL COLONIC FERMENTATION AND TRANSIT IN PATIENTS WITH QUIESCENT ULCERATIVE COLITIS

C. K. Yau1, R. E. Burgell1, K. M. Taylor2, M. G. Ward2, J. S. Barrett1, J. G. Muir1, P. R. Gibson1

Introduction: Reduced saccharolytic fermentation has been described in patients with quiescent ulcerative colitis (UC). Such defects may differ across colonic regions along with acute variations in dietary fibre intake. These aspects deserve further study.

Aims & Methods: We aimed to define regional colonic fermentation by direct intestinal pH-transit profiling in patients with quiescent UC following acute variations in fermentable fiber intake. A randomized, double-blind, crossover trial was performed. Patients with quiescent UC (Partial Mayo Score ≤1; faecal calprotectin <150 μg/g) and healthy controls who were not taking any results showed that the phenotype of South Asian Crohn’s disease was not significantly different to Caucasian Crohn’s disease in this cohort. In the South Asian UC group there was more pancolitis (p = 0.051) and less proctitis (p = 0.008). There were more vegetarians in the South Asian group. OPLS-DA was able to separate patients with IBD from healthy controls, and also UC from Crohn’s disease, in the Caucasian cohort, but this separation could not be replicated in South Asians (negative Q2 values).

Conclusion: The separation between Caucasian and South Asian healthy controls may reflect differing lifestyles including diet. Caucasian IBD patients could be separated from healthy controls, and Crohn’s disease from UC, replicating previous studies. South Asian IBD patients could not be separated from healthy controls which may be due to lower numbers of South Asian patients in this study, and specifically less Crohn’s disease patients where stronger discriminating models have been shown in Crohn’s disease in previous studies. In Crohn’s disease, Caucasians and South Asians could be separated, but Caucasian and South Asian patients could not be distinguished in the UC cohort, possibly suggesting the metabolic milieu in Crohn’s disease is stronger and less influenced by the impact of ethnicity.

Disclosure of Interest: All authors have declared no conflicts of interest.

*Montreal classification
+OPLS-DA model examining the differences in urinary metabolic profiles between these cohorts
+Q value cannot be calculated if OPLS-DA model has negative Q2 values
OPLS-DA models also separated South Asian healthy controls from Caucasians healthy controls, and South Asian Crohn’s disease from Caucasian Crohn’s disease, but in UC no robust model could be made.
antibiotics (including sulfasalazine), probiotics or fiber supplements were removed. At 7-day run-in, subjects were fed study meals high (11 g oligosaccharides, 2 g resistant starch) or low (<1 g) in fermentable fiber over a 12-h period before ingesting the pH-motility capsule, subjects then crossed over to the other diet 3 days after passage of the capsule. Endpoints were diet-associated differences in overall, caecal and distal colonic pH, and colonic transit time (CCT), taken as time between the ileocecal junction and capsule exit. Caecal pH was defined as the minimum pH following passage through the ileocecal junction whereas maximum pH was arbitrarily used as distal colonic pH.

Results: 15 UC patients (aged 24–72 y; 9 males) and 9 controls (aged 22–69 years, 4 males) were studied. A decrease in overall and distal colonic pH was observed in controls with high vs low fiber diet (Table 1). In UC patients, a high fermentable fiber intake reduced caecal pH but paradoxically tended to increase distal pH. A subserved for UC extent and changes in overall (r = 0.08; P < 0.001, Spearman’s correlation) and caecal pH (r = 0.53; P = 0.04) after a high fermentable fiber diet (Figure 1). No differences in CCT were observed between diets in either cohorts but subgroup analysis in the UC cohort showed heterogeneous responses to a high fermentable fiber diet: 64% patients had slower CCT whilst 36% had unchanged or faster CCT. In contrast, majority (63%) of controls had no changes in CCT after a high fiber diet.

1 paired t-test or 2Mann-Whitney test

Conclusion: A high fermentable fiber diet partially increased colonic fermentative activity in patients with quiescent UC compared to controls. Moreover, contrary to controls, UC patients exhibited an increase in distal pH and heterogeneous colonic transit responses after a high fermentable fiber intake. Our findings suggest that abnormalities in motility and regional defects in the function of the colonic microbiota exist despite quiescent disease.

P1610 FECAL MICROBIAL DYSBIOSIS IN CHINESE PATIENTS WITH INFLAMMATORY BOWEL DISEASE

H. Ma, H. Zhang
Department Of Gastroenterology, First Affiliated Hospital of Nanjing Medical University, 230 Guangzhou Rd, Nanjing 210029, China

Contact E-mail Address: mahaiqin2010@163.com

Introduction: Microbiota dysbiosis in the gut has been suggested to play an important role in the pathogenesis of inflammatory bowel disease (IBD). In the present study, we sought to elucidate the effects of iron supplementation on hypoxia-mediated responses in the intestinal epithelium. For this purpose, serum starved Caco-2 monolayers were subjected to normoxia (21% O2) or hypoxia (0.2% O2) in the presence and absence of ferric ammonium citrate (FAC) and the iron chelator deferoxamine (DFO). Total RNA was isolated and changes in the expression of tumor necrosis factor (TNF), interleukin (IL)-1β, DMT-1, FPN and ferritin was assessed by real-time quantitative PCR. Western blot analysis was performed with antibodies against ferritin, p-NF-kB, IκBα, p-FOXO6, p-p38 and LC3. mRNA synthesis in Caco-2 cells under hypoxia was blocked using actinomycin D. Chromatin immunoprecipitation experiments were carried using antibodies against NF-κB and primers for promoter binding regions of TNF and IL-1β. Healthy volunteers (n = 10) were subjected to hypoxic conditions resembling an altitude of 4,000 m above sea level for 3 h using a hypobaric chamber. Serum samples were collected the day prior to hypoxia, and one day, one week and one month after hypoxia.

Introduction: Environmental hypoxia has been established to influence the development of inflammatory bowel disease (IBD). Adaptive responses to low oxygen tension are mediated through hypoxia inducible factor (HIFs), which are tightly regulated by oxygen and iron levels through the action of hemoxygenases. Dietary iron is mainly absorbed by duodenal enterocytes through the divalent metal transporter (DMT)-1. Once iron is inside the enterocytes, it is either sequestered into ferritin or transported out of the enterocyte into the circulation by ferroportin (FPN). Regulation of uptake, storage and export of iron is mediated by signals reflecting oxygen and intracellular iron levels in enterocytes, and systemic iron regulation is the liver hormone hepcidin, which regulates and is regulated by systemic iron levels. Hepcidin expression is induced by cytokines and results in anemia of inflammation.

Results: Hypoxia-induced the mRNA expression of TNF and IL-1β concomitantly with the iron transporters DMT-1 and FPN. In Caco-2 cells under hypoxia, hepcidin mRNA was induced p-mTOR and blocked autophagy. Iron overload enhanced decay of TNF, but not IL-1β mRNA. Iron also prevented binding of NF-κB to the promoter of TNF and IL-1β. Healthy volunteers presented reduced serum levels of iron, as well as transferrin saturation. Ferritin levels were unchanged indicating an increase of inflammation and suggesting enhanced intracellular iron accumulation in enterocytes following hypoxia.

Conclusion: Our results suggest that hypoxia-mediated iron uptake is crucial to counteract hypoxia-induced pro-inflammatory gene expression, and identify iron intracellular uptake and storage as a hypoxia protective mechanism to reduce mucosal inflammation.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** In both forms of inflammatory bowel disease (IBD), Crohn’s disease (CD) and ulcerative colitis (UC), inflammation of the gut wall is associated with extracellular tissue acidification. Low extracellular pH stimulates the family of proton-sensing G-protein coupled receptors (GPRCs); ovarian cancer G-protein coupled receptor 1 (GPR1), T-cell death-associated gene 8 (TDAG8) or G-protein coupled receptor 4 (GPR4), which activate specific signal transduction cascades. Recent studies reported a link between IBD and this family of pH-sensing receptors; in genome-wide association studies (GWAS), TDAG8 has been identified as an IBD-risk gene. The mechanism behind the influence on disease and IBD remains unclear. OGR1 and TDAG8 are both suggested to act in opposition by regulation of the inflammatory response; enhancing or inhibiting inflammatory pathways respectively, however the interplay between OGR1 and TDAG8 is unclear.

**Aims & Methods:** In this study we aimed to investigate the role of OGR1 in IBD patients. Expression of OGR1 in surgical specimens from non-IBD (n = 5), CD (n = 10) and UC (n = 10) patients was determined by immunohistochemistry, RT-qPCR and Western blotting. Clinical disease activity was assessed by the Harvey–Bradshaw Index (HBI) and the Modified Truelove and Witts activity index (MTWI)10 for CD and UC patients, respectively. Nonparametric Spearman’s rank correlation analysis was performed.

**Results:** OGR1 immunostaining of human surgical samples from non-IBD patients revealed OGR1 expression mainly in lamina propria cells, with weaker staining in epithelial cells. OGR1 staining in IBD patients was stronger compared to controls; however, in IBD patients OGR1 is highly expressed in both epithelial and lamina propria cells. Further, paired samples taken at the same time, from non-inflamed and inflamed intestinal tissue from IBD patients showed stronger OGR1 staining in the inflamed mucosa compared to the non-inflamed mucosa. Accordingly, mRNA and protein expression of OGR1 was significantly increased in IBD compared to non-IBD patients. Additionally, a significant positive correlation was observed between OGR1 expression and the clinical score in both the non-inflamed (r = 0.731, p = 0.0069) and the inflamed mucosa (r = 0.7698, p = 0.0054).

**Conclusion:** Expression of OGR1 is significantly increased in patients with IBD. OGR1 expression correlates with IBD disease activity, suggesting an active role for OGR1 in IBD pathogenesis. OGR1 appears to be a therapeutic target among the pH-sensing receptors involved in IBD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** Increased **Bifidobacteria** and **Lactobacilli** in the SA group is consistent with the previous study. A possible explanation is the consumption of fermented foods in the SA group although there was no difference between healthy SA and Caucasian controls. There is a trend towards lower diversity in the SA group and reduced **Bacteroides** which are consistent with the UC dysbiosis described in the literature. Functional analysis of this unique microbial profile through metagenomic and metabolomic techniques may explain the different disease behaviour in the SA group.

**Introduction:** There is evidence for vitamin D as an immunomodulator in patients with IBD, but results from clinical trials to date are inconclusive. It is uncertain whether vitamin D supplementation may affect the intestinal microbiota.

**Aims & Methods:** This study aimed to assess the effect of vitamin D replacement in deficient patients with and without ulcerative colitis (UC) on inflammation and faecal microbiota. Vitamin D was replaced over 8 weeks to patients with active UC, inactive UC, and non-IBD controls with baseline 25(OH) vitamin D < 30 nmol/L, and markers of inflammation and stool collected for microbiota analyses by next generation sequencing.

**Results:** Eight patients with active UC, 9 with inactive UC and 8 non-IBD controls received 40,000 units of vitamin D weekly for 8 weeks. No demographic differences were noted across the groups. Mean baseline 25(OH) vitamin D levels were 34 (range 12–49) nmol/L. Vitamin D supplementation increased mean 25(OH) vitamin D to 111 (range 71–158) nmol/L (P = 0.001), and reduced para-thyroid hormone levels from mean 4.3 to 3.3 pmol/L (p = 0.017). No change in baseline medications for UC took place in patients with UC, except for one patient with active UC who ceased his 5-aminosalicylic. Faecal calprotectin levels reduced from median 275 to 91 μg/g (p = 0.023) in patients with active colitis, but did not change in patients with inactive colitis or non-IBD controls. Similar improvements in albumin, platelet count and symptomatic disease activity indices were noted. No changes in overall bacterial diversity were noted. There was a trend towards an increase in abundance of *Ruminococcus gnavus* post vitamin D supplementation in active UC patients, but this did not reach statistical significance.

**Conclusion:** Vitamin D supplementation was associated with reduced intestinal inflammation in patients with active UC. A randomised controlled trial evaluating vitamin D in IBD is required along with further investigation of potential mechanisms by which vitamin D may alter specific microbial composition.

**Introduction:** Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity, which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

**Aims & Methods:** Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity, which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

**Results:** Luminal UDCA-LPE reduced the PLA2 activity in stool by 36.4%-8%. Concomitantly no inflammatory phenotype was observed when compared to knd2-/- mice not treated with UDCA-LPE. The improvement was documented in regard to stool consistency, calprotectin levels in stool, and macroscopic/analytic as well as histologic features of the mucosa. The pattern of colonic microbiota distribution obtained in the UC phenotype mice was reversed by UDCA-LPE to the control mice pattern. Construction of the bacterial ectophospholipase A2 activity improves mucosal inflammation in a genetic mouse model of UC. It is assumed that the remaining mucus PC shield is better preserved when luminal PLA2 is suppressed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory bowel diseases (IBDs), Crohn’s disease (CD) and ulcerative colitis (UC), are typically associated with a loss of homeostasis in local pH. Genome-wide association studies (GWAS) identified over 240 non-overlapping single-nucleotide polymorphisms (SNP) associated with IBD, G-protein-coupled receptor 65 (GPR65) or Toll death associated gene 8 (TDAG8) has recently been reported to be a genetic risk factor for IBD. The gene of the lead SNP GPR65 SNP (rs8005161) within the GPR65 gene confers increased IBD risk. In response to extracellular acidification, GPR65 activates second messengers: cAMP, via the Gs signaling pathway, and G12/13/Rho signaling.

**Results:** Sequenced genotype frequency of rare homozygote rs8005161 in the SIBDCS was 1.17%, minor allele frequency (MAF) - 10.3%. The variant rs8005161 was more frequent in UC patients (M AF 14.53% vs 10.05% in the non-IBD group), whereas no statistically significant association with IBD, CD or UC was found for the other variants (GPR65 rs3742704, GALC rs1805078) by Taqman genotyping. No significant differences were observed in the cAMP production between IBD (WT/CC, CT, TT) and non-IBD (WT/CC) genotype carriers upon pH shift from 7.6 to 6.6. A decreased activation of GTPase Rhôo was detected in IBD (WT/CT, TT) patients as compared to non-IBD (WT/CC) patients (r=0.807), but no differences between rs8005161 TT, CT and CC patients was observed.

**Conclusion:** The minor T allele of the GPR65 associated SNP rs8005161 was significantly enriched in UC patients. Rhôo signaling was reduced in IBD patients as a result of a reduced activation of GTPase Rhôo signaling in IBD versus controls. However, no differences in cAMP signaling in IBD TT/CC subjects compared to healthy CC subjects were observed. Our results suggest impaired Rhôo signaling in IBD patients upon a pH shift, indicating a mechanistic explanation for increased IBD risk with GPR65 polymorphisms.

**Introduction:** Macrophages contribute to fibrosis through the release of different mediators and the pattern of secretion may vary according to their phenotype. Recent evidences have identified Wnt pathway as an emerging modulator of fibrosis.

**Aims & Methods:** The aim of the present study is to analyze the pattern of expression of macrophage markers and Wnt ligands in surgical resections from Crohn’s disease (CD) patients with different disease behavior. CD patients were categorized according to Montreal classification (age at diagnosis, location and behavior). mRNA was isolated from resections of patients presenting an structuring (B2) or a penetrating (B3) behavior or from patients with colorectal cancer (control). The expression of macrophage markers (CD206, CD86, iNOS, Argenae), Wnt ligands (Wnt1, Wnt2, Wnt3, Wnt4, Wnt5a, Wnt5b, Wnt6, Wnt7a, Wnt7b, Wnt8a, Wnt8b, Wnt9b, Wnt10a, Wnt10b and Wnt16) and DKK1 (inhibitor of Wnt signaling) was analyzed by RT-

**Results:** B3-patients seem to present a higher infiltration of macrophages since increased expression of markers classically used to detect pro-inflammatory (CD68) and regulatory/pro-resolving/pro-fibrotic phenotypes (CD206, ARG2) was detected in this group. These patients also presented a generalized increased expression of Wnt ligands together with augmented DKK1 mRNA levels. B2-patients showed a more complex situation with ligands that present increased (Wnt3), reduced (Wnt2B) or unchanged expression in the absence of significant variations in the levels of macrophage markers (Table). Table. Relative (G/A) mRNA expression (fold induction vs control group) of genes with detectable levels. Data are expressed as Mean±SEM with n ≥ 7 in all groups and analyzed by ANOVA + Keenan-Keuls test. (P< 0.05 vs control; #p < 0.05 vs B2).

**Conclusion:** Crohn’s disease patients presenting a structuring (B2) or a penetrating (B3) behavior undergoing surgical resection differ in the pattern of macrophage infiltration and Wnt signaling.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** M2 macrophages play a key role in injury repair and fibrosis. We have reported that STAT6-dependent macrophages mediate mucosal repair after TNBS-induced acute colitis 3 and that, in a chronic model, STAT6-deficient animals accumulate macrophages expressing the CD16 marker that promote intestinal fibrosis 2.

**Aims & Methods:** We aim to analyze whether the expression of the pro-fibrotic mediator TGFβ is related with this macrophage phenotype and the relevance of these cells in murine intestinal fibrosis. Murine peritoneal macrophages obtained from both WT or STAT6 (-/-) mice were treated with IL-4 (20 ng/ml), IL-10 (10 ng/ml) or vehicle and the mRNA expression of CD16 and TGFβ was analyzed 72h later by qPCR. WT or STAT6 (-/-) mice were weekly administered with TNBs (0.5, 0.5, 0.75, 0.5, 1, and 1 mg, intrarectally) or saline and were sacrificed 7 weeks after the first TNBs administration. The mRNA expression of CD16, TGFβ, Vimentin, Coll1a1, a-SMA, MMP2 and TIMP1 was evaluated in murine intestinal mucosa by qPCR. In all cases results were expressed as fold induction vs vehicle and the correlation between different measurements was analyzed using Pearson’s correlation coefficient (r).

**Results:** A positive and significant correlation between CD16 mRNA and TGFβ mRNA was observed in isolated macrophages from WT mice (r = 0.637, P = 0.03) and STAT6 (-/-) mice (r = 0.677, P = 0.002) receiving different treatments. In the mucosa of WT and STAT6 mice the expression of TGFβ showed a significant positive correlation with CD16 mRNA (r = 0.60, P < 0.001), and with the expression of several fibrotic markers (vimentin: r = 0.637, P < 0.001; Colla1: r = 0.5101, P = 0.0003; a-SMA: r = 0.4126, P = 0.0048; MMP2: r = 0.5729, P = 0.0001; and TIMP1: r = 0.3958, P = 0.0071).

**Conclusion:** The expression of TGFβ is associated with CD16 positive cells and is involved in murine intestinal fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: The present study is to analyze the pattern of expression of macrophages and the expression of Wnt10b in human macrophages from clinical samples from Crohn’s disease (CD) patients with A2-stratifying and B3-penetrating behavior according to Montreal classification (age at diagnosis, location and behavior) as well as from non-inflamed tissue from cancer patients. Resections were immediately processed and lamina propria mononuclear cells characterized by flow cytometry. Macrophages were identified within singlet viable leukocytes as CD45 + CD14 + CD64 + . The percentage of CD206, CD16, CD163, CD86 and Wnt10b positive cells was analyzed in macrophages. Data are expressed as Mean±SEM % with n≥5 in all groups (P<0.05 vs control; Student's t test).

Results: The percentage of macrophages identified as CD45 + CD14 + CD64 + constituted the 0.22±0.03% of total events in the control mucosa while represented the 1.35±0.40% in the mucosa from CD patients (p<0.05). A high proportion of myofibroblasts/macrophages expressed CD206 in both, control (83.3±4.8%) and CD (89.6±3.9%). In these CD206+ cells, an increased expression of CD16 in CD mucosa was observed (Control: 34.5±6.8%; CD: 59.7±6.4%) while that of CD163 was similar in both groups (control: 72.8±8.4%; CD: 85.2±7.3%). The analysis of Wnt10b in CD206+ showed a significantly higher expression in CD patients (56.6±4.2%) than in control samples (30.1±10.4%). Additionally, CD86+ macrophages were more abundant in control (1.7±0.3) and CD (29.3±10.2) mucosa.

Conclusion: The mucosa of CD patients accumulate pro-inflammatory macrophages measured as CD86+ cells while those macrophages expressing the M2-marker CD206 after their phenotype increasing the expression of both, CD16 and CD163. This could be the profibrotic mediator Wnt10b.

Introduction: For inflammatory bowel disease (IBD), anaemia is the most frequently observed extra intestinal finding, prevalence of which varies from 6% to 74%. It’s of great importance to determine and treat anaemia as it lowers patients’ life quality and leads to labour loss. The main causes of anaemia in IBD are iron deficiency anaemia (IDA) and anaemia of chronic disease (ACD). In this study, we aim to specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD).

Aims & Methods: In this study, we specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD).

Results: We specified the following types of anaemia: IDA only (29.7%), IDA and ACD together (4.8%) while that of CD163 was similar in both groups (control: 72.8±8.4%; CD: 85.2±7.3%). The analysis of Wnt10b in CD206+ showed a significantly higher expression in CD patients (56.6±4.2%) than in control samples (30.1±10.4%). Additionally, CD86+ macrophages were more abundant in control (1.7±0.3) and CD (29.3±10.2) mucosa.

Conclusion: The mucosa of CD patients accumulate pro-inflammatory macrophages measured as CD86+ cells while those macrophages expressing the M2-marker CD206 after their phenotype increasing the expression of both, CD16 and CD163. This could be the profibrotic mediator Wnt10b.

Introduction: Intestinal fibrosis is a common complication of IBD and macrophages can contribute to fibrosis through the release of different mediators. We have recently reported that Wnt10b increases the deposition of collagen and promotes intestinal fibrosis in TNBS-treated mice (P015 ECCO 2017).

Aims & Methods: The aim of the present study is to analyze the pattern of expression of macrophages and the expression of Wnt10b in human macrophages from clinical samples from Crohn’s disease (CD) patients with A2-stratifying and B3-penetrating behavior according to Montreal classification (age at diagnosis, location and behavior) as well as from non-inflamed tissue from cancer patients. Resections were immediately processed and lamina propria mononuclear cells characterized by flow cytometry. Macrophages were identified within singlet viable leukocytes as CD45 + CD14 + CD64+. The percentage of CD206, CD16, CD163, CD86 and Wnt10b positive cells was analyzed in macrophages. Data are expressed as Mean±SEM % with n≥5 in all groups (P<0.05 vs control; Student’s t test).

Results: The percentage of macrophages identified as CD45 + CD14 + CD64+ constituted the 0.22±0.03% of total events in the control mucosa while represented the 1.35±0.40% in the mucosa from CD patients (p<0.05). A high proportion of myofibroblasts/macrophages expressed CD206 in both, control (83.3±4.8%) and CD (89.6±3.9%). In these CD206+ cells, an increased expression of CD16 in CD mucosa was observed (Control: 34.5±6.8%; CD: 59.7±6.4%) while that of CD163 was similar in both groups (control: 72.8±8.4%; CD: 85.2±7.3%). The analysis of Wnt10b in CD206+ showed a significantly higher expression in CD patients (56.6±4.2%) than in control samples (30.1±10.4%). Additionally, CD86+ macrophages were more abundant in control (1.7±0.3) and CD (29.3±10.2) mucosa.

Conclusion: The mucosa of CD patients accumulate pro-inflammatory macrophages measured as CD86+ cells while those macrophages expressing the M2-marker CD206 after their phenotype increasing the expression of both, CD16 and CD163. This could be the profibrotic mediator Wnt10b.

Introduction: IBD is a chronic disorder of the gastrointestinal tract characterized by disruption of epithelial barrier function and gut inflammation. Evidence supports a relevant role of succinate, an intermediate of the tricarboxylic acid cycle1, in inflammation and the succinate receptor, SUCNR1, has been recently reported with rheumatoid arthritis2.

Aims & Methods: To analyze the role of SUCNR1 in a murine model of colitis induced by TNBS. WT or SUCNR1C11−/− mice received TNBS (3.5 mg/20g mice, intrarectally) or vehicle (EtOH 40%) and were weighed daily (results are expressed as percentage vs the weight at day 0 and mice were sacrificed 2 and 4 days after TNBS administration. Colon length and mucosal histology were evaluated. The mRNA expression levels of the inOS, Arginase I, COX-2, TNF-α, IL-1β, IL-6 and IL-10 was assessed by qPCR.

Results: Treatment of mice with TNBS induced a loss of body weight that peaked 4 days after TNBS administration. Colon length and mucosal histology were evaluated according to Wallace Score (1–10). The mRNA expression levels of iNOS, Arginase I, COX-2 (Table 1) were significantly different between TNBS-treated WT mice, as compared with TNBS-treated WT mice: a) the loss of body weight was significantly (P < 0.05) attenuated (96.99 ± 0.7% vs 91.78 ± 1.1%); b) the reduction in colon length was prevented (6.6 ± 0.2 vs 5.2 ± 0.2); and c) the mRNA expression was significantly (3.5 ± 0.2 vs 4.8 ± 0.5) increased two days after TNBS treatment. The increase in the expression of pro-inflammatory molecules was significantly prevented (P < 0.05) in TNBS-treated SUCNR1C11−/− mice compared with TNBS-treated WT mice.

Conclusion: Activation of the succinate receptor SUCNR1 mediates murine colitis. These findings highlight the biological significance of SUCNR1 and open the door to novel approaches for IBD treatment.

Aims & Methods: Our aim was to investigate the role of ZIP7 in IBD initiation and progression. We investigated the expression of ZIP7 in the intestinal mucosa of IBD patients and in interleukin-10–deficient (Il10C11−/−) mice, and assessed the relation between ZIP7 and disease activity. ZIP7 upregulated downregulated lenivius was used to infect IEC6 and HEC cells, then we evaluated the expression of inflammatory factors, mucosal tight junction proteins (Occludin and ZO-1), and proteins related with endoplasmic reticulum stress (IRE1, XBP1, TRAF2, ASK1 and p-JNK). In addition, we used siRNA to silence IRE1 and SP600125 to inhibit the JNK pathway respectively, then evaluated the effect of endoplasmic reticulum stress on mucosal tight junction proteins.

Results: We found that ZIP7 was downregulated both in the intestinal mucosa of IBD patients and in Il10C11−/− mice, which was associated with disease activity. In IEC6 and HEC cells, the expression of mucosal tight junction proteins was consistent with the level of ZIP7, but the expression of inflammatory factors, mucosal tight junction proteins (Occludin and ZO-1), and proteins related with endoplasmic reticulum stress associated proteins were on the contrary. After the silence of IRE1 and the inhibition of JNK pathway, the expression of mucosal tight junction proteins was partly returned in ZIP7 downregulated cells.

Conclusion: ZIP7 induces disruption of the intestinal barrier, which was associated with activation of endoplasmic reticulum stress in IBD. It is expected to provide a novel mechanism of IBD and provide a new target for the treatment of IBD.

Introduction: Enteric glia cells (EGC) are essential for intestinal homeostasis. In healthy intestines, EGC reduce IEB permeability and the reactive EGC functional impact on IEB permeability was studied (i) in vitro by grafting the treated rat EGC in colon wall of Sprague Dawley rats. In vivo colon wall grafting with control EGC did not modified the permeability whereas colon wall grafting with EGC preconditioned by TI significantly reduced

Results: Analyses reveal that non-activated T lymphocytes are capable of interacting with EGC. They also show that activation of T cells with anti-CD3/anti-CD28 antibodies increases the number of T lymphocytes interacting with EGC. Interestingly, an increased number of EGC-T cell interactions was observed after pretreatment of EGC with inflammatory stimuli. This phenomenon was also noted with activated T cells. Characterization of T cells show that both CD4 and CD8 cells are capable of contact with EGC.

Conclusion: Our present data reveal that EGC interact with T cells. These contacts are favored by T cell activation but also by EGC exposure to inflammatory cytokines. Further experiments are required to characterize these neuro-immune interactions but they suggest that EGC-T cell contact may play a crucial role in case of inflammatory bowel diseases. This work is supported by the Association François Aupetit.

Contact E-mail Address: malvine.derkerdiner@univ-nantes.fr

Introduction: Enteric glial cells (EGC) are essential for intestinal epithelial barrier (IEB) homeostasis. In healthy intestines, EGC reduce IEB permeability and promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn’s Disease (CD) and Ulcerative Colitis (UC), both EGC phenotype and IEB functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC in case of chronic inflammation is not well documented. We investigated whether EGC-IEB interactions are altered in an inflammatory environment and in IBD patients.

Aims & Methods: Rat EGC as well as human EGC from control, CD and UC patients were stimulated with the cytomix TI (TNFalpha + IL1beta + 100 ng/ml) or LPS for 2 or 4 days. Reactive EGC phenotype were characterized and reactive EGC functional impact on IEB permeability was studied (i) in vitro using human intestinal epithelial cells (IEC6) in a non-co-tact co-culture model, or (ii) in vivo by grafting the treated rat EGC in colon wall of Sprague Dawley rats.

Results: Rat and human control EGC induced a significant reduction of IEB permeability in vitro, whereas IBD EGC induced a significant increase of IEB permeability. IBD EGC were also used to characterize the subpopulations of T cells (CD4+, CD8+) that contact glial cells.

**P1626** PROSTACYCLIN REVERSES COLITIS THROUGH THE DOWN REGULATION OF INTESTINAL EPITHELIAL PERMEABILITY

C. Pochard1, P. Aubert1, C. Gesret1, N. Cenac1, A. Bourreille1, G. Meuret1, E. Coron1, M. Neunlist1, M. Rolli-Derinderen1

11235 Inserm, TENS, Nantes/France

**Introduction:** In inflammatory bowel disease (IBD) both intestinal epithelial barrier (IEB) permeability and PTGIS expression are altered. Nevertheless the role of the lipid mediator PG12 produced by PTGIS in IEB permeation is unknown. The present study concerns the control of IEB permeability by PG2 and its involvement in the development of colitis.

**Aims & Methods:** The role of PG12 production from control or IBD biopsies was established using high sensitivity liquid chromatography tandem mass spectrometry. Consequences of flolan PG12 analogous supplementation were evaluated in a DSS-induced mice model of colitis, measuring disease activity index (DAI), inflammation (pro-inflammatory cytokine mRNA) and IEB permeability (sulfonic acid flux). Molecular mechanisms involved were assessed by quantification of junctional and pro-proliferative pro-apoptotic protein expression (western blot and immunostaining). Eventually PG12 impact on reversing IEB breakdown was assessed ex vivo measuring permeability of mice or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IBD biopsies both treated or not with flolan.

**Results:** Biopsies from IBD patients had lower PG12 production compared to control patients, and addition of flolan reduced their permeability. In vivo PG12 supplementation significantly reduced DAI, and inflammation (Interferon mRNA) as well as reduced IEB permeability. DSS-induced cleavage of Caspase 3 is normalized by flolan.

**Conclusion:** This study not only presents a role of PG12 in controlling IEB permeability through the regulation of apoptosis mechanisms, but also reveals that increased permeability in IBD patients can be fixed by PG12 supplementation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ulcerative colitis (UC) is a clinical type of inflammatory bowel diseases. The pathogenesis of UC remains unclear. Nowadays the role of Th17 helpers type 17 (Th17) as well as cytokines they release is discussed in pathogenesis of autoimmune inflammation in UC.

**Aims & Methods:** The aim of study is to analyze the serum levels of following cytokines: interleukin (IL)-17A and F, 21, 22, 23, 10 in UC patients both in the acute stage of disease and remission. Forty eight UC patients in the acute stage and twenty patients in remission were included into the study. Serum cytokine levels were analyzed using multiplex immunoassay for Th17 cytokines (Bio-Rad, USA). Statistical analysis was performed using STATISTICA 6.0 Software Package. The control group consisted of 11 healthy volunteers.

**Results:** Statistically significant increase of IL-17A level (15 pg/ml [12.11;23.38]; 14.68 pg/ml [11.29;17.19] respectively) was observed in patients with UC both in acute stage and remission compared to controls (7.36 pg/ml [5.18;8.06]; p = 0.00007, p = 0.00029 respectively). The same trend was observed regarding IL-21, which median values were higher both in acute stage (156.51 pg/ml [133.44;233.53]) and remission (144.02 pg/ml [133.44;154.43]) compared to control group (98.31 pg/ml [89.14;124.86]), and showed statistically significant differences (p = 0.00077, p = 0.00054 respectively). Besides it was revealed that IL-17F and IL-22 were also higher in acute stage (136.5 pg/ml [68.05;228.185] and 3.76 pg/ml [1.55;8.33], respectively) compared to controls (48.7 pg/ml [38.7;87.6], and 2.6 pg/ml [1.7;3.2], respectively), however differences were not statistically significant (p = 0.06; p = 0.172, respectively). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation.Statistically significant increase of IL-10 in remission (27.99 pg/ml [17.53;33.55]) compared to controls (4.36 pg/ml [3.26;15.25], p = 0.0046) was found as well. IL-10 was also higher in patients with acute stage (21.93 [3.61;35.35]) compared to controls, however differences were not statistically significant (p = 0.065). IL-10 as an anti-inflammatory cytokine characterizes the activity of regulatory T-cells which suppress autoimmune inflammation. In addition, it was revealed that the level of IL-23 which stimulates Th17 differentiation was both higher in acute stage (258.4 pg/ml [55;367.49]) and remission (244.93 pg/ml [124.3;301.93]) compared to controls (124.3 pg/ml [107.9;296.04]), however differences were not statistically significant.

**Conclusion:** Increase of IL-17A, IL-17F, IL-21, IL-22 levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. IL-17A and IL-21 produced by Th17 cells might be considered as markers of active autoimmune inflammation in UC patients.

Introduction: The steroid-refractoriness is a common complication of ulcerative colitis (UC) with an unproven antirefractory mechanism of action (MoA) that has been implicated in corticosteroid failure. However, there are no conclusive studies on the molecular functions involved in UC steroid-refractoriness.
Aims & Methods: Therefore, we decided to know in depth the MoA related to the steroid-refractoriness of UC patients with UC treated with glucocorticoids. RNA from rectal biopsies was obtained before and on the 3rd day of glucocorticoid treatment. Then, whole-genome expression using microarrays (Illumina, USA) and profiles microRNA by sequencing (Illumina, USA) were analysed. After quality control, omics data were compared between phenotypes. The results of these comparisons were integrated into mathematical models generated by means of Systems Biology.
Results: These models reproduce the updated molecular interactions on glucocorticoids and UC, and integrating our experimental data, we identified a potential MoA that includes 64 key proteins, 18 of them capable of perfectly classifying patients with a good response to glucocorticoids and the non-responders. The biological functions of these proteins have been associated with inflammation (e.g. RelA), glucocorticoid receptor transcription (e.g. NR3C1 and NCOA3) and angiogenesis (e.g. VEGF), mainly. But among these 18 proteins, the ANP32E has never been related to either steroid-refractoriness or ulcerative colitis. ANP32E is a 30 kDa protein (A-type) that is part of the chromatin (flanking DNA regions recognized by the glucocorticoid receptor). Additional WB and immunofluorescence assays confirm differences in the intestinal levels of ANP32e and in the nuclear localization at baseline, between patients with drug refractory UC.
Conclusion: In conclusion, this study has identified a potential new MoA related to UC steroid-refractoriness involving chromatin remodeling modifications.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1630 CO-HOUSING DSS TREATED MICE WITH HEALTHY MICE RESULTS IN FASTER NORMALIZATION OF THE INTestinal MICROBIOTA AND PROMOTES RECOVERY
M.R. Spalinger1, L. Hering1, C. Gottièr1, S. Lang1, G. Rogler2, M. Scharf3

Contact E-mail Address: marianne.spalinger@usz.ch
Introduction: The intestine is populated with myriads of bacteria, which form a complex ecosystem and have tremendous impact on our health. In inflammatory bowel disease (IBD), shifts in microbiota composition and a reduction in overall diversity (decreased Shannon index, \( p < 0.01 \)) and a marked shift in the composition of the microbiota (increased abundance of Verrucomicrobia, Cyanobacteria and some families of Firmicutes [mainly Clostridiae], although overall abundance of Firmicutes was decreased \( \text{p} < 0.01 \)) was observed between the percentage of expression of sulfomucins at surgery, at 6 or 12 months after ileo-colonic resection (1). In the present study, correlation between the percentage of expression of sulfomucins and clinical recurrence was evaluated for 5 years. Colonic phenotype of the ileum as assessed by the expression of sulfomucins (colon mucin-type) and saIomucins (small intestine mucin-type) (1). In the present study, correlation between the percentage of expression of sulfomucins and clinical recurrence was evaluated for 5 years. Statistical analysis: results expressed as median (range), correlations were assessed by the Spearman correlation test, differences between groups by the unpaired T test.
Results: After ileo-colonic resection, clinical follow up at 5 years was completed by 17/19 (89.4%) CD patients enrolled (12 males, age 41 [17–73]). The percentage of expression of sulfomucins (colon phenotype) as assessed in the ileal surgical specimens was significantly correlated with the CDAI score at 4 years \( (r = 0.62; \text{p} = 0.007) \) and at 5 years \( (r = 0.6; \text{p} = 0.010) \). Differently, in the ileal biopsies at 6 months with vs without clinical recurrence, both at 12 months \( (r = 0.53; \text{p} = 0.03) \) and at 5 years \( (r = 0.53; \text{p} = 0.02) \). The ileal expression of sulfomucins in the ileal biopsies at 12 months was higher in patients with vs without clinical postoperative recurrence at 2 years \( (40 [10–99] \text{vs} 5 [0–30]; \text{p} = 0.044) \). The expression of colon mucin-type in the ileal biopsies at 12 months was higher in patients with vs without clinical recurrence, both at 12 months \( (30 [1–40] \text{vs} 0 [0–35]; \text{p} = 0.02) \) and at 2 years \( (30 [0–40] \text{vs} 0 [0–33]; \text{p} = 0.029) \). No correlations were observed between the percentage of expression of sulfomucins at surgery, at 6 or 12 months and the haematochemical parameters considered.
Conclusion: In CD, colonic phenotype of the ileum as assessed by the expression of ileal sulfomucins, may represent a predictive marker of clinical recurrence after ileo-colonic resection for CD.

Introduction: In Crohn’s Disease (CD), colonic phenotype of the ileum has been reported in severe lesions, but not in CD ileum with no lesions or with early post-operative recurrence (1).
Aims & Methods: In a prospective study at 5 years, we aimed to address whether colonic phenotype of the ileum may represent a subclinical marker of clinical postoperative recurrence in CD. At this purpose, clinical recurrence was assessed yearly for 5 years in a cohort of CD patients with colonic phenotype of the ileum already defined at surgery, 6 and at 12 months after ileo-colonic resection (1). A cohort of CD patients with clinical recurrence already assessed and reported at 6 and 12 months after ileo-colonic resection (1), was clinically followed up for additional 4 years. In the 5 years follow up, indication for treatments, haematochemical, radiological and/or endoscopic assessments was given according to current European guidelines (2). Haematochemical assessments included whole blood count, ESR, serum CRP evaluation yearly for 5 years, with possible additional assessments, according to clinical indications. Clinical recurrence (CDAI > 150) was assessed yearly for 5 years. Colonic phenotype of the ileum was already reported at surgery, at 6 and 12 mos, according to the expression of sulfomucins (colon mucin-type) and saIomucins (small intestine mucin-type) (1). In the present study, correlation between the percentage of expression of sulfomucins and clinical recurrence was evaluated for 5 years. Statistical analysis: results expressed as median (range), correlations were assessed by the Spearman correlation test, differences between groups by the unpaired T test.
Results: After ileo-colonic resection, clinical follow up at 5 years was completed by 17/19 (89.4%) CD patients enrolled (12 males, age 41 [17–73]). The percentage of expression of sulfomucins (colon phenotype) as assessed in the ileal surgical specimens was significantly correlated with the CDAI score at 4 years \( (r = 0.62; \text{p} = 0.007) \) and at 5 years \( (r = 0.6; \text{p} = 0.010) \). Differently, in the ileal biopsies at 6 months with vs without clinical recurrence, both at 12 months \( (r = 0.53; \text{p} = 0.03) \) and at 5 years \( (r = 0.53; \text{p} = 0.02) \). The ileal expression of sulfomucins in the ileal biopsies at 12 months was higher in patients with vs without clinical postoperative recurrence at 2 years \( (40 [10–99] \text{vs} 5 [0–30]; \text{p} = 0.044) \). The expression of colon mucin-type in the ileal biopsies at 12 months was higher in patients with vs without clinical recurrence, both at 12 months \( (30 [1–40] \text{vs} 0 [0–35]; \text{p} = 0.02) \) and at 2 years \( (30 [0–40] \text{vs} 0 [0–33]; \text{p} = 0.029) \). No correlations were observed between the percentage of expression of sulfomucins at surgery, at 6 or 12 months and the haematochemical parameters considered.
Conclusion: In CD, colonic phenotype of the ileum as assessed by the expression of ileal sulfomucins, may represent a predictive marker of clinical recurrence after ileo-colonic resection for CD.

Introduction: Immunization of a quadrivalent influenza vaccine (A/California/7/2009(H1N1)pdm09, A/Switzerland/9715293/2013(NIB-88) (H3N2), B/Phuket/3073/2013, and B/Texas/2/2013) began in the 2015/2016 season. We assessed the immunogenicity and booster effect of quadrivalent influenza vaccine for adult inflammatory bowel disease patients treated with immunosuppressive drugs and/or anti-TNF-α agents.

Aims & Methods: Single vaccination group and booster group were randomly assigned to adult patients with crohn’s disease or ulcerative colitis, and quadrivalent influenza vaccine was administered subcutaneously. Serum samples were collected at 3 points (before vaccination, 4 weeks after the first vaccination, and after the end of the influenza season) in the single group and 4 points in the booster group (before vaccination, 4 weeks after the first vaccination, 4 weeks after the second vaccination and after the end of the influenza season). Antibody titer against influenza A strains in patients who maintained blood concentrations (SP%: 0.82; B/Texas: p = 0.79; B/Phuket: p = 0.82; B/Texas: p = 0.84). In patients treated with infliximab, serum protection rate (SP%) and seroconversion rate (SC%) tended to be lower in Indian and Pakistani groups. UC incidence was significantly higher in the Pakistani and Caucasian groups. UC incidence was significantly higher in the Indian population compared to Caucasians and Pakistanis (p < 0.001). Data for disease phenotype (Montreal classification) was collected onto the Epicom database. Chi-squared test was used to detect differences in IBD incidence between ethnic groups. A p value < 0.05 was considered significant.

Results: A total of 132 patients with IBD were randomly assigned to single vaccination and booster groups. Eighteen patients received immunomodulatory monotherapy and 20 received anti-TNF-α single agent therapy. Nineteen patients received combination therapy of immunosuppressant and anti-TNF-α agents. No significant difference between the single vaccination group and booster group was observed (American indian: H1N1: p = 0.81; H3N2: p = 0.79; B/Phuket: p = 0.82; B/Texas: p = 0.84). In patients treated with infliximab, serum protection rate (SP%) and seroconversion rate (SC%) tended to be lower in Indian and Pakistani groups. UC incidence was significantly higher in the Pakistani and Caucasian groups. UC incidence was significantly higher in the Indian population compared to Caucasians and Pakistanis (p < 0.001). Data for disease phenotype was available for 160/219 patients with UC (24% E1, 42% E2 and 34% E3). There was no significant difference in disease extent between ethnic groups.

Conclusion: The incidence rates for IBD in seven urban populations in England are similar to recent data from Western Europe (IBD 18.5/100,000, UC 9.8/100,000 CD 6.3/100,000 and IBDU 2.4/100,000). Ethnic-adjusted incidence rates showed that Indians have higher incidence of UC than Caucasians and Pakistanis with highest observed incidence in Northwest London. These findings are consistent with previous data suggesting that Indians have a higher predisposition for UC. Genetic, environmental and dietary factors may be responsible for differences and further analyses are underway. Better understanding of the susceptibility of Indians to UC may lead to the underlying cause of UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The global incidence of inflammatory bowel disease (IBD) is increasing. Migration may influence disease epidemiology. The UK demographics are affected by sustained migration from South Asia. The incidence of UC in South Asians (SA) was previously reported as higher than the Caucasian population.1,2 These single centre studies were done over 20 years ago. The current epidemiology of IBD in the multiethnic UK is unknown.

Aims & Methods: We aimed to describe the UK incidence of IBD and distribution within ethnic groups. Census data (2011) was used for background population size, ethnic groups and to identify areas with high SA populations where Indians and Pakistanis were the predominant groups. The incidence was calculated by using the number of subjects in each ethnic group in the background population as the denominator. Adult patients (>16 years) with newly diagnosed IBD (fulfilling Copenhagen diagnostic criteria) were prospective recruited over one year in 7 catchment areas with high SA population. Data including demographics, ethnic codes and disease phenotype (Montreal classification) was collected onto the Epicom database. Chi-squared test was used to detect differences in IBD incidence between ethnic groups. A p value < 0.05 was considered significant.

Results: Over 1 year IBD was diagnosed in 351 cases: 219 ulcerative colitis (UC), 107 Crohn’s disease (CD) and 26 inflammatory bowel disease unclassified (IBDU). Collective crude incidence rates were 15.54/100,000 for IBD, 9.69/100,000 for UC, 4.80/100,000 for CD and 1.01/100,000 IBDU. (Table 1) Crude IBD incidence rates varied between populations: lowest was 6.81/100,000 in Pennine, North Manchester and highest 26.11/100,000 in Leicester. Overall incidence of UC was higher than CD (9.69/100,000 vs 4.80/100,000) and was consistent for all populations except Pennine (3.31/100,000 for CD and 2.76/100,000 UC). Of the total number of IBD cases recruited 298/351 were coded as Caucasian, Indian or Pakistani. IBD, UC and CD incidence was similar between Pakistani and Caucasian groups. UC incidence was significantly higher in the Indian population compared to Caucasians and Pakistanis (p < 0.001). Data for disease phenotype was available for 160/219 patients with UC (24% E1, 42% E2 and 34% E3). There was no significant difference in disease extent between ethnic groups.

Conclusion: The incidence rates for IBD in seven urban populations in England are similar to recent data from Western Europe (IBD 18.5/100,000, UC 9.8/100,000 CD 6.3/100,000 and IBDU 2.4/100,000). Ethnic-adjusted incidence rates showed that Indians have higher incidence of UC than Caucasians and Pakistanis with highest observed incidence in Northwest London. These findings are consistent with previous data suggesting that Indians have a higher predisposition for UC. Genetic, environmental and dietary factors may be responsible for differences and further analyses are underway. Better understanding of the susceptibility of Indians to UC may lead to the underlying cause of UC.

Disclosure: The increasing incidence of anal canal (AC) carcinomas in men and women requires better knowledge on Human papillomavirus (HPV) infection at this site and its risk factors. Higher incidence of AC cancers in Crohn’s disease (CD) patients is strongly suggested in the literature, without knowledge on HPV involvement. A gastroenterology population offers the opportunity to study a mixed and non-sexually at risk selected population and to study anal HPV infection in CD patients.

Aims & Methods: The aim of the study was to assess AC HPV infection prevalence and risk factors in a gastroenterology population. The ‘Human PAPILLOMavirus ANaL infection’ - PAPILLAN- study took place in a French university hospital gastroenterology unit. Consecutive patients were prospectively recruited at the occasion of a colonoscopy, whatever the indication. On the day of colonoscopy, under local anesthesia, AC smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Results: A total of 469 consecutive patients (median age 54 years, 52% women) had suitable anal swabs for HPV DNA detection. Among them 101 had initial anal bowel disease (IBD), 70 had CD. 112 patients had at least one immunosuppressive treatment for IBD or another condition. Overall 34% of the population had a detection of any HPV type in AC smears. HR HPV prevalence was 18%, LR HPV prevalence was 9% and HPV16 prevalence was 7%. Most prevalent HR HPV types were, by decreasing order: HPV16, HPV51, HPV52 and HPV39. Among all patients with HPV positive or HR HPV positive samples, 65.6% and 65.9% were women, respectively (p = 0.0001; p = 0.0035, compared to men). Regarding medical history, HR HPV and HPV16 prevalence were signif- icantly higher in Crohn’s disease patients (90%, p = 0.0051; 14%, p = 0.0072, compared to the rest of the study population). Eleven (12%) patients (50%) with perianal CD had an AC infection with any HPV. Multivariable analysis associated female gender and history of sexually transmitted disease with the presence of HPV, lifetime and past year number of sexual partners, active smoking and immuno- suppressive treatment (OR 5.3) with the presence of HR HPV.

Conclusion: We demonstrated that CD patients harbor more frequent AC infec- tion with HR HPVs and that gut colonization with ESBL-E is associated with an independent risk factor for HR HPV infection at this site. These findings strongly support prophylaxis with vaccination and adequate screening in our patients.

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) is the most frequently found multi-resistant bacteria colonizing the gut of inflammatory bowel disease (IBD) patients. Changes in the micro- biome may act as a trigger in IBD inflammation process.

Aims & Methods: The aim of the study was to analyze whether gut colonization with Enterobacteria is associated with clinically relevant disease activity activity increase in ulcerative colitis (UC) and in Crohn’s disease (CD). All consecutive patients with confirmed UC and CD diagnosis, previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010-2016) were included in the study, interviewed, rectal swabs were collected, Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines. To clinically evaluate disease activity UC patients were evaluated according to Mayo score, Montreal classification, adapted Truelove and Witts criteria and CD patients according to Crohn’s disease activity index (CDAI), suggested by ECCO IBD guidelines (2016).

Results: A total of 101 patients with UC and 47 patients with CD were tested for gut colonization with ESBL-E. We found that 12 (11.9%) of the UC patients and 5 (10.6%) of the CD patients were colonized with ESBL-E. Statistical signifi- cant differences were found in all UC clinical disease activity scores between patients with and without gut colonization with ESBL-E and showed tendency towards statistical significance in CD. The mean disease activity according to Mayo score in UC patients without ESBL-E colonization was 3.44 (SD = 2.07), whereas in patients with ESBL-E colonization it was 5.08 (SD = 2.84) (p = 0.015).

Most of the UC patients without ESBL-E colonization (n = 63; 70.8%) were in clinical remission, whereas half of the patients with ESBL-E colonization (n = 0;
50% had mild to moderate to severe disease activity, according to Montreal classification disease activity index section (p = 0.037). Most of the UC patients with out ESBL-E colonization (n = 81; 91%) had mild disease activity, whereas half of the patients with ESBL-E colonization (n = 6; 50%) had moderate disease activity, according to modified Truelove and Witt’s criteria (p < 0.001). Most of the CD patients without ESBL-E colonization (n = 38; 90%) had moderate disease activity, whereas most of the patients with ESBL-E colonization (n = 3; 60%) had severe disease activity, according to CDAI (p = 0.05).

Conclusion: Gut colonization with ESBL-E might increase disease activity in out-patients with IBD. Such clinical findings could be clinically relevant and help to improve diagnostic and treatment protocols for IBD patients, because eradication of ESBL producing bacteria might reduce IBD disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Uptake of FCa home testing was 73% (48/66), median tests 4 (IQR 3, range 1–6). Median SUS score was 92.5 (IQR 15, range 45–100) which corresponds to a ‘superior product’. Qualitative interviews confirmed that TCUC was efficient, effective, easy to learn and well liked. Improvements suggested included optimisation of the graphical display on smartphones and decreasing the number of QoL questionnaires from three to one, with a preference for IBD-Control.

Disclosure of Interest: Patients with UC will collect digital data in real-time, with good adherence to symptom, QoL, outcome questionnaires and FCa home testing. Usability was classified as ‘superior’ but further improvements are possible. Larger studies are required to determine cost effectiveness.

Aims & Methods: We followed 198 IBD outpatients (144 CD and 54 UC) for 3 years to indentify potentional risk factors of unfavourable disease outcome. Baseline body composition were measured by bioelectrical impedance analysing (BIA) method to evaluate nutritional status. Penalized logistic regression was used for the multivariate modelling of the outcome, with two sets of - prespecified - predictor variables age, sex, CU/CD, BMI, FFMI.

Results: According to our results 19.2% of the patients (n = 38) were underweight (had BMI <18.5 kg/m²) and 29.8% (n = 59) had alarming low fat-free mass index (FFMI) and were at risk of sarcopenia. Overall 31.5% (n = 62) of the patients needed steroid therapy and 53.5% (n = 106) was given anti-TNF. Almost third of the participant (30.8%, n = 61) were hospitalized due to disease flair or its complication at least once during the follow-up time. The mean period of hospitalization was 19.14 ± 3.27 days. 20.2% (n = 40%) of all participants have undergone intestinal surgery. Hospitalization was positively associated with sarcopenia risk: alarming low FFMI was associated with an OR of 1.81 (95% CI: 1.33–4.47, p = 0.0046). The risk of operation was higher in patients with lower BMI: OR = 1.55 (95% CI: 1.05–2.29, p = 0.0278) for 5 units decrease; no other association was significant in the models.

Conclusion: Our results suggests that low BMI is a risk factor of surgery in inflammatory bowel disease patients. Furthermore alarming low FFMI is a predictor of need of hospitalization and that suggets more serious flares. Identification of malnutrition and altered body composition has notable importance in disease outcome among IBD patients.

CONTRAST-ENHANCED ULTRASOUND IS HELPFUL IN THERAPEUTIC DECISION MAKING IN PATIENTS WITH STRICTURING CROHN’S DISEASE
Z. Zelinkova1, B. Kadlecova2, D. Podmanicky3
1Department Of Gastroenterology, St. Michael’s Hospital, Bratislava/Slovak Republic
2IBD Center, Bratislava/Slovak Republic
3Department Of Surgery, St. Michael’s Hospital, Bratislava/Slovak Republic
Contact E-mail Address: zuzana.zelinkova@msm.sk
Introduction: The majority of Crohn’s disease (CD) develop structuring complications of the disease at some point. The proper selection of patients with potential benefit of therapy escalation is crucial in order to avoid unnecessary bowel disease resection in the affected bowel segment; at intravenous contrast-enhanced ultrasound (CEUS) has been shown to correlate with disease activity but there are no data available on the benefit of CEUS for the therapeutic decision making in this clinical setting.
Aims & Methods: The aim of the study was to evaluate the clinical outcomes of CD patients with structuring disease managed based on the CEUS findings. CD patients with structuring disease were recruited from two IBD centres between June 2015 and February 2017. Patients with penetrating disease complications were excluded. CEUS was performed at therapeutic step-up to antiTNF or intravenous immunosuppression (SonoVue, Bracco Imaging). Patients having rapid uptake (within 20 second after injection) were indicated for therapy escalation, patients without uptake with obstructive symptoms were referred for surgery; patients without uptake and no obstructive symptoms remained at the stable medication. In patients with the minimal follow-up of one year clinical and endoscopic remission was evaluated.
Results: In total, 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensified or switched to another biological; 10 pts had therapy step-up to antiTNF or intravenous immunosuppression). Three remaining pts improved subsequently on stable therapy with antiTNF and one patient with longstanding symptomatic colonic stricture was referred for surgery. Ten patients (37%) had no rapid uptake at the CEUS; seven out of these pts had symptomatic strictureing without any changes in the medication. Three patients had no symptoms and no therapeutic changes were made. Twenty-five patients had follow-up longer than 12 months (median 18 months, range 13-23). In the group of patients with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery.
Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with stricturing Crohn’s disease.

Introduction: Inflammatory bowel disease (IBD) commonly affects patients during their reproductive years, making the interaction between fertility, pregnancy, and IBD an important issue for both genders. As these are the reproductive years, patients and physicians often have concerns regarding the interaction between IBD, medications and surgery used to treat IBD, and reproduction, pregnancy outcomes, and neonatal outcomes.
Aims & Methods: The aim of the study was to determine IBD patient’s reproductive behaviour and evaluate the factors that affect family planning. Finally we investigated the factors that may affect the family planning decision in IBD patients. Family planning was not the subject of the study and none of these patients had recurrence at the surveillance colonoscopy at 12 months.
Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with stricturing Crohn’s disease.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1645 
DIAGNOSTIC DELAY AND PREDICTIVE FACTORS FOR CROHN’S DISEASE IN AN ALGERIAN POPULATION
Y. Chelbi, R. Boulares
Constantine, Ben Badis Hospital, Constantine/Algeria
Contact E-mail Address: Yacinchechli4@yahoo.fr
Introduction: Crohn’s disease (CD) is a chronic inflammatory bowel disease whose diagnostic delay (DD) is highly variable. A delay in diagnosis of MC can result in severe damage. Rapid therapeutic response is dependent on the patient’s CD and the CD medication used.
Aims & Methods: All patients with certain or probable CD between 2004 and 2016 identified by The department’s inflammatory disease hospital registry were included. The socio-demographic characteristics collected included: the patient’s personal area at the time of diagnosis in urban, rural or semi-urban, distant from the nearest hospital (CH). Clinical symptoms and phenotype of CD to diagnosis according to the Montreal classification were collected
Results: Among 247 patients with CD; 90 had a median SD of 03 months. A DD > 7 months was considered a diagnostic delay observed in most patients is 157. In univariate and multivariate analysis at diagnosis, the female sex (54.25%), young age (37.24%), absence of emaciation (27%), presence of extra-digestive manifestations (25.91%) and Isolated lesions (L1) (34%) and penetrating phenotype (B3) (22.67%) were associated with significant delay. Factors Influencing SD may be a function of the country’s health system, but also linked to the particular clinical and evolutionary profile of the disease. The objective of this study was to measure the DD of CD, to describe its distribution and evolution over time and to The factors associated with a long DD (> Q3).

TUBERCULOSIS IN INFLAMMATORY BOWEL DISEASE UNDER TUMOUR NECROSIS FACTOR ALPHA ANTAGONIST–THE RISK BEYOND SCREENING
L. Carvalho, M.A. Túlio, J. Carmo, J. Rodrigues, T. Bana, E. Costa, C. Chagas
Gastroenterology, Centro Hospitalar Lisboa Ocidental, Lisboa/Portugal
Contact E-mail Address: lilipecavalho@gmail.com
Introduction: Tumour necrosis factor alpha antagonist (anti-TNFα) has revolutionized the treatment of the inflammatory bowel disease (IBD). Considering that it plays a central role in immune-mediated modulation, there are some concerns about its safety and ongoing infectious treatment. The main patient-related reasons for “voluntary infertility” were fear of congenital abnormality secondary to medications of IBD (68%) and concern about genetic risk of IBD in child (56%). 50% of male and 75% of female patients were concerned about safety issues from conception do delivery. Pregnancy was planned in 77% of cases, the childbearing and delivery was without any complication. Prematurity and low birth weight occurred in 6-6 cases (10%-10%). IBD was in remission in most cases, during pregnancy 25% of the patients had flare. 40% of women could breastfeed their baby after 6 months.
Conclusion: The management of IBD in women during their reproductive years should include consideration of their family planning decisions, and education counseling regarding the overall safety of medications and the importance of medication adherence should occur prior to conception. Disease control prior to desired conception and throughout pregnancy is the most important factor to keep in mind when caring for the IBD patients. Educating the patients will help to achieve successful outcomes both for patients and babies.
Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We intend to know the incidence of tuberculosis in IBD patients under anti-TNFα therapy in a single tertiary referral centre, analyzing the tuberculosis screening methods and demographic characteristics. IBD patients treated with anti-TNFα therapy between January 2000 and December 2016 were retrospectively analyzed.

Results: During this period 166 patients received anti-TNFα therapy. Before anti-TNFα treatment, screening for LT was performed through medical history, chest x-ray, tuberculin skin test (TST) and/or IGRA. Forty-two patients (25%) had a positive screening and received tuberculosis prophylaxis prior to anti-TNFα therapy. Seven patients (4.2%) developed tuberculosis while under anti-TNFα treatment (four women, mean age 44 ± 7 years and mean IBD duration 10 ± 8 years). Six of them had a negative LT screening (methods: 4 TST and 2 IGRA) and one patient had positive TST screening, been treated with isoniazid before starting anti-TNFα therapy. During screening, three patients were under immunosuppressive and one under corticosteroid therapy. In the IGRA negative screening patients, the diagnosis of tuberculosis occurred within the first 10 weeks after starting anti-TNFα therapy. There were five cases of miliary tuberculosis and two of pulmonary disease. Despite difficult diagnosis, all patients were treated successfully, six of whom needed hospitalization.

Conclusion: In our centre the incidence of tuberculosis in IBD patients under anti-TNFα therapy was 4.2% and most of them presenting with a severe disease pattern. The therapeutic regime of tuberculosis was effective and no mortality was recorded. All this patient had a previously negative screening, two of them with IGRA, been considered a high sensitivity and specificity screening method. Therefore, a surveillance strategy for IBD patients with anti-TNFα therapy is needed.

Introduction: The MediCrohn study was designed to evaluate the level of agreement between the Harvey Bradshaw Index (HBI) translated into a patient-based questionnaire completed through a mobile app, and the original HBI questionnaire assessed by the clinician (considered as reference).

Aims & Methods: Patients completed the HBI score through a mobile app designed for both Android and iPhone devices and thereafter (<48 h later), the questionnaire was completed onsite by the gastroenterologist who was blinded for the patients’ responses. We assessed agreement between HBI scores of the clinician and patient on the total sum score and per item. HBI score <5 was considered as inactive disease.

Results: 135 patients participated in the study and completed the HBI trough a mobile app (mean age: 36.4 ± 8 years, 58% women). The proportion of agreement between clinician and patient assessment, both evaluating CD as active or in remission was 91.1%. Only in 12 cases (11%), the patient classified CD as active, whereas the physician evaluated it as inactive. No active cases remained undetected by the patient evaluation. Sensitivity, specificity, positive and negative predictive values are shown in Table. The highest agreement was seen for the questions: “abdominal mass” and “general well-being” whereas “number of liquid stools per day” was the item with the lowest agreement.

Introduction: Current endoscopic activity scores for Ulcerative Colitis (UC) do not take into account the extent of mucosal inflammation. Recently, two endoscopic scores that combine the assessment of severity and disease extension were developed, the Modified Mayo Endoscopic Score (MMES)1 and Degree of Ulcerative Colitis Burden of Luminal Inflammation (DUBLIN)2. Results: 82 patients were selected, 51.2% (n = 42) were female, mean age 49.4 ± 13.7 years. MMES ranged between 0–13.8 and DUBLIN between 0–9. MMES and DUBLIN scores presented good correlation (r = 0.945, p < 0.001). MMES was higher in patients with histoactivity defined by Nancy (3.7 ± 4.0 vs. 0.8 ± 1.5; p < 0.001) and Geboes (4.0 ± 4.2 vs. 1.3 ± 2.4; p = 0.005). DUBLIN was also higher in patients with histoactivity defined by Nancy (1.9 ± 2.1 vs. 0.5 ± 0.8; p = 0.001) and Geboes (2.0 ± 2.3 vs. 0.7 ± 1.2; p = 0.005). There was no significant association between both scores and analytically activity. Relapse occurred in 36.6% (n = 30) of patients, with a cumulative risk of 9.8, 18.4, 25.9, 31.5 and 42.0% at 12, 24, 36, 48 and 60 months, respectively. Mayo Endoscopic Subscore (MES) (p < 0.001), MMES (p = 0.001), DUBLIN (p = 0.001) and Nancy score (p = 0.001) presented a significant association with relapse. In multivariate analysis, MES (OR = 2.32; p < 0.001), MMES (OR = 1.19; p < 0.001) and DUBLIN (OR = 1.36; p < 0.001) were predictive of relapse independently from histoactivity. Areas under the ROC curve were: 0.71 (p < 0.0001) for MES, 0.75 (p = 0.001) for DUBLIN, and 0.001 for prediction of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002-0.072; p = 0.03). Conclusion: MMES and DUBLIN scores correlate with each other and with histoactivity. These scores act as independent predictors of relapse. MMES was superior to MES in the prediction of relapse.

Introduction: Magnetic resonance enterography (MRE) is an imaging technique recommended to determine and confirm the extension and activity of Crohns disease (CD) in the small bowel and discriminate penetrating disease and complications. MRE diagnosis allows to optimize medical treatment in IBD patients.

Aims & Methods: The aim of this study is to evaluate the impact of MRE on medical decision making in IBD patients and determine the maintenance of this new treatment along the time. Consecutive MRE studies performed in patients with confirmed or suspected Crohn’s disease between January 2011 and August 2014 were included in three centers. Medical charts were retrospectively reviewed. MRE indication, demographic and IBD data were collected at time of MRE. Three months after MRE, medical decision (conservative approach with maintenance therapy, significant change in medical therapy or surgery) was assessed. After twelve months of follow-up, the treatment decided after MRE was reviewed.

Results: A total of 474 MRE studies were performed and indications for MRE were: assessment of small bowel involvement in 40 (8.3%) patients with indeterminate colitis (IC) and 20 (4.2%) with suspected-IBD patients or evaluation of severity and extension of the disease in 414 (87.5%) CD patients (232 F; mean age 37 ± 13 years). Only 4 patients with suspected-IBD (4/20.2%) had involvement of small bowel on MRE confirming the CD diagnosis. Twenty-one patients with IC (21/40.52%) changed the diagnosis to CD. In 199/474 (40.5%) MRE determined a change on medical decision and 140 (70.3%) patients modified maintenance treatment because of MRE findings. Of them, 127 (63.8%) underwent “set-up” treatment by prescribing immunosuppressants (IS) (n = 45), anti-TNF agents (n = 22), anti-TNF escalation (n = 8), adding IS to anti-TNF agents (n = 9) and changing anti-TNF agents (n = 5). In addition, 13 (9.2%) patients underwent “top-down” therapy due to stop IS (n = 7), anti-TNF (n = 3) or anti-TNF de-escalation (n = 3). Surgery was indicated on 62 (62/196;31.1%) patients after MRE. After one year of follow-up, the medical decision was maintained in 65.4% (288/440) of patients.

Conclusion: RE is a very helpful tool for the medical management of CD patients. MRE provides major information to optimize treatment in the long-term of patients with active CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn’s disease (CD) is a chronic progressive destructive disease, resulting in cumulative structural bowel damage, which may predict long-term disability. The Lémann Index (LI) has been developed to measure CD-related bowel damage, including bowel surgery, presence of strictureing and penetrating lesions (Pariente and al, Gastroenterology 2015). The first Inflammatory Bowel Disease - Disability Index (IBD-DI) has recently been validated (Gower-Rousseau, Gut 2015).

Aims & Methods: The aim of the present study was (1) to identify factors associated with bowel damage and with disability in CD and (2) to evaluate the correlation between the LI and the IBD-DI. We performed a prospective study in the tertiary referral center of the Claude Huriez Hospital Lille from September 2016 to November 2016, including all consecutive CD outpatients.

Bowel damage was assessed by the LI calculated according to the published LI protocol. Abdominal and pelvic Magnetic resonance imaging (MRIs) were reviewed and red by the same couple of one gastroenterologist and one radiologist. The IBD-DI was also calculated for all patients. Factors associated with LI and IBD-DI levels were identified by means of bivariate analyses of variance. Results: 230 patients were prospectively and rigorously included. Median age was 34.0 (interquartile range [IQR]: 26.0–46.0) and median disease duration was 10.0 (IQR: 5.0–17.0) years. 65 patients (50%) underwent at least one resection surgery. The median LI was 10.8 (IQR: 0.6–17.5). Disease duration (p < 0.0001) and CD activity (p < 0.0001) were associated with higher LI scores. The correlation coefficient between the LI and the IBD-DI was 0.12 (0.002-0.072; p = 0.03).

Conclusion: MRE provides major information to optimize treatment in the long-term of patients with active CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The aetiology of Crohn’s disease (CD) and ulcerative colitis (UC) is not known. Recent data suggest a different cytokine profile between CD and UC.

Aims & Methods: The aim of this study was to analyse the expression of mRNA of proinflammatory, regulatory anti-inflammatory cytokines, chemokines and their ligands (IL-6,-8,-10,-12, IL-23, TNF-α, CCR1, -2, -3, -4, -5, -6, -7, -8, -9, -10, -11,-12, -13, -14, -15,-16, -17, -18, -19, -20, -21, -22, -23, -24, -25, -26, -27, -28, -29, -30, -31, -32, -33, -34,-35, -36, -37, -38), and transcription factor FoxP3 in the inflamed and non-inflamed intestinal biopsy samples of mucosa in IBD patients. We performed a cross-sectional study. The cohort consisted of 87 consecutive IBD patients (47 CD and 40 UC) who underwent colonoscopy at the IB centre of University Hospital Bratislava. We took biopsies from non-inflamed and if present also from inflamed mucosa from sigma (CD, UC) and terminal ileum (CD). mRNA was extracted from mucosal biopsy samples, isolated by a RLT buffer and PCR products were amplified using SYBR green method.

Results: In UC patients, we observed higher expression of IL-8 (p = 0.04), IL-23 (p = 0.019), TLR2 (p = 0.002), CCR1 (p = 0.007), CCR2 (p = 0.037), CCR5 (p ≤ 0.001), CD206 (p = 0.011), TNFα (p = 0.002) and IL-6 (p = 0.006) in the inflamed mucosa from sigma. In CD patients, we observed increased expression of IL-6 (p = 0.005), and IL-8 (p = 0.001) in the inflamed mucosa of a terminal ileum and decreased expression of CCL5. Also, in group of patients with CD we did not observe the difference of the expression of mRNA cytokines between the inflamed and non-inflamed mucosa of sigma.

Conclusion: There was a significant difference in the mRNA cytokine profiles between CD and UC patients.

**Introduction:** Although thiopurine-induced myelotoxicity and hepatotoxicity rarely occur during maintenance thiopurine therapy for inflammatory bowel disease (IBD), current guidelines advise laboratory monitoring every 3 months. This study was performed to assess the current laboratory monitoring regimen in thiopurine maintenance therapy with regards to consequences of myelotoxicity and hepatotoxicity.

**Aims & Methods:** In this multicenter cohort study, we evaluated adult IBD patients with quiescent disease who were on maintenance thiopurine therapy between 2000–2016. Data collection started after 12 consecutive months of thiopurine treatment. The primary outcome was therapy adjustment, i.e. therapy cessation or dose reduction, due to myelotoxicity (leukocyte count \( < 4.0 \times 10^9/\text{l} \), platelet count \( < 150 \times 10^9/\text{l} \) and/or hepatotoxicity (alkaline phosphatase (AP), gamma-glutamyltransferase (γ-GT), alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) above the upper limit of normal (ULN)).}

**Results:** This study included 223 IBD patients (55% female, 64% with Crohn’s disease, mean age at diagnosis 27.2 years (SD 11.5)). Median follow-up was 3.2 years (IQR 1.9–4.7). The mean monitoring frequency was 3.3 assessments per treatment year (SD 1.8). Toxicity was observed in 445/2402 laboratory assessments (18.5%) in 120 patients. In total, 20 (0.8%) therapy adjustments were performed and 25 laboratory assessments (1.0%) led to additional diagnostic procedures. Myelotoxicity, observed in 244 assessments, led to 11 dose reductions and in 3 patients therapy was stopped. For hepatotoxicity, observed in 201 assessments, 2 dose reductions were performed and in 4 patients therapy was stopped. Ninety percent of observed toxicity were mild leukopenia (leukocyte count \( < 3.0 \times 10^9/\text{l} \)) or mild hepatotoxicity (\( < 2 \times \text{ULN} \)), primarily in the first years of treatment. Dose adjustments were more often associated with moderate leukopenia (leukocyte count \( < 3.0 \)) than with mild leukopenia (\( p < 0.01 \)). In total, 2 complications were recorded, 1 patient was hospitalized because of pancreatitis and received red blood cell transfusion, and 1 patient was treated for a CMV infection. Both patients presented with symptoms in clinic with preceding normal laboratory values. No mortality due to thiopurine-induced toxicity was observed.

**Conclusion:** Although mild toxicity is common during maintenance thiopurine therapy, adjustments based on laboratory assessments are rare. Therefore, a less intensive regimen to monitor thiopurine-induced toxicity should be considered.

**Introduction:** Intestinal fibrosis represents one of the main sources of morbidity for patients with Crohn’s disease (CD), as its onset is associated with the development of CD-related complications which increase the likelihood of hospitalization and surgery. Ultrasound elasticity imaging (UEI) is a non-invasive ultrasonographic technique developed to evaluate tissue fibrosis by measuring tissue strain after application of a force. We have recently demonstrated that UEI can reliably detect severe ileal fibrosis in patients with Crohn’s disease. We therefore hypothesized that a more severe range of fibrosis might influence the therapeutic response to anti-tumor necrosis factor (TNF) treatment.

**Aims & Methods:** The aim of this explorative study was to assess the ability of UEI to predict therapeutic outcome in active CD patients treated with anti-TNF antibodies. 30 patients with ileal or ileocolonic CD (20 males, age 38.8 ± 14.5) initiating anti-TNF treatment were enrolled in the study. All patients completed the induction phase and underwent scheduled maintenance therapy with anti-TNF for 16.1 ± 8.5 months. Patients underwent bowel ultrasound and UEI at baseline and 14 weeks after initiation of anti-TNF. Bowel wall stiffness at UEI was quantified by calculating the strain ratio (SR) between the bowel wall and the surrounding mesenteric tissue. Receiver operating characteristic curve analysis was used to identify the best SR cut off able to predict surgery/bowel obstruction. Transmural healing at 14 weeks was defined as a bowel wall thickness ≤3 mm. Frequency of CD-related surgeries or hospitalizations due to bowel obstruction was recorded during the follow-up. The data are given as mean values ± standard deviation.

**Results:** Five patients (16.6%) underwent surgery or hospitalization for bowel obstruction during the follow up. Frequency of CD-related surgeries or hospitalizations was significantly greater in patients with SR ≥ 2 at baseline than in patients with SR < 2 (p = 0.02). A significant reduction in bowel thickness was observed after 14 weeks of anti-TNF treatment (from 5.8 ± 1.5 mm to 5.1 ± 1.7 mm, p < 0.05), while SR values remained unaltered (1.5 ± 1.3, p = 0.5). A significant inverse correlation was observed between values of strain ratio at baseline and thickness variations following anti-TNF therapy (p = 0.007). Eight out of 30 patients (27%) achieved transmural healing at 14 weeks. Baseline SR was significantly lower in patients with transmural healing than in patients not achieving this endpoint (1.06 ± 0.16 vs 1.67 ± 0.17, p < 0.05).

**Conclusion:** This explorative study shows that UEI is able to predict therapeutic outcomes, including CD-related surgeries and transmural healing, in patients with Crohn’s disease treated with anti-TNF therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
**P1657** CLINICAL CHARACTERISTICS OF RECTAL-SPARING ULCERATIVE COLITIS

A. Ito, O. Teppeli, T. Katutoshi
Dep. Medicine, Inst. Gastroenterology, Tokyo Womens Medical University, Tokyo,Japan

Contact E-mail Address: itowayne@iee.twmu.ac.jp

**Introduction:** Ulcerative colitis (UC) generally involves the entire large intestine except for the rectum to the ileocecal junction. However, some patients with moderate or severe UC lack any obvious rectal involvement (known as rectal-sparing [RS]-UC).

**Aims & Methods:** In this study, we evaluated the differences in the clinical characteristics between patients with rectal UC with or without RS. Of the 437 inpatients with rectal UC who achieved remission between April 2001 and September 2016 (follow-up period: 915±53 days, mean ± SD), 57 patients were classified as RS-UC and 340 patients without RS (standard [S]-UC) group. Patients of the two groups were compared for gender, age at onset, site of involvement, disease duration, pretreatment clinical activity index (CAI, Lichtiger score), Hb, C-reactive protein (CRP), total dose of prednisolone (PSSL) before the achievement of remission, duration of hospitalization, endoscopic and ultrasonographic features, UC endoscopic severity index (UCEIS), and relapse rates (RS). Of 1300, 300, 500, and 1000 days post-remission. Patients with RS were defined as those without any detectable rectal inflammation despite not receiving local treatment, such as rectal enemas or suppositories. Remission was defined as CAI ≤5.

**Results:** Relapse was defined as the need to restart remission induction therapy, such as intensive intravenous PSSL, initiation of treatment with biological agent, or readmission and dose escalation of tacrolimus to achieve a high blood trough level (≥2 ng/dl).

- **Results:** RS was observed in 57 (10.4%) patients. There were significant differences in CRP (RS-UC: 5.1±6.0, S-UC: 2.3±3.4 mg/L) and pretreatment endoscopic scores (Mayo: RS-UC: 2.7±0.3, S-UC: 2.4±0.5). UCEIS: RS-UC: 6.1±5.1 and S-UC between the two groups (P<0.05). There was no significant difference in the relapse rate at 100 days after remission (RS-UC: 18%, S-UC: 15%). However, the two groups showed significant differences in the relapse rates at 300 days (RS-UC: 38%, S-UC: 17%), 500 days (RS-UC: 50%, S-UC: 48%) and 1000 days (RS-UC: 77%, S-UC: 62%) after remission.

- **Conclusion:** Our results showed that RS is not an uncommon finding among patients with UC. Based on the higher CRP, endoscopic score, and relapse rates in the RS group, than the standard UC group, we recommend aggressive treatment in UC patients with RS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1658** EVALUATION OF COLONIC MUCOSA WITH FLEXIBLE SPECTRAL IMAGING COLOR ENHANCEMENT (FICE) IN PATIENTS WITH LONG TERM ULCERATIVE COLITIS DURING DYSPLASIA SCREENING

G. Bengt1, S. Kaya Özdemir2, H. Akinpınar3
1Gastroenterology, Dokuz Eylül University Hospital, İzmir/Turkey

Contact E-mail Address: sedozdinc@yahoo.com

**Introduction:** Ulcerative colitis (UC) associated colorectal cancer risk (CRC) is related to the age of onset and duration and anatomic extent of the disease. The risk of dysplasia increases with the duration of the disease (1). Current guidelines recommend beginning the surveillance colonoscopy after eight to ten years of disease; random biopsies should be obtained from 4 quadrants of every 10cm of the colon. In addition, any suspicious areas should be biopsied. Recent endoscopic imaging technologies provide a more detailed visualization of the superficial microstructure of the mucosa and vascularity. Thus it is possible to get targeted biopsies. The purpose of this study is to evaluate the image patterns of dysplasia change in ulcerative colitis, and their histopathological correlation, by using a virtual chromosendoscopy technique, FICE and to investigate the effectiveness of this technique.

**Aims & Methods:** The purpose of this study is; to evaluate the image patterns of dysplastic changes in ulcerative colitis, and their histopathological correlation, by using a virtual chromosendoscopy technique, FICE and to investigate the effectiveness of this technique. Eighteen follow-up patients of our inflammatory bowel disease polyclinic, with UC at least 8 years of disease history and who are in clinical remission were included to this study. Screening colonoscopy was performed to the patients included in the study. Entire colon and especially the dysplasia suspected areas visualised with standard endoscopy first, and then with FICE; random and targeted biopsies were taken. Image patterns were compared with histological diagnosis. Normal, colitis and polyp images acquired by FICE, were evaluated by seven endoscopists and statistical analysis was performed. **Results:** In a total of 18 patients, by evaluating 120 colonic segments, 1831 images were measured. Biopsy indication was found in 17 of 18 patients. Of the 17 patients, 6/17 were classified as RS-UC and 11/17 as S-UC. Of the 1831 images taken by FICE separately, from each areas of normal colonic mucosa, polypoid lesions and colitis. A total 584 biopsies were taken, 492 (84.2%) random and 92 (15.7%) targeted biopsies. While there were no dysplasia in random biopsies, microscopic dysplasia was detected in 3 diminutive polyps taken as targeted biopsy. The analysis of the FICE images by voting by seven endoscopists showed that, the best imaging channels are; 2, 6, 9 for normal mucosa; 3, 7, 9 for polyps; and 2, 3, 9 for colitis. When all the images are analyzed, channels 2 and 9, were found to be significantly different from other channels. When the most rated channels, and 9, were compared to the WLE, the FICE image is better for evaluation of the mucosal and vascular structure. However, there were no significant difference between channels 2 and 9.

**Conclusion:** There were no significant superiority of FICE, in dysplasia screening. Consistent with the literature in this study, we showed us that FICE image is better for detecting diminutive polyps, and evaluating surface patterns without magnification. In clinical remission in patients with UC, FICE can have a role in the assessment of the severity of inflammation. For this purpose, more clinical trials are needed. Our study is the first study in UC. Channels 2 and 9 are the best image channels of FICE in UC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The gut microbiome is thought to be relevant to the pathogenesis of inflammatory bowel disease (IBD). We aimed to explore associations between microbial diversity and specific IBD endotypes as well as inflammatory disease activity in an inception cohort of treatment-naïve IBD patients as well as with inflammatory activity in symptomatic non-IBD patients and healthy controls. The term ‘dysbiosis’ expresses alterations in the gut microbial community.

**Aims & Methods:** Patients were grouped according to the international criteria, including endoscopic and histopathological assessment. Clinical disease activity in Crohn’s Disease (CD) patients was measured by the Harvey-Bradshaw index (HBI), and in ulcerative colitis (UC) patients by the Simple Clinical Colitis Activity Index (SCCAI). Inflammatory activity was assessed by CRP and faecal calprotectin (FCal), (IgCAL® ELISA, Buhlmann laboratories AG).

**Results:** Stool samples were collected within 60 days prior to and 14 days after the diagnosis, and stored at ~80 °C. Antibiotic treatment within the last two months was an exclusion criterion. Identifiable microbial profiles were generated by 16S RNA analyses, using the GA-mapTM Dysbiosis Test. Dysbiosis was defined as non, mild or severe (1). Differences in disease activity between levels of dysbiosis severity were analysed using ANOVA at a significance level of 0.05. Intra-group associations between inflammatory activity and log-transformed microbiota profiles were analysed using ANCOVA. P-values corrected for multiple testing, using Benjamini-Hochberg correction, are presented. Presenting stool samples were compared to stool samples of diarrhoea patients and healthy controls.

**Conclusion:** CRP was available for 52 CD, 74 UC, 10 IBD-U patients, and 88 symptomatic non-IBD patients. HBI was available for 50 CD patients, while SCCAI was available for 77 UC patients. Disease activity: No association was found between FCal and dysbiosis in UC patients (P =0.08), CD patients (P =0.22), and healthy controls (P =0.57). However, an association was found between FCal and dysbiosis in symptomatic non-IBD patients (P =0.04) and in healthy controls (P =0.005). An association was found between FCal and dysbiosis in CD patients (P =0.02), while not for UC and symptomatic non-IBD patients. No association was found between HBI and dysbiosis in CD patients (P =0.23), and between SCCAI and dysbiosis in UC patients (P =0.32). Microbiota: Increasing dysbiosis severity in UC, CD and non-IBD patients yielded lower abundance of Faecalibacterium prausnitzii, and higher abundance of Proteobacteria, a profile typically observed in gut inflammatory conditions. In addition, the commensal bacteria Bifidobacterium yielded lower abundance with increased dysbiosis severity in UC and non-IBD patients, and in combination with elevated levels of FCal and/or CRP in UC patients. In the healthy controls, increasing dysbiosis severity yielded higher abundance of Proteobacteria.

Introduction: Crohns disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn's disease. MR imaging is one of the most recommended technique for detection of large and small bowel lesions. Hence, we aimed to evaluate clinical utility of the 3-point MR enterocolonography (MRC) classification for assessing CD activity based on endoscopic findings.

Aims & Methods: A total of 120 patients (70 for derivation cohort and 50 for validation cohort) with CD was enrolled and undergone MREC and ileocolonoscopy or balloon-assisted enteroscopy (BAE). MREC was evaluated for each bowel segment: rectum, sigmoid, descending, transverse, ascending colon, terminal, proximal ileum, and jejunum, according to the consensus of two observers in the derivation phase, and independently by three observers in the validation phase, using a 5-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Results: BAE was performed in 49 (70%) and 37 (74%) patients in the derivation and validation cohort, respectively. The AUCs of MREC classification were 89.0% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase, using a 5-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Conclusion: For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 5-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large bowel and small bowel segments.

P1661 RISK FACTORS FOR METABOLIC SYNDROME AND ITS COMPONENTS IN INFLAMMATORY BOWEL DISEASE
Department Of Medicine And Ageing Sciences And Center For Excellence On Ageing And Translational Medicine (cesi-met), “G. D’Annunzio” University and Foundation, Chieti/Italy

Contact Email Address: efk78@gmail.com

Introduction: Metabolic Syndrome (MetS) is a combination of biochemical and anthropometric disturbances and a recognized risk factor for cardiovascular disease. A higher prevalence of this condition has been previously reported in IBD patients, correlating to age as in the general population.

Aims & Methods: The aim of this study was to assess the effect of individual disease activity-related putative risk factors for MetS in a group of IBD patients, as well as any protective effects of treatment on MetS or its components. Consecutive IBD patients and age- and sex-matched controls were included during a 1-year period. MetS was diagnosed according to the “harmonized” criteria as the presence of >3 criteria among elevated waist circumference, blood pressure, blood glucose, serum triglycerides, or reduced HDL levels. All subjects underwent colonoscopy; endoscopic disease activity was assessed according to SES-CD and Mayo endoscopic scores. CRP, fecal calprotectin (FC), hemoglobin and ferritin levels were also measured.

Results: We enrolled 145 consecutive IBD patients (53 Crohn’s disease and 92 ulcerative colitis; 58 M:87 F; mean age 51±18 yrs) and 250 age- and sex-matched controls. Overall, MetS prevalence was 37% in IBD and 21.6% in controls (OR=2.1, 95%CI:1.32–3.39). Prevalence according to sex or disease type did not show significant differences. At multivariate analysis, age and BMI >25 were associated to an increased probability for a positive MetS status both in IBD (OR=3.41, and OR=6.01) and controls (respectively OR=3.47 and OR=3.74). In patients under 50 years, age (OR=1.24), CRP (OR=1.9) and FC (OR=1.35) positivity were associated to MetS status, while a BMI >25 increased risk at any age (<50ys OR=3.8, >50ys OR=1.56). Interestingly, anti-TNFα treatment was not associated to MetS status at any age. Interestingly, anti-TNFα treatment was protective in both groups, but reached statistical significance only in older subjects (OR=0.08). Regarding individual MetS components, in the <50ys subgroup, age and CRP positivity associated with an impaired glycemic (respectively, OR=1.15 and OR=2.28) and lipidemic status (respectively, OR=1.23 and OR=2.3). In older patients, CRP positivity only associated to impaired HDL status (OR=5.41). Importantly, anti-TNFα treatment favourably associated to HDL status (OR=0.2).

Conclusion: MetS prevalence is increased in IBD compared to healthy controls at any age. Patients with increased BMI and/or inflammatory markers are at higher risk for MetS, while anti-TNFα agents appear to be protective. The components associated to MetS are differently distributed according to age, with the inflammatory ones prevailing in subjects <50 years and metabolic disturbances in older patients. These results indicate that MetS and its related long-term neoplastic and cardiovascular complications may reduce MetS occurrence and associated risks in subjects >50 years, in younger patients more effective inflammation control measures may prevent MetS and its related long-term neoplastic and cardiovascular complications.

P1662 C-REACTIVE PROTEIN/ALBUMIN RATIO IS A GOOD PREDICTOR OF RESPONSE TO INTRAVERSE CORTICOSTEROIDS IN ACUTE SEVERE ULCERATIVE COLITIS
S. Monteiro1, T. Cárdia Gonçalves1, F. Dias De Castro2, S. Leite1, M.J. Moreira1, J. Cotter2
1Gastroenterology, Hospital Senthora da Oliveira-Guimaraes, Guimaraes/Portugal
2Iecs/3S, PT Government Associate Laboratory, Guimaraes/Braga/Portugal

Contact Email Address: sara.s.monteiro@gmail.com

Introduction: Patients with acute severe ulcerative colitis (ASUC) have a high risk of response medical therapy or colectomy. Recently, the C-reactive protein (CRP)/albumin ratio on admission, to predict response to intravenous corticosteroids in patients with ASUC. Retrospective assessment of systematically hospitalized patients with first episode of ASUC, who required intravenous corticosteroids. Demographic, clinical, laboratory and endoscopic variables were evaluated on admission. The response to intravenous corticosteroids was defined as clinical and endoscopic improvement in at least 75% of patients and patients who required rescue medical therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

Results: 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3±14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with a lack of response to intravenous corticosteroids, p<0.001 and p=0.008, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p=0.028, 2.8 vs 3.5 (g/dL), p=0.005, respectively. The CRP/albumin ratio was 51.4% higher in unresponsive patients 40.06 vs 22.14, p=0.022, showing a good accuracy for predicting non-response to intravenous corticosteroids with an AUC of 0.746, p=0.01.

Conclusion: A high value of CRP/albumin ratio was significantly associated with the lack of response to intravenous corticosteroids, at the 3rd day of treatment. This index may also better risk stratification on admission, of patients with acute severe ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1663 INSUFFICIENT VARIATION OF MEDIUM CORPOSCULAR VOLUME (MCV) IN INFLAMMATORY BOWEL DISEASE UNDER THYPOPURINES PREDICTS DIFFICULTY IN ACHIEVING MUCOSAL HEALING AND COMBINATION WITH ANTI-TNF - THE OTHER SIDE OF THE MCV FLOW STUDY
J. Roseira1, H. Tavares De Sousa1, A. Marreiros2, P. Queirós1, A.M. Vaz2, T. Gago1, L. Contente1, H. Guerrero2
1Gastroenterology, Algarve Hospital Center, Portimão/Portugal
2Biomedical Science Department, University of the Algarve, Faro/Portugal

Contact Email Address: jsr-roseira@hotmail.com

Introduction: The MCV flow study confirmed the association ΔMCV ≥7fl at week 26-28 of Azathioprine monotherapy (mAzA) with favourable outcomes in a Portuguese IBD population.

Aims & Methods: For this work, our aims were to evaluate the need for step-up therapy in those under mAzA with ΔMCV ≤7 and to identify predictors of combined deep remission outcomes (DeepRem), at the same timepoint, for the patients who subsequently began combination therapy with Anti-TNF (AzaExperienced + Anti-TNF). Evaluation of patients under mAzA with ΔVGM < 7 at key timepoint week 26-28 treatment, included for The MCV flow study. Demographic characterization and severity of pre-treatment disease was evaluated (Montreal classification, previous surgery status, Mayo score and Crohn’s disease activity index (CDAI)). ΔMCV’s association with DeepRem (Steroid-free clinical remission (CDAI ≤150, Mayo < 2) + mucosal healing (MH)+C-reactive protein (CRP) <10) and need for biological therapy at the end of week 26-28 was verified. ΔMCV was also an independent predictor in patients who subsequently started combination therapy. Statistical: Chi-square test; Binary logistic regression.

Results: A total of 106 IBD patients were evaluated [56.6% women, mean age 39±15.2 years; 58 ad, 14% operated] at week 26-28 of mAzA. Identified strong association between an average ΔVGM ≥ 7 (n=70; 66%) with DeepRem (p < 0.05), while a ΔVGM < 7 was associated with biological therapy need (p < 0.05). 45 patients were later started with Anti-TNF therapy

Reference
Aims & Methods: The aim of this prospective study was to evaluate whether elevated FC values can predict short-term clinical and/or endoscopic relapse. We enrolled 60 IBD patients (30 ulcerative colitis - UC, 30 Crohn’s disease - CD) who were in remission and endoscopically normal. FC was measured using quantitative immunochromatographic point-of-care test (Quantum Blue® Calprotectin, Bühlmann Laboratories AG, Switzerland). Patients were followed-up by FC examination and clinical activity assessment every second month until relapse or up to 24 months. Histocolonoscopy was performed at inclusion and at the time of clinical relapse.

Results: During the follow-up 36 (60%) relapsed and 24 (40%) remained in remission. The mean time to relapse in all patients was 13.9 (range 2-20) months. Significant association in median FC levels was seen 2 months (p < 0.001) before endoscopic relapse. ROC analysis indicated that a cut-off of >0.95 µg/mL (OR 24, 95% CI = 5.117, p = 0.001) in mean FC values 2 months before relapse could predict relapse in UC patients with 83.3% sensitivity and 82.9% specificity. In CD patients a cut-off parameter of >1.55 µg/mL (OR 193, 95% CI = 22.1682, p < 0.001) could predict relapse within two months with 91.7% sensitivity and 94.6% specificity. Constantly normal FC values during the follow-up were predictive for deep remission.

Conclusion: It is seen that FC elevates two months before clinical and/or endoscopic relapse. FC is a suitable marker for predicting relapse and building a follow-up strategy for IBD patients in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
be required to obtain a 2x2 contingency table. Pooled analysis was done using a random-effects model. Subgroup analysis was performed at real-time Kudo pit pattern based and real-time CLE for characterization of visible lesions. Heterogeneity was assessed using Chi squared and I^2 statistics.

Conclusion: Our search strategy identified 172 studies of which only 20 met the inclusion criteria. The pooled results are outlined in the table. Real-time CLE and magnification endoscopy had the best performance characteristics. However there was a lot of heterogeneity in the results. Most CLE and magnification studies were single centre, single expert user which could explain these results. CLE studies were also affected by attrition bias with some studies reporting non-interpretable mages in a significant proportion.

2Department Of Biochemistry And Human Nutrition, Pomeranian Medical University, Szczecin/Poland
3The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom

Contact E-mail Address: diaz.e.yung@gmail.com

Introduction: Microscopic colitis (MC) is a clinical syndrome of severe watery diarrhoea with few or no endoscopic abnormalities. The incidence of MC is reportedly similar to that of other inflammatory bowel diseases. The need for histological confirmation of MC frequently guides reimbursement health policies. With the advent of high-definition (HD) coloscopes, the incidence of distinct endoscopic findings reported in MC has risen. This has the potential to improve diagnosis times, increase cost-effectiveness of MC management and diminish the workload and costs of busy modern endoscopy units.

Aims & Methods: Publications on distinct endoscopic findings in MC available until 31st March 2017 were searched systematically (electronic and manual) in PubMed. The following search terms/descriptors were used: collagenous colitis(CC) OR lymphoid colitis(LC) AND endoscopy, colonoscopy, findings, microscopic colitis, erythema, macrovascular structure, abnormalities. An additional search for MC AND perforation was made.

Results: Eighty (n = 80) articles, predominantly single case reports (n = 45), were retrieved. Overall, 1,582 (4,119 female: 61.6:14.1) years patient(pts) with MC and endoscopic findings were reported. The majority of articles (n = 62) were on CC (756 pts; 77.5% female). We identified 16 papers comprising 779 pts (68.9% female) with LC and 7 articles describing 47 pts (72.3% female) confirmed to have MC. The youngest patient was 10 and the oldest 97 years old. Aside from diarrhoea, symptoms included abdominal pain, weight loss, bloating, flatulence and oedema. In the study group we found 616 (38.9%) pts with macroscopic findings. The most common colonic findings were non-ulcerous lesions i.e. pseudomembranes, a variable degree of vascularule pruning & dwindling, mucosal lacerations & abnormalities such as erythema/edema/nodularity, or surface textural alteration (n = 537; 87.2% pts). Isolated linear ulcerations were identified in 5 pts(0.8%) and in conjunction with non-ulcer lesions in 74 pts(12.9%). The location of endoscopic findings was not reported in 26 articles. Distinct endoscopic findings were described in the left (descending, sigmoid, rectum –23/20/10 studies), right (cecum, ascending–7/21 studies) & transverse colon (14), as well as duodenum (7) and terminal ileum (2). Colonic perforation was reported in 9 patients (0.57%).

Conclusion: Endoscopic findings are recognized with increased frequency in pts with MC. This could improve MC diagnosis by prompting a more extensive biopsy protocol in such cases and an earlier initiation of treatment. Procedure-related perforation has been reported in this group, therefore, cautious air insufflation is advisable when endoscopic findings are recognised.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: iulianaeche.89@gmail.com

Introduction: It is well recognized that patients with inflammatory bowel disease (IBD) are at risk for nonalcoholic fatty liver disease (NAFLD). Our aim was to evaluate the prevalence and to quantify hepatic steatosis in IBD patients using the controlled attenuation parameter (CAP).

Aims & Methods: We prospectively recruited all IBD patients presenting for a disease flare or follow-up visit in our clinic, during a 18 month period. Patients were considered as alcohol intake if they have more than 20 g/day and those with coexisting viral hepatitis were excluded from analysis. Clinical characteristics and laboratory data were recorded. Hepatic steatosis was evaluated by conventional ultrasound, hepatic steatosis index (HSI) and transient elastography with CAP (Fibroscan, Echo chiff, Paris). Significant steatosis (S ≥ 1) was defined for a CAP value over 236 [1], and the cut-off of HSI for detecting NAFLD was set at ≥ 36 [2].

Results: Altogether 62 IBD patients (35 ulcerative colitis, UC and 27 Crohn’s disease, CD), mean age 45 ± 15 years, 50% female, were included in the analysis. The two groups (UC, CD) were similar regarding disease activity (remission/flare/48.5/53.1% in the UC group, 55.6/44.4% in the CD group), BMI (24.1 and 24.5 kg/m2), and disease duration (21 and 21.1 months). Hepatitis B and C virus infections were excluded (HBsAg 498 and 513 mg/dL). UC patients had higher mean cholesterol values (205.9 vs. 176.4 mg/dL) and 11% of them were diabetic (compared to none in the CD group). Mean CAP was higher in CD compared to UC—246 vs. 225 dB/m, while HSI was 4.9 for UC patients versus 3.4 for IBS. As expected, UC patients had higher FIB-4 score (21/32, 35.3%) and CAP even more (23/62, 37.1%), yielding an 8% detection rate. NAFLD-IBD patients were more likely to have CD phenotype, history of resection, and longer disease duration.

Conclusion: In our cohort, about one in three IBD patients had fatty liver disease, as quantified by CAP. Diagnostic performance of CAP was better than conventional ultrasound and HSI in detecting fatty liver in IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Irritable Bowel Syndrome (IBS) is a common gastrointestinal disorder that affects around 11% of global population. Despite the high prevalence of IBS, the cause of this disorder remains unknown and the criteria used to diagnose IBS are still unclear. In recent years, disturbances in the intestinal microbiota have been associated to the pathophysiology of IBS. Recently, two accurately defined Firmicutes (Fpra) and Eubacterium rectale (Eco) have been shown to discriminate between Inflammatory Bowel disease (IBD) and Healthy subjects (H). Therefore, the purpose of this study was to verify the capability of Fpra and Eco abundances to distinguish among healthy subjects, IBS, and IBD patients, in order to create a non-invasive system of diagnostic support for IBS patients.

Aims & Methods: A cohort consisting of 33 H and 14 IBS was enrolled. IBS patients were separated by subtypes: IBS with constipation (C-IBS), IBS with diarrhea (D-IBS), and alternating IBS (A-IBS). Rome IV criteria were used to diagnose IBS patients. Moreover, 29 ulcerative colitis (UC) and 15 Crohn’s disease (CD) patients were also included. All subjects were recruited by the Gastroenterology Services of the Hospital Universitari Dr. Josep Trueta (Girona) and Hospital Universitari de Bellvitge (Hospitalat del Llobregat, Spain). Fpra total and Eco abundances were quantified by qPCR.

Results: We found lower abundance values of Fpra in IBS patients when compared with H (P = 0.005). In contrast, Eco abundance was higher in IBS patients, although the differences observed were not significant (P = 0.221). When comparing among subtypes of IBS (C-IBS, D-IBS, and A-IBS) no significant differences were observed, although Fpra abundance was lower in C-IBS. We also used Fpra in combination with Eco as a complementary indicator of dysbiosis (Ratio Fpra/Eco). This ratio allows a good discrimination between H and IBS (FDR = 0.04). When it comes to discrimination between IBS and IBD patients, significant differences were observed in Fpra/Eco ratio between UC and IBS patients (P = 0.008), but not between IBS and CD patients (P = 0.775). Concerning disorders different to IBS, significant differences were also observed between D-IBS and CD (P > 0.001), between H and UC (P = 0.037), and between CD and UC (P = 0.027).

Conclusion: Fpra abundance is a good biomarker to discriminate between healthy subjects and IBS patients. The use of Fpra/Eco ratio allows to distinguish IBS from H and UC patients. In contrast, none of the used biomarkers was able to differentiate IBS and CD patients. These results show that IBS and CD patients share similar dysbiosis parameters opening the need of further study to stabilize any eventual pathogenic link.

1Department of Inflammatory Bowel Disease and IBD and Irritable bowel syndrome (IBS) may present in a similar manner [1] [2]. Measuring faecal calprotectin concentration is often recommended to rule out inflammatory bowel disease, however, there are no tests to positively diagnose irritable bowel syndrome and invasive tests are still used to rule out other pathologies [3, 4]. There is a chance, therefore, for novel, non-invasive diseasespecific biomarkers. Volatile organic compounds (VOCs), originating from physiological metabolic processes in the human body, are excreted as waste products through stool samples. For this reason, several biological, non-invasive, simple and low-cost biomarker studies of inflammation that are useful in clinical practice for both diagnostic screening and therapeutic or course response monitoring are being evaluated in recent years Evolution of the disease. In this sense, stool markers, and especially calprotectin, have become of great importance in recent years as screening to select patients requiring more diagnostic studies and as a marker of activity for therapeutic follow-up [5]. Can the VOCs from stool samples show differences between ulcerative colitis and Crohn’s disease.

Aims & Methods: Five healthy individuals (control group- CON) and nineteen patients diagnosed with IBS were selected for the analysis of their stool VOCs. Healthy participants Healthy control samples (Control) (n = 5) were collected from healthy volunteers working in the Digestive Diseases Area and they were defined as healthy volunteers based in a group of CD-UC-CON where was analyzed 10 CD patients, 9 UC patients, and 5 controls with 455 samples. Data from stool samples was obtained using eNose MOOSY32 [6].

Results: Figure 1 shows the scatter 3D plot with three voltage parameters for the group UC-CON. These results show that IBS and CD patients from H and UC patients. In contrast, none of the used biomarkers was able to differentiate HBD and CD patients. These results show that IBS and CD patients share similar dysbiosis parameters opening the need of further study to stabilize any eventual pathogenic link.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Czech Registry of Inflammatory Bowel Disease (IBD) Patients on Biological Therapy (CREdIT) was launched in March, 2016 in order to collect and analyze the data from Czech centers appointed to provide biological therapy to IBD patients.

Aims & Methods: The objective is to provide information on the CREdIT registry after its first year of operation. Basic demographic data (sex, age, diagnosis, Montreal classification or disease extent) were collected together with information on disease activity, therapeutic regimen, concomitant medication and adverse events. Patients who began biologic therapy prior to enrolment into the registry as well as those who start their treatment are included, and labeled as “retrospective” and “prospective” cohort, respectively.

Results: Among 30 centers providing biological therapy to patients with Crohn’s disease (CD) and ulcerative colitis (UC) in the Czech Republic, 24 participated as of 1st of March 2017. The centres enrolled 2129 IBD patients (CD, 1595; 74.9%; UC, 505, 23.7%; IBD-U, 29, 1.4%), with median of 63 (range 4-528) patients per center. Majority belong to the retrospective cohort (65%), the remaining 35% represent the prospective cohort. According to the latest data check, patients are treated with infliximab (1273, 59.8%), adalimumab (739, 34.7%), vedolizumab (73, 3.4%), and golimumab (42, 2%). Treatment intensification on disease activity, therapeutic regimen, concomitant medication and adverse events.

P1675 COST EFFECTIVENESS OF IBDC FACIAL CALPROTECTIN AS A SURROGATE MARKER OF MUCOSAL HEALING POST INDUCTION OF BIOLOGICAL AGENTS IN INFLAMMATORY BOWEL DISEASE

Dep. Of Gastroenterology, Mercy University Hospital, Cork/Ireland

Contact E-mail Address: jafaralsafi@hotmail.com

Introduction: Traditionally in our unit all IBD patients started on anti-TNF therapy are followed up at 3 months and we aim to do a colonoscopy at 6 months to assess for mucosal healing. Recently we have started using a relatively new technology, called IBDoc, which allows testing the faecal calprotectin at home using a smartphone application and the results are automatically updated in our database.

Aims & Methods: We aimed to evaluate the cost effectiveness of using IBDoc faecal calprotectin post induction of biological agents. The data was collected retrospectively from ourIBDoc data base. All patients that were commenced on anti-TNF therapy for IBD and trained in using IBDoc at home were included. IBDoc faecal calprotectin was tested at 3 and 6 month post induction of biological agents.

Results: Total number included in the study was 131 patients. 40% had normal calprotectin at 3 month saving 53 follow up clinic visits (cost of clinical visit 128 euro) and 75% had a normal faecal calprotectin at 6 months saving 40 routine colonoscopy (cost of colonoscopy 337 euro). 78 patients had a raised faecal calprotectin at 3 month, of which 28% had a normal faecal calprotectin at 6 months saving 22 follow-up colonoscopy. In total 53 clinical visits and 62 colonoscopies were avoided.

Conclusion: This study demonstrate a significant cost effectiveness of using IBDoc faecal calprotectin post induction of anti-TNF therapy, as well as reducing the waiting time for both clinic visits and colonoscopies.

Introduction: In patients with inflammatory bowel diseases (IBDs), comprising Crohn’s disease (CD) and Ulcerative colitis (UC), a patient-tailored therapy is an unmet need that requires accurate monitoring of the intestinal disease activity.

We demonstrated recently, that the expression of microRNA (miR)-320a follows the disease activity in murine colitis models1. In this prospective study we evaluated the potential of miR-320a as a biomarker to monitor the disease activity in IBD patients as well as its potential to distinguish UC/CD from infectious colitis.

Aims & Methods: The miR-320a was measured by qRT-PCR analysis in peripheral blood samples from 36 CD and 54 UC patients with acute flare of disease (n = 51) and in remission (n = 37) as well as in healthy control patients (n = 20) and in patients with infectious colitis (n = 9). Disease activity was assessed clinically applying the Crohn’s disease activity index (CDAI) and the partial Mayo score (pMayo) for UC patients as well as the simple endoscopic score Crohn’s disease (SES-CD) and the endoscopic Mayo score (eMayo) to score endoscopic disease activity.

Results: Both in CD and in UC patients, miR-320a expression in remission was significantly increased as compared to healthy controls (49 ± 8.7 ± 17 vs. 17 ± 3; both p < 0.001) but distinctly reduced as in CD/UC patients with acute flare (1718 ± 488; p = 0.006; 531 ± 107, p = 0.001). In CD patients with acute clinical flare (CDAI > 220), miR-320a expression level were significantly increased as compared to CD patients in clinical remission (CDAI < 15, 267 ± 637 vs. 57 ± 9; p < 0.001) and showed a strong correlation with endoscopic disease activity (r = 0.70). Similarly, in UC patients, miR-320a also revealed a significant increase in patients with low (pMayo 3-4), moderate (pMayo 5-6) and severe clinical disease activity (pMayo > 6) as compared to UC patients in remission (259 ± 47; 281 ± 26; 1090 ± 204 vs.76 ± 13, all p < 0.001).

Conclusion: The miR-320a expression in peripheral blood from IBD patients followed the clinical and endoscopic disease activity and may distinguish between IBD and infectious colitis. Therefore, miR-320a might serve as biomarker to non-invasively assess the disease activity in IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1677 RISK FACTORS ASSOCIATED WITH A HIGH RISK OF COLORECTAL CANCER IN PATIENTS WITH ULCERATIVE COLITIS. PRELIMINARY RESULTS FROM THE IBSEN COHORT

P. Klepp, M. C. Smaastuen, M. Hoivik, B. Mom, I. Study Group
1Clinical Medicine, University of Oslo, Oslo/Norway
2University of Oslo, Oslo/Norway

Contact E-mail Address: paskeleep@gmail.com

Aims & Methods: Our aim was to evaluate how individual disease variables contribute to the development of colorectal cancer. A population-based inception cohort of patients with ulcerative colitis patients diagnosed between 1990–1994 have been prospectively followed at one, five, 10 and 20 years after inclusion. In this cohort of patients with ulcerative colitis patients diagnosed between 1990–1994, 239 patients were included (table 1). A total of 135 serum sample from patients with CD and UC. IFX concentration in serum samples were determined using a well established IFX-specific ELISA assay (Promonitor®) and the test assay Quantum Blue®. According to the manufacturer, the lower and upper limits of quantification are: In the Quantum Blue assay 0.4 μg/ml and 20 μg/ml respectively In the Promonitor assay 0.035 μg/ml and 14.4 μg/ml respectively. All statistics were carried out using the statistical programs IBM SPSS statistics 21 and Epidat version 4.2.

Results: The IFX levels measured by the point-of-care method were higher than those measured by established ELISA (Promonitor level: mean 4.67, median 3.2 s.d. d. 4.39 (0.035–14.4)); Quantum Blue level mean 6.31; median 3.75 s.d. 6.27 (0.4–20). The intraclass correlation coefficients were 0.81 (p < 0.001). The standard ELISA had a high (r = 0.89) and significant (p < 0.001 correlation with the Quantum Blue® assay. A Bland-Altman analysis showed a bias of 1.88% confirming the overall excellent correlation of the two methods. The results for each measurement stratified according to a common accepted therapeutic strategy are listed in Table 1. The agreement was excellent in 7 μg/ml lower than 3 and higher than 7 with a high agreement. We estimated a simplified score to convert the “point-of-care” level into “Promonitor” level and facilitate dose management: *Nivel de Promonitor = 0.793 + 0.615*Nivel QB*.

Conclusion: Our aim was to evaluate the clinical usefulness of establishing a simplified score to convert the “point-of-care” level into “Promonitor” level and facilitate dose management.

P1679 THE ADDITION OF AN IMMUNOSUPPRESSANT IS AN EFFECTIVE OPTIMIZATION STRATEGY AFTER LOSS OF RESPONSE TO ANTI-TNF ALPHA MONOTHERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A TWO-YEAR STUDY

F.S. Macaluso, C. Sapinzi, M. Ventimiglia, S. Renna, G. Rizzato, R. Orlando1, M. Di Pisa2, M. Affronti1, E. Orlando1, M. Cottone1, A. Orlando1

2Gastroenterology and Endoscopy Unit, “Villa Sofia-Cervello” Hospital, Italy, Palermo/Italy

Contact E-mail Address: fsmacaluso@gmail.com

Introduction: In patients with inflammatory bowel disease (IBD) the addition of an immunosuppressant (IM) after loss of response to anti-TNF alpha monother- apy is regarded as an emerging strategy of therapeutic optimization. However, few clinical data have been reported to date.

Aims & Methods: The aim of this study was to evaluate efficacy and tolerability of a “selective” combination therapy in patients with IBD. All consecutive patients with loss of response to anti-TNF alpha monotherapy despite an intensive dose optimization who added an IM from October 2014 to October 2016 were entered in a prospectively maintained database. The steroid-free remission and the clinical response, this latter defined as a clinical improvement (reduction of Harvey-Bradshaw Index ≥ 3 for Crohn’s disease and of Mayo Partial Score ≥ 2 for ulcerative colitis compared with baseline) with a concomitant reduction of steroid dosage compared with baseline and discontinuation within twelve weeks, were considered as responses. Few clinical data have been reported to date.

Results: Among 630 patients treated with biologics during the study period, 46 (33 Crohn’s disease and 13 ulcerative colitis) were included (table 1). A total of 31 patients (67.4%) were treated with an intravenous anti-TNFz (infliximab, as originator product or biosimilar), while 15 (32.6%) with a subcutaneous anti-TNFz agent (10 adalimumab and 5 golimumab). The mean doses of thiopurines used in combination therapy were below those regarded as therapeutic in IBD, methylxanthine was mostly employed at a dose of 15 mg/week, and all patients treated with mycophenolate mofetil were able to tolerate the target dose of 1500 mg/day. The mean duration of follow-up was 12.8 ± 7.3 months. Twenty-one patients (45.7%) remained on combination therapy at the end of follow-up: 15 (32.6%) maintained a steroid-free remission, and 6 patients (13.0%) achieved a clinical response.

All patients who experienced a treatment success, median value of C-reactive protein decreased from the baseline to the end of follow-up (13.2 vs. 3.0, p = 0.01; normal values < 5 mg/L). Adverse events leading to treatment discontinuation were reported in 8 out of 46 patients (17.4%).

Conclusion: In patients with IBD the addition of an immunosuppressant is an effective and safe optimization strategy after loss of response to anti-TNF alpha monotherapy. Low doses of IM are sufficient to achieve a clinical response in this setting.

Introduction: Extra-Intestinal Manifestations (EIM) are frequently (up to 40%) encountered in patients with Crohn’s Disease (CD). Commonly, their presence is associated to a more severe degree of luminal disease and lower response to conventional therapy (i.e. immunosuppressants). Drug trough levels are associated with biological drug response, while the role of Anti-drug Antibodies (AAA) is still debated. Moreover, the predicting factors associated with AAA development have not been thoroughly studied yet. To the best of our knowledge, there are no studies correlating the presence of EIM and AAA development.

Aims & Methods: The aim of our prospective study was to identify an association between the presence of EIM and the development of AAA in CD patients treated with biological therapy. We prospectively enrolled 60 CD patients (32 males, median age = 46y, range = 21–72) treated either with adalimumab (ADA n 39, 63%; IFX n 21, 35%) with a median follow-up of 80 (range 14–206) weeks. Blood samples were drawn at standardized time points assessed using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States).

Results: ADA were detected in 27 (45%) patients and their development has proved to be more frequent in subjects treated with IFX rather than those in therapy with ADA (n 14, 66.6% vs 13, 33.3%, P = 0.017). EIM were observed in 26 (43.3%) patients, without any significant difference between ADA and IFX patients (n 17, 51.5% vs n 9, 42.9%, P = 1). We found that ADA treated patients with EIM were more likely to develop AAA (n = 9, 52.9% versus n = 4, 18.2%, P = 0.039) while no statistically significant association between EIM and AAA development was observed in IFX treated patients (n = 5, 55.5% versus n = 9, 75%, P = 0.64).

Conclusion: We found that ADA-treated patients with EIM tend to develop more frequently AAA. Assuming that the presence of AAA reduces the effectiveness of biological therapy, the presence of EIM may be considered a predictive factor for loss of response to biological therapy with anti-tumor necrosis factor alpha drugs.

2Department Of Histopathology, St James’s University Hospital, Leeds/United Kingdom

Contact E-mail Address: jackjohnkane@goolemail.com

Introduction: Patients with microscopic colitis (MC) often present with abdominal pain and diarrhoea1, and small cross-sectional surveys suggest that up to one-third may meet diagnostic criteria for irritable bowel syndrome (IBS)2. However, the impact of IBS-type symptoms in patients with MC, in terms of their effect on psychological health and quality of life has not been assessed. Aims & Methods: We conducted a cross-sectional survey of individuals with MC. We analysed demographic data, symptoms that met the Rome III criteria for IBS, mood (via hospital anxiety and depression scale (HADS)) and somatoform-type behaviour (via patient health questionnaire-15 (PHQ-15)) and quality of life (QOL) (via SF-36) in order to determine risk factors for, and impact of, IBS-type symptoms in patients with MC.

Results: In total, 157 individuals with MC returned completed questionnaires, 53 (36.0%) of whom met the Rome III diagnostic criteria for IBS. The commonest IBS subtypes in MC were collagenous colitis (52.9%, n = 83), followed by lymphocytic colitis (38.2%, n = 60), and MC-not otherwise specified (8.9%, n = 14). Individuals meeting the Rome III criteria for IBS had significantly higher levels of anxiety (HADS-anxiety score 8.6 vs. 5.0, P = 0.001), depression (HADS-depression score 6.1 vs. 3.5, P = 0.001), and somatoform-type behaviour (PHQ-15 score 12.5 vs. 7.9, P < 0.001) compared with individuals who did not. Individuals meeting the Rome III criteria scored significantly worse on all domains of the SF-36, except for physical functioning. There were also trends towards these individuals being younger (65 years vs. 69.2 years, P = 0.011) or taking proton-pump inhibitors (58.5%, n = 31 vs 42.4%, n = 39, P = 0.062).

Conclusion: More than one-third of individuals with MC met diagnostic criteria for IBS and these individuals reported higher levels of anxiety, depression, and somatisation plus impaired quality of life. Management strategies for these symptoms are required.

Introduction: Ustekinumab (UST) has been shown to be effective in refractory Crohn’s disease (CD) in phase III trials. The aim of the present study was to prospectively evaluate the association between UST trough levels and anti-ustekinumab antibodies, with the response and remission to induction and maintenance UST treatment in CD patients.

Aims: We performed a prospective study including all CD patients refractory to anti-TNF who received subcutaneous UST from September 2015 to November 2016 in the tertiary French referral center of Gastroenterology in Cliniques Universitaires de Lille. During induction patients received 90mg of SC UST at week 0, 4 and 12. During the maintenance phase patients received 90 mg of SC UST every 8 weeks that could be optimized by shortening injection 77% of patients received concomitant immunosuppressant and 42% received corticosteroids. At the end of the induction phase (week 12) clinical response was observed in 57% patients. There was no significant difference in mean UST trough levels in patients who responded to UST induction (median 1160 ng/ml; IQR: 603–1644) as compared to patients who did not respond (median 1556 ng/ml; IQR: 494–2758, p = 0.24). Forty-three (90%) patients received at least 4 injections of UST, with 12 patients who were optimized at the time of dosages. Clinical response was observed in 30.4% (70%) patients. Median UST concentration in clinical responder was 1359 ng/ml (IQR: 554–2086) and 2392 ng/ml in non-responder (IQR: 1496–3494), with no significant difference between the two groups of patients (p = 0.20). UST antibodies were undetectable for the 48 patients.

Conclusion: We confirmed that UST treatment is effective in the majority of CD patients refractory to anti-TNF agents. Median trough levels to UST are not correlated to response and remission to UST induction and maintenance treatment, with no antibodies developed against UST.

Introduction: Inflammatory bowel diseases (IBDs) are chronic conditions characterized by elevated costs (both direct and indirect). Over the last years also a significant healthcare burden associated with IBD has emerged, due to an increasing use of biological therapies and hospitalization costs. Despite the creation of local or regional databases in Italy data regarding healthcare expenditure are lacking.

Aims: The aim of this study was to evaluate costs comprehensive of biological treatments and hospitalizations in a series of patients with ulcerative colitis (UC) and Crohn’s disease (CD) and their correlation with demographic and clinical variables. Disease severity was evaluated by clinical scores (partial Mayo score for UC, Harvey Brashaw Index for CD). We analyzed retrospectively patients treated by biologics referred to our IBD Unit between May 2015 and April 2016 who underwent at least six months follow-up (last visit October 2016). As regards biological therapies costs burdens our Centre pharmacy for each drug (Infliximab, Adalimumab, Golimumab, Vedolizumab) and for single patient were evaluated. About hospitalizations the average costs of hospital care specific for a department through fares for homogeneous groups of patients i.e. Diagnosis-Related Group (DRG) were collected. The mean overall monthly expenditure for each case was then evaluated.

Results: We collected clinical-economical data of 142 patients in biological treatment for IBD, with no significative differences between UC and Crohn’s disease. The results show the positive correlation between the number of hospitalizations and the average costs per patient. The amount of costs for hospitalizations amounts for more than 80% of the total costs. We analyzed in groups different for sex and age and disease activity only the last one was associated with increased costs with R² = 0.84 for UC and 0.95 for CD. The cost increases in patients with more lines of therapy in UC (not in CD) but the difference wasn’t significative.

Conclusion: In our study the main cost is due to biological therapy but the subjects enrolled were the most severe in comparison to the whole IBD population under conventional therapy. No differences were found between the type of biologic administered and the way of administration (intravenous or subcutaneous) so the therapeutical choice could be driven by clinical reasons and not only economic ones.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Useklinumab (UST) has been shown to be effective in refractory Crohn’s disease (CD) in phase III trials. The aim of the present study was to prospectively evaluate the association between UST trough levels and anti-ustekinumab antibodies, with the response and remission to induction and maintenance UST treatment in CD patients.

Aims: We performed a prospective study including all CD patients refractory to anti-TNF who received subcutaneous UST from September 2015 to November 2016 in the tertiary French referral center of Gastroenterology in Cliniques Universitaires de Lille. During induction patients received 90mg of SC UST at week 0, 4 and 12. During the maintenance phase patients received 90 mg of SC UST every 8 weeks that could be optimized by shortening injection interval to every 4 weeks in case of loss of response. Clinical response was defined by decrease Harvey Bradshaw Index (HBI) by 3 points, clinical remission by HBI < 5, loss of response by new increase of HBI. UST trough levels and anti-ustekinumab antibodies were correlated with Hb and transferrin saturation (13.63 /C6 26.50 vs 17.75, p = 0.003), previous surgery (OR 2.845 95% CI 1.111–7.284, p = 0.02) and pene-trating pattern in CD (OR 8.252 95% CI 1.289–52.919, P < 0.001). Hb and CRP had a negative correlation (p = 0.016, p = 0.022). In UC, CRP and FC normalization was associ-cated to transferin saturation (13.63 /C6 1.66 vs 12.47 ≥ 1.38, p = 0.005 and 51.33 ≥ 26.0 vs 27.63 ≥ 9.96, p = 0.048). There was no difference in the parameters evaluated comparing groups 1 and 2. There was also no significative difference in the variation of Hb and iron values after treatment with ferric saccharate and ferric carboxymaltose.

Conclusion: In a population of patients with IB, iron deficiency was the main cause of anaemia and the two forms of intravenous iron replacement were equally effective. In the group of patients with UC, elevated CRP was associated with anaemia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The monitoring of appropriateness, costs, and clinical outcomes of biological therapy in inflammatory bowel disease (IBD) is a relevant need. Aims & Methods: We aimed to evaluate all these issues in Sicily through a web-based network of all prescribing centers. The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed by a super Hub coordinator centre and a Harvey-Bradshaw Index (HBI) for UC, and to a Harvey-Bradshaw Index (HBI) for CD.

As clinical end-point, we set remission (corresponding to a Mayo Partial Score <2) for UC, and to a Harvey-Bradshaw Index (HBI) for CD, and response (reduction of mean stool frequency and/or stools/day/week), clinical response (defined as 50% reduction of mean stool frequency/day/week), and clinical remission (defined as no effect on anti-TNF despite the fact that 2 patient had even tested both anti-TNF agents. In the cases that failed anti-TNF, further treatment with vedolizumab (n = 14) did not gain clinical remission despite the use of a third anti-TNF agent (certolizumab pegol). Four patients had an adverse event (vomiting, anxiety, fatigue and eczema—all reversible). Two patients had a serious adverse event (septicemia).

Results: From January 2013 to January 2017, 1578 patients were included. Incident cases were 1151 (808 Crohn’s disease [CD], 335 ulcerative colitis [UC], no significant difference in efficacy was observed between IFX originator (n = 5) and its generic (n = 10) at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF agent in UC; no difference was found between GOL and IFX in UC. Being naive to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

Conclusion: In one of the largest “real-life” series of IBD patients on biological therapy reported to date, ADA in CD had a higher success compared to IFX at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF agent in UC; no difference was found between GOL and IFX in UC. Being naive to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

Introduction: Recent studies have shown that FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols)-free diet is effective in subjects with Irritable Bowel Syndrome (IBS). Patients with Inflammatory Bowel Diseases (IBD), and celiac disease (CD) can experience functional gastrointestinal symptoms unrelated to inflammation, but data about the use of low FODMAPs diet in these settings is still scarce.

Aims & Methods: To evaluate the usefulness of a low FODMAPs diet on patients with IBS, non-active IBD, and CD on strict gluten-free diet (GFD), we performed a dietetic interventional prospective study evaluating the effect of a low FODMAPs diet on subjects affected by IBS, CD following at least a 1-year-GFD and IBD who had been experiencing gastrointestinal symptoms without signs of active inflammation. Each subject was put on a low FODMAPs diet after being evaluated by filling out questionnaires concerning on quality of life and symptoms experienced (IBS-SSS and SF-36), and was re-evaluated twice, first after 1 month and second after 3 months.

Results: 127 subjects were enrolled: 56 with IBS, 30 with IBD and 41 with CD. The analysis of the IBS-SSS survey showed that abdominal symptoms improved after 1 month of low FODMAPs diet in all subjects, with statistically significant difference within each group at T0 (average score in IBS: 293 ± 137 SD, average score in IBD: 206 ± 86 SD, average score in CD: 222 ± 65 SD, p < 0.0001). Furthermore, by analysing the SF-36 questionnaire, while we did not observe any significant difference between the three groups, in terms of response to diet (p = NS), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire’s domains.

Conclusion: A low FODMAPs diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Introduction: Vedolizumab (VDZ) is a new biologic agent approved for the treatment of adult patients with moderately to severely active ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Method: The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed by all Sicilian centres prescribing biologics. These centres continuously enter in a web based software all real-life data about pre-scriptions and outcomes of biological therapy in patients with inflammatory bowel disease (IBD). Herein we report data on efficacy of VDZ on intestinal and articular symptoms after 10 and 24 weeks of treatment. As clinical end-point, we set steroid-free remission (corresponding to a Mayo Partial Score < 2 for UC, and to a Harvey-Bradshaw Index < 5 for CD), and clinical response (reduction of Harvey-Bradshaw Index ≥ 3 for CD and Mayo Partial Score ≥ 2 for UC compared with baseline with a concomitant reduction of steroids dosage at week 10, and complete discontinuation at week 24).

Results: From July 2016 to April 2017, 163 patients (84 with CD and 79 with UC) were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients reaching 24 weeks of follow-up, 29 (40.8%) were in steroid-free remission, and 10 (14.1%) had a clinical response. No significant difference in terms of clinical benefit (rate of remission plus clinical response) among patients with UC and CD was reported at week 10 (68.4% vs. 64.3%, respectively; p = 0.58) and at week 24 (54.3% vs. 55.6%, respectively; p = 0.91), and no difference was observed comparing naïve and non naïve patients, neither at week 10 (61.5% vs. 67.7%, respectively; p = 0.48) nor at week 24 (30.0% vs. 39.9%, respectively; p = 0.11). At multiple regression analysis, a longer duration of disease (OR 0.961, p = 0.047) and presence of steroid-dependence (OR 0.189, p = 0.033) were predictors of reduced rates of clinical benefit at week 10, while a lower serum level of C-reactive protein at baseline (OR 0.950, p = 0.031) was predictor of clinical benefit at week 24. An improvement of articular symptoms was reported in 39.5% of patients with active spondyloarthritis at baseline at week 10, and in 45.4% of patients at week 24. The only factor associated with articular response was the coexistence of clinical benefit on intestinal symptoms, both at week 10 (OR 8.471, p = 0.05) and week 24 (OR 5.600, p = 0.08). Three inductions or flares of spondyloarthritis during treatment with VDZ were reported.

</tbody>
</table>

Conclusion: In this large cohort of Sicilian IBD patients, VDZ showed good efficacy after 10 and 24 weeks of treatment, particularly in those with a shorter duration of disease and a limited inflammatory burden. A subset of patients reported improvement also on articular symptoms, probably as a consequence of the concomitant control of gut inflammation.

Introduction: Combined immune suppression of anti-tumour necrosis factor (antiTNF) biologicals and thiopurines is superior to respective monotherapies in remission induction and maintenance of response in inflammatory bowel disease (IBD) due to the mutually positive pharmacokinetic effect of thiopurines on antiTNF levels and vice versa. It has been suggested that for this synergistic effect, reduced dose of thiopurines might be sufficient but the data supporting this hypothesis are still limited.

Aims & Methods: The aim of the study was to assess the differences of infliximab trough levels according to the dose of concomitantly used thiopurines. All IBD patients treated with infliximab (Remicade®) in two IBD centres between November 2015 and April 2017 were eligible. Infliximab trough levels were routinely measured in all patients with maintenance infliximab therapy using commercially available ELISA kit (Ridscreen®, R-Biopharm). All patients in remission with stable dose regimen of 5mg/kg every 8 weeks at the time of the first assessment of infliximab trough levels were identified retrospectively from the medical records. The differences in the proportion of patients with adequate trough levels (3–12 µg/mL) between patients on infliximab monotherapy, reduced (below 2mg/kg) azathioprine (AZA) dose vs. full (2 to 2.5 mg/kg) AZA dose were analyzed statistically.

Results: Out of a total of 214 IBD patients treated with infliximab, there were 154 in remission at the time of the first assessment of infliximab trough levels. After excluding patients with previously intensified dose regimen, 125 patients were further investigated. Among these 125 pts, 41 pts (33%) were on infliximab monotherapy, 58 pts (46%) were using combined immune suppression with a reduced dose of AZA and 26 (21%) were using the full AZA dose concomitantly with infliximab. Both groups, patients with infliximab monotherapy as well as patients using the reduced AZA dose had significantly lower percentage of patients with therapeutic levels of infliximab compared with the group using the full dose AZA co-medication (41% vs. 64% vs. 81%; infliximab monotherapy, reduced AZA dose and full AZA dose, respectively; p<0.001 for both comparisons, infliximab monotherapy vs. reduced AZA dose vs. full AZA dose).

Conclusion: The proportion of patients with adequate infliximab trough levels is significantly higher in patients with full dose of concomitant azathioprine compared with the patients using a reduced dose of azathioprine. Thus, in order to maximize the chances for sustained benefit from infliximab maintenance treatment, the combined immune suppression should comprise full dose of azathioprine.

Introduction: The primary drugs used for inflammatory bowel disease (IBD) treatment have some adverse effects and often are ineffective, so the need for more potent and more reliable medications is clear. A significant role at all the stages of the inflammatory process is attributed to reactive oxygen species, therefore the use of antioxidants is a promising direction of the IBD therapy.

Aims & Methods: C60 fullerene are the effective free radicals scavengers [1], therefore the evaluation of possible protective properties of water-soluble pristine C60 fullerene using the simulation of acute ulcerative colitis (UC) in rats was aimed to be discovered. The pristine C60 fullerene aqueous colloidal solution (C60-FAS; initial concentration 0.15 mg/ml) was prepared according to the protocols described before [2]. UC was simulated by acetic acid intracolonic instillation. C60-FAS was intraperitoneally or intrarectally applied at dose of 0.5 mg/kg C60 daily for 2 times after UC induction. The colon injury was estimated semi-quantitatively on macro- and light microscopy levels using 10- and 14-grade score, respectively, and the grade of total injury (GTI) was calculated. Permeability of colon epithelium was estimated by phenol red dye daily excretion. The states of the colon, liver, pancreas and spleen were assessed by histological (hematoxylin-eosin staining) and biochemical (plasma blood liver enzymes activity) methods, quantitative blood indices were calculated and leukograms were analyzed.

Results: Colon wall edema, hyperemia and hemorrhage on bowel internal surface, ulcers of different size, epithelium desquamation and inflammatory features manifested by submucosa lymphoid and histiocyte infiltration and extravasation appeared under UC condition. Therapy with G60 FULLERENES MANIFESTATION IN INFLUXIMAB TROUGH LEVELS IS DOSE-DEPENDENT

Conclusion: G60-FAS corrects local and systemic morphofunctional changes, conditioned by the induction of acute UC. The protective properties of C60 fullerene against bowel, hematopoietic system and liver due to its local application are more expressed compared to their systemic one, but their impact on pancreas is controversial. Thus, water-soluble pristine C60 fullerene could be used as efficient therapeutic agents at ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Tacrolimus, a calcineurin inhibitor, has been shown to be safe and effective when used as salvage therapy for steroid-refractory ulcerative colitis (UC). Its pharmacological effect has been reported to be dependent on trough level in blood, though little is known regarding predictive factors in relation to the clinical efficacy of tacrolimus in UC patients.

Aims & Methods: The aim of this study was to identify factors related to prediction of short- and long-time efficacy of tacrolimus for UC. We retrospectively reviewed the medical records of patients with moderate to severe steroid-refractory UC who were treated with tacrolimus as induction therapy at Shimane University Hospital between January 2010 and March 2016. Oral tacrolimus was administered at a whole-blood trough level of 10–15 ng/mL to induce remission and then 5–10 ng/mL to maintain remission. Following tacrolimus therapy for 3 months, patients in clinical remission were given azathioprine for maintenance at an appropriate dosage. Using the Rachmilewitz clinical activity index (CAI), clinical remission was defined as a score of ≤4. Predictive factors associated with short- and long-term tacrolimus efficacy were analyzed by evaluating various clinical parameters.

Results: Thirty-six patients received oral tacrolimus for induction, of whom 22 (61.1%) and 27 (75%) experienced clinical remission at 2 and 12 weeks, respectively, after starting therapy. In order to achieve short-term efficacy, the remission rate at 2 weeks was significantly associated with CAI at 2 weeks. Interestingly, of the 22 patients in clinical remission within 2 weeks, 21 (95.5%) remained in remission at 12 weeks. In contrast, only 6 of 14 (42.9%) who did not achieve clinical remission at 2 weeks were not in clinical remission at 12 weeks. For evaluating the long-term efficacy of tacrolimus induction therapy, relapse-free periods were assessed using the Kaplan-Meier method. The relapse-free rate at 48 weeks was higher in patients who achieved clinical remission within 2 weeks compared to those without remission at that time point (79.0% vs. 60.0%).

Conclusion: Tacrolimus induction therapy was effective for patients with moderate-to-severe steroid-refractory UC. Our results clearly indicate that clinical remission achievement within 2 weeks is useful for predicting both short- and long-term outcomes in UC patients treated with that therapy.

Introduction: UC is a potentially severe disease that carries an increased risk of complications and colectomy. Immunosuppressant and biological therapies are relevant tools for complex patients. The ACCENT study showed that in Crohn’s disease (CD), scheduled IFX infusions vs. episodic are associated with greater efficacy. However, the difficulties of economic access had conditioned to our IBD center, to use IFX in moderate to severe UC as a bridge to thiopurines in 6 mp/aza naïve. In UC, the mentioned strategy was sufficiently compared with a regimen of scheduled IFX treatment, that currently we use.

Aims: Similarly to be compared in moderate to severe UC the results of induction with IFX (in thiopurine naïve pts) continuing with 6 mp/aza maintenance vs. similar induction followed by scheduled IFX maintenance strategy.

We included a cohort of moderate to severe UC treated with IFX in an IBD center (2006 to 2015) comparing results between IFX bridge followed by thiopurines (re-induction when available for moderate to severe relapse) vs. scheduled IFX (w/ 2.6, w/ 8 and w/ 12 interval infusions maintenance).

Conclusion: Kaplan Meier/Log rank test: a) Cumulative incidence of colectomy (difference is 7.46% (p = 0.06) in re-induced pts. b) survival time relapse free, c) survival time corticosteroid free.

Introduction: Arthropathies are the most common extra-intestinal manifestation (EIM) in patients with inflammatory bowel disease (IBD). Psychological and behavioural factors, including illness perceptions and coping strategies, perceived by IBD patients with arthropathies may differ from patients without arthropathies and may change during follow-up. Understanding these differences and changes over time, creates knowledge for health care professionals about interventions that may be effective in IBD patients with arthropathies.

Aims & Methods: This longitudinal follow-up study evaluates the differences in illness perceptions, cognitive and emotions regarding a disease and coping strategies (behavioral efforts and strategies to deal with a chronic disease) and illness outcomes between IBD patients with and without arthropathies, and examines the changes of these variables in IBD patients with arthropathies after 12 months.

In total, 204 IBD patients with (n=123) and without (n=81) arthropathies completed questionnaires at baseline and after 1 year follow-up to assess illness perceptions (Revised Illness Perception Questionnaire), coping strategies (Coping with Rheumatic Stressors Questionnaire) and illness outcomes including quality of life (Short Form-36), and activity and work impairment (Work Productivity Activity Index). Linear regression analyses were used to assess the impact of arthropathies on illness perceptions, coping and illness outcomes compared with IBD patients without arthropathies. Mixed model analyses were used to evaluate the change of these variables in IBD patients with arthropathies over time.

Results: Linear regression models demonstrated that arthropathies in IBD were associated with the illness perceptions stronger ‘illness identity’ (β = 0.31 (95% CI 0.31-0.36); p < 0.001), stronger ‘cyclical timeline’ (β = 0.33 (95% CI 0.33-0.34); p = 0.001), more ‘concerning disease’ (β = 0.20 (95% CI 0.16-0.22); p = 0.006), stronger ‘emotional representations’ (β = 0.27 (95% CI 0.20-0.35); p = 0.002) than without arthropathies.

Introduction: CT-P13, the first biosimilar monoclonal antibody to infliximab (IFX) has previously been confirmed to be efficacious in inducing mucosal healing in ulcerative colitis (UC) patients.

Aims & Methods: The aim of this study was to evaluate the efficacy of CT-P13 therapy in maintaining mucosal healing in UC. Patients diagnosed with UC, who were administered CT-P13 from June 2014 at 4 Hungarian and one Czech IBD Centre were prospectively enrolled. Sigmoidoscopy was performed at week 14 and week 54 to assess mucosal healing. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore of 0. CT-P13 trough levels, antibody positivity, serum inflammatory markers as CRP level, fecal calprotectin were assessed at the time of induction and during follow-up and at weeks 14 and 54, previous use of anti TNF drug and the need of dose intensification as possible predictive factors for mucosal healing at week 54 were evaluated. Relevant data of seventy-five UC patients were included in the study of which 74 patients completed the induction therapy and 54 patients had already completed the 54 week treatment period. Mucosal healing was shown in 55.4% of the patients at week 14 and in 61.7% at week 54 (p = 0.033). Complete mucosal healing was present in 24.3% at week 14, but in 36.8% at week 54. The positive interventions including cognitive behavioural therapy (CBT) or physical exercise.

Introduction: Anti-tumor necrosis factor (anti-TNF) agents, infliximab (IFX) and more recently adalimumab (ADA) and golimumab (GOL), have been shown effective and safe in the treatment of moderate-to-severe ulcerative colitis
were treated with IFX (p < 0.001). ADA and GOL were more often used as a second-line or third-line. The principal indication for steroid-resistant patients was IFX. No significant difference was observed between IFX and ADA both at week 8 (p = 0.18; response IFX p = 0.08) and at week 16 (p = 0.5; remission p = 0.97), though there was a trend towards a higher rate of response at week 8 with IFX (79% vs 64%). IFX and ADA were more effective than GOL at week 8 (response IFX vs GOL p = 0.020; remission: ADA vs GOL p = 0.027). At week 16 only IFX seems to be more effective than GOL in inducing clinical response (p = 0.048) but not remission. No significant difference among the three drugs was observed in patients naïve to anti-TNFs. Treatment was discontinued in 2 patient in IFX group and in 6 patients in GOL group and in 6 patients with ADA because of persistent disease activity.

Conclusion: This single-center study shows that IFX is more effective than both in the induction (8 weeks) and in the maintenance of response (16 weeks). ADA is more effective than GOL in inducing remission at 8 weeks but no significant difference is observed in the medium-term. However, GOL was used mainly as a second or third-line. In naïve patients, efficacy among anti-TNFs is comparable. Our results may help clinicians in the choice of an anti-TNF in UC. We should prefer in steroid-resistant patients to get a faster response, ADA and GOL should be the first option in steroid-dependent patients naïve to anti-TNFs.

Introduction: Vedolizumab (VDZ), a gut-selective monoclonal anti-a4ß7-integrin antibody, is used for treatment of Crohn’s disease (CD) and ulcerative colitis (UC). Data from large real-world cohorts can further characterise safety events not fully elucidated in a clinical trial setting, such as the risk of serious infections, as identified with anti-tumour necrosis factor-alpha (TNFα) therapy in the TNFα blockade/anti-TNFα/ENCORE® trials.

Aims & Methods: We conducted a systematic review and meta-analysis of real-world safety outcomes reported for VDZ in UC and CD. MEDLINE-, Cochrane-, and EMBASE-indexed publications and conference abstracts (n ≥ 10) from May 1, 2014–January 10, 2017 were searched for studies reporting real-world VDZ safety outcomes. Reports for patients <18 years of age or for off-label VDZ use were excluded. A meta-analysis was conducted using the DerSimonian-Laird random effects method to obtain a weighted mean of adverse events (AE) rates.

Results: Two hundred and eighty published studies were identified, with 33 reporting safety rates on 2857 VDZ-treated patients (CD: 1532; UC: 829; unspecified/other: 36; three studies [n=460] did not report individual UC/CD data) over a VDZ exposure/follow-up period ranging 0.5–18 months (20 studies). Among included studies, the mean age of patients ranged from 21 to 67 years, with mean disease duration ranging from 7 to 16 years. Most VDZ-treated patients (62–100%) had prior exposure to ≥1 anti-TNFα therapy and 6–64% of VDZ-treated patients were receiving concomitant corticosteroids and immunomodulators. The most common non-infectious AEs were acute or acnec-like lesions (7%; 95% confidence interval [CI] 3–11%), fatigue (6%; 95% CI 3–15%) and arthropalgia (5%; 95% CI 3–10%) (Table 1). The most common infectious AEs were upper respiratory tract infections (6%; 95% CI 3–9%) and sinusits (4%; 95% CI 1–19%) (Table 1). Infusion-reaction-related occurred in 2% (95% CI 1–4%) of patients (n = 811), and malignancies were reported in <1% of patients (<1–4%; 2 studies). Overall, the pooled AE rate reported in VDZ-treated patients was 21% (95% CI 14–32%); 10% (95% CI 6–16%) for infections, 8% (95% CI 6–10%) for serious infections and 7% (95% CI 3–13%) for serious infections (Table 1).

Disclosure of Interest: All authors have declared no conflicts of interest.

*Includes paradoxical skin manifestations, acne, generalised exanthematous pustulosis, dry skin, erythema nodosum, palmar erythema. Includes spontaneous nausea. Includes liver test abnormalities (transaminis transientis), drug-induced liver injury (not specified). Includes severe musculoskeletal syndrome, exacerbation of pre-existing enteropatic arthritis. Includes pneumonia, lower respiratory tract infections, respiratory tract infection (not specified).

Conclusion: Pooled analysis of AE rates across multiple studies support the favourable, long-term benefit-risk profile of VDZ in real-world clinical practice, with low rates of infusion-related reactions, serious infections and malignancies reported, and no identification of new safety signals. These results are consistent with integrated safety data reported for VDZ in six clinical trials (>4000 patient-years), despite the selection of complex patients failing previous immunosuppressive or biologic therapies. Limitations of incidental reporting in real-world studies include potential underestimates of AE rates and the reporting of AEs not regularly observed in clinical trials; for example, due to the variability in concomitant medication use and sub-optimal screening of prior infections.

United European Gastroenterology Journal 5(5S)
Introduction:

Although many biologies (Bs) have been approved for the treatment of ulcerative colitis (UC) patients who have responded inadequately to conventional therapy, the selection of Bs is controversial due to the lack of head-to-head trials. Indirect economic comparisons of these costly drugs are available from National Healthcare perspectives that are not the Italian ones.

Aims & Methods:
The objective is to evaluate cost-utility of Bs for the treatment of refractory moderate-to-severe UC both in Italy and in the Lombardy Region. A Markov model (considering 3 transition states: remission, clinical response, relapse) is constructed using the software R (a R markovchain-package) to evaluate incremental cost-utility ratios (ICUR) of adalimumab (ADA), infliximab (IFX), infliximab biosimilar (IFX-B), golimumab (GOL) and vedolizumab (VED) treatments of patients over a 10-year time horizon from the perspective of the Italian (N) and Lombardy Region (R) healthcare system. Clinical parameters were derived from clinical trials. Costs (actualised by -1.5%) were obtained from the National database and Regional public tender. Utility was expressed as QALY (Quality Adjusted Life Years).

Results:
 Costs per treatment were different from a N and R perspective (ADA -55%; IFX -16.7%; IFX-B -29.6%; GOL -9.6%; VED -10%). Direct healthcare costs (treatment cost, visits, lab tests, hospital admissions) were calculated over 10 years of treatment per patient: ADA (N: 114,227, R: 110,438), IFX (N: 130,955, R: 103,081), IFX-B (N: 110,438; R: 78,852, -28.6%), GOL (N: 118,602, R: 96,923, -18.3%), VED (N: 113,852, R: 102,932, -9.6%) with associated QALY respectively of 6.68, 6.66, 6.66, 6.70, 7.02. From a N perspective, IFX-B was dominating compared to all other treatments. The ICUR of VED/IFX-B was 49,483 for 10 years (willingness to pay €490/QALY). From a R perspective, ADA was dominating compared to all other treatments. The ICUR of VED/ADA was 101,818 for 10 years (€102,932/QALY).

Conclusion:
National and Regional cost-utility analyses produced different results. As Regional price discounts can occur, local analysis is needed to estimate the economic impact of therapies to ensure optimal choice.

Disclosure of Interest:
All authors have declared no conflicts of interest.

P1698 ENDOSCOPIC SUBMUCOSAL DISSECTION OF ULCERATIVE COLITIS-ASSOCIATED DYSPLASIA: A SINGLE CENTER-BASED EXPERIENCE
Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: gi.dry.yang@gmail.com

Introduction:
Dysplasia is considered as the precursor of colitis-associated cancer in the long standing ulcerative colitis (UC). Although endoscopic submucosal dissection (ESD) has been suggested as an endoscopic resection technique for non-polyoid dysplasia, only a few studies investigated the feasibility of ESD as a treatment option of non-polyoid dysplasia.

Aims & Methods:
We aimed to investigate the feasibility of ESD for the resection of ulcerative colitis-associated dysplasia (UCAD) in UC. From August 2009 to January 2017, 19 UC patients with low grade dysplasia (LGD), high grade dysplasia (HGD) or early colon cancer were admitted for ESD and their medical records were retrospectively reviewed.

Results:
Mean age of the 19 patients was 55.5±15.4 years and mean duration between UC diagnosis and dysplasia detection was 13.7±6.5 years. Nine were male. Five of 19 patients directly underwent colectomy without ESD trial due to non-lifting sign (n=4) or surface ulceration (n=1). Of these, preoperative single HGD (n=3) or ECC (n=1) patients showing non-lifting sign were diagnosed as invasive cancer and a single preoperative LGD case with non-lifting sign had multifocal LGDs in the colectomy specimen. As a result, ESD was performed for 14 of 19 patients. Major and minor axes of the lesion was 23.4±9.0mm and 18.1±9.1 mm, respectively. The lesions were located at the rectum (n=9), sigmoid colon (n=2), descending colon (n=1), and transverse colon (n=1). The gross morphologic showed Paris IIa (n=7), IIb (n=4), Is (n=1), and Ib+Is (n=2). No lesions contained ulcerations. The borders were distinct in 6 and vague but endoscopically assumable in 8 cases. Mean UC endoscopic index of severity of the surrounding mucosa was 0.3±0.1. Mean resection time was 54.8±25.7 minutes. En bloc resection and R0 resection rates was 92.9% and 71.4%, respectively. There was no perforation or clinically significant bleeding.

Mean hospitalization period after ESD was 1.14±0.36 days. Final histology of ESD specimens revealed 1 indefinite for dysplasia (IND), 1 sessile serrated adenoma/poly, 7 LGDs, 3 HGDs, and 1 intramucosal adenocarcinoma. Synchronous lesions were present in 5 patients. Synchronous dysplasia in 4 patients were removed endoscopically. However, colectomy was done in one patient having synchronous adenocarcinoma and endoresection by ESD and the other developed both metachronous and recurrent LGDs at 8 months after ESD.

Conclusion:
According to our ESD series for dysplasia, ESD seems to be feasible for the endoscopic resection of UC-associated dysplasia. However, meticulous surveillance colonoscopy is mandatory to monitor local recurrence and metachronous dysplasia. Non-lift sign and surface ulceration are highly suggestive of invasive colitic cancer.

Disclosure of Interest:
All authors have declared no conflicts of interest.

References
clinical scoring as compared to only half of the low-producers, but statistical significance was not reached due to the small number of patients (high: 101% vs. low: 50%, p = 0.167). However, remission rates after 6 weeks were significantly higher in high-producers compared to low-producers: (high: 80% vs. low: 0% remission; p = 0.048). Secondary endpoints showed no significant difference in the two groups.

Conclusion: Quantification of TNF-expression in PBMCs and the resulting classification in low- and high-producers could be a potential predictive marker for response to anti-TNF-treatment in IBD patients.

P1701 EVALUATION OF CONCOMITANT CORTICOSTEROID AND VEDOLIZUMAB USE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD) IN REAL-LIFE CLINICAL PRACTICE

T. Ylisaakko-Oja1, J. Aaltonen1, S. Torvinen1, A. Eber1, H. Nuutinen1, T. Blomster2, A. Jussila2, M. Pajala3, J. Jokelainen1, S. Herrala3, K. Tamminen1, T. Sipponen1
1Takeda Oy, Helsinki/Finland
2Department Of Gastroenterology, Helsinki University Hospital and University of Helsinki, Helsinki/Finland
3Department Of Medicine, Turku University Hospital, University of Turku, Turku/Finland

Objective: To analyze vedolizumab use in inflammatory bowel disease (IBD) patients who were on concomitant corticosteroids at the time of initiating vedolizumab treatment. The main aim of the study was to analyze vedolizumab treatment of IBD patients who received at least one vedolizumab infusion since 2014. Key data collection points were at baseline, week 14 and month 6 of vedolizumab treatment. The main aim of the study was to analyze vedolizumab treatment persistence in patients with Crohn’s disease (CD) and ulcerative colitis (UC).

Methods: We included 50 patients (mean age 45.5 y; male 56%) with Crohn's disease (CD, n = 26) and Ulcerative colitis (UC, n = 24). 44 (88%) IBD patients had previous anti-TNF therapy. Baseline median HBI was 8 (5–16) and median pM Mayo was 6 (5–7). Median VTL (Interquartile range, IQR) at weeks 6, 10 and 14 were 38.6 (20.3–53.5), 25.4 (13.4–45.6) and 17.7 (10.1–33.7) ug/ml, respectively. VTL measured at week 6 were significantly higher in clinical responders as compared to non-responders: median (IQR) 55.8 (46–64.1) vs 33.3 (13.4–20.6) ug/ml, p = 0.04. Week 6 VTL were also higher in CRP responders (<5 mg/l): median (IQR) 48.1 (32.5–55.8) vs 32.8 (19.7–44.3) ug/ml, p = 0.04. Week 6 VTL were inversely correlated with CRP (rho = −0.39, p = 0.006). By ROC curve analysis cut-off identified as 44.3 ug/ml for clinical response at week 6 (AUC 0.677, sensitivity 61.9%, specificity 79.3%, p = 0.02). Week 6 VTL were significantly higher in IBD patients in clinical remission at their last follow-up (mean 20 weeks) compared to non-remitters: median (IQR) 55.8 (46–64.1) vs 33.3 (25.9–40.4) ug/ml, p = 0.0035. The ROC curve analysis identified a cut off of 44.3 ug/ml (AUC 0.813 sensitivity 88.9%, specificity 73.2%, p = 0.0006). Week 14 VTL were also significantly higher in IBD patients in clinical remission at 22 weeks compared to non-remitters: median (IQR) 38.3 (20.5–49.8) vs 13.4 (8.4–20.6) ug/ml, p = 0.0035. The cut off identified by ROC curve analysis for this outcome was 16.4 ug/ml (AUC 0.820 sensitivity 100% specificity 63%, p = 0.0019). AVA were detected in 2% of patients at week 6, in 5.9% at week 10 and in 4.5% at week 14 and were not correlated with clinical response.

Conclusion: These preliminary data suggest that obtaining a VTL of 44.3 ug/ml after the first 2 Vedolizumab infusions is correlated with early clinical and biological (CRP) response and with clinical remission at a mean follow-up of 20 weeks. Week 14 VTL are correlated with clinical remission at week 22 and the identified cut off is 16.4 ug/ml. Immunogenicity of Vedolizumab is low in these patients.

All other authors have declared no conflicts of interest.

Introduction: Strictures in Crohn’s disease (CD) may occur in different segments along the gastrointestinal (GI) tract. In contrast to ileocolic strictures, endoscopic balloon dilation (EBD) is a potential treatment option for the treatment of upper gastrointestinal (UGI) tract strictures that is rarely reported. We therefore performed a comprehensive efficacy and safety analysis of EBD for CD-associated strictures in this multi-centre cohort study.

Aims & Methods: Individual patients characteristics were retrieved from electronic case report forms. Upper GI tract was defined as esophagus, stomach and duodenum up to the ligament of Treitz. Time-to-event analysis was performed to assess symptom recurrence, re-dilation or surgery. Kaplan-Meier estimates were used for survival analysis. For the multivariable Cox regression models, all variables that were available for at least 85% of subjects were considered for inclusion and the score method was used to choose the best model with two factors for each outcome.

Results: A total of 73 CD patients and 127 performed dilation procedures were included. Stricture location were: duodenum n = 46, stomach n = 14; esophagus n = 9; stomach and duodenum n = 4. Technical success rate was 94.1%, resulting in clinical efficacy in 88.9% of patients. Major complications, defined as perforation, bleeding or dilation-related surgery, occurred in 2.9% of all procedures. During a median follow up period of 36 months, 89.4% of patients underwent re-dilation and 29.8% required surgical intervention. The multivariable Cox regression analyses indicated that a younger age at diagnosis was associated with symptom recurrences (HR 0.82 (0.71, 0.95), p = 0.003). In a Cox model that included 13 selected variables and rank correlation showed no relationship between adherence to 5-ASA and the risk factors for each outcome.

Introduction: The goal of maintenance therapy in Ulcerative Colitis (UC) is to keep clinical and endoscopic steroid-free remission. 5-aminosalicylate (5-ASA) represents the first line maintenance therapy1. Non-adherence to 5-ASA is associated with an increased risk of disease relapse, colorectal cancer and worsening of quality of life2. Adherence rate has been analysed in several studies with controversial results3-4.

Aims & Methods: The aim of this study is to quantify the prevalence of adherence to 5-ASA, to identify risk factors to non-adherence and its correlation with the clinical disease. Observational, analytical retrospective, single tertiary centre, cohort study of all UC patients followed-up in our IBD unit, until January 2016, with 5-ASA maintenance treatment prescribed by an electronic management program. Adherence was considered when 80% of the prescribed 5-ASA was dispensed at pharmacy and if patients were prescribed 5-ASA or a higher median age (52 (±11) vs 43 (±13), p = 0.001) and received more non-UC chronic drugs (OR = 2.3, 95CI = 1.5–3.4, p = 0.001). The independent variables, age and intake of other non-UC drugs, included in the multivariate analysis reached a predictive capacity of 65% outcomes of adherence. There was no significant reduction in the risk of moderate-severe flares that required corticosteroid therapy when comparing both adherent and non-adherent groups and rank correlation showed no relationship between adherence to 5-ASA and the risk factors of the univariable analysis. A Spearman’s rank coefficient analysis was performed to correlate percentage of adherence with relapse rate.

Results: The study cohort included 433 patients, 55% males with a median age at the first 5-ASA prescription analysed of 49 years (IQR 39–61). 17% had a proctitis, 31% a left-side colitis and 52% an extended disease. 30% of patients suffered from extraintestinal manifestations and 8 from a complication. The mean dose of 5-ASA taken was 2.6 g/day (range 0.7–4.8) distributed in a daily dose of 3 (±1) of the patients. Adherence prevalence to 5-ASA was 65%. Adherent patients had a higher median age (52 (±11) vs 43 (±13), p = 0.001) and received more non-UC chronic drugs (OR = 2.3, 95CI = 1.5–3.4, p = 0.001). The independent variables, age and intake of other non-UC drugs, included in the multivariate analysis reached a predictive capacity of 65% outcomes of adherence. There was no significant reduction in the risk of moderate-severe flares that required corticosteroid therapy when comparing both adherent and non-adherent groups and rank correlation showed no relationship between adherence to 5-ASA and the risk factors of the univariable analysis. A Spearman’s rank coefficient analysis was performed to correlate percentage of adherence with relapse rate.

Adherence to 5-ASA in our population is low. Older patients that take other non-UC chronic treatments show higher adherence. With a one year prescribed and dispensed analysis, non-adherence to 5-ASA is not related with a higher risk of flares that require corticosteroid therapy. Patients treated with adjuvant maintenance therapy, show better results throughout the course of the disease.

Conclusion: The ICC developed a uniform web-based registry to study post-marketing safety and effectiveness of novel IBD-drugs. A feasibility study with 230 patients starting vedolizumab showed successful data-capture, managing, and reporting with the ICC-case series in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlying the importance of country specific post-marketing data.

Introduction: Azathioprine (AZA) and thiopurine are widely used for induction and maintenance of remission in patients steroid-resistant or dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.

Aims & Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients six year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985–2015, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5mg/kg. Blood chemistry was analysed before administration of the drug, every 10–15 days for the first 3 months and then every 1–2 months following the institution of treatment.

Results: Out of 2722 consecutive IBD outpatients visited in the index period, AZA was prescribed to 415 patients, 227 (54.7%) were affected by Crohn’s disease (CD) and 188 (45.3%) by ulcerative colitis (UC). One hundred and fifty-eight patients with a follow-up <72 months were excluded from the study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) with UC. One hundred and forty-two (55.2%) were male

(continued)
and 115 (44.8%) female (average age of 35.68 ± 14.22 SD years, range 14–74 y.). Six years after the institution of treatment, 130 (50.6%) patients still were in steroid-free remission (85 CD vs 45 UC, 59.5% and 39.5%, respectively, p = 0.0017), 71 (27.6%) had a relapse requiring retreatment with steroids (29 CD vs 42 UC, 20.3% and 36.6%, respectively, p = 0.0048), 56 (21.8%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.2% and 23.7%, respectively). Loss of response from 1st to 6th year of follow-up was low, about 20%.

**Conclusion:** Six years after the onset of treatment 56% of patients did not require further steroid courses. After the first year loss of response was low in five subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1708 CLINICAL EFFICACY AND SAFETY OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE IN THE ELDERLY: A UK TERTIARY REFERRAL CENTRE EXPERIENCE**

J. Digby-Bell
Dept. Of Gastroenterology, St. Thomas’ Hospital, London/United Kingdom

**Contact E-mail Address:** jdigbybell@doctors.org.uk

**Introduction:** Many patients, especially the elderly or those with comorbidities, are excluded from clinical drug trials and little real-life data exists on the safety and efficacy of anti-TNF.

**Aims & Methods:** We aimed to compare the clinical efficacy and safety of anti-TNF therapy in patients over 60 years in a tertiary IBD centre in London, UK. We interrogated our IBD biobanks database from January 2009 to November 2015 and performed retrospective data analysis until end of follow up in April 2017. Data was collected on demographics, endoscopy, calprotectin, CRP, clinical scores, serious infections, malignancy, drug levels and anti-drug antibodies. Patients with an age of ≥60 when starting anti-TNF therapy were identified and <60 comparators were selected at random in a 2:1 ratio. Primary endpoints: week 14 and week 54 steroid free clinical remission (Harvey Bradshaw Index < 5 or Simple Colitis Activity index < 3) Secondary endpoint: proportion of patients remaining on anti-TNF at the end of follow up

**Results:** See table.

**Conclusion:** Only a small number of ≥60 patients started anti-TNF (29 out of greater than 650). This may reflect our local population or that clinicians favour non anti-TNF therapies in this elder group. Overall there was similar clinical efficacy at weeks 14 and 54 of anti-TNF therapy between the ‘young’ and ‘old’ groups. There was a higher discontinuation rate after 1 year of therapy in the older group (p = 0.043). There were more adverse events in the older group (7/29) including 3 new cancer diagnoses compared with the younger group (3/58). 4 patients had detectable anti-drug antibodies in the older group despite 2 of them having therapeutic thiopurine suggesting that the elderly may have more immunogenicity than the young. Further studies with more patients across multiple sites are required to clarify safety and efficacy in the elderly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Abstract No: P1709 TACROLIMUS IN REFRACTORY ULCERATIVE COLITIS-12 MONTH OUTCOME IN A SINGLE-CENTRE UK DISTRICT HOSPITAL**

N. Jayasooriya, L. Everson, S. Mann
Gastroenterology, Barnet and Chase Farm Hospital, Royal Free Trust NHS, Barnet/United Kingdom

**Contact E-mail Address:** nishami.jayasooriya@nhs.net

**Introduction:** Rescue therapy is required for patients with moderate - severe ulcerative colitis (UC) who have failed to respond to steroids and thiopurines. Anti-Tumour Necrosis Factor agents (Anti-TNFs) are widely used before considering a colectomy. Calcineurin inhibitors such as ciclosporin and Tacrolimus may be considered as alternatives to biologics. There have been some case series in assessing the use of Tacrolimus in such patients although the United Kingdom experience is limited. (1, 2)

**Aims & Methods:** We aimed to review the outcome of patients who received Tacrolimus as rescue and subsequent maintenance therapy for refractory symptoms of UC. This was a retrospective single-centre case review series. All patients who were refractory to standard medical therapies and being considered for a colectomy were reviewed by a Gastroenterologist with an interest in Inflammatory Bowel Disease. Demographic data, indications for treatment, clinical course and outcomes were reviewed from Electronic Patient Records (EPR).

**Results:** Fourteen patients (F = 6; mean age of 54 years) received Tacrolimus. 8 patients (57%) had evidence of pancolitis and six patients (43%) had distal colitis. All patients had previously received thiopurines and 11 patients (78.6%) had also received anti-TNFs. Three patients declined Anti-TNF treatment. All patients were steroid-dependent prior to commencing Tacrolimus. One patient received ciclosporin before the switch. The remaining 13 patients were initiated on Tacrolimus in the out-patient setting at a starting dose of 0.1 mg/kg/day in 2 divided doses. Patients took Tacrolimus for a mean period of 18.8 months (range: 2 months to 49 months). Eight patients (57%) achieved a steroid-free remission within 6 months. An additional 3 patients (23%) had a clinical response within 6 months, but required one course of steroids during this time period. Three patients (23%) failed to respond to Tacrolimus; 1 patient remains steroid-dependent and does not wish to proceed to surgery, 1 patient was switched to infliximab and 1 patient proceeded at 10 months to have an elective subtotal colectomy. Tacrolimus was withdrawn in all 3 non-responders. Of the 11 (78.6%) initial responders, 12-month outcome included withdrawal of Tacrolimus in 7 patients (63.6%). Reasons for withdrawal included: n = 1 renal impairment; n = 1 started on infliximab; n = 3 referred for leucapharesis; n = 1 re-started on Azathioprine and n = 1 referred for proctocolectomy. Three patients (21.4%) remain in steroid-free clinical remission with a good quality of life and

Introduction: Adalimumab (ADA) and golimumab (GOL) are effective in the induction and maintenance treatment of moderate-to-severe ulcerative colitis (UC). No comparable data between the 2 drugs are available up to now. Therefore, the aim of the present study was to analyze the efficacy of ADA and GOL in patients (pts) with moderate-to-severe UC.

Aims & Methods: We reported the Sicilian Network experience on the comparative efficacy of ADA and GOL in patients (pts) with moderate-to-severe UC. From June 2015 until April 2017, 191 consecutive pts with moderate to severe UC were treated with ADA or GOL. The efficacy was evaluated at 8 week and at the end of the follow up considering “clinical response” (reduction of at least 2 points of Partial Mayo Score with concomitant steroid reduction or discontinuation) and “clinical remission” (Partial Mayo Score <2 without steroids). The presence of clinical response or clinical remission was defined as “clinical benefit”. Endoscopic Mayo Score was evaluated. These real life data confirmed the efficacy of subcutaneous anti-TNFα in the treatment of moderate to severe UC, ADA resulted to be more effective than GOL in inducing and maintaining clinical benefit.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1712 PREVALENCE OF CIPROFLOXACIN RESISTANCE IN INFLAMMATORY BOWEL DISEASE PATIENTS WITH GUT COLONIZATION WITH EXTENDED SPECTRUM BETA-LACTAMASE PRODUCING ENTEROBACTERIA ACCORDING TO BACTERIAL PLASMID GENES

V. Skuja, a K. Pekarska, a H. Dauvarte, 1, V. Vasuka, 1, D. Dobelniece, 1, A. Lejnieks, 1, A. Derovs 3

Introduction: Ciprofloxacin is one of the most frequently used antibiotics in hospitalized inflammatory bowel disease (IBD) patients. Also discrepancies between clinical guidelines and real clinical situations are observed in terms of antibiotic use in patients with IBD. In the last few years an emerging resistance to ciprofloxacin, ranging from 43% to 82%, has been described in extended spectrum beta-lactamase producing bacteria (ESBL-E) colonizing the gut. 1, 2

Aims & Methods: The objective of this study was to evaluate the gut colonization with ESBL-E in IBD patients, determine the resistance to ciprofloxacin and bacterial plasmid genes associated with that. Rectal swabs were collected from all consecutive patients with confirmed ulcerative colitis (UC) and Crohn’s disease (CD) hospitalized in two largest tertiary medical care centers in Riga, Latvia during a 7-year period (2010-2016). Enterobacteria were cultured and screened for ESBL presence according to EUCAST guidelines, resistance to ciprofloxacin and bacterial plasmid genes CTX-M, TEM and SHV were detected.

Results: A total of 148 patients with confirmed IBD diagnosis were included in the study: 67 (45.4%) had UC (47.3% with CD). We found that 12 (12%) of the UC patients and 5 (11%) of the CD patients were colonized with ESBL-E. The isolated ESBL producing strains from UC patients included Escherichia coli (n=10), Klebsiella oxytoca (n=1) and Escherichia hermanii (n=1). The isolated ESBL producing strains from CD patients included only Escherichia coli (n=5). The isolated bacterial plasmid genes associated with ESBL production in UC included CTX-M (n=11; 92%), TEM (n=4; 33%), SHV (n=1; 8%), in CD – CTX-M (n=4; 80%) and TEM (n=3; 60%). In UC 6 (50%) and in CD 1 (20%) out of patients colonized with ESBL-E were resistant to ciprofloxacin. In 1 case of the ciprofloxacin resistance CTX-M, TEM and SHV gene combination was observed, in 1 case CTX-M and TEM gene combination was observed, in 4 cases only CTX-M gene was present and in 1 case only TEM gene was present.

Conclusion: Higher gut colonization rate with ESBL-E in IBD patients, mostly with E. coli, expressing CTX-M gene was found comparing with the literature. 2. Higher resistance to ciprofloxacin was found in ESBL-E isolated from UC patients, compared to UC patients. 3. CTX-M and TEM genes are associated with resistance to ciprofloxacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNFs are well-established in therapeutic management of Crohn’s disease (CD). Real-life data on their pattern of use in a French clinical setting are, however, limited to this day.

Aims & Methods: The objective of this study was to examine for characteristics of CD patients and anti-TNF use in a real-life setting in France through the general sample of health insurance beneficiaries (EGB database) which includes reimbursable data from a sampled 1/97th of the French population. A cohort of 1280 patients with CD in the EGB database between 01/01/2010 and 31/02/2014 was retrospectively constituted, of which 189 (14.8%) initiated an anti-TNF treatment during that period and were studied for the analysis. An additional analysis was performed based on French hospital discharge data (medical information systems program [PMSI]) from 8142 CD patients to compare results from the EGB database but only support infliximab use due to its exclusive hospital availability in France (adalimumab can be prescribed in both hospital and retail markets).

Results: 48.7% of anti-TNF treated patients were male and the mean age at the initiation of an anti-TNF treatment was 38 years. The mean duration between diagnosis and start of treatment was 7.2 years, for an ALD [Long Term Illness] assignment to an ALD. Concomitant treatments such as corticosteroids and immunosuppressants were prescribed at least once in 63% and 47% of patients respectively. Around 35% of patients initiated a treatment with infliximab and 43% with adalimumab. Results at 12 months after anti-TNF initiation are presented in the table below:

Table 1: Anti-TNF use in patients initiating an anti-TNF treatment with at least 12 months of follow-up At 12 months, 13.6% of patients underwent surgery. Results from the hospital discharge database confirmed some of our observations. Optimization rate for infliximab 12 months after initiation was similar (33.5% at 12 months for infliximab). Treatment discontinuation rates were also within the same range observed and stable over time, with 10% of patients discontinuing infliximab treatment each year and a discontinuation rate after 12 months of treatment of 27.2%.

Anti-TNF use at 12 months after initiation N Results
Drug survival rate for the first line anti-TNF 108 69.8% [62.3–76.1] Survival rate for the first line adalimumab 47 71.7% [59.9–80.6]
Survival rate for first line infliximab 61 66.3% [55.9–74.8]
Anti-TNF dose optimization rate 85 41.5% [34.5–49.3]
Dose optimization rate for adalimumab 53 33.6% [25.2–43.8]
Dose optimization rate for infliximab 63 38.2% [30.1–47.8]
Switch rate to another anti-TNF 126 17.5% [12.6–24.1]
Switch rate from adalimumab to infliximab 70 13.6% [8.1–22.4]
Switch rate from infliximab to adalimumab 88 14.9% [9.6–23.0]
Anti-TNF treatment discontinuation rate 108 31.4% [25.0–38.9]
Discontinuation rate for adalimumab 47 28.2% [19.4–40.0]
Discontinuation rate for infliximab 61 33.7% [25.2–44.0]

Conclusion: A total of 49 patients had complex APF treated with anti-TNF in Crohn’s disease patients in France. Aims: Recruitment of each patient.

Disclosure of Interest: None declared.

achieved clinical remission, 31% a partial clinical response and 12% a primary failure. Maintenance of a clinical response after a year of anti-TNF-α treatment. After a mean time of 13 months, 42% of the patients had a loss of response. The analytical study found that the absence of recto-colonic involvement, CRP negativity and normalization of platelet count under treatment and achievement of clinical remission after the induction phase were predictive factors of long-term good response to anti-TNF-α treatment. Clinical remission after the induction phase was the only independent predictive factor of long-term remission under maintenance treatment after multivariate analysis. However, previous studies assessing early therapeutic adaptation and patient involvement could better evaluate this perspective in the event of a partial clinical response. In addition, rectal involvement and recto-vascular fistulas are factors of poor response for which aggressive and specific treatment is essential.

Introduction: The management of chronic inflammatory bowel disease (IBD) has experienced significant advance with the development of biologic therapy. Infliximab (IFX) was the first monoclonal antibody approved for IBD. The patent expiry of biologics and their relatively high costs that result in a significant economic burden on the healthcare system, has led to the development of biosimilar agents. The biosimilar IFX has been authorised for use in all the indications as the reference IFX. The demonstration of biosimilar IFX efficacy and safety equivalence was based on two pivotal clinical trials in rheumatic diseases. As a result of the extrapolation to IBD, there is growing controversy regarding the appropriate use of biosimilar IFX. The efficacy and safety of infliximab reference in inducing and maintaining remission in IBD has been extensively proven in clinical trials. However, the role of biosimilar IFX, has not been systematically investigated in clinical practice.

Aims & Methods: We aimed to compare the safety and efficacy in inducing and maintaining remission in IBD, between the reference IFX group and biosimilar IFX group. This retrospective, multicenter study was carried out at 4 tertiary hospitals (Hospital 10 de March 3 to December 2013) and all the data included in the analysis included patients from cohorts of consecutive patients. One cohort composed of patients who were started original IFX since 2013. The second cohort included patients who were treated from the introduction of biosimilar IFX. Adverse events (AEs), demographic, clinical, endoscopic and laboratory data were collected on all patients. Efficacy was assessed according to response and remission at 14th, 34th week. For CU, response was defined as a decrease in partial Mayo score of 2 or more from baseline and a partial Mayo score of 1 or less was used to remission. For CD, response was defined as a decrease in Harvey-Bradshaw score of 3 or more from baseline, and a Harvey-Bradshaw score of 4 or less was used to remission. We used Student’s t for independent samples and Chi-square test. Time to withdrawal due to adverse effects was estimated using Kaplan-Meier survival analysis, and the log rank test was used to test for treatment group differences.

Results: The analysis included 346 consecutive IBD patients. 104 treated with original IFX and 242 with biosimilar IFX. 103 patients were diagnosed with UC, 238 with CD and 5 with indeterminate colitis. Overall median follow-up was 21 months. Baseline clinical activity scores were not significantly different among the 2 groups. Frequency of concomitant azathioprine and systemic steroids were not different among both groups. Patients in biosimilar infliximab group were more likely to experience previous biologic treatment failure (29.2% versus 20.2% in the original IFX, p = 0.0163). There were no significant differences in patients achieving response and remission at weeks 14 and 54. There were no significant differences in rate of withdrawals among the 2 groups (37.1% versus 38% for biosimilar IFX, p = 0.811). There were no significant differences in cumulative discontinuation rate due to AEs in original IFX and biosimilar IFX (42.42, (95% CI 39.49-45.34) months versus 44.61 (95% CI 42.66-46.56) months, log-rank test p = 0.292).

Conclusion: The study experience showed similar efficacy and safety profile of biosimilar IFX compared to original IFX.

Introduction: Acute severe Colitis (ASC) is a severe complication of inflammatory bowel disease (IBD), for which there is no consensus definition. Its diagnosis is performed on clinico-biological and endoscopic criteria. Low endoscopy is essentially a tool for the positive diagnosis of ASC as well as for the diagnosis of IBD.

Aims & Methods: The objective of this study is to describe the endoscopic aspect of ASC and its interest in therapeutic management in our series of 48 cases it is a prospective descriptive and analytical study of a series of 48 cases of acute severe colitis (ASC) collected during a period of 3 years (2014-2016) in the gastroenterology department.

Results: The average age of our patients is 39.8 years with extremes ranging from 14 to 58 years, a female predominance was found with a sex ratio, M/F = 0.77. The ASC was inaugural in 20 (41.66%), while 28 cases (58.33%) are known to have IBD, with 24 cases of UC (58.7%). Initial endoscopy was performed in all patients. The average time to perform endoscopy (from the onset of symptoms) was 37 days (2 to 75 days). Severe endoscopic aspects were present in 30 patients: deep ulcer (29 cases), spontaneous bleeding (4 cases), friability (4 cases). Other endoscopic lesions found were erythema (12 cases), erosions (5 cases), superficial ulcer (25 cases), pseudo polyps (14 cases), contact bleeding (27 cases). Biopsy was performed in all patients, histology was in favor of UC in 64.58% cases. CMV viral inclusions were found in 2.08% of cases. First-line medical treatment is based mainly on parenteral corticosteroid therapy, has been established in all cases. A second-line treatment with anti-TNF was introduced in 5 cases (10.41%) while surgical treatment was introduced in 15 cases (31.25%) of which 12 cases had severe endoscopic colitis. steroid refractory disease was associated with endoscopic severe colitis (p = 0.04). In mono-varied analysis, endoscopic severe colitis was found in patients with sex ratio greater than females (53.6 vs 43.3). With a statistically significant difference p = 0.020.

Conclusion: Endoscopy in ASC occupies an important place to specify the morphological severity and thus make the positive diagnosis, the severe endoscopic colitis constitutes one of the predictive elements of steroid refractory disease requiring the use of a second therapeutic palliation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1717 BASELINE CALPROTECTIN DOES NOT PREDICT RESPONSE TO BIOLOGICAL THERAPY IN ULCERATIVE COLITIS

D. Storey1, T. Skouras2, A. Bond1, S. Dodd3, S. Subramanian1

Introduction: Response to biological drugs in ulcerative colitis (UC) is variable with induction response rates of 64.5% (vs 29.3% for placebo), 50.4% (vs 34.6% for placebo), 51.0% (vs 30.3% for placebo), 47.1% (vs 25.5% for placebo) for infliximab, adalimumab, golimumab and vedolizumab, respectively. Apart from prior exposure to anti-tumour necrosis factor (anti-TNF) agents and concurrent immunomodulatory therapy, predictors of clinical response and remission to biological therapy are not yet well defined. We sought to investigate the utility of baseline faecal calprotectin (FC) and early change in FC in predicting clinical response and remission to biological therapy in UC.

Aims & Methods: Patients who were commenced on any biological therapy for UC and had a baseline FC at the time of commencement were included in this retrospective study. Disease activity was monitored serially by calculation of Simple Clinical Colitis Activity Index (SCCAI) or by Physician global assessment (PGA) or by treatment persistence. Clinical response was defined as decrease in SCCAI ≤ 3 or a decrease in PGA score to one point below baseline. The ability of FC and fold change in FC to predict response and remission at 6 months was estimated using Mann-Whitney test.

Results: A total of 94 patients were commenced on biological therapy of who 70 had an active disease and commenced vedolizumab with a mean age of 41.8 (SD: ±18.2). Fifty-one (72%) and 39 (55%) patients commencing anti-TNF therapy were on concurrent immunomodulators (IM) and steroids respectively compared to 9 (38%) and 16 (67%) patients respectively for vedolizumab. Sixty-one (85%) patients treated with vedolizumab and anti-TNF agents were severely UC (72.2% and 73.5% respectively. The calprotectin values were similar for responders (482.5 (750 (IQR 330-1300) n = 16) and non-responders (400 (107, 2100) [n = 5]) to vedolizumab (P = 0.56). Similarly, responders (909 (13, 2100) [n = 26]) and non-responders (850 (240, 2100) [n = 13]) to anti-TNF agents had comparable calprotectin values at baseline, P = 0.93.

Conclusion: In a single-centre series of biologic treated UC patients, baseline FC did not predict clinical response at 6 months. Disclosure of Interest: S. Subramanian: Advice report member for Abbvie, Janssen and Behringer-ingleheim On speaker bureau for Dr Falk, Abbvie and MSD. All other authors have declared no conflicts of interest.

Introduction: The prevalence of Crohn’s disease is important for planning of health care and allocation of clinical resources. In 2005, a National Patient’s Registry in Poland was established to collect demographic and clinical data. The aim of the study was assess the efficacy and tolerance of different medications in real-life treatment during the study period, data regarding medical treatment were collected from Registry.
Aims & Methods: The aim of the study was to assess and compare the efficacy of medications in reference to demographic and disease data and disease location and behaviour. The study included 6030 of patients who have been enrolled to the Polish National CD Patient’s Registry, conducted in 9 gastroenterology centers in Poland. Patient’s phenotype according to: Montreal classification, demographics, smoking, alcohol consumption, extraintestinal manifestation and medical treatment have been evaluated. The impact of demographic factors on the use of drugs from different groups (mesalamine, prednisone, azathioprine, methotrexate, anti-TNF, ) and medications efficacy and tolerance was assessed. The efficacy assessment was evaluated according to subjective 4-step scale. Similarly treatment tolerance was assessed according to 2-step scale.
Results: No gender effects were observed on the use or efficacy of individual drug classes, although greater tolerability of prednisone and azathioprine was observed in men (respectively 95.56 vs 93.82 and 93.94 vs. 91.65, both p < 0.05). Smoking did not affect the effectiveness and tolerability of the used medications. However surprisingly fewer smokers were treated with azathioprine, methotrexate, and anti-TNF in comparison to non-smokers (38 vs 45%, 0.5 vs 1.55%, 0.5 vs 11%, all p < 0.05). In patient’s declaring casual alcohol use, the efficacy and tolerability of prednison was significantly better than in patients declaring abstinence (89 vs 84 and 96 vs 93%; p < 0.05). Referring to the Montreal classification, efficacy of mesalamine, prednisone and azathioprine was significantly higher in A1 group with the lowest in A2 patients (A1: 90, A2:83, A3: 86 for prednisone, p < 0.05). Regarding relation to localization of the disease, the efficacy of treatment with immunosuppressive agents (azathioprine and methotrexate) in L3 was significantly lower compared with L1 and L2, despite of increased use of immunosuppressive drugs in L1 (76 vs 82%, p < 0.05). As predicted, the use of immunosuppressive and anti-TNF drugs was higher in complicated disease behavior (B2 and B3) than in B1, however efficacy of infliximab was similar in B1 in comparison to others (B3: 15.5% B1: 7% of infliximab use).
Conclusion: This is the first study comparing efficacy and tolerability of treatment methods used in “real-life” practice in Poland during last 8 years. Most observations are in compliance with data from clinical trials. Positive effect of casual alcohol consumption on efficacy of medications requires further observation. Interestingly some unexpected relationships, concerning similar efficacy of infliximab in different disease behavior was found. This effect requires also further observations in regards to more frequent use of anti-TNF drugs in last years.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1719 EFFICACY OF VEDOLIZUMAB INDUCTION THERAPY IN PATIENTS WITH SEVERE, THERAPEUTIC RESISTANT INFLAMMATORY BOWEL DISEASE

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha therapy in patients with moderate-to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy is individualized, it should be approved by the steering committee of five Hungarian IBD-specialists. This results in that VDZ therapy is available exclusively for patients in whom conventional treatment was ineffective or contraindicated.
Aims & Methods: The aim of our non-interventional prospective study was to assess the efficacy of induction VDZ therapy in 41 patients with Crohn’s disease (CD) and 25 with ulcerative colitis (UC) received VDZ induction therapy between September 2016 and April 2017 in Hungary. Efficacy of induction therapy was assessed based on the changes of activity indices on week 14.
Results: Of 41 enrolled IBD patients were therapeutic failure or intolerant for infliximab and/or adalimumab therapy. The mean age was 38.6 years (range 18–67; median 40) and the average disease duration was 11.7 years (range 1–36; median 10). In 16 cases moderate and in 25 cases severe disease activity was observed. Extraintestinal manifestations occurred in patients, and in cases the IBD was associated with primary sclerosing cholangitis (PSC). Rate of the therapeutic responders for VDZ induction therapy was 80.49% (N = 33). Complete clinical remission was observed in 19 cases (46.34%) 8 cases (19.51%) of which were steroid-free remission. In one case VDZ therapy had to be interrupted due to development of IBD associated colorectal cancer and in one case due to MCV infection.
Conclusion: Our results suggest that induction VDZ therapy is effective and it is a safe therapeutic option in anti-tumor necrosis factor alpha failure or intolerant IBD patients with moderate or severe disease activity.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1720 OUTCOMES OF TREATMENT FOR LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE RECEIVING BIOLOGIC THERAPY

Introduction: Tuberculosis (TB) reactivation is of particular concern in patients with inflammatory bowel disease (IBD) treated with biologic therapies. Screening for latent tuberculosis infection (LTBI) is indicated prior to initiating treatment. In patients with IBD, the development of LTBI is more common. Several studies have suggested the risk of reactivation following treatment for LTBI the risk of reactivation still exists. The efficacy of LTBI treatment in IBD patients receiving biologic therapy and the timing of biologic therapy initiation has not been extensively studied.
Aims & Methods: In order to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic, we conducted a retrospective review of all IBD patients diagnosed with LTBI following a tuberculin skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1996 and August 2016. LTBI was extracted included in the study. Their mean age was 38.3 ± 14.4 years and 68.6% were male (Table 1). The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen was isoniazid (INH) for 9 months (n = 26, 74%). Biologic therapy used were infliximab (n = 14, 40%), adalimumab (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to
starting biologic therapy. The median time from initiation of LTBI treatment to biologic was 43 days (IQR 19–34). The mean duration of follow-up was 2.9 ± 3.3 years. The median calculated annual risk of developing active TB without treatment was 0.52% (0.08%–1.3%). Of the cohort studied, only one patient taking adalimumab monotherapy after completing 6 months of INH therapy developed reactivation of TB. The estimated TB reactivation rate in our cohort was 0.98 cases per 100 patient-years of follow up.

**Table 1:** Cohort Characteristics and Estimated Post-treatment Tuberculosis Reactivation Rate

**Conclusion:** Treatment for LTBI in patients with IBD treated with biologics is effective, but does not eliminate the risk of reactivation, which occurred at a rate of 0.98 cases per 100 patient-years in our cohort. Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

**Introduction:** Resection in Crohn’s disease (CD) intends to be a curative surgery, but the presence of a damaged gut. The aim of our study was to describe the characteristics and management of patients with residual disease after surgery (RD) and to compare these with patients with curative surgery (CS) in post operative CD patients.

**Aims & Methods:** PRACTICROHN was a retrospective study that included adult patients from 26 Spanish hospitals who underwent CD-related ileocolonic resection with ileocolic or ileorectal anastomosis between January 2007 and December 2010. Clinical data was retrospectively collected from clinical charts. RD was defined when lesions were still present after surgical resection. Postoperative recurrence (POR) was defined by clinical symptoms (diarrhea, abdominal pain) and endoscopic Rutgeerts score ≥2, and/or CT or MRI confirmation of disease activity. Categorical variables were compared with the χ2 test or Fisher’s exact test Kaplan-Meier method was used to assess time to clinical recurrence and a log-rank test to obtain statistical significance.

**Results:** Three hundred and sixty-four patients were analyzed (mean age 40 years [SD 13.5%] 50% men). Of these, 27 (7.5%) had RD after surgery. Median age at diagnosis was shorter in patients with RD than CS: 23 (IQR 19–34) years vs 29 (IQR 23–40), p = 0.02. At the time of resection BI (+) behavior was more frequent in RD than in CS: 6 (22%) vs 26 (8%), p = 0.05; and location was mainly L1+L4 in CS (190, 57%) and L3+L4 in RD (19.70%), p = 0.02. Four (16%) patients in RD were receiving immunomodulators at the time of surgery vs 132 (41%) of CS. p = 0.02. More patients in RD vs CS presented postoperative complications (12 (44%) vs 87 (26%), p = 0.06) as well as hospitalizations the first year after surgery (10 (37%) vs 42 (12%) p = 0.001). No differences in smoking habit, perianal disease or length of resection were found between the two groups. More patients were performed an endoscopy within the first year after surgery in the RD vs CS:16 (59%) vs 122 (36%), p = 0.03 but no difference in prophylactic treatment were found in RD vs CS groups. POR was more frequent among patients with RD (69% vs. 29%, OR = 0.001). Median time to POR was longer in patients who received prophylaxis vs those who didn’t received it (698 vs 392 days; p = 0.41) in CS and in RD presented POR with median time to POR being longer in patients who received prophylaxis (no median found vs 1529 days) p = 0.04. Table 1.

**Conclusion:** Residual disease is a rare situation after intestinal resection in CD. Patients with residual disease after surgery, are more frequently followed-up endoscopically within the first year. Conversely, similar proactive recurrence prevention was observed compared to curative surgery. In the case of residual disease although prophylactic treatment is useful, most of the patients will present POR. RD is a factor of poor poor prognosis in post-operative CD patients.

**P1722 SEVERITY OF BILE ACID MALABSORPTION CORRELATES WITH LENGTH OF ILEAL RESECTION IN CROHN’S DISEASE**

T. Skouras1, Y. Prasad2, S. Dodd3, S. Subramaniam4

1Gastroenterology, Royal Liverpool University Hospital, Liverpool/United Kingdom
2Royal Liverpool University Hospital, Liverpool/United Kingdom

**Contact E-mail Address:** Thomas.skouras@nhs.net

**Introduction:** Bile acid malabsorption (BAM) is a common cause of diarrhea in Crohn’s disease (CD) patients with ileal resection and can lead to complications such as renal and biliary stone disease. BAM is usually diagnosed by selenium labelled homotaurocholic acid test (75SeHCAT) but its availability is limited. Thus, a large proportion of resected CD patients either remain undiagnosed or subject to empirical therapy. There is a paucity of studies examining the correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM.

**Aims & Methods:** We identified all CD patients with a prior surgical resection who underwent 75SeHCAT testing at our institute. Testing was based on the treating clinician’s discretion. The length of resected ileum was recorded from histopathology report. We conducted a Spearman’s correlation test to check for correlation between length of resected ileum and percentage retention on 75SeHCAT. Response to bile salt sequestrant and 75SeHCAT retention values was tested using Mann-Whitney test.

**Results:** A total of 97 patients were treated with a mean age of 46.4 (SD 14.5). The median length of resected ileum was 22.5 cms (range 1.5–95 cms) with a median of 1 resection (range 1–4). Overall, 90 patients (92.8%) had 75SeHCAT retention values of <5%, 5 (5.2%) patients between 5–10% and only 2 patients had values of >15%. There was moderate correlation between 75SeHCAT retention and length of ileal resection (Spearman’s rho: 0.4041, P < 0.001). Data on response to treatment was available for 60 patients, of who 41 (42%) responded and 19 (19%) failed to respond to bile salt sequestrants. The 75SeHCAT retention values was comparable among responders (median 0.02%, range 0.1–6.6) and non-responders (median 0.02%, range 0.1–6.6, Mann-Whitney test, P = 0.72).

**Conclusion:** There was moderate correlation between length of ileal resection and severity of BAM as defined by 75SeHCAT retention values. Response to bile salt sequestrant therapy was not dependent on 75SeHCAT retention values.

P1723 A MICROBIAL SIGNATURE OF PSYCHOLOGICAL DISTRESS IN IRritable BOWEl SYndrome

J. Peter, C. Fourrier, L. Knoblach, B. Keip, G. Moser
Internal Medicine III Dept De Gastroenterology And Hepatology, Medical University of Vienna, Vienna/Austria

Contact E-mail Address: gabrielle.moser@meduniven.ac.at

Introduction: Irritable Bowel Syndrome (IBS) is associated with alterations along the brain-gut-microbiota axis. Previous studies have suggested a parallel segregation of microbial features with psychological burden in IBS (1,2,3).

Aims & Methods: This study aimed at examining microbial correlates of psychological distress, anxiety, depression and stress perception. 16S rRNA fecal microbial analyses (Illumina MiSeq, V1-2 amplified from total DNA) in 48 IBS patients (Rome-III criteria, mean age 42 years, 35 female subjects, 25 diarrhoea-predominant, 22 constipation-dominant and 18 alternating-type IBS). Assessment of psychological and clinical variables with validated questionnaires, microbial analysis via qHIME. Machine learning to predict psychological distress through a composite model of bacterial features. Correlational analysis and comparisons in bacterial abundance among subgroups defined by thresholds in psychological variables.

Results: Thirty-one patients (65%) showed psychological distress, 22 (31%) anxiety, and 10 (17%) depression. Psychological distress was uncorrelated with IBS severity (Spearman’s ρ = 0.05, p = 0.736). Microbial beta diversity was significantly associated with distress and depression (q = 0.044 each). A random forest model using 148 microbial estimators was able to correctly classify patients regarding presence of psychological distress (AUROC = 0.98). Patients exceeding thresholds of distress, anxiety, depression and stress perception showed significantly higher abundances of Proteobacteria (LDA = 2.5). Patients with anxiety were characterized by higher abundances of Bacteroidaceae (LDA = 3.0). Differentially abundant with Lachnospiraceae (q = 0.05, p = 0.018), anxiety positively with Anaerostipes (ρ = 0.65, q = 0.001).

Conclusion: A microbial signature accurately predicted the presence of psychological distress. Psychological variables significantly segregated gut microbial features, underscoring the role of brain-gut-microbiota interaction in IBS. Supported by Austrian Society of Gastroenterology and Hepatology (ÖGGH) and funds of the Oesterreichische Nationalbank, Fund project number: 16506.

Introduction: Saccharomyces boulardii (SB) CNCM I-745 demonstrated clinical efficacy in the secondary prevention of post-antibiotic Clostridium difficile infection (CDI), but the mechanism remains unclear. Cholic acid (CA) is a primary bile acid (BA), synthesized by the liver which triggers the germination of C. difficile spores in the intestine. Physiologically, the gut microbiota transforms primary BAs (cholic acid and chenodeoxycholic) into secondary (deoxycholic and lithocholic). CA loses its germinating properties after transformation and appears to become protective against CDI. The goals of this work in healthy volunteers (HV) were to: 1) Describe the effect of antibiotics on the quantity of ‘germination’ primary BA including CA in human stools 2) Describe whether SB enhances transformation to ‘protective’ secondary BA in human.

Aims & Methods: This work was an ancillary of a previous study conducted in 4 groups of HV at Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, Massachusetts. The previous results of this work showed that SB CNCM I-745 can modulate shifts in the microbiota and reduces diarrhea during an antibiotic therapy. Group 1 (n = 12) received SB CNCM I-745 500 mg twice daily for 14 days. Group 2 (n = 12) received Amoxicillin-Clavulanate (AC) (875/125 mg twice daily) for 7 days. Group 3 (n = 12) received AC for 7 days and SB for 14 days. Group 4 (n = 12) did not receive any treatment. Groups 1, 2, 3 had successive stool samples at D-28, 0, 3, 7, 10, 13, 21. Group 4 had stool samples at D0, 7 and 21. The fecal concentrations of 28 BAs were measured by HPLC-MS, and expressed as % of total. An ANOVA was performed.

Results: AC alone (group 2) significantly reduced the rate of fecal secondary BA at day 7 compared to control (group 4) (54.8 ± 10.1 vs 83.1 ± 7.4%, p = 0.017). In group 3 (AC plus SB), the decrease in secondary BA rate was significantly less than AC (71.23 ± 7.4 vs 57.80 ± 9%, p = 0.04), and this difference was prolonged over time. Similarly, the AC+SB group showed a significantly lower (and sustained) increase in CA than in the AC alone group.

Conclusion: Antibiotics alter the transformation of BA by microbial enzymes into secondary BAs. Probiotics may reverse this transformation. Cholic Acid rates, a primary BA which facilitates C. difficile spore germination in vitro, increases in stool during antibiotic therapy. The concomitant administration of SB during AC treatment significantly reduces this CA peak. These results highlight new human data on a potential mechanism for post-antibiotic CDI: alteration of the microbiota can encourage germination of C. difficile spores via increased CA concentrations and reduced concentrations of secondary BAs. The effectiveness of SB in preventing recurrent CDI may be explained, in part, through modulation of microbiota changes that influence the balance of pro- and anti-germination BA concentrations.

1. Castellari, M., Warren, R. L., Freeman, J. D., Dorelioni, L., Krzywinski, M., Strachan, P., Barnes, R., W. G., Fischbach, M. A. & Holt, A. 2012. Fusobacterium nucleatum infection is prevalent in human colorectal adenomas and cancers, some specific bacterium have been identified as a related factor. Recent studies have reported a high abundance of Fusobacterium nucleatum (F. nucleatum) in colorectal cancer (CRC) subjects compared to normal subjects12. F. nucleatum is also known as a pathogenic species of oral microbiota, but it is not known if F. nucleatum plays a role in other part of the digestive tract. F. nucleatum may affect metabolic pathways for the carcinogenesis1. We examined whether there is relationship between F. nucleatum oral cavity and CRC.

Aims & Methods: We assessed the abundance of Fusobacterium in CRC, colorectal mucosa and saliva. We extracted DNA from mucosal biopsies and measured bacterial levels by quantitative PCR of the 16S ribosomal RNA gene. We also investigated the homology of F. nucleatum in oral cavity and CRC.

Results: In 51 CRC cases, Fusobacterium positivity was significantly higher in CRC compared to controls (p < 0.05). Fusobacterium was more detected in CRC (12.9%) than in normal tissue (7.6%) respectively. The detection rate of F. nucleatum was 96% in saliva and 95% in CRC by next-generation sequencing. A total of 15 patients with CRC were included to check the homology of F. nucleatum in saliva and CRC. From the 15 patients, 9 were F. nucleatum-positive in saliva (60%) and 8 from these patients were F. nucleatum-positive in saliva. From these patients who were F. nucleatum-positive in saliva and CRC, we next looked for the results of AP-PCR and 6 patients have shown common band patterns.

Conclusion: The results support a link between the abundance of F. nucleatum in oral cavity and CRC. Our data also indicate that there may be a route from the oral cavity to the CRC in F. nucleatum positive cases. We are now identifying DNA sequences, specific for the objective strains.

P1727 HUMAN MILK Oligosaccharides: A NEW STRATEGY AGAINST POST-ANTIBIOTIC CLOSTRIDIUM DIFFICILE INFECTION?

L. K. Vigsnaes
Business Development, Glycom A/S, Horsholm/Denmark

Contact E-mail Address: louise.vigsnaes@glycom.com

Introduction: Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk and which are now becoming commercially available. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulate the gut microbiota by increasing bifidobacteria and reducing certain pathogenic bacteria (1,2). Also, HMO bacterial consumption results in the production of beneficial metabolites such as short chain fatty acids and decrease pH compared to a control with no added HMOs. Additionally, HMOs reduced the level of C. difficile in some cases completely eraditing C. difficile below detection limits. This antimicrobial effect of HMOs on C. difficile was pH-independent, hence another mechanism is causing the anti-pathogenic activity of HMOs.

Conclusion: Conclusively, the results show that HMOs can impact C. difficile infection in an in vitro system, which suggests HMOs as a potential approach to reduce risk of antibiotic associated diarrhoea and post-antibiotic C. difficile infection.

Introduction: It has been reported that the composition of human gut microbiota changes with aging, body mass index (BMI), diet and other environmental factors. In particular, the relationship between gut microbiota and obesity has been underlined frequently because intervention in the microbiota may reduce body fat. In this study, we investigated the relationship between obesity and composition of gut microbiota in healthy Japanese population.

Aims & Methods: Participants were 1,082 healthy Japanese adults (410 males, 672 females) who participated in the Iwaki Health Promotion Project in 2014. Faecal samples were analysed by 16S rRNA gene-targeted sequencing to determine family composition of gut microbiota. They were classified into obese group (BMI ≥ 25) and normal weight group (BMI < 25) according to Japanese standard and were stratified into 7 age groups, 19-29, 30-39, 40-49, 50-59, 60-69, 70-79 and 80-90. The family composition of gut microbiota in each age group was compared between obese and normal group.

Results: There were 235 obese participants, and 847 normal ones. The proportion of Bacteroidaceae decreased substantially, and Ruminococcaceae increasing slightly with aging in obese group. The proportion of Bifidobacteriaceae, Lachnospiraceae and Porphyromonadaceae decreased gradually with aging in both groups.

Conclusion: Changes in composition of gut microbiota with aging were different between obese and normal group. Some previous researches observed differences of gut microbiota between obese and normal group, but many of the researches did not take aging into consideration. Our study indicated that different intervention stratified with age could be needed.

Introduction: The production of bacteriocins is considered as the key metabolic function of gut microbiota and as the inherent property of probiotic strains. Bacteriocins and metabolites of probiotic microorganisms (metabiotics) can optimize host-specific physiological functions related to human health.

Aims & Methods: This study aims to: (a) detect the bacteriocin genes of probiotic strains Lactobacillus helveticus D75 (NCBI Reference Sequence NZ_CP020029.1) and Lactobacillus helveticus D76 (NCBI Reference Sequence NZ_CP016827.1) and (b) evaluate in vitro effects of the carboxylic and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain A756 (components 25% acetic acid, 0.007% L-cysteine, 10% L-helveticin of Lactobacillus helveticus D75 and Lactobacillus helveticus D76). The variation in antimicrobial activity of Lactobacillus helveticus D75 and Lactobacillus helveticus D76 was estimated by the microdilution method. The identification of bacteriocin genes was performed by PCR using helveticin J gene primers. Amplified fragments were sequenced using ABI PRISM® 310 Genetic Analyzer and were analyzed using NCBI/BLASTX.

Results: The identical sequences of 537 bp homologous to gene fragment of helveticin of Lactobacillus helveticus DPC 4371 (lhv_1632 gene) were detected.
in DNA of both probiotic strains. Sequencing of these fragments showed differ-
ences compared to the reference DNA of DPC 4571 strain (A instead of G at position 46, C instead of T at position 249 and A instead of T at position 537), but all these replacements do not lead to changes in the amino acid sequence of a bacteriocin. For Lactobacillus acidophilus D76 another bacteriocin gene fragment of 283 bp was identified (in addition to 537 bp fragment). The latter had 95% homology with the helveticin J gene of Lactobacillus helveticus R0052 (R0052_09025 gene). In NCBI BLASTX database the sequences homolo-
gous to the helveticin gene of Lactobacillus helveticus DPC 4571 were found in 17 Lactobacillus species related to Lactobacillus acidophilus, Lactobacillus amylovorans, Lactobacillus crispatus, Lactobacillus gallinarum, Lactobacillus helveticus and Lactobacillus kitasatosan. The addition of the carboxylic and amino acids mixture (Actioflor®-S) results in 2-2.5-fold enhanced antimicrobial activity of both tested probiotic Lactobacillus strains against test pathogens (Lactobacillus coli D75 and Salmonella Enteritidis 209), most likely due to an increase in bacteriocin gene expression.

Conclusion: Study shows that there are at least two bacteriocins in Lactobacillus helveticus D76 and one bacteriocin in Lactobacillus helveticus D75. Carboxylic ac and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain M17 probably induces bacteriocin synthesis in probiotic strains Lactobacillus helveticus D75 and Lactobacillus helveticus D76 and enhances their antimicrobial activity against test pathogens Escherichia coli D75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression.

P1735 GLASGOW-BLACHFORD SCORE ACCURATELY PREDICTS THE NEED OF TRANSFUSION IN ACUTE LOWER GASTROINTESTINAL BLEEDING. A DIAGNOSTIC ACCURACY EVALUATION STUDY

S. Machlab1, E. Martinez-Bauer2, P. Garcia-Iglesias1, A. Lira1, C. Marmol1, G. Llibre1, J.P. Da Costa1, M. Gallach1, V. Puig-Divi1, F. Junquera2, R. Campo1, X. Calvet1, E. Brullet1, Gastroenterology, Hospital Universitari Parc Tauli, Sabadell/Spain

Contact E-mail Address: smachlab@tauli.cat

Introduction: The incidence of acute lower gastrointestinal bleeding (LGB) is increasing in Western countries, but the predictors of its outcome are not well studied to be defined.

Aims & Methods: The aim of this study was to compare the accuracy of Glasgow-Blachford score (GBS) with three available risk scores (State, Velayos and Newman) for predicting the need of any clinical intervention (endoscopic therapy or surgery) in patients admitted for acute LGB. A retrospective study from January 2013 to December 2015 in a university tertiary care hospital. Patients with acute LGB were identified using the International Classification of Diseases (9th Revision) and Clinical Modification codes for admission diagnosis. Scores were retrospectively calculated according to clinical reports data. Area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, positive and negative predictive values were calculated for four scores. Also the best cut-off of each score was chosen from using the AUROC curve values. Results: A total of 298 (51% men) consecutive patients with acute LGB were identified. Median age was 76.1 years (range 25.4–96.5), 201 (67.4%) of patients were older than 70 years. Five patients (1.7%) died, 18 (6%) developed recurrent bleeding, 89 (29.9%) needed transfusion, 30 (12.1%) received endoscopic therapy, and 3 (1%) underwent transcatheter arterial embolization. No patients required any surgical intervention. AUROC of GBS score was 0.87 (95%CI:0.82–0.91) for the need of transfusion, and 0.82 (95%CI:0.76–0.87) for the need of any clinical intervention. AUROC for the need of transfusion and clinical intervention were 0.68 (95%CI:0.61–0.74) and 0.67 (95%CI:0.60–0.73) for the Strate score, 0.77 (95%CI:0.71–0.83) and 0.74 (95%CI:0.68–0.80) for the Velayos score and 0.78 (95%CI:0.72–0.85) and 0.74 (95%CI:0.68–0.81) for the Newman score, respectively. GBS was significantly more accurate than LGB risk scores for predicting the need of transfusion. Although AUROC of GBS was also numerically better for predicting the need of any clinical intervention, the difference was only significant when comparing with the Strate score. All the risk scores were more accurate for determining the need for transfusion than for the need of clinical intervention. Sensitivity, specificity and positive and negative predictive values for each score are shown in table 1.

Table 1: Prediction values of the different scores for detecting the need of transfusion (TRF) or clinical intervention (CI). 1Best cut-off scores for Blachford score were 6 for transfusion and 4 for clinical intervention. Values are expressed as%.

<table>
<thead>
<tr>
<th>Score</th>

<td>95 46 41 96</td>
</tr>
<tr>
<td>Newman &gt; 192</td>
<td>40 39 93</td>
</tr>
</tbody>
</table>

Conclusion: The GBS was superior to the 3 LGB risk scores for predicting the need for transfusion and clinical intervention. The GBS may be an useful tool for risk stratification in acute LGB.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1734 ACCURACY OF THE NASOGASTRIC TUBE AND THE BUN/CREATININE RATIO FOR DISTINGUISHING BETWEEN UPPER AND LOWER SOURCES OF GASTROINTESTINAL BLEEDING. A SYSTEMATIC REVIEW

S. Machlab1, E. Martinez-Bauer2, P. Garcia-Iglesias1, A. Lira, C. Marmol1, G. Llibre1, J.P. Da Costa1, M. Gallach1, V. Puig-Divi1, F. Junquera2, R. Campo1, X. Calvet1, Gastroenterology, Hospital Universitari Parc Tauli, Sabadell/Spain

Contact E-mail Address: smachlab@tauli.cat

Introduction: The insertion of a nasogastric tube (NGT) and assessment of the BUN/creatinine ratio were recommended as initial measures to distinguish between upper and lower gastrointestinal bleeding (American College of Gastroenterology 2016). As the nasogastroscope is one of the most bothersome interventions for the patient, we evaluated the evidence supporting these recommendations.

Aims & Methods: The aim of the study was to identify the diagnostic accuracy (sensitivity, specificity, positive predictive value, negative predictive value and likelihood ratios) of the NGT and the BUN/creatinine ratio for distinguishing between upper and lower sources of gastrointestinal (GI) bleeding. We conducted a systematic review of the literature in order to identify studies assessing the diagnostic accuracy of the NGT or BUN/creatinine in patients with melena, hematochezia or rectorrhagia without hemorrhages. The search was performed in November 2016 in five data bases (Pubmed, Scopus, Web of Science, Cochran Plus Library and OpenGrey).

Results: Four studies met the selection criteria (two evaluating the NGT, one BUN/creat and one both). The two methods had a low sensitivity for detecting upper GI bleeding source. Both a positive NGT aspiration and BUN/creatinine ratio above 30 markedly increased the probability of an upper GI source with a positive likelihood ratio ranging from 2 to 11. Unfortunately, the sensitivity of both tests for upper GI bleeding was very low (negative likelihood ratios around 0.3). Characteristics and results of the studies selected are shown in table 1.

Conclusion: Neither test reliably rules out an upper GI source of bleeding. Therefore, in cases of uncertainty, an upper GI endoscopy will be necessary to make a definite diagnosis.

P1736 ACUTE LOWER GASTROINTESTINAL BLEEDING IN PATIENTS TREATED WITH NON-VITAMIN K ANTAGONIST ORAL ANTICOAGULANTS COMPARED WITH WARFARIN IN CLINICAL PRACTICE: CHARACTERISTICS AND CLINICAL OUTCOME

G. Diamantopoulou1, C. Konstantakis1, G. Theocharis1, V. Theopistos1, G. Skroubis1, C. Triantos1, V. Nikolopoulou1, K. Thomopoulos1
1Gastroenterology - University Hospital of Patras, Patras/Greece
2Surgery, University Hospital of Patras, Patras/Greece

Contact E-mail Address: geodiamant@hotmail.com

Introduction: Acute lower gastrointestinal bleeding (ALGB) occurs in patients taking anticoagulants either warfarin or non Vitamin K oral anticoagulants (NOACs). The use of NOACs has been increasing compared with warfarin in recent years. We investigated patients with ALGB on anticoagulation therapy and we analyzed characteristics, management and clinical outcome in patients treated with NOACs versus warfarin.

Aims & Methods: All patients with ALGB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

Results: Out of 587 patients with ALGB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age range of 75.9 (2.9) vs 77.1 (1.9). The bleeding site was in the small bowel in 2/43 and 6/68 respectively. Causes of bleeding were not different between the two groups except for polyps/neoplasia (8/43 vs 6/68, p=0.003). Endoscopic hemostasis was more commonly needed in patients on NOACs versus warfarin (17/43 vs 8/68, p=0.049). Blood transfusions and need for other interventions (embolization and/or surgery) were not different. Also recurrence of bleeding (4/43 vs 11/68) and mortality (3/43 vs 6/68) were low and not statistically different between the two groups.

Conclusion: ALGB in patients on NOACs although presents some differences it has a similar clinical outcome to patients with ALGB on warfarin.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1737 NOBLADS - THE NEW RISK SCORE TO PREDICT THE SEVERITY OF ACUTE LOWER GASTROINTESTINAL BLEEDING

M. Patita, G. Nunes, R. Barosa, L. Ramos, C. Fonseca
Gastroenterology, Hospital Garcia de Orta, Almada/Portugal

Contact E-mail Address: martapatita21@gmail.com

Aims & Methods: We aimed to evaluate the accuracy of the NOBLADS score to predict severe LGIB and the outcome of patients admitted by LGIB. We performed a retrospective, observational and unicentric study. Including patients admitted for acute LGIB and submitted to endoscopic evaluation between January/2015 and March/2016. LGIB was classified as severe if ≥2 units of erythrocyte concentrate (UCE) were required and/or if hematoctit drop ≥20%. Total score ranges from 0-8; when total score is ≥2, it is considered high risk for severe LGIB.

Introduction: A new risk score for acute lower gastrointestinal bleeding (LGIB) has recently been validated, based on 8 admission criteria–nonsteroidal anti-inflammatory drugs use, absence of diarrhea, absence of abdominal tenderness, score >10 on abdominal pain score, platelet count ≤150 platelets/µL, systolic blood pressure <90 mmHg, serum creatinine ≥1.5 mg/dL, disease score ≥2 (Charlson comorbidity index) and syncope (NOBLADS). Results: 173 patients were included (male: 50.3%, mean age: 69 ± 17 years), with LGIB managed by hematocita (91.9%) or melena. Endoscopic evaluation was performed 1.7 ± 2 days after admission, with the most frequent findings being diverticular hemorrhage (n=53) and ischemic colitis (n=29); no lesions were found in 8.3% of cases. Thirty-three patients required intervention (endoscopic n=27, radiological n=2, surgical n=4) and 36 (20.8%) repeated endoscopic intervention. 28.9% of patients presented severe LGIB and the NOBLADS score determined the severity of LGIB with an under the curve value of 0.92 ± 0.018. Overall, higher score values were associated with a requirement for transfusion support, intervention and longer hospitalization (p<0.001 for trend test). Patients at high risk for severe LGIB (score ≥2, n=39) presented a significantly higher number of transfused UCEs (3.6 vs 0.08, p<0.001), intervention (38% vs 13%, p<0.001) and days of hospitalization (12.8 vs 3 days, p<0.001).

Conclusion: The NOBLADS score is simple and quick to apply. It predicts with high accuracy the risk of severe LGIB and allows to identify patients that are more likely to require transfusional support, intervention and prolonged hospitalization. In clinical practice, NOBLADS score may be useful to select on admission patients who will benefit from hospitalization or from earlier intervention.

**P1740 RISK OF COLORECTAL CANCER IN ASYMPTOMATIC INDIVIDUALS WHOSE FIRST DEGREE RELATIVES WERE AFFECTED BY CRC AT DIFFERENT AGES OF ONSET: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 9.28 MILLION SUBJECTS**

J.L. Huang, M. C. Wong, C. Chan, J. Lin, W. W. Cheung, M. Liang, Y. Fang, C. Yu, E. Fung
*Chinese University of Hong Kong, Hong Kong/Hong Kong Prc*

Contact E-mail Address: martin_wong@cuhk.edu.hk

**Introduction:** The current literature is mixed regarding whether first-degree relatives (FDRs) of patients who suffered from colorectal cancer (CRC) at much earlier age are at substantially increased risk of CRC. Aim & Methods: The present systematic review and meta-analysis examined the CRC risk conferred by family history of CRC in FDRs according to their age of onset. We searched Ovid Medline, EMBASE and grey literature from their inception to December 2016, and included all screening studies that investigated the relative family history of CRC and incidence/prevalence of CRC. Two reviewers independently worked on selection, assessment and data extraction of eligible articles. A random effects meta-analysis was employed to pool relative risks (RR) and odds ratios. Subgroup analyses were performed according to the age of onset of CRC in FDRs of asymptomatic subjects (<40 vs. ≥40; ≤50 vs. ≥50: <60 vs. ≥60 years). Statistical heterogeneity was assessed by the I² statistic. Publication bias was evaluated by an inverted funnel plot analysis with Begg’s regression model.

**Results:** Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs of asymptomatic subjects conferred a significantly higher risk of CRC (RR = 1.76, 95% CI = 1.57–1.97; p < .001, I² = 95.7%). Earlier age of onset of CRC in FDRs was associated with significantly higher risk of CRC in index subjects (RR = 3.29, 95% CI. 1.67–6.49 for ≤40 vs. RR = 1.42, 95% CI. 1.24–1.62 for ≥40 years, p = 0.017; RR = 2.81, 95% CI. 1.94–4.07 for ≤50 years vs. RR = 1.47, 95% CI. 1.28–1.69 for ≥50 years, p = 0.001). The Begg’s test did not identify any publication bias (Kendall’s tau = 0.122, p = 0.159).

**Conclusion:** A family history of CRC in FDRs whose age of onset is earlier than 40 or 50 years conferred a significantly higher risk of CRC to asymptomatic individuals, implying that age of onset could potentially enhance the discriminatory capability of CRC prediction scores.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1741 IS THERE ANY DIFFERENCE IN RISK OF COLORECTAL CANCER AMONG ASYMPTOMATIC SUBJECTS WHOSE SIBLINGS VS. PARENTS WERE AFFECTED? A SYSTEMATIC REVIEW AND META-ANALYSIS**

J.L. Huang, M. C. Wong, C. Chan, J. Lin, W. W. Cheung, M. Liang, Y. Fang, D. Fung, C. Yu

**Introduction:** Few studies compared the risk of colorectal cancer (CRC) among individuals with probands who were parents, siblings, and those with two or more probands. Aim & Methods: This systematic review and meta-analysis tested the hypothesis that the risk of CRC conferred by family history of CRC in parents vs. siblings vs. ≥2 first-degree relatives (FDRs) was similar. The Ovid Medline, EMBASE and grey literature were searched from their inception to December 2016, and all screening studies that examined the association between detection of CRC and family history of CRC in FDR were included. Two reviewers independently searched, assessed and extracted data from eligible studies. The relative risks (RR) and odds ratios were pooled based on a random effects meta-analysis. We conducted subgroup analyses according to the identity of FDRs affected (parents vs. siblings vs. ≥2 FDRs), and examined statistical heterogeneity by the I² statistic. Potential publication bias was explored by funnel plot analysis with Begg’s regression test.

**Results:** We identified 56 case-control and 7 cohort studies, consisting of 9.28 million subjects who were finally included in the meta-analysis. Asymptomatic individuals with siblings affected (RR = 2.44, 95% CI = 1.90–3.13); parents affected (RR = 2.18, 95% CI = 1.95–2.45) and ≥2 FDRs affected (RR = 2.68, 95% CI = 1.39–5.18) had statistically similar risk of CRC. We did not identify any publication bias based on the Begg’s regression test (p = 0.159).

**Conclusion:** The risk of CRC was similar among subjects whose siblings; parents or ≥2 FDRs were affected by CRC. Information on the identity of the FDRs affected does not seem to be necessary when the risk of CRC in asymptomatic individuals is predicted.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1742 GILBERT SYNDROME IS NOT THAT INNOCENT?**

N. Arber1, M. Menachem1, L. Ari2, G. Lion1, B. Ezra1, H. Gitl1, H.G. Amira1, J. Mazoyer1, S. Shapira1

**Introduction:** Gilbert’s syndrome is considered to be entirely benign. Some studies have shown a reduced risk for cardiovascular disease (CVD). There is conflicting data regarding cancer risk among Gilbert patients. Aims & Methods: We aimed to evaluate the association of Gilbert syndrome with CVD and cancer. Clinical and epidemiological data was obtained from consecutive healthy subjects undergoing annual screening at the Integrated Cancer Prevention Center in Tel Aviv. The annual check-up includes: thorough examination by specialists in internal medicine, surgery, dermatology, plastic surgery, OBGYN, urology, oncology, oral surgery, gastroenterology. Blood work (smac 24, blood count, TSH, CRP, PSA), vaginal, PSA and mammography (>40yrs), LDCT in heavy smokers and all needed imaging when clinically indicated. Peripheral blood DNA was extracted from all subjects. Gilbert syndrome was determined by clinical criteria (normal liver function tests but mild elevation in unconjugated bilirubin < 3mg/dl without any hemolysis. In the majority of the cases the diagnosis was confirmed genetically by the homozygous mutation (TA)7TA7 in the promoter region of UGT1A1 enzyme. Prevalence of CVD and cancer were compared between subjects with/without Gilbert syndrome. Mortality data was obtained from the Israeli ministry of health and cancer incidence from the Israeli registry.

**Results:** A total of 6258 (49%) men and 6461 (51%) women, mean age 47.0 ± 11.5 years, were included of which 1.019 had clinical Gilbert. Gilbert was significantly more common among men (11.5% versus 4.6% P < 0.001). The rate of Gilbert disease was equal in Sephardic and Ashkenazi Jews. Malignancy and CVD were diagnosed in 678 (5.3%) and 1.837 (14.4%) subjects respectively. The prevalence of any CVD was significantly higher in the Gilbert group (OR 1.23 95% CI 1.04–1.46 p = 0.017), as was non-hypertension (OR 1.37 95% CI 1.12–1.68 p = 0.003) and CVA (1.1% versus 0.6% p = 0.06). Higher rate of kidney and bladder cancers (2.64, 1.22–5.70, p = 0.019) was also observed in the Gilbert group. In contrast, the prevalence of breast cancer was much lower among the Gilbert patients (0.36% vs 0.97%, P = 0.034).

**Conclusion:** In Israel Gilbert syndrome is not that innocent. In a large cohort it seems to be associated with increased risk of hypertension, CVD and CVA. Bladder cancer is higher but females are protected from breast cancer. Further studies are mandated in order to better understand these findings and determine proper screening and surveillance practices in Gilbert disease.

**P1743 CHARACTERISTICS AND PREDICTORS OF INTERVAL CANCER: A CASE-CONTROL STUDY**

I. Laish1, J. Mizrahi2, F. Konikoff1
1Meir Medical Center, Kfar Saba/Israel
2Stony Brook University Hospital, New York/United States of America

Contact E-mail Address: ido.laish@gmail.com

**Introduction:** Interval colorectal cancer is largely related to a poor endoscopic performance (missed lesions, incorrect resection margins or different polyps) contributing to the development of the polyp (accelerated growth). Thus, quality endoscopic measures and Lynch syndrome were highly investigated for their association with interval cancer. However, most reports came from the Western world and not the Middle East, and differences in ethnicity or environmental factors might potentially have impact on the biology of tumor progression. In addition, patient-related factors were less investigated for their association with interval cancer. The aim of this study was thus to assess tumor and patient characteristics and predictors of interval cancer in a population from Israel.

**Aims & Methods:** This retrospective cohort study included all patients that were diagnosed with colon cancer in our institution between 2005–2014. Cases included patients with a previous colonoscopy within 1–10 years before the diagnosis of cancer, with either negative or insignificant findings or benign polyps. Only full colonoscopies with at fair or good preparation were included. Interval cancer was defined on an individual basis, when cancer occurred within the recommended surveillance interval according to accepted guidelines. Cases were further stratified according to time since index colonoscopy (<3, 3-10) years). Positive controls were cancer patients without previous colonoscopy, and "negative" controls were sex- and age-matched patients with two negative colonoscopies within the study period who were randomly selected on a 1:1 ratio. Tumor characteristics (location, staging) and patient-related factors (age, gender, positive family history of colon cancer, aspirin use, diabetes, diverticulosis) were compared between cases and control groups.

**Disclosure of Interest:** No conflicts of interest were declared.
Aims: To identify the metabolic risk factors associated with colorectal neoplasia (advanced adenomas and cancers) and evaluated their impact in colorectal cancer screening. Prospective, multicenter study was performed from January 2013 to December 2015 at eight high-quality colonoscopy centers. Aims & Methods: We retrospectively analyzed colonoscopy data of 2338 and 2636 patients, respectively, using standard quality control criteria. Risk factors, and colonoscopic pathologic findings were assessed in patients with metabolic syndrome (target group) who underwent preventive colonoscopy (FIT positive or screening colonoscopy). This data was compared with consecutive controls (without metabolic syndrome). We used the screening population criteria (asymptomatic, without family or personal history of colorectal neoplasia).

Results: 1500 individuals were enrolled; 726 persons (494 men, 68%) in the target group (metabolic syndrome) and 774 persons (353 men, 46%) in the control group (without metabolic syndrome). The significantly higher prevalence of advanced adenomas was observed in the target group (18%; 95% CI 15–21%) compared to the control group (9%; 95% CI 7–11%; OR 1.8; p=0.002). Similarly, the prevalence of all adenomas was higher in the target group (48%; 95% CI 44–51%) than in the control group (35%; 95% CI 32–38%); however, the difference was not statistically significant (p=0.179). Individuals with isolated high cardiovascular risk (SCORE >10%) had higher prevalence of both non-advanced adenomas (51%; 95% CI 46–56%; p=0.037) and advanced adenomas (22%, 95% CI 18–26%; p=0.049) compared to the individuals with isolated DM2. Advanced adenomas were more likely in patients aged 65–75 years.

Conclusion: Colorectal neoplasia is positively associated with metabolic syndrome. Cardiovascular risk factors (SCORE >10%) is a stronger risk factor than the presence of diabetes mellitus type 2. Individuals with SCORE >10% should be considered as a risk group of colorectal cancer. Based on our findings, colonoscopy is the primary screening method is appropriate. This project has been supported by the Czech Ministry of Health grant NT 13673 and MO 1012.

P1747 CONTRIBUTION OF GERMLINE MUTATIONS TO NON FAMILIAL EARLY ONSET CANCERS

A. Mannucci1, F. Calabrese1, R. A. Zuppardo1, U. Elmore2, F. Aleotti2, M. Rechavi2, A. Ferrand2, M. Bonnet1, M. Rechavi1

2Centre Hospitalier Universitaire, Grenoble, France

Contact E-mail Address: alessandromannucci1@gmail.com

Introduction: Early onset gastroenterological cancers lacking a positive family history are an increasingly worrisome entity. On one hand, early onset is the cornerstone of genetically determined oncological problems, but on the other negative family history does not support the suspect of familial syndromes.

Aims & Methods: We addressed the contribution of germline mutations to non familial early onset cancers. Patients with pancreatic, gastric, esophageal, duodenal and colorectal cancers were enrolled from 2015 to 2017 at the Gastrointestinal Personalized Medicine unit. Eligibility criteria were the juvenile onset and the negativity for clinical criteria of hereditary cancer syndromes. Early onset colorectal cancer was defined as <45 yrs for the other cancers, the threshold was defined at 50. Eligible patients provided informed consent. Genes were sequenced by means of a validated Next Generation Sequencing panel of oncological susceptibility genes and confirmed by means of Sanger sequencing.

Results: Among 12 colorectal cancer patients (7F, 5M), NGS analysis showed 2: MSH2 and MSH6 occurring de novo, given the absence of family history; 3 variants of unknown significance (VUS) (2 MSH2 and 1 MLH1); and 7 were negative. Age-stratification revealed that, among those <35 years (n = 4), 1 had MSH2 gene mutation and 3 were negative. In the 36-40 age group (n = 3), 1 had a MSH2 VUS and 2 were negative. In the age group 41-45 (n = 5), MSH6 mutation and 2 VUS were found, alongside 2 negative results. Among the colorectal cancers, 17% of patients had a de novo mutation of Lynch Syndrome, 25% had a VUS, and 58% were negative.

Conclusion: A significant percentage (17%) of early onset colorectal cancers resulted in Lynch Syndrome even when family history is not suggestive of hereditary cancer. We reliably infer the determinant role of genetics, even when the family history does not support the hypothesis. Elsewhere, our results suggest that the already known susceptibility genes seldom contribute to sporadic early onset cancers. Other genes and mechanisms may explain the early onset phenotype. Our data show that NGS is often non conclusive in early onset GI cancers, and further development is needed to better classify VUS (25%).

Introduction: Colibactin producing E. coli strain (11G5), non pathogenic properties on CRC murine models. Aim of this work was to evaluate the impact of chronical infection by colibactin-producing E. coli on CRC carcinogenesis process.

Aims & Methods: Mice were infected or non-infected mice. These results can be linked with our in vivo optical imaging observations and our results about the increase of neutrophils chemo-attractants CXCL1 and CCL20 measured by qRT-PCR after infection. Analysis of T cells, macrophages, B cells and myeloid suppressive cells are in progress.

Conclusion: Here we can observe an increase of lymphoid follicle associated with tumor volume after colibactin-producing E. coli infection. Our first results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic E. coli and tumor development.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1749 INVESTIGATING THE DIRECT INTERACTION BETWEEN CD24 AND β-CATENIN IN INTESTINAL TUMORIGENESIS

N. Arber1, A. Foka1, S. Shapira2, D. Kazanov3, F. Bedny2, B. Eliš3, C. Varel3
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Histopathology and Bio-Imaging Group, Translational Sciences, Sanofi R&D, France
3Gastroenterology, Tel-Aviv Sourasky Medical Center, Tel-Aviv/Israel

Introduction: CD24 is a glycosylphosphatidylinositol-linked protein that functions as an adhesion molecule and is overexpressed at an early stage of CRC (Sagiv et al., 2006). The Wnt/β-catenin signaling pathway plays an important role in the CRC carcinogenesis process. C57BL6/J mice carrying the ApcMin mutation develop ~24±3.7 adenomas and several carcinomas in the small intestine by the age of 16 weeks compared to the ~7±1.7 polyps that ApcMin/CD24−/− (double KO) mice developed. Mice colonscopy showed a significant reduction in the number and size of polyps upon depletion of CD24 alleles. The ApcMin mice displayed severe spleenomegaly (355±68 mg) compared (141±49 mg) in double KO mice similar to WT mice. Hb level in the ApCMin was 5.8±2.5, significantly lower than in the double KO mice (8.2±0.9) and their WT littermate.

Aims & Methods: We aimed to study the cellular interactions between CD24 and β-catenin, and effects of their interaction on intestinal tumorigenesis. CD24-inducible 293T-Rex cells previously developed in our lab (Shapira et al., 2011) and SW480 CRC cells stably transduced with CD24 (Naumov et al., 2014) were used to study this interaction in vitro. Co-immunoprecipitation and immunofluorescence staining were used to investigate the interaction between the two proteins. Far western blotting (FWB) analysis was used to confirm this direct interaction by probing the standard WB membrane with the purified CD24 protein.

Results: In vitro: Western blotting analyses showed that expression of CD24 in 293T-Rex cells induced the activation of β-catenin, while down-regulation of CD24 in SW480 cells caused a decrease in the level of active β-catenin. Cyttoplasmic/nuclear fractionation showed that more active β-catenin entered the cell. It was in cells that expressed higher levels of control (clone 4). In addition, in both cell lines, TOP/FOP luciferase reporter assay showed a significant increase in Luciferase activity upon CD24 expression induction. Co-immunoprecipitation studies of CD24 and β-catenin indicated that these two proteins might be interacting. In addition, in HEK-293T cells and SW480 cells, immunofluorescent staining of CD24 and β-catenin showed that these two proteins co-localize on the cellular membrane. Furthermore, far western blotting analysis suggests that a direct interaction between the proteins exist.

Conclusion: 1. CD24 plays a major role in intestinal tumorigenesis. 2. CD24 interacts with the Wnt pathway by activating β-catenin. 3. CD24 interacts directly with β-catenin. 4. Down-regulation of CD24 may be an important aim in the therapy of CRC.

P1750 YM155 AS AN INHIBITOR OF CANCER STEMNESS SIMULTANEOUSLY INHIBITS AUTOPHOSPHORYLATION OF EGFR AND G9A-MEDIATED STEMNESS IN EGFR-POSITIVE CANCER CELLS

C. Cheng1, A. Ho2
1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan
2Division Of Gastroenterology, Chang Gung General Hospital, Taiwan/Taiwan

Contact E-mail Address: aisheng49@gmail.com

Introduction: Cancer stem cells survive as the leading reason to tumor recurrence after tumor repressive treatments. Therefore, it is worth discovering specific and efficient inhibitors against cancer stemness for applications in reducing tumor recurrence. Previously, literature has indicated that YM155 can significantly reduce the formation of gastric cancer and suppress EGFR activity. However, the pharmaceutical mechanism of YM155 is not completely clear.

Aims & Methods: The aim of this study attempted to investigate the potential mechanism of YM155 against cancer stemness in EGFR-positive cancers. The tumorspheres derived from EGFR-mutant HCC827 and EGFR-wild-type HCT116 and A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models.

Results: We found that higher EGFR autophosphorylation (Y1068) in HCC827-, A549-, and HCT116-derived tumorspheres compared to the parental cells, which induced tumorsphere formation through activating G9α-mediated stemness property. YM155 was demonstrated to inhibit the tumorsphere formation by unexpectedly blocking the autophosphorylation of EGFR and G9α-mediated stemness pathway. The chemical and genetic inhibitions of EGFR and G9α revealed the significant role of EGFR-G9α pathway in maintaining the cancer stemness property.

Conclusion: In conclusion, this study not only revealed that EGFR triggered the formation of tumorspheres through elevating the G9α-mediated stemness, but also demonstrated that YM155 inhibited the formation of tumorspheres by simultaneously blocking autophosphorylation of EGFR and activity of G9α as a potent anti-stemness agent against EGFR-positive cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Promoter hypermethylation-induced epigenetic silencing of tumor related genes played a key role in the initiation and development of colorectal cancer (CRC). Using Methylated DNA Immunoprecipitation (MeDIP), we identified that Fibroblast Growth Factor 14 (FGF14) was preferentially methylated in CRC.

Aims & Methods: We aimed to investigate the epigenetic regulation and biological function of FGF14 in CRC. The expression of FGF14 in 10 CRC cell lines and 24 pairs of CRC tissues and paired adjacent normal tissues by real-time PCR. CRC cells were treated with DNA demethylating agent 5-aza-2'-deoxycytidine (5-Aza). The methylated status of FGF14 in CRC cell lines and CRC tissues were determined by real-time MSP. The biological function of FGF14 in CRC was interrogated by cell viability assay, colony formation, immunofluorescence and flow cytometry, as well as in vivo study.

Conclusion: FGF14 was downregulated or silenced in all (10/10) CRC cell lines, while it was frequently expressed in normal colon tissues. The expression of FGF14 was significantly lower in primary CRCs as compared to their adjacent normal tissues (P < 0.01). The loss of FGF14 gene expression was restored by treatment with DNA demethylating agent 5-Aza. Re-expression of FGF14 in CRC cell lines inhibited colony formation, suppressed cell viability, and induced cell apoptosis via AMPK/mTOR pathway, accompanied with enhanced protein expression of cleaved caspase-3, cleaved caspase-7, cleaved caspase-9 and PARP. In xenograft mouse model, overexpression of FGF14 significantly reduced tumor growth (P < 0.001).

Conclusion: FGF14, which induces cell apoptosis via AMPK/mTOR pathway, is a novel tumor suppressor down-regulated by epigenetic inactivation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A cancer with a number of somatic mutations is defined as “hypermutator”, and shows therapeutic features, such as high sensitivity to immune checkpoint inhibitor. However, to date, analyses of hypermutator have not been done with a large number of cases.

Aims & Methods: The aim of this study is to analyze the incidences and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutation in digestive system cancers in 1145 cases (age: 67.4±11.3 yrs., M:F=755:390), those underwent surgery after full informed consent during 2014 to 2015. Genomewide sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next generation sequencer (Iontorrent. Precise trimmer, Alientrimmer dk). We confirmed hypermutator by DNA sequencing and microarray analysis.

Results: The 1145 subjects included 583 colorectal cancers (CRC), 229 gastric cancers (GC), 103 metastatic liver tumors, 100 hepatocellular carcinomas (HCC), 45 pancreatic cancer, 23 GISTs, 15 esophageal cancers, and 411 cancer-associated genes using next generation sequencer.

Conclusion: Hypermutator was recognized in 5–10% of digestive system cancers, associated with a somatic mutation of mismatch repair genes. Further research is needed to clarify the characteristics of hypermutator in digestive organs in the therapeutic aspects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1756 UNBIASED ANALYSIS OF REGULATION OF TRANSCRIPTION FACTORS UPON ER STRESS IN THE LS174T COLORECTAL CANCER CELL LINE EXPLORES CTBP2 AS A POTENTIAL REGULATOR OF STEMNESS

Introduction: In the intestinal epithelium, stem cells are located at the bottom of the crypt and their maintenance and differentiation is essential for sufficient cell maintenance using a transcriptomics approach. On thapsigargin treated LS174T cells, a cell line with a transcriptomic profile resembling intestinal stem cells, we performed a TF DNA-binding assay (catTFRE) in which TFs present in the cell are bound to plasmid DNA, co-extracted and quantified using mass-spectrometry. We confirmed downregulation using immunoblot in colorectal cancer cell lines. Additionally, we examined CtBP2 expression in colorectal cancer cell lines. Additionally, we examined CtBP2 expression in colorectal cancer cell lines.

Methods: The aim of this study is to analyze the incidence and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutation in digestive system cancers in 1145 cases (age: 67.4±11.3 yrs., M:F=755:390), those underwent surgery after full informed consent during 2014 to 2015. Genomewide sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next generation sequencer (Iontorrent. Precise trimmer, Alientrimmer dk). We confirmed hypermutator by DNA sequencing and microarray analysis.

Introduction: Location and somatic gene signature of CRCs may impact prognosis and thereby response. A relative specific CRC-related dysbiosis has been characterized.

Aims & Methods: The aim was to characterize colon microbiota in CRC patients regarding location, gene markers and outcome. Patients (N = 173) signed consent for stool DNA (metagenome shotgun sequencing on Illumina HiSeq (2014) analysis of stool DNA: 72 CRC (53 sporadic-S, 19 Lynch-L), 87 asymptomatic subjects (normal colonoscopy), 14 first degree healthy relatives from Lynch families. "MOCA1" pipeline was used, library sorted (Pherd quality score 20 Alignment score > 40). After extraction of < 5% of human genes or phage sequences. Quality sequences were aligned (REFMG v.0.1) and most abundant genes constructed (MBMA program v.0.1). The Shuman program (shuman.c3bi.pasteur.fr) was used. The number of bacteria was estimated (REFMG program). The linear model (GLM) was implemented in the DESeq2 R kit. Differences between Control (N = 87) and CRCs (N = 69), between L (N = 19) and S CRCs(N = 50), and between LCRCC (N = 19) and Healthy Lynch relatives were obtained after interaction of age, BMI and gender was considered (GLM model). The p < 0.1 value was retained as a cut-off (Benjamini and Hochberg).

Results: There was no difference for gender, age (p = 0.08) and BMI (p = 0.187) in the L and S CRCs. Significant differences were observed between Normal and CRCs, C-CRC and L-CRC, L-CRC and first degree relatives based on the common component (similarity of sequences); 13 species differentiated Normal and CRCs and two were more prevalent in L-CRCs. The panels of bacteria linked with location, MSI, Ras mutations, methylation phenotypes and survival were identified. No significant link was observed with TNM Staging (I (N = 17, 2L and 15S), II (N = 12, 5L and 7B), III (N = 20, 10L, 10B), IV (N = 22.1L, 21S). DFS might be dysbiosis dependent.

Conclusion: CRC dysbiosis is location-dependent. Several bacteria are associated with Ras mutation, MSI, and methylation status. They may directly or through epigenetic changes impact the prognosis. Microbiota signature should be taken in consideration in trials.

Introduction: Colorectal serrated lesions (SLS) include hyperplastic polyp (HP), traditional serrated adenoma (TSA) and sessile serrated adenoma (SSA/p). SSA/Ps are well-known precursors of colorectal cancer (CRC) characterized by BRAF mutation and microsatellite instability (MSI), whereas the molecular characteristics of TSAs are not fully understood.

Methods: The aim of this study is to analyze the incidence and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutation in digestive system cancers in 1145 cases (age: 67.4±11.3 yrs., M:F=755:390), those underwent surgery after full informed consent during 2014 to 2015. Genomewide sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next generation sequencer (Iontorrent. Precise trimmer, Alientrimmer dk). We confirmed hypermutator by DNA sequencing and microarray analysis.

Results: The 1145 subjects included 583 colorectal cancers (CRC), 229 gastric cancers (GC), 103 metastatic liver tumors, 100 hepatocellular carcinomas (HCC), 45 pancreatic cancer, 23 GISTs, 15 esophageal cancers, and 411 cancer-associated genes using next generation sequencer.

Conclusion: Using an unbiased transcriptomics approach we identified transcription factors that are lost on protein level upon ER stress. Furthermore, our data suggests that the significant loss of the transcriptional regulator CtBP2 contributes to intestinal epithelial stem cell differentiation.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Aims & Methods: We aimed to identify epigenetic alterations associated with the development of TSAs and to clarify the associations between clinical, pathological and molecular characteristics in colorectal lesions. The genome-wide DNA methylation status in TSAs consisting of protruding and flat components was identified. The significance of identified genes and CIMP markers (MINT1, -2, -12, -31, p16 and MLH1) and BRAF/KRAS mutations were analyzed in 847 colorectal lesions and 61 samples of normal colonic tissue. Effects of ectopic expression on CRC cell growth in a preclinical setting in TSA were identified. Methylation of CDK4, SMOC1 and CIMP markers in TSAs and SSA, but significantly downregulated in TSAs. Immunohistochemical analysis showed that CDK4 was expressed in normal colon and SSA/Ps, but is significantly downregulated in TSAs. Analysis of colorectal lesions revealed that SMOC1 is strongly associated with CIMP methylation and CIMP-low.

Conclusion: Methylation of SMOC1 is associated with CIMP-low development but is rarely observed in SSA/Ps. Immunohistochemical analysis of SMOC1 may be a useful marker to discriminate between SSA/Ps and TSAs. Our data suggests SMOC1 methylation may play a role in the neoplastic pathways arising in TSAs.

Introduction: The number of individuals partaking in colorectal cancer (CRC) screening still remains to be low even after the implementation of the Korean Government’s National Cancer Screening Program for CRC. The aim of this study is to identify factors associated with partaking in CRC.

Aims & Methods: The Korean National Health and Nutrition Examination Survey (KNHANES) 2007 ~ 2010 datasets were used to develop a CRC screening participation screening score. 10,577 individuals aged ≥50 who completed the survey and not previously diagnosed with CRC were selected. Both logistic regression (LR) analysis and artificial neural network (ANN) were used to develop predictive models. Multilayer perception ANN was constructed based on 16 clinical variables. We then validated the models using the KNHANES 2011 and 2012 (n = 9956) datasets and compared them with each other.

Results: Out of 10,527 individuals selected, 57.0% (n = 6003) responded unscreened for CRC. Among various demographic and socioeconomic factors, including age, gender and education, level, private health insurance, self-reported depression, self-reported health status, and residence were found to be independently associated with CRC screening participation. LR analysis produced screening score (range 0–10.3), and a cutoff point of ≥5.5 defined 49% as unscreened for CRC and yielded area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the AUC of ANN based predictive model was 0.743.

Conclusion: The ANN produced better performing model than LR analysis based model in identifying population with low CRC screening participation. Sensible approaches should be implemented to encourage partaking in CRC screening in the identified individuals.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1760 CD24 PREDICTIVE LEVELS- A SIMPLE NOVEL BLOOD TEST FOR EARLY DETECTION OF COLORECTAL CANCER

Introduction: Background: CD24, a mucin-like cell surface molecule, highly expressed in solid tumors and hematological malignancies (HM) (Gastro 2006, Clin Can Res 2007, Can Res 2008). nLab was found to inhibit the growth CD24 cancer cells (Gastro 2009). We have shown that a simple non-invasive blood test evaluating CD24 levels on PBL had good sensitivity and specificity for detecting colorectal neoplasia in subjects undergoing screening colonoscopy (Kraus et al., 2009).

Aims & Methods: We aimed to improve a simple, noninvasive blood test that can efficiently identify individuals with different types of cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer (PC), gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnich matched healthy individuals served as controls. Hemoglobin and hematocrit were measured. They underwent a thorough and extensive workout at the Integrated Cancer prevention center at Tel Aviv Medical Center (Eur J Intern Med. 2013) All samples were collected and processed identically. For each sample, 20,000 leukocytes were analyzed by flow cytomtery. An internal template data has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition have been completed. The template file include compensation adjustment, which is uniformly applied to all the data collected in order to minimize fluorescence overlap among detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig.1a) (P < 0.013), PC (Fig.1b) (P < 0.018), biliary tract (P < 0.45E-12), HM (Fig.1c) (P < 0.013), Brain (Fig.1d) (P < 0.013), MDS (P < 0.1) and Lymphoma (P < 2E-07) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 72.4% and 77.4%, and for PC 70.6% and 75.9%, respectively.

The positive (PPV) and negative predictive (NPV) values of CD24 for the detection of CRC was 38% and 94.8%, and for PC 17.1% and 97.3%, respectively. Specificity and sensitivity for HM were also statistically significant (data not shown). The CD24 test could not discriminate between patients with cervical, stomach and lung cancers and healthy subjects.

Conclusion: Conclusions: CD24 expression in PBLs is a promising blood test for the early detection of CRC. PC and HM.

Introduction: Colonoscopy is considered the gold standard for prevention and early detection of colorectal cancer (CRC), however its effectiveness is directly related to quality of bowel preparation. Two of the quality measures of colonoscopy,ecal intubation rate and adenoma detection rate, are both associated with adequate bowel preparation. Data on factors associated with quality of preparation using Picolax® are limited.

Aims & Methods: We aimed to evaluate factors associated with a good bowel preparation using Picolax® (Sodium picosulfate/magnesium citrate) in the Israeli heterogeneous population. Consecutive outpatients referred for colonoscopy were prospectively assessed by a nurse practitioner filling out a questionnaire. Hemoglobin, thyroid function test, drinking behavior during the course of preparation using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition have been completed. The template file include compensation adjustment, which is uniformly applied to all the data collected in order to minimize fluorescence overlap among detection channels.

Results: The number of individuals partaking in colorectal cancer (CRC) screening still remains to be low even after the implementation of the Korean Government’s National Cancer Screening Program for CRC. The aim of this study is to identify factors associated with partaking in CRC.

Aims & Methods: The Korean National Health and Nutrition Examination Survey (KNHANES) 2007 ~ 2010 datasets were used to develop a CRC screening participation screening score. 10,577 individuals aged ≥50 who completed the survey and not previously diagnosed with CRC were selected. Both logistic regression (LR) analysis and artificial neural network (ANN) were used to develop predictive models. Multilayer perception ANN was constructed based on 16 clinical variables. We then validated the models using the KNHANES 2011 and 2012 (n = 9956) datasets and compared them with each other.

Results: Out of 10,527 individuals selected, 57.0% (n = 6003) responded unscreened for CRC. Among various demographic and socioeconomic factors, including age, gender, ethnicity, including age, gender, ethnicity, and education, level, private health insurance, self-reported depression, self-reported health status, and residence were found to be independently associated with CRC screening participation. LR analysis produced screening score (range 0–10.3), and a cutoff point of ≥5.5 defined 49% as unscreened for CRC and yielded area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the AUC of ANN based predictive model was 0.743.

Conclusion: The ANN produced better performing model than LR analysis based model in identifying population with low CRC screening participation. Sensible approaches should be implemented to encourage partaking in CRC screening in the identified individuals.

Conclusion: Diabetics require a more intense bowel preparation aided by Bisacodyl which helps others. Those without both doses of bisacodyl 8 hours and preparation should end no later than 8 hours prior to colonoscopy. Patients should be instructed to drink a minimum of 8 glasses of water with each dose of picolax.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1762 IMPROVED ADENOMA DETECTION WITH ELUXEO LINKED COLOR IMAGING (LCI) AS COMPARED TO CONVENTIONAL WHITE-LIGHT HIGH-DEFINITION COLONOSCOPY–A RANDOMIZED CONTROLLED TRIAL

Introduction: Colonoscopy is the gold standard method of colorectal cancer and polyp screening, but polyps are missed during a colonoscopic examination at a rate that varies from 6% to 27%. Improved adenoma detection rates can be achieved with optimized endoscopic visualization methods. A recently developed new Fujinon endoscope system, Eluxeo carries a new function of electronic chromoendoscopy, Linked Color Imaging (LCI), that enhances the coloring and visualization of membranes and is in high contrast which are difficult to see with the conventional endoscopes. In our prospective randomized study, we evaluated the effectiveness of LCI, a new endoscopic visualization technique that may enhance image quality to improve colonic adenoma detection.

Aims & Methods: Up till now 247 eligible patients, older than 54 years, admitted for screening outpatient colonoscopy were randomly enrolled to undergo high-definition white-light colonoscopy (WLC) or LCI colonoscopy during instrument withdrawal. The colonoscopic procedures were performed by three experienced endoscopists using the 7000 processor with the conventional high-definition Fujinon EC 590z or a new EC 760z VS Eluxeo colonoscope. All of the colonoscopic procedures were made under Propofol deep sedation guided by an anesthesiologist team. The minimum withdrawal time was defined as more than 6 minutes. All colonoscopies were routinely assisted with pure CO2 insufflation. The primary outcome parameter of our study was to assess and compare the polyp and adenoma detection rate with the two endoscopic techniques.

Results: A total of 247 patients were randomized (mean age 58.7 years), 101 patients enrolled in the WLC group and 146 patients in the LCI group. No significant differences have been observed in the patient demographics and colonoscopy withdrawal time between the two groups. Patients having both colorectal polyps and adenomas were detected more frequently in the LCI group than in the control group: 60.9% and 43.8% versus 55.4% and 33.6% respectively, however, this was not statistically significant (p = 0.32 and 0.16). In contrast, the total number of adenomas relative to the total number of polyps detected with LCI withdrawal were significantly higher than with conventional WLC: 105 vs. 124 adenomas, respectively (p < 0.0005).

Conclusion: The LCI enhancement of the Fujinon Eluxeo colonoscopy system was superior to the conventional HD-WLC in detecting patients with colonic adenomas, which was mainly due to the ability of the more sensitive detection of minute (less than 5 mm) adenomas.

Introduction: Long non-coding RNAs (lncRNAs) play role in colorectal cancer (CRC) development, however, lncRNA expression profile in CRC and its relation to the epigenetic regulatory system still remain incomplete.

Aims & Methods: We aimed the perform whole genomic lncRNA expression profiling and the analysis of underlying functional interactions of aberrantly expressed lncRNAs. lncRNA expression levels were analyzed on 60 colonic biopsy samples (20 CRCs, 20 adenomas, 20 normals) by Human Transcriptome Microarray (HTA) 2.0. Expression alteration of certain candidates was verified by qPCR. Furthermore, in silico validation was performed on HGU133 Plus 2.0 array data and also on TCGA COAD dataset. miRNA targets prediction was performed on miRcode algorithm and miRNA expression was analyzed on miRnome 3.0 Arachnoid exacrine lncRNA-miRNA coexpression pattern analysis was also performed.

Results: According to HTA results in adenomas 12 lncRNAs (e.g. LIN00278) were upregulated and 6 lncRNAs (e.g. RP11.749D18.1) were downregulated compared to normals, while in CRCs 1 lncRNA (UCAI) was overexpressed and 8 lncRNAs (e.g. LIN00350) were underexpressed compared to adenomas (p < 0.05; `-2 ≤ Fc ≤ 2). In CRC samples 8 lncRNAs (e.g. AC123023.1) were overexpressed and 9 lncRNAs (e.g. RP13-497K6.1) were downregulated compared to normals. 42% of lncRNAs upregulated in CRC samples showed transcriptional regulation in adenomas (p < 0.05; `-0.6 ≤ Fc ≤ 2), while 42% of lncRNAs (p < 0.05; `-2 ≤ Fc ≤ 2) in adenomas were upregulated. In CRC samples 32 lncRNAs were downregulated (LIN01133). In line with aberrant expression of certain lncRNAs in tumors, miRNA and mRNA targets expression showed systematic alterations, e.g. UCA1 upregulation in CRC samples in parallel with miR-1 downregulation accompanied by CMET target mRNA overexpression (p < 0.05).

Conclusion: The defined lncRNA sets (e.g. UCAT1, UCA1) may have a regulatory role in adenoma and CRC development and in tumor cell growth pathways. A subset of CRC-associated lncRNAs showed significant differential expression in colorectal adenomas, which raise the possibility to develop potential adenoma specific markers and achieve early detection of colon lesions.

Introduction: Serine protease inhibitors (Serpins) play an important role in the regulation of proteolytic cascades of different tissues. KLK14, acting via PAR-2, represents an auto- crine/paracrine regulator of colon tumorigenesis and alpha1-antitrypsin is a natural inhibitor of KLK14. Therefore its role in regulating the proteolytic cascade in colorectal tumorigenesis is of great importance.

Aims & Methods: The aim of this study was to analyze AI-antitrypsin (AAT) expression in tissue samples at different stages in the process of colorectal cancer development. We examined a total of 245 colon samples. Of those, there were 101 colorectal carcinoma tissues, for 70 of which paired normal mucosa was also examined. A total of 74 colorectal adenomas were examined. Quantitative real time PCR was used to measure AAT expression. Clinical evaluation of AAT levels was demonstrated in terms of disease-free survival (DFS) and overall survival (OS).

Results: Alpha-antitrypsin expression was found to be significantly associated with shorter disease-free survival stage (p = 0.028). On contrary, proportional hazard regression model using univariate analysis revealed that high status alpha-antitrypsin expression is a significant factor for disease-free survival (DFS) (p = 0.002) and overall survival (OS) (p = 0.026) in patients with colorectal cancer. Kaplan-Meier survival curves demonstrated that low alpha-antitrypsin expression is significantly associated with longer DFS (p = 0.001) as well as OS (p = 0.021).

Conclusion: Our data suggests that alpha-antitrypsin expression could be considered as a potential biomarker of unfavorable prognosis for colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Real-time differentiation between neoplastic and non-neoplastic colorectal lesions may be crucial during colonoscopy. While adenomas are
neoplastic, and therefore should be resected, hyperplastic polyposis never turn malignant and do not require specific endoscopic therapy. The aim of our prospective, randomized study was to distinguish subcentimeter hyperplastic and adenomatous polyps based on Fujinon FICE versus Eluxeo BLI electronic chromoendoscopic technology with high-definition colonoscopy with and without optical zoom magnification.

Aims & Methods: In order to create a digital and visual picture library of polyps, patients undergoing screening or diagnostic colonoscopy were considered for inclusion. Patients with at least one histologically verified <10mm polyp were included. A short (20sec) video-clips and at least one still picture of each polyp without and with 50x optical zoom at standard white-light (WLI), and with FICE-light or BLI-light were recorded with Fujinon EC 590Z and EC760Z endoscopes and stored in an anonymized database. Once the video-library was completed each of our 5 colonoscopic experts (ML, SLM, OL, DZS, and SZA) independently and randomly reviewed all of the cases with a standardized electronic questionnaire. In each case, all of the observers had to assess the color, the vascularization and the surface of the polyps, and the pit pattern was also assessed. A Kudo classification system was used to assign polyps to one of five groups: 1) Type I (non-neoplastic polyp), 2) Type II (adenomatous polyp), 3) Type III (adenocarcinoma), 4) Type IV (metastatic tumor), and 5) Type V (other). The sensitivity, specificity and accuracy of EC-V1 for diagnosis of hyperplastic polyp were 88.9%, 98.5% and 97.7%, respectively. As regards the sensitivity, specificity and accuracy of EC-V3 for diagnosis of SMm cancer without vessel permeation does not metastasize. In contrast, SMm lesions show a substantial proportion (i.e. methylen blue dye) is always required. Since dye staining complicates the procedure, the new observation method without use of dye has been strongly desired. On the other hand, EC with NBI (EC-NBI) allows ultra-magnified microvessels observation without using any dye solution.

Aims & Methods: The aim of this study was to validate the evidence whether the observation of surface microvessels using EC-NBI was useful in predicting the histopathology of colorectal lesions. The study included 438 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and June 2015. A total of 576 lesions (45 Non-neoplastic polyps, 304 adenomas, 71 intramucosal cancer, 21 slightly invasive submucosal cancer (SMs) and 135 massively invasive submucosal cancer) were retrospectively evaluated. We used the Kudo classification for the degree of submucosal invasion and classified cancers accordingly. SMs cancer without vessel permeation does not metastasize. In contrast, SMm lesions show a substantial proportion (~10%) of lymph node metastases. We named the ultra-magnified microvessels findings as endoscopic vascular pattern (EVP) and pattern classified into the following 3 groups: EVP-1, the surface microvessels were very fine obscure; EVP-2, the surface microvessels were more clearly shown and showed a regular vessel network, and their caliber and arrangement were uniform; and EVP-3, the surface microvessels were thick, and their caliber and arrangement were not homogenous. Results: The sensitivity, specificity and accuracy of EVP-3 for diagnosis of hyperplastic polyp were 88.9%, 98.5% and 97.7%, respectively. As regards the sensitivity, specificity and accuracy of EVP-3 for diagnosis of SMm were 82.2%, 98.0% and 94.3%, respectively.

Conclusion: Endoscopic vascular pattern was helpful in predicting the histopathology of colorectal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1767 CONSIDERATION OF RECTAL NEUROENDOCRINE TUMOR (NET) IN OUR HOSPITAL
M. Akita
Internal Medicine, Mitoyo General Hospital, Kanonji City/Japan

Contact E-mail Address: m_akita1976@yahoo.co.jp

Introduction: Rectal NETs are recommended to undergo endoscopic therapy, those with a tumour diameter of ≤10mm and up to the deep submucosal layer. However, no clear guideline has been established on the radical criteria and additional resection. Prognosis of the disease is also unclear. The validity of the diagnosis and treatment recommended in the guideline for rectal NETs will be examined in the cases treated at our hospital.

Aims & Methods: We examined the macroscopic features, pathological features, treatment methods, and prognosis of 22 patients diagnosed as having a rectal NET and treated at our hospital between 2007 and May 2016.

Results: The mean age of the patients was 65.2 years (range, 49–88 years); male-to-female ratio, 15:7; diagnosis opportunity, 21 asymptomatic cases and 1

and/or investigation. While miss rates for endoscopic and imaging modalities were low, 19% of missed cancer diagnosis were due to lack of appropriate investigations following outpatient or inpatient review for colorectal alarm symptoms or IDA; this might be improved by increasing specialist inpatient in-reach services and senior review of outpatient cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Till now, narrow-band imaging (NBI) could make it possible to analyze the surface microvessels of colorectal lesions for differentiating neoplasms from non-neoplasms and for predicting the histopathological diagnosis. The electronic chromoendoscopy (EC) is the next generation of ultramagnification endoscopy that allow visualization of the glandular structure and cellular atypia. EC has visualized living tumor cells in vivo and obtained an ultra-magnification pathological image simply by applying the scope to the target mucosa during an endoscopic examination. However, in colorectal Villous adenoma and right-sided colorectal cancer.

Contact E-mail Address: bart@docs.org.uk

Introduction: Colorectal cancer (CRC) is the 4th commonest cancer in the UK but the diagnosis is often delayed until new symptoms appeared for development of bowel cancer screening. However not all patients are eligible for this. Furthermore, colorectal investigations have the potential to miss the diagnosis and this was regarded as gold standard. The overall accuracy with WLI versus FICE versus BLI technology of the 5 experts without zoom and with 50x optical zoom to differentiate between hyperplastic and adenomatous lesions was 77.62% and 84.31%, vs. 74.58% and 83.90% vs. 88.84%, respectively. There was an excellent correlation between the histopathological results and our Kudo classification with both FICE and BLI technology. Both 50x times optical zoom and BLI technology were independently and significantly improved our confidence rate that was associated with a more precise histological prediction as compared to non-zoom, WLI or FICE endoscopic polyp assessment.

Conclusion: The new electronic chromooendoscopic technology with Eluxeo BLI significantly improved the reliability of the prediction, and supported for colorectal investigations in the diagnosis of non-neoplastic polyps with Eluxeo BLI electronic chromoendoscopy provide a potential for real-time endoscopic diagnosis of hyperplastic polyps to support ressect and discharge strategy. (Study was supported by ECT grant GINOP 2.1.1.-15-2015-00128)

Introduction: The aim of this study was to validate the evidence whether the observation of surface microvessels using EC-NBI was useful in predicting the histopathology of colorectal lesions. The study included 438 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and June 2015. A total of 576 lesions (45 Non-neoplastic polyps, 304 adenomas, 71 intramucosal cancer, 21 slightly invasive submucosal cancer (SMs) and 135 massively invasive submucosal cancer) were retrospectively evaluated. We used the Kudo classification for the degree of submucosal invasion and classified cancers accordingly. SMs cancer without vessel permeation does not metastasize. In contrast, SMm lesions show a substantial proportion (~10%) of lymph node metastases. We named the ultra-magnified microvessels findings as endoscopic vascular pattern (EVP) and pattern classified into the following 3 groups: EVP-1, the surface microvessels were very fine obscure; EVP-2, the surface microvessels were more clearly shown and showed a regular vessel network, and their caliber and arrangement were uniform; and EVP-3, the surface microvessels were thick, and their caliber and arrangement were not homogenous.

Results: The sensitivity, specificity and accuracy of EVP-3 for diagnosis of hyperplastic polyp were 88.9%, 98.5% and 97.7%, respectively. As regards the sensitivity, specificity and accuracy of EVP-3 for diagnosis of SMm were 82.2%, 98.0% and 94.3%, respectively.

Conclusion: Endoscopic vascular pattern was helpful in predicting the histopathology of colorectal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
symptomatic condition (lumbago); lesion site (Rs/Ra/Rb); 1/2/19 cases; mean tumor size: presence of biopsy sample; biopsy grade; I/II/III/IV cases; 11/14 (78.5%); presence:absence of endoscopic ultrasonography, 11/11 cases; and M3/M4/M5, 1/1/91 cases. The TNM classification of the cases was as follows: T1a, 16 cases; T1b, 5 cases; T2, 1 case; N1, 1 case; and M1, 1 case. The treatment was determined by the protocol of the endoscopic resection group/endoscopic mucosal resection with ligation/endoscopic mucosal resection/endoscopic submucosal dissection/surgery/drug therapy in 5/7/2/1/1 case. Of 19 endoscopic treatment cases, 15 corresponded to a tumor diameter of ≤10 mm, with negative resection margin and vascular invasion as criteria for curative resection, and 3 cases of unknown stumps were recognised. In the EMRL group, all cases were negative. In all the cases except the case of other-disease death, it elapsed without recurrence. Both surgical cases showed a positive vascular invasion, and one case was a confirmed N1, but neither of the patients survived without a relapse. In the case with hepatic and bone metastases, medication was administered, and the effect was temporarily effective, but the patient died a year and a half later.

Conclusion: Endoscopic treatments are considered appropriate for rectal NETs with a tumor diameter ≤10 mm, using fluorescence endoscopic technique, with minimal metastases, and not >10 mm in diameter. Among the treatment options, EMRL is considered useful and well tolerated. However, follow-up observation and case accumulation seem necessary to determine the long-term prognosis in NET, which may recur after years.

**P1769** SELECTIVE ERADICATION OF K-RAS MUTATED CANCER CELLS BY DELIVERY OF BACTERIAL TOXINS

N. Arber1, B. Ilana2, D. Kazanov1, S. Shapira1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: Inactivation of TP53 is the most frequent genetic damage in human cancer. In addition, hyperactivation of the RAS pathway is common in many human malignancies (Lung (LC)~40%, pancreatic (PC)>95%) and colorectal cancer (CRC)~50%). Despite multiple attempts, targeting these pathways for the treatment of cancer, for example through the development of RAS pathway inhibitors has not proven to be effective thus far. Herein, we propose to exploit the hyperactive RAS pathway and TP53 mutation status of human cancer to deliver targeted antimodeler therapy. We previously reported that a recombinant adeno virus, carrying a pro-apoptotic gene (PUMA) under the regulation of c/EBPδ (PY4) was effective in killing cancer cells expressing the hyperactive RAS cells harboring hyperactive RAS (Giladi et al., 2007). Furthermore, we had shown, both in vitro and in vivo, that replacing the pro-apoptotic gene with a bacterial toxin can improve the efficacy of this system (Shapira et al., 2015).

Aims & Methods: We aimed to establish a tight regulated dual system by expressing a toxin under PY4 elements in cancer cells, while sparing normal cells by expressing the anti-toxin under p53 responsive elements (RGC) specifically in non-malignant cells. Adenoviral vectors carrying the toxin (PY4-MaxF-mcherry) and an anti-toxin (RGC-mCherry) were cloned into an E1/E3 human type5 adenoviral vector. Virus particles were produced in 293E cells and purified by the End Point Dilution Assay and their potency was tested in vitro. Cell death was measured qualitatively by using the fluorescent microscopy and was quantified by the enzymatic MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cell lines engineered and fused to the lentivirus envelope. Cell death was measured qualitatively by using the fluorescent microscopy and was quantified by the enzymatic MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cell lines harboring mutated Ras. Those three constructs were cloned into a ''first generation'' lentivirus (LV) and pseudotyped with the lentivirus envelope. The anti-CD24 antibody fragment has a high affinity and specificity toward CD24, allowing targeted precision of viral transduction (Figure 1). These Lentivirus particles contain DNA molecules with flanked LTRs allowing their integration into the CD24 expressing target cells DNA and formation of double-strand breaks due to the action of the integrase enzyme whose activity was stimulated by the IN derived peptides. Massive cell death was induced upon exposure of the infected cells to the IN peptide compared to the control peptide.

Conclusion: The use of IN derived peptides together with the CD24-targeted lentiviruses approach suggests a novel strategy to specifically promote death of CD24-expressing cancer cells.

All authors have declared no conflicts of interest.

**P1771** ILF3 STABILIZES AND ACTIVATES EGFR-MEDIATED G9A PATHWAY FOR MAINTAINING CANCER STEMNESS PROPERTY IN EGFR-POSITIVE CANCERS

C. Chen1, 2A. Ho2
1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan
2Division Of Gastroenterology, Cheng Hsin General Hospital, Taipei/Taiwan

Contact E-mail Address: aisheng49@gmail.com

Introduction: A specific inhibitor of interleukin enhancer binding factor 3 (ILF3), YM155, suppresses EGFR phosphorylation and signal transduction involving in the formation of cancer stemness tumourospheres in vitro, suggesting that ILF3 as an oncogene participates in the maintaining of cancer stem cell property through stabilizing EGFR-mediated stemness pathway. Since cancer stemness cells is the leading reason for tumor recurrence in the tumor repressive treatments, and EGFR enhances the formation of cancer stemness, it is worthy of investigating the function of ILF3 for maintaining the cancer stemness property in the EGFR-positive cancers.

Aims & Methods: The tumourspheres derived from EGFR-wild-type and KRAS-mutant colorectal HCT116 and lung A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models in this study. YM155 was utilized to test the putative growth inhibiting involving in the formation of tumourospheres as the cancer stemness markers. Meanwhile, the differentiating stemness markers were also compared between ILF3-knockdowned and the control shLuc cells. Then, the protein level and phosphorylation of EGFR were investigated in the YM155-treated and ILF3-knockdowned cells. The results showed that EGFR was regulated and stabilized by ILF3. The ILF3-knockdowned cells were also transplanted into SCID mice for evaluating the function of ILF3 in vivo.

Results: We found that higher EGFR autophosphorylation (Y1068) in HCC116- and A549-derived tumourospheres compared to the parental cells. The results of RNAseq evaluated that CD133 was a positive stemness marker, whereas MARCH4 as a negative marker. Knockdown of ILF3 reduced the cell proliferation in the A549 cells in vitro and in vivo, demonstrating that ILF3 was an oncogene involving in cancer cell survival. Moreover, inhibition of ILF3 by YM155 blocked the autophosphorylation of EGFR and inhibited the EGFR-downstream G9a activation, leading to a reduction of stemness property. Moreover, Knockdown of G9a reduced the CD133 expression and increased MARCH4 expression, revealing that G9a was essential for maintaining for cancer stemness property in the EGFR-positive cancers.

Conclusion: In conclusion, this study demonstrated that ILF3 played an important role maintaining the EGFR-mediated stemness pathway in cancer stemness tumourospheres, and that ILF3/stabilized and phosphorylated EGFR to enhance the activation of G9a, leading to increasing CD133 and decrease MARCH4 expressions. Therefore, we suggested that the ILF3 inhibitor, YM155, was potential for utilization in cancer therapy against the EGFR-positive cancers.

**P1770** USE OF A COMBINATION OF LENTIVIRUS PARTICLES AND A SPECIFIC PEPTIDE FOR ERADICATION OF CD24-EXPRESSING

N. Arber1, F. Eynat2, L. Abraham2, S. Shapira1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Kaplan Medical Center, Hadassah-Hebrew University, Rehovot/Israel

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: Lentiviral replication is driven by a molecular motor consisting of the reverse transcriptase, protease and integrase (IN). The genomic RNA of the virus is used to produce a copy of viral DNA by reverse transcription, and the integrase catalyses the covalent insertion of this DNA into the chromosomes of the infected cells. Integration of the viral DNA—which is 9 kilobase pairs (kb) long when packaged in retroviral capsids—is random and can result in cellular mutagenesis. Perturbation of the viral integration process could cleavage and ligation resulting in the appearance of double-stranded breaks in the host genome that eventually leads to apoptosis. CD24 is a heavily glycosylated cell-surface GPI-anchored protein. We have previously shown that CD24 is an important player in the multistep process of GI carcinogenesis (Gastro 2006, Clin Can Res 2007, Can Res 2008) as well as in many other human malignancies (Cervical, Bladder, Squamous squamous cell carcinoma, Glioma, Breast etc.).

Aims & Methods: We aimed to develop and specifically direct lentiviruses to eradicate CD24-expressing cancer cells. We hypothesized that selective eradication could be achieved through a combination of cleavage and ligation resulting in the appearance of double-stranded breaks in the host genome that eventually leads to apoptosis. CD24 is a heavily glycosylated cell-surface GPI-anchored protein. We have previously shown that CD24 is an important player in the multistep process of GI carcinogenesis (Gastro 2006, Clin Can Res 2007, Can Res 2008) as well as in many other human malignancies (Cervical, Bladder, Squamous squamous cell carcinoma, Glioma, Breast etc.).

Conclusion: The use of IN derived peptides together with the CD24-targeted lentiviruses approach suggests a novel strategy to specifically promote death of CD24-expressing cancer cells.

P1772 EFFICACY AND SAFETY OF TWELVE CHEMPREVENTIVE REGIMENS FOR THE RECURRENT OF COLORECTAL ADENOMAS: A NETWORK META-ANALYSIS

H. Chen
Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: chenhant08@hotmail.com

Introduction: Although various pharmacological agents have been trialed for recurrent colorectal adenomas, their comparative effectiveness remains unknown. We conducted both direct and indirect comparisons of twelve chemopreventive agents for recurrent colorectal adenomas.

Aims & Methods: MEDLINE, EMBASE, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov were searched up to May 1, 2016. RCTs were assessed by a random-effects model within a Bayesian framework. Agents for each outcomes were ranked by surface under the cumulative ranking area (SURCA). This study is registered with PROSPERO, number CRD42016041923.

Results: 33 RCTs were eligible, enrolling 44,647 participants treated by twelve regimens: 9 aspirin and other NSAIDs, 11 antioxidants, 4 dietary supplements, 3 calcium, 4 folic acid, 2 calcium plus antioxidants, 2 aspirin plus folic acid and 1 aspirin.

Conclusion: In this network meta-analysis, aspirin was more effective than placebo in both pairwise and network comparisons, these agents include NSAIDs, antioxidants, dietary supplements, calcium as well as folic acid.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
5. Brand L, Munding J, Pox CP, et al. β-catenin, Cox-2 and p53 immunostaining prediction studies (n=1). In vivo studies were performed using female CD1-nude mice, fed diets supplemented with 7% (w/w) corn oil, 6.1% (w/v) EPA-triglyceride oil +9.0% (v/w) control oil, 600ppm aspirin or a combination of both EPA and aspirin (n=14) for 4 weeks. After the first 2 weeks, 5×10⁴ MC38 and MC38r cells were injected as subcutaneous tumours on the right flank, before sacrifice 2 weeks later. Tumour volumes were measured by calipers.

Results: The human and mouse CRC cell lines tested displayed varying levels of sensitivity to EPA (IC₅₀ range: 19.1 ± 2.2 μM to 242 ± 2 μM). HT29 cells were sensitive to EPA in CRC cells. Human and mouse CRC cell lines were screened for their sensitivity to EPA by MTT assay in vitro (n = 3). The MC38/MC38r and CT26/MC38r cell lines expressed COX2, indicating that COX2 is required for tumour growth in mice without affecting normal tissue. Oncotarget 7: 7096–7109.

P1774 PROGNOSTIC ROLE OF GLASGOW PROGNOSTIC SCORE IN PATIENTS WITH COLORECTAL CANCER: EVIDENCE FROM COCHRANE DATABASE STUDIES

Y. Liu¹, X. He², J. Pan³, S. Chen², L. Wang⁴
1Institute of Gastroenterology, Hangzhou/China
2Department of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University Medical School, Hangzhou, China, Hangzhou/China
3Department Of Endocrinology And Metabolism, Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou/China
4The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Contact E-mail Address: liu.chi@163.com

Introduction: Colorectal cancer (CRC) is the third most common cancer world wide. The Glasgow Prognostic Score (GPS) is a simple tool that likely influences understanding of the cancer and treatment of patients with CRC. However, GPS was not defined for patients with CRC, who, with its ability to predict survival, could be useful for patients with CRC. The GPS was also widely studied, but the results were controversial.

Aims & Methods: To investigate the correlation between GPS and prognosis of patients with CRC to further clarify its clinical significance. We performed a comprehensive and systematic search of databases and other sources, and we identified six eligible studies. The results of the six studies were similar and consistent, and the inheritability of the GPS was high. The GPS was more useful for predicting survival among patients with CRC.
P175 COST EFFECTIVENESS OF THE FIRST SURVEILLANCE COLONOSCOPY IN POPULATION WITH ADVANCED COLORECTAL POLYPS OR MULTIPLE POLYPS FROM COLORECTAL CANCER SCREENING PROGRAM

L. Carol1, M. González1, M. Batlle1, A. Burón2, X. Bessa Casserras2, M. Andreu García1, A. Alvarez-Urturi1. 1Gastroenterology, Hospital de la Mar, Barcelona/Spain; 2Hospital del Mar, Barcelona/Spain

Contact E-mail Address: l.carol.le@parcadelsalut.mar

Introduction: The implementation of the CRC screening program has generated an increase in surveillance colonoscopies. However, the intermediate-high risk group that included advanced lesions (size ≥10 mm, villous component or high-grade dysplasia) or the presence of 3 or more polyps, has a low incidence of metachronous risk lesions when performing colonoscopy at 3 years according to the current recommendations. Identifying predictors of metachronous lesions would provide a better risk stratification and improve the efficiency of surveillance programs.

Aims & Methods: We aimed to identify the cost effectiveness of the first surveillance colonoscopy and the predictive factors of metachronous lesions at 3 years in individuals with advanced lesions or ≥3 polyps detected at baseline screening colonoscopy. This was an analysis of all cases with advanced polyps and/or multiplicity from CRC screening program population of Barcelona detected at baseline colonoscopy during the years 2010-2011 and with a performed colonoscopy after 3 years. Epidemiological and clinical data of all individuals were collected as well as the morphological data of all polyps. For the statistical study, a bivariate analysis and logistic regression were performed.

Results: 638 cases were identified, with mean age of 64 years. 342 were men (62.6%). 23.8% required more than one colonoscopy for the complete removal of all the polyps. A complete surveillance colonoscopy at 3 years was performed in 518 cases (82%) with an average surveillance time of 38 months [15-75]. Mean fecal hemoglobin was 440 nmol/g. 51.8% suffered from hypertension, 15% from diabetes mellitus, 46.5% from dyslipidemia and 12.3% from chronic obstructive pulmonary disease. 45.8% of individuals were overweight (BMI ≥25) and 34.7% were obese (BMI ≥30). Surveillance colonoscopy was normal or with low-risk polyps in 420 cases (80.1%); and advanced polyps or multiplicity were identified in 98 cases (18.3%) in 73 advanced adenoma in 59 cases (11.4%), ≥3 adenomas in 62 cases (11%) and ≥3 small adenomas and/or serrated in 71 cases (13.7%). The presence of ≥3 adenomas and/or serrated polyps was the only variable that was associated with increased risk of the diagnosis of advanced adenomatous or serrated lesions in surveillance colonoscopy (p < 0.001).

Conclusion: In individuals with advanced polyps and/or multiplicity the incidence of metachronous risk lesions at 3 years is low. Assessment a quality baseline colonoscopy with complete removal of all the polyps could allow to increase the interval of surveillance, maintaining and ensuring the compliance of the surveillance in 3 years in the cases with multiplicity in the baseline colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P177 POPULATION-BASED COLORECTAL CANCER SCREENING IN THE CZECH REPUBLIC–FIRST RESULTS OF THE NEW PROGRAM SETTINGS

S. Suchanek1, T. Grega1, O. Majek2, O. Nego1, B. Seifert1, L. Dusek2, M. Zavoral1. 1Department Of Gastroenterology, Military University Hospital, Prague/Czech Republic; 2Institute Of Biostatistics And Analyses, Masaryk University, Faculty of Medicine, Brno/Czech Republic; 3Department Of General Practice, Department of GP First Faculty of Medicine Charles University, Prague/Czech Republic

Contact E-mail Address: stepan.suchanek@uvn.cz

Introduction: The organized non-population based National Colorectal Cancer (CRC) Screening Program in the Czech Republic has been running since year 2000. In January 2014, the transition to population based setting has been implemented. Currently, the annual immunochromatographic FIT (FIT) is offered at the age 50-54, followed by FIT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10 years’ interval.

Aims & Methods: Main aim was to assess the impact of the first 30 months of the population-based CRC screening program on the target population participation and colorectal neoplasia detection. The data from National Reference Center (health insurance companies database) and Preventive Colonoscopies Registry in years 2013 (non-population based settings) and 2014-2015 (population-based settings) were evaluated and compared.

Results: In year 2014, there were 1,500,897 individuals (53% of all CRC screening target population) invited to FIT or colonoscopy, with 17.3% response. It resulted in the coverage increase by 4.3 percent points in comparison with year 2013 (11% in year 2014). The CRC screening coverage continued in year 2015 with the target population participation at 33.1%. This has influenced the increase of number of detected adenomas (by 42%) and cancers (by 20%) detection in year 2014. In year 2015, all the results remained stable (details resulted in the table).

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: roberta.maselli@humanitas.it

Introduction: Colorectal Endoscopic Submucosal Dissection (ESD) is recommended for superficial neoplastic lesions at high risk of submucosal invasion. ESD allows an en-bloc resection but ESD experience is still limited in Western centers.

Aims & Methods: The aim of this retrospective study was to evaluate technical and clinical outcomes of colorectal ESD, in a single tertiary European center. We retrospectively analyzed all consecutive patients treated by ESD for colorectal lesion at Humanitas Research Hospital (Milan, Italy) from January 2011 to September 2016. The primary outcomes were technical success, defined as en-bloc resection and clinical success, defined as curative resection (R0) without need for surgery. Secondary study outcomes were complication rate and ade- nona/carcinoma recurrence. Complications were divided in early (<24 hours) and delayed (>24 hours) and included bleeding and perforation. Recurrences were identified as the presence of adenoma or carcinoma at the endoscopic follow-up performed at 6 months, 1, 3 and 5 years. Data were analyzed by STATA 14 statistical software.

Results: A total of 185 lesions in 185 patients (M/F 97/89, mean age 67.6 ± 11.5). Lesions were located in the rectum (64.3%), left colon (9.7%), transverse (11.9%) and cecum (14%). Mean lesion size was 39.3 ± 1.2 mm. A high-grade dysplasia was found in 64 (34.6%), high-grade dysplasia (HGD) in 78 (42.2%) and adenocarcinoma in 42 (22.7%) cases. Only 1 NET (0.5%) was found. En bloc resection was achieved in 88% of lesions. Clinical success (R0) was obtained in 84.8% of lesions. The follow-up was going on in the remaining 28 patients (15.2%) needed surgery for unfavorable histology. A total of 12 complications were reported: 10 early complications (8 perforations and 2 bleeding) and 2 delayed complications (1 bleeding and 1 perforation). All but one adverse events were managed endoscopically. Surgery was required in the only case of delayed perforation. All patients untreated with surgery (n = 156) underwent follow-up evaluation. In particular, all patients had 6 months follow up, 97 patients had 1 y follow-up, 26 patients had 3 y follow-up, 9 patients had 5 y follow-up. Adenoma recurrences were found in 3.8% at 6 months and in 2% at 1 year. We did not find any adenoma recurrence at 3 years and 5 years. No cancer recurrence occurred in the follow-up period.

Conclusion: ESD is a feasible strategy to manage superficial colorectal tumors. This study demonstrates favorable technical and short-term clinical outcome of colorectal ESD, but further studies are needed to confirm the long-term efficacy.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1778 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY CANCER AND HIGH GRADE DYSPLASIA IN COLORECTUM

P. Zhou1, T. Chen1
1Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: chentian066@yahoo.com

Introduction: Although endoscopic submucosal dissection (ESD) is a widely accepted treatment for colorectal neoplasm, little is known about large consecutive studies evaluating long-term outcomes of early cancer and high grade dysplasia. We aimed to assess the efficacy and safety of ESD for early cancer and high grade dysplasia in colorectum and evaluated the long-term outcomes, including local recurrence and metastasis.

Aims & Methods: We performed a retrospective analysis of data collected from 514 consecutive patients with 520 colorectal early cancer and high-grade dysplasia treated with ESD between January 2007 and December 2013. Histology and patient data were collected during an average follow-up time of more than 5 years to determine tumor stage and type, resection status, complications, tumor recurrence, and distant metastasis.

Results: The overall rates of en bloc resection, complete resection, R0 resection, major complications were 94.4%, 91.5%, 89.2% and 2.1%, respectively. Large tumors and snare-assisted ESD were independent factors of piecemeal resection. ESD of colorectal tumors increased the risk for complications. During the follow-up period, all patients remained free from metastasis. However, local recurrence occurred in 4 patients (0.8%); large tumors and piecemeal resection were risk factors.

Conclusion: ESD is effective and safe for resection of early cancer and high grade dysplasia in colorectum and long-term outcomes are favorable. ESD is indicated for the treatment of colorectal early cancer and high grade dysplasia to obtain curative resection and prevent the local recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1779 LOW UPTAKE OF PSYCHOLOGICAL THERAPIES AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME IN SECONDARY CARE

O. Craig1, C. Black1, L. Houghton2, A.C. Ford1
1Leeds Gastroenterology Institute, St. James’s University Hospital, Leeds/United Kingdom
2Leeds Institute Of Biomedical & Clinical Sciences, St.James’s University Hospital, Leeds/United Kingdom

Contact E-mail Address: ofcraig@gmail.com

Introduction: Patients with irritable bowel syndrome (IBS) often have co-existent mood disorder and psychological illness. Meta-analyses of randomised controlled trials consistently demonstrate that psychological therapies, such as cognitive behavioural therapy (CBT) and hypnotherapy, are effective treatments for IBS. In the UK the National Institute for Health and Care Excellence (NICE) recommends considering the use of these in patients with no response to pharmacological therapies, and for refractory symptoms.

Aims & Methods: We performed a cross-sectional survey to examine willingness of patients with IBS to engage with psychological therapies. We collected complete symptom data from consecutive, unselected referrals to secondary care seen in a specialist IBS clinic. All participants completed the validated Rome IV questionnaire for IBS, the IBS severity scoring system (IBS-SSS), the hospital anxiety and depression scale (HADS) to assess mood, and the patient health questionnaire-12 (PHQ-12) to examine somatof orm-type behaviour. They also provided their opinion on possible treatment options, and were asked to rate medical therapies, dietitian input, psychological therapies, including CBT and hypnotherapy, and an overview of the condition and/or reassurance in order of preference.

Results: Among 93 adults with confirmed IBS (74 (79.6%) female, mean age 36.0 years (range 16 to 77 years), 35 (37.7%) had high levels of anxiety, 22 (23.7%) had high levels of depression, and 23 (24.7%) had severe levels of somatof orm-type behaviour. Despite this, only 10 (10.8%) of 93 patients ranked psychological therapies as their first-choice treatment option. In total, 8.8% of patients with high levels of anxiety ranked psychological therapies as their first-choice treatment option, versus 13.2% without (P = 0.64), 9.5% of those with high levels of depression, versus 12.1% of those without (P = 0.91), and 17.4% of patients with severe somatoform behaviour, versus 9.2% of those without (P = 0.26). Those with severe symptoms according to the IBS-SSS were no more likely to select psychological therapies as their first-choice treatment option than those with milder or moderate symptoms (7.7% versus 21.7%, P = 0.10).

Conclusion: Despite high levels of psychological comorbidity and NICE recommendations, patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies such as CBT or hypnotherapy. Those with anxiety, depression, somatof orm-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

P1780 GUT SYMPTOMS AND TRANSIT DISTURBANCE IN PARKINSON’S DISEASE ARE PAN-ENTERIC BUT NOT UBQUITOUS: A WIRELESS MOTILITY CAPSULE STUDY

V. Passannanti, N. Zarate Lopez, R. Sweis, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassannanti@gmail.com

Introduction: Symptoms of gastrointestinal dysfunction are among the most common non-motor complaints in Parkinson’s patients. These may involve muscles from the oropharynx to the anorectum, and the autonomic and enteric nervous systems are often involved, resulting in secondary bowel dysmotility.

Aims & Methods: The objectives of this study were to evaluate a technology measuring the spectrum of gut dysfunction, the Wireless Motility Capsule (WMC), in Parkinson’s disease. We also wanted to correlate transit measures with gastrointestinal symptoms. Fifteen PD patients and 7 controls (table1) were included. PD severity was scored with the modified Hoehn and Yahr (H&Y) staging scale. GI symptom burden was identified by Wexner constipation score and Gastrosparesis Cardinal Symptom Index (GCSI). Acidity, motility and transit data were obtained, as standard, by WMC. All medications affecting pH and motility, including L-dopa, were discontinued for 5 days before and for the duration of the WMC study. Were analyzed data about gastric emptying time (GET), small bowel transit time (SBTT), colonic transit time (CTT) and whole gut transit time(WGTT).

Results: One patient could not swallow the capsule, and of the 14 patients completing the study, 8 reported GI symptoms. Compared to non-symptomatic patients, those with GI symptoms showed significant delayed transit in the stomach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small study, used the risk lower constipation scores were correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correlation between the Wexner constipation score and CTT in all patients (p < 0.01) but not GCSI and GET (p > 0.10). The results of Wireless Motility Capsule did not differ between non-symptomatic PD and controls.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1781 OUTLET DYSFUNCTION IS PREVALENT IN SEVERE FUNCTIONAL BLOATING: PRELIMINARY REPORT FROM A MULTICENTER ITALIAN STUDY

P. Iovino1, M.C. Neri1, L. D’Alba1, S. Gallotta1, G. Chiariom1

4Gastroenterology, AOUI Verona - Gastroenterology, AOUI Verona; Verona/IT, Verona/Italy

Contact E-mail Address: piovino@unisa.it

Introduction: Bloating and abdominal distension are common and bothersome symptoms and a frequent complaint of patients affected by functional gastrointestinal disorders (FGID). Recent studies demonstrated that an impairment in
the handling of gas is a relevant underlining mechanism in FGID patients with bowel gas accumulation who were grouped according to IBS and in patients with bloating. Aims & Methods: Our aim is to study the relationship between the defeation pattern, the severity of bloating and the abdominal girth measurements in FGID patients consulting for bloating as primary complain with/without visible abdominal distension. We designed a prospective, multi-center study of patients with severe abdominal bloating (VAS score ≥ 24 on a 100-mm scale) as primary complain with/without visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Combined dysfuncion tests included Rome III criteria. All patients were prescribed a lactose-free diet supplemented by dietary advice according to the NICE guidelines for two weeks. A belt around the abdomen at standardized sites provided assessment of abdominal girth measurements. During the 2-week run-in period, each patient completed a daily diary log including abdominal bloating and pain/discomfort scores (100-mm VAS), Bristol Stool Form and stool frequency. At randomization visit, all patients filled in a questionnaire on adequate relief of bloating on a Likert scale and a further abdominal bloating 100-mm VAS. An additional subset of patients at standardized sites provided assessment of abdominal girth two hours after a meal. All patients reporting insufficient adequate relief of abdominal bloating at the end of the run-in period underwent a standardized balloon expulsion test (BET) scored as either successful or failed. A straining questionnaire was also administered.

Results: 76 patients (66 female, 39.8 ± 12.2 mean age, 6 IBS-D, 6 IBS-M, 30 IBS-C, 9 IBS-U, 6 FC, 16 FB, 3 FD) completed the 2-week run-in period. A significant negative correlation was found between adequate relief and both bloating and abdominal girth changes (r = -0.53 and -0.52, p < 0.001, respectively). 53/76 (70%) patients reported inadequate relief (worse or no improvement). Among the non-responders the vast majority (68%) failed the BET. Multiple regression analysis showed that BET (successful or failed) and its dependent variable, was significantly related to bloating severity. No relationship was demonstrated for abdominal girth changes, FGID diagnosis and straining questionnaire.

Conclusion: In this prospective, multicenter trial simple diet advise was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outlet dysfunction was prevalent and correlated with subjective bloating perception. The study is ongoing, but our data may support bowel retaining as primary treatment option for functional bloating.

Introduction: Faecal Incontinence (FI) is a common and socially disabling condition, more prevalent among females over 50 years old. Detailed anatomical and physiological assessment of each patient is important to determine the correct cause of FI and selection the most appropriate therapy. Conventional and High Resolution (HR) Anorectal Manometry (ARM) is a useful tool to categorize anal and/or rectal dysfunction in addition to provide physiological assessment of both anal sphincters and rectum.

Aims & Methods: To evaluate symptoms and anorectal function of patients affected by FI, we included 358 patients with FI (77% female (F) and 23% men (M), mean age 63 range 22–92 year referring to the outpatient unit of Digestive Pathophysiology of S. Giovanni-Addolorata Hospital, Rome from January 2006 to December 2016. Clinical presentation (history, symptom profile and severity) and anorectal physiological evaluation (digital examination, manometry, rectal sensory testing, balloon evacuation test) were analyzed. The manometric parameters obtained with conventional and HR-ARM were: resting pressure, squeeze pressure, rectal compliance, rectal sensibility and the anorectal pattern during the defecatory maneuvers.

Results: 114 out of 358 patients (32%) reported both FI and difficulty evacuating stool and/or rectal urgency. Among these patients with coexistence UI (47%). Proctological surgery (n = 122, 34%), pelvic surgery (n = 77, 21%) and traumatic anal or vaginal history (n = 144, 40%) were statistically associated with FI (p < 0.05). Normal manometric parameters were found in 16 patients (4%). Manometric alterations observed were: internal anus sphincter (IAS) dysfunction: 228 (64%); isolated external anal sphincter (EAS) dysfunction: 274 (76%); combined sphincter dysfunction IAS and EAS: 198 (55%); isolated dysynergic defecation: 100 (28%); rectal hypersensibility: 130 (36%).

Conclusion: In our study, in accordance with the literature, we observed a female prevalence in FI. FI is significantly associated with previous proctological/pelvic surgery and traumatic anal/vaginal delivery. Furthermore, patients with FI referred difficulty evacuating stools, too. In fact in patients with dysynergic-type constipation, the FI may be confused with an encopresis. Finally we observed these prevalent manometric alterations: combined dysfunction IAS and EAS, and rectal hypersensibility. Manometric findings could help physicians to identify appropriated patients for a biofeedback therapy.

Patients who exhibited MAB (confirmed by SeHCAT test) were treated with HLA-DQ8 Haplotype (%) 14.1%(9/64) 6.3%(4/63)
HLA-DQ2 Haplotype (%) 23.8%(15/63) 31.7%(20/63), ingested less lactose than the "No-IBS" group (P = 0.024). Intake of other FODMAPs was similar in both groups (P = 0.346). Compared to the "No-IBS" group, individuals with IBS had a greater likelihood of depression (OR 1.5 (0.97-2.32); p = 0.05), anxiety (2.84(1.44-4.39), p < 0.001), recent life event stress (1.51(1.03-2.20); P = 0.03) or medical and/or surgical co-morbidity (OR 2.90(1.30-5.45), P < 0.001). The IBS group also had lower quality of life (FL-SF) and quality of life (SF-8).

Results: From 1999/2115 (94.7%) members of the community that completed psychiatric disease (HADS), life event stress (LES) and quality of life (SF-8).

References
Bohn, L. "Nutrient intake in patients with IBS compared with the general population." Nutr Gastroenterol Motil 2013.
Bohn, L. "Diet low in FODMAPs reduces symptoms of IBS as well as traditional dietary advice: a randomized controlled trial." Gastroenterology 2015.
Van Oudenhove, L. "Depression and Somatization Are Associated With Increased Postprandial Symptoms in IBS Patients." Gastroenterology 2016.

Conclusion: FODMAP intake was similar in IBS and No-IBS groups in the community (lactose intake was lower in IBS subjects, likely due to avoidance of dairy products (Long 2017)). However, as expected, IBS patients in the community had a greater likelihood of psychiatric disease, life event stress and clinical co-morbidity. Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive dysfunction (Zhu 2013). (ClinicalTrials: NCT0126597)

P1784 INTAKE OF FERMENTABLE OLIGO-, DI- AND MONOSACCHARIDES AND POLYOLS (FODMAPS) INCREASES THE RISK OF IRRITABLE BOWEL SYNDROME (IBS) IN INDIVIDUALS EXPOSED TO PSYCHOSOCIAL STRESS IN THE COMMUNITY: RESULTS OF A LARGE, PROSPECTIVE, POPULATION-BASED STUDY

Introduction: The cause of IBS is uncertain; however, food intolerance shares many features with this condition. Consumption of FODMAPs has been shown to induce IBS-type symptoms (Shepherd 2008) and clinical trials have shown that a low FODMAP diet can improve symptoms in this patient group (Halmos 2014). However, FODMAP intake is not higher in IBS than in health (Bohn 2015) and it is not proven that the outcome of low FODMAP diet is better than standard dietary advice in this condition (Bohn 2015). Recent, experimental research has shown that psychological factors are associated with increased postprandial symptoms in IBS patients (Zhu 2013, Van Oudenhove 2016). This study was designed to assess the relative importance of, and interaction between, psychiatric disease, social stress and diet in the aetiology of IBS in the general community.

Aims & Methods: This population based study tested the hypothesis that high FODMAP intake increases the risk of IBS more in individuals with psychiatric disease and/or life event stress than other members of the community.

Subjects aged 16–74 were randomly selected from five South-Chinese communities. All subjects completed questionnaires by face-to-face inquiry with investigators including demographic information, gastrointestinal symptoms (Rome III), dietary intake (food frequency chart validated in Chinese community), psychosocial (HADS), life event stress (LES) and quality of life (SF-8).

We included 772 patients with IBS (Rome III criteria) who attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate o-roal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to assess anxiety and depression (HAD), overall IBS symptoms (IBS-SSS), bowel habits (BSF), quality of life (IBS-QOL), extraintestinal somatic symptoms (PHQ-12), sense of coherence (SOC), fatigue (MFI), GI-specific anxiety (VSI) and physical and sexual abuse.

Results: Based on validated HAD cut-off levels (≥8), anxiety and depression were present in 55% and 26% of the IBS patients, respectively. More women were anxious (p < 0.001), but for depression no gender differences were detected (p = 0.76). IBS patients with anxiety or depression were younger (p < 0.001, and more commonly reported sexual and/or physical abuse (p < 0.001) than IBS patients without anxiety or depression. The presence of anxiety or depression did not differ between IBS subgroups based on the predominant bowel habit (p = 0.41, p = 0.18). For an overview of comparisons of data from questionnaires and pathophysiological examinations, see table 1. Both the presence of anxiety and of depression were associated with reports of more severe GI and extraintestinal symptoms, GI-specific anxiety, fatigue, and lower sense of coherence. Regarding pathophysiological examinations, the findings were more inconsistent. OATT was similar between groups, as was stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge
test. Quality of life (IBS-QOL) was reduced for all domains in patients with anxiety and depression (p = 0.001 for all comparisons).

Conclusion: The presence of anxiety and depression seems to clearly potentiate the already substantial disease burden in IBS patients. However, the association with other pathophysiological findings is less distinct. This group of patients with complex and severe symptoms will benefit from a holistic management approach.

Introduction: Irritable bowel syndrome (IBS) and lactose intolerance may co-exist and readily cause diagnostic confusion due to similar symptomatology (1, 2).

Aims & Methods: This study aimed to examine the incidence of lactose intolerance in healthy controls and in subjects diagnosed with IBS based on Rome III criteria, as an effort to investigate the association between IBS and lactose intolerance. The patient population consisted of individuals between 18 and 80 years of age who attended between June-December 2013. Patients diagnosed with IBS based on Rome III criteria comprised the IBS group, and subtypes of IBS. Control subjects were healthy volunteers over 18 years of age with no IBS-like symptoms. All participants ingested 25 g of lactose dissolved in 250 ml of water based on Rome III criteria, as an effort to investigate the association between IBS and lactose intolerance.

Results: Of the total 200 participants, 100 (50%) were in IBS and 100 (50.0%) were in control group. There were 133 females (66.5%), and the mean age was 40.5 ± 12.3 years. Of the total 70 patients (35.0%) with lactose intolerance, 47 (47.0%) were in IBS and 23 (23.0%) were in control groups (p = 0.001). Symptoms related to IBS were more common in participants with lactose intolerance in both groups (p = 0.001, p = 0.001 respectively). A comparison of the two groups with regard to symptoms after lactose challenge test showed the presence of complaints in 35 (35.0%) patients in IBS group as compared to 24 (24.0%) subjects among controls (p = 0.092). The incidence of lactose intolerance in patients with IBS subtypes of diarrhea-predominant IBS, constipation-predominant IBS, mixed IBS, and unspecified IBS were 27 (57.4%), 7 (4.9%), 10 (21.3%) and 3 (6.4%), respectively, with no significant differences (p = 0.161, p = 0.124, p = 1.000, and p = 0.661 respectively).

Conclusion: A significantly increased frequency of lactose intolerance was found among IBS patients than in controls. In additional, symptoms associated with lactose intake occurred at a higher frequency in IBS patient, although the difference was insignificant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The population prevalence of Rome IV functional gastrointestinal disorders (FGIDs) and their cumulative effect on health impairment is unknown. We sought to address this issue.

Aims & Methods: An Internet-based health survey was completed by 5931 of 6300 general population adults from three speaking English-speaking countries (2100 each from US, Canada, and UK). The survey included questions on demographics, medication, surgical history, somatisation, quality of life, doctor-diagnosed organic GI disease, and criteria for the Rome IV FGIDs. Comparisons were made between those with Rome IV FGIDs on against non-GI and organic GI disease controls.

Results: The number of subjects having symptoms compatible with a FGID was 2083 (35%) compared to 3421 (57.7%) non-GI and 427 (7.2%) organic GI disease controls. The most frequently met diagnostic criteria for FGIDs was bowel disorders (n = 1665, 28.1%), followed by gastroduodenal (n = 627, 10.6%), anorectal (n = 440, 7.4%), oesophageal (n = 414, 7%), and gallbladder disorders (n = 10, 0.2%). On average, the 2083 individuals who met FGID criteria qualified for 1.5 FGID diagnoses, and 742 of them (36%) qualified for FGID diagnoses in more than one anatomic region. The presence of FGIDs in multiple regions was associated with increasing somatisation, worse mental and physical quality of life, greater use of medical therapies, and a higher prevalence of abdominal surgeries; all p < 0.001, see table. Notably, individuals with FGIDs in multiple regions had worse somatisation and quality of life scores than organ GI disease controls.

Conclusion: Roughly a third of the general adult population fulfills diagnostic criteria for a Rome IV FGIDs. As a third of this subgroup has FGIDs in multiple GI regions, this overlap is associated with increased health impairment. Study Support: The Rome Foundation

Introduction: Although correlations between features of irritable bowel syndrome (IBS) and health-related quality of life (HRQoL) have been reported, these were based on between-person rather than within-person variation. We investigated the longitudinal within-person correlations between features of IBS.

Aims & Methods: We used a longitudinal cohort of 276 IBS patients, who filled out questionnaires once annually over five years on the following features: gastrointestinal (GI) symptom severity (GSRS), quality of life (QOL), GI specific anxiety (VSI), general anxiety and depression (HADS), coping resources (CRI), and sense of coherence (KASAM). For each participant, scores were centered on their own mean, and within-person correlations were computed for all pairs of features.

Results: Aggregate within-person correlations are shown in figure 1. Within-person correlations were strong for the triad GI symptom severity, GI specific anxiety, and QOL (r ≥ 0.47 to 0.64). Another set of features was comprised of general anxiety, depression, coping resources, and sense of coherence (r ≥ 0.39 to 0.57). Within-person correlations between the two sets were weak (r ≤ 0.00 to 0.37). However, within-person correlations tended towards bimodal distributions across the population, especially for GI symptom severity and depression (r ~ 0.6 for half of participants, and r ~ 0.4 for the other half).

Conclusion: Here we show that, within individual IBS patients, GI symptom severity is strongly associated with GI specific anxiety and QOL, but not with four other psychological features. The presence of negative within-person correlations in some individuals may imply a lack of relation, but could also signal long-term causative processes.

Introduction: No population-based studies have investigated the symptom burden and healthcare utilization associated with Rome IV defined irritable bowel syndrome (IBS).

Aims & Methods: The aim of the current study was to assess these variables in IBS subjects in the general population. An Internet survey was completed by 6300 individuals distributed equally between United States, United Kingdom and Canada. Equal sex, age and education distribution across the countries was ensured by use of quota-based sampling. The survey included questions on demographics, the Rome IV diagnostic questionnaire, the patient health questionnaire (PHQ-12), the 8-item Short Form (SF-8) quality of life (QOL) questionnaire, health care utilization and past gastrointestinal (GI) disease diagnoses by doctors. Respondents with an organic GI disease were excluded from the IBS population.

Results: From the 6300 individuals who completed the survey, 369 were excluded due to inconsistent responses, leaving 5931 (49.2% female; mean age 47.4 ± 17.1 years) to be included for analysis (1949 US, 1994 UK, 1988 Canada). 305 (5.1%) of those fulfilled Rome IV diagnostic criteria for IBS, after 36 individuals were excluded due to organic disease. Compared to the non-IBS population, the IBS population was younger (mean age 44.7 ± 14.5 years; p = 0.004) and predominantly female (66%; p < 0.001). Apart from reporting more frequent GI

point difference) subscales (Table). Patients with GSS ≥3 also had a lower EQ-5D index score compared to those with GSS <3 (0.67 vs 0.72) (Table). Women reported a slightly lower mean total IBS-QOL score compared to men, but had a notably lower score (14-point difference) on the body image subscale (Table). No difference in mean EQ-5D score was observed between sexes. IBS-QOL total and EQ-5D index scores were similar between patients aged <65 and ≥65 years, though the younger subgroup generally had lower scores on the IBS-QOL, including on the food avoidance and sexual subscales (Table).
symptoms, IBS subjects also reported more somatic symptoms; 103 (34%) had abdominal pain at least 3 times/week, 232 (76%) subjects reported sensation of bloating at least 3 times/month, and 232 (76%) scored ≥7 on PHQ-12, indicating high somatic symptom burden (p < 0.001 for all). They also had poorer self-rated overall health, more general body pain, and more health-related impairment of social activities (p < 0.001 for all). See table 1 for details. IBS subjects also reported more frequent visits to the doctor compared to the non-IBS population, both for non-GI and GI related problems. 232 (76%) reported seeing a doctor at least once/year for any health issue and 195 (63%) vs. 114 (38%) had seen a doctor for GI problems (p < 0.001 for all). IBS subjects also reported higher frequency of visits to gastroenterologists, gynaecologists and surgeons in secondary care; p < 0.001 for all. The use of medication for pain (both submitted and over the counter), GI related symptoms, depression and anxiety was increased amongst subjects with IBS, as was the rate of abdominal surgery (p < 0.001 for all), appendectomy excluded. See table 1 for details.

P1794 ARTERIAL PH AND LACTATE HAVE SIGNIFICANT IMPACT ON THE OUTCOMES OF PATIENTS WITH ISCHAEMIC COLITIS

C. Simões1, V. Magno Pereira2, M. Silva3, J. Carvão4, A. Oliveira5, C. Baldaia6, G. Serrão7, L. Joaquin1, J. Veloso1

3Gastroenterology, Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact Email Address: magnovitorj@gmail.com

Introduction: Ischaemic colitis (IC) encompasses a number of clinical entities resulting in insufficient blood supply to the colon. The incidence of adverse outcome in patients with IC remains high.

Aims & Methods: We conducted a multicenter retrospective cohort study including consecutive patients with IC diagnosed between January 2013 and December 2016, according to the Modified Brandt and Boley criteria (clinical, colonoscopy, pathology consistent with IC and negative culture). The following data were collected: age, sex, clinical symptoms (evidence of IC), organ failure, laboratory findings (hemoglobin, platelet number, leucocytes, C-reactive protein, creatinine, sodium, potassium, arterial pH and arterial lactate and LDH), endoscopic and CT findings, surgery and death. Logistic regression was used to study association with predictor variables: surgery and overall mortality.

Results: In this study, 349 patients were registered and 193 fulfilled the predefined criteria: 121 (62.7%) were females and mean age was 72-years-old (IQR: 23–94). At admission a total of 165 (85.5%) patients presented with hematochezia, 112 (58%) with abdominal pain, 82 (42.5%) with diarrhea, 27 (11.9%) with shock and 7 (3.6%) with occlusion. Twenty three (11%) required surgery. In-hospital, 30-day and overall follow-up mortality rates (up to 205 weeks) were 7.3%, 6.7% and 14%, respectively. On multivariate analysis, surgery was independently associated with shock (OR: 4.8; p = 0.011) intestinal occlusion (OR: 3.5; p = 0.046), and arterial lactate (OR: 1.3; p = 0.012). On univariate analysis, hemoglobin, hematocrit, C-reactive protein, LDH, the number of risk factors, arterial pH, and the need of red blood support were significantly (p < 0.05) associated with in-hospital and 30-day mortality. Creatinine was also associated with intra-hospital mortality. The variables that correlated independently in the multivariate analysis with in-hospital mortality were male gender (OR: 4.3; p = 0.03), and arterial pH (OR: 0.001; p = 0.036) and with 30-day mortality was the need of blood cell support (OR: 2.1; p = 0.008).

Conclusion: In our cohort of predominant elderly patients, arterial pH, shock and lactate were significantly associated with need of surgery. Arterial pH on admission was also independently associated with in-hospital mortality. Early identification of these factors can aid in the decision making in this context and select the best care level for each patient.

P1795 THE RISK PREDICTIVE VALUES OF ACG CLASSIFICATION IN A COHORT OF ISCHEMIC COLITIS—REFINING THE DEFINITION OF MILD DISEASE

V. Magno Pereira1, C. Simões2, M. Silva2, J. Carvalho2, A. Oliveira2, C. Baldaia2, G. Serrão1, L. Jasmins2, J. Veloso3

3Gastroenterology, Hospital São João, Oporto/Portugal

Contact E-mail Address: carolina baptista simoes@gmail.com

Introduction: Although most cases of colon ischemia (CI) are mild and self-limiting, when severe it implies high mortality rates. We aimed to evaluate the risk profile and validation of classification of disease severity proposed by American College of Gastroenterology (ACG) guidelines (2015), created to provide a management algorithm for these patients and select the level of care.

Aims & Methods: A retrospective multicenter study was conducted on adult patients with definite CI (clinical, colonoscopy, pathologic and culture criteria), between 2013 and 2016. Data was collected on clinical presentation, comorbidities, organ failure, management and outcome. Each case was classified according to ACG guidelines after assessment of the number of risk factors (gender, systolic blood pressure <90 mm Hg, heart rate >100 beats per min, abdominal pain without rectal bleeding, BUN > 20 mg/dl, Hgb < 12 g/dl, LDH > 350 U/l, serum sodium < 136 mEq/l, WBC > 15 x 109 /cmm). Patients were then classified as mild (0 risk factors (RF)), moderate (1–3 risk factors), and severe (more than 3 risk factors or any of the following: perianal signs, pneumatocele or portal venous gas, gangrene on colonoscopic examination and pan-colonic or isolated right-colon ischemia involvement on imaging by colonoscopy or computed tomography).

Results: 349 cases with the clinical diagnosis of IC were analyzed. 193 patients met the inclusion criteria of definitive diagnosis of CI (62.7% females; mean age 72 years ±13). ACG classification of mild, moderate and severe disease was attributed respectively to 21% of patients (0 intra-hospital deaths), 45% (2 deaths) and 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9% with 2, 15% with 3, 16% with 4, 8% with 5, 4% with 6 and 1% with 7. No patient with 0 or 1 RF died. Only 1 patient with 2 RF died. The remaining 13 deaths were verified with at least 3 RF. The univariate analysis revealed a statistical correlation between RF and intra-hospital or 30-day mortality as well as the need for surgery (mean = 4.06, sd = 1.85). ACG classification presented high predictive accuracy for in-hospital and 1-month mortality with a AUROC of 0.78 respectively. For a cutoff of 2 ACG RF, the sensitivity (SE) for death was 100%, specificity (SP) 52%, with a positive predictive value (PPV) of 14% and negative predictive value (NPV) of 100%. For 3 ACG RF the results were: SE 93%, SP 61%, PPV 16% and NPV 99%. 3 or more risk factors are associated with an increased mortality and 18.42 for 1-month mortality (CI 2.34–144).

Conclusion: No patient in this cohort with less than 2 ACG RF died, suggesting that the ACG classification as mild disease may include 0 and 1 risk factor without changing the prognosis. Short-term mortality risk increases significantly in patients with at least 3 ACG RF.

P1796 HOW COST AFFECTS THE TREATMENT CHOICE FOR IRREVERSIBLE BOWEL SYNDROME WITH DIARRHEA PATIENTS: A COST-EFFECTIVENESS ANALYSIS OF TRICYCLIC AGENTS AND RIFAXIMIN

E. D. Shah, E. Andraska, J. Li, S. Zhang, W.D. Chey
Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America

Contact E-mail Address: ersjah@umich.edu

Introduction: Drug pricing and third party payer coverage exert a profound effect on access to prescription therapies in patients with irritable bowel syndrome with diarrhea (IBS-D). We performed a cost-effectiveness analysis to assess the trade-offs associated with treating IBS-D patients with a tricyclic agent (TCA) or rifaximin.

Aims & Methods: We constructed a decision analytic model evaluating three treatment strategies for IBS-D in the United States healthcare system: first-line therapy with TCA-only, first-line rifaximin followed by second-line TCA for nonresponders, and first-line TCA followed by second-line rifaximin for nonresponders. This model accounted for direct and indirect costs of therapy with TCA-only, first-line rifaximin followed by second-line TCA for nonresponders, and first-line TCA followed by second-line rifaximin for nonresponders.

Results: Based on the average acquisition cost of rifaximin (USD 29.78/pill), second-line rifaximin could be cost-effective from a societal perspective (Table 1). However, at contemporary WTP thresholds neither rifaximin strategy was cost-effective from a payer perspective despite greater effectiveness than TCA alone. Dependent on WTP, a 12-62% price reduction (USD $18.46-$26.34/pill) would enable the first-line TCA followed by second-line rifaximin to be more cost-effective than a TCA-only strategy (Table 1). An 84-88% price reduction (USD $3.53-$4.71/pill) would enable first-line rifaximin followed by second-line TCA to be more cost-effective than TCA-only, though first-line TCA followed by second-line rifaximin would remain the more cost-effective strategy. Our model was robust in tornado analysis and most influenced by rifaximin treatment interval. Sensitivity analysis on rifaximin retreatment interval suggests that current pricing may be based on longer retreatment intervals than those found in clinical literature (Fig 1a). Sensitivity analysis with a lower TCA responder rate could enable first-line rifaximin to be the preferred strategy, albeit at a reduced price (Fig 1b).

Conclusion: Rifaximin is an effective therapy for IBS but is less cost-effective than TCA as currently priced. We propose an evidence-based pricing strategy which would maximize the cost-effectiveness of rifaximin in IBS-D patients.

Introduction: Colonoscopy has been widely used for diagnostic and therapeutic purposes. Although the incidence is very low, perforation is one of the most serious complications. It is important to decide whether to try endoscopic clipping or to perform prompt surgical management.

Aims & Methods: We retrospectively reviewed charts of all patients who experienced colonoscopy-associated perforation in a single center between May 2009 and July 2015, and totally 45 patients were enrolled.

Table: The risk factors surgical treatment in colonoscopy-associated perforation

Results: Diagnostic cases in purpose, sigmoid colon in location and non-clipping status were significantly more common in surgery group than conservative group (Table). Endoscopic clipping was performed in 31 cases (immediate; 23, delayed; 8), and immediate clipping group had significantly lower rate of operation (p = 0.013) and better clinical outcome (duration of antibiotic: p = 0.006, hospital stay: p = 0.001). Among 18 surgical cases, 13 patients had primary closure and 5 patients had complex surgery (2; segmental resection, 3; Hartmann’s procedure). The early (<24hr) surgical management significantly decreased the possibility of complex surgery (p = 0.002), as well as had better clinical outcomes such as duration of antibiotic use, fasting time and length of hospital stay (p = 0.003, p = 0.001, p = 0.005, respectively). In therapeutic cases, all five perforated patients who had surgery within 1 day could be managed by simple primary closure, but all four patients who had surgery after 1 day required complex surgery.

</table>

1 first-line rifaximin strategy was dominated (less effective and more expensive) than a second-line rifaximin strategy at all price points. ICER = incremental cost effectiveness ratio; QALY = quality adjusted life year; TCA = tricyclic antidepressant; IBS-D = irritable bowel syndrome with diarrhea; USD = US dollar.

Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

**P1798** PATIENTS’ AND CLINICIANS’ VIEWS OF AND EXPERIENCE WITH A NOVEL CLINICAL PATHWAY FOR FUNCTIONAL GASTROINTESTINAL DISORDERS

E. C. Linedale1, A. Mikocza-Walusz1, P.R. Gibson2, J. M. Andrews3

1 Department Of Medicine, The University of Adelaide, Adelaide/Australia/SA
2 Gastroenterology, Monash University, Melbourne/Australia/VIC
3 Contact E-mail Address: eecshla.linedale@adelaide.edu.au

Introduction: Despite diagnostic criteria and effective management options for functional gastrointestinal disorders (FGID), confidence in managing these disorders in primary care is low, and long waiting lists for specialist care are common. New models which efficiently transfer specialist-held expertise to primary care practitioners is needed.

Aims & Methods: We aimed to explore and describe the patient and primary healthcare provider (PHCP) experience of a novel non-specialist-dependent algorithm-based approach to the diagnosis and management of FGID (ADAM-FGID). Consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over 2 years, with non-specific gastrointestinal symptoms (no alarms) were randomised to waitlist control or the algorithm (1:2). Algorithm patients were screened for organ disease with an alarms-based questionnaire and panel of routine blood/stool tests. When patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All others were classified using Rome III criteria. and received a letter explaining their FGID diagnosis and dietary/psychological management options. Waitlist control patients were not screened. All participants completed follow-up surveys at 6, 26 and 52 weeks. Referring doctors of the algorithm group were sent a feedback survey at study completion.

Results: 89 participants were screened (42 years [SD 14], 62% female). 35 had clinical alarming warranting gastroenterologist review and 45 were diagnosed with FGID (9 excluded). At 6 week follow up: 35/36 FGID respondents had read the diagnostic/management letter, and most (n=30) were satisfied with the information (96%, 8% partially satisfied). Few discussed it with their PHCP (n=13), yet most (n=28) commenced management (n=33 by 12 months). Dietary management options were preferred over psychological therapies (n=30 vs n=16) (p<0.001), as were do-it-yourself options above therapist consultation. 61% (n=22) of patients saw symptom improvement at 6 weeks, (18/21 at 12 months). 2 did not accept the diagnosis, and 3 consulted a specialist privately. 19/36 participants had no concerns at 6-week follow-up (19/21 at 12 months). Common concerns included symptom persistence (6-week n=10, 12-month n=10) and fear of missed pathology (6-week n=4, 12-month n=4). Most respondents (74%, 46/62) found the approach acceptable (FGID group: acceptable 12/36, moderately acceptable 10/36; Screen Fail Group: acceptable 20/26, moderately acceptable 4/26). Others expressed dissatisfaction with the healthcare system (n=4), diagnosis (n=3), screening questionnaire (n=1) and lack of improvement in symptoms (n=1). All responding PHCPs (23/30; 14 FGID group, 9 screen-fail group) found the approach acceptable (13 acceptable, 12 moderately acceptable).

Conclusion: An algorithm-based approach to the diagnosis and management of FGIDs, which does not rely on specialist input is feasible, acceptable and effective. A larger scale randomised controlled trial of this new clinical pathway for the diagnosis and management of FGIDs, in primary care is warranted.

Introduction: Colonoscopy every 5 years, starting at the age of 40 years, is considered the first-choice screening strategy in first degree relatives (FDR) of patients with colorectal cancer CRC, as these individuals are considered at higher risk of developing CRC than average-risk individuals. However, this practice has a low adherence and remains opportunistic. Recently, it has been suggested that annual fecal immunochemical testing (FIT) might be a valid alternative to colonoscopy in this setting. However, there are scarce data regarding cost-effectiveness of these strategies from the perspective of healthcare services.

Aims & Methods: This study was aimed to compare the cost-effectiveness of annual FIT and colonoscopy every 5 years, to reduce CRC mortality, in FDR of patients with CRC. A Markov model was constructed to simulate the efficacy and cost of annual FIT (cut-off 10 μg Hgb/g feces) or colonoscopy every 5 years of
previously unscreened FDR, starting at age 40 years and ending at age 75. A 5-year gap between each strategy was assumed. The model was adjusted to the incidence of CRC in Spain and real prevalence of advanced adenoma and CRC in the familial-risk population (http://dx.doi.org/10.1371/journal.pmed.1002008.g001). The main outcomes were quality-life-year (QALY) gained compared to natural lifetime, lifetime burden of colonoscopy, lifetime burden of colonoscopy complications, and the incremental cost-effectiveness ratio (ICER). We applied a willingness-to-pay threshold of €25,000 per QALY gained. Data from a prospective EuroQol survey carried out on 920 Spanish patients at different disease stages were used for QALY measurement. Sensitivity analysis was performed to evaluate the robustness of the model.

Results: In a hypothetical cohort of 10,000 asymptomatic FDR, annual FIT and colonoscopy every 5 years were cost-effective over no screening. Taking no screening as the CER for annual FIT and colonoscopy every 5 years was 1989 and 4472 euros/QALY, respectively. Compared to no screening, annual FIT and colonoscopy every 5 years reduced CRC mortality by 59% and 81%, respectively. The annual FIT strategy saved 33% of colonoscopies and was associated with a number of colonoscopies reduced compared to colonoscopy every 5 years. The results were robust in sensitivity analyses.

Conclusion: Assuming a 50% adherence, annual FIT is less costly than colonoscopy every 5 years for CRC screening and reduces mortality in the familial-risk population. These data suggest that FDR of patients with CRC could be included in organized nationwide FIT-based screening programs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Faecal occult blood test (FOBT) is a non-invasive and easily performed test which has demonstrated to reduce CRC incidence and mortality in the populations. Fecal calprotectin (FCP) has good evidence for detecting inflammatory bowel disease but its value in CRC and adenoma detection in the symptomatic population is less well studied. Most patients with symptoms have benign pathology but in an effort to detect most cancer or pre-cancerous lesions, almost all patients undergo colonoscopy.

Aims & Methods: To evaluate and compare the diagnostic accuracy of the combination of FOBT plus FCP versus each test alone in symptomatic patients referred for diagnostic colonoscopy. A total of 171 patients who completed colonic investigations and returned stool samples, were prospectively recruited and included in the final analysis. FOBT was performed by SENTRY FIT 270 test (Sentinel Diagnostics, Milan, Italy) and FCP by the Elia Calprotectin immunoassay (Thermo Fisher Scientific, Waltham, United States). Reference cut-off levels for FOBT and FCP were 117 ng/ml for FOBT and 90 μg for FCP respectively. The diagnostic accuracy of FOBT and FCP were evaluated by a logistic regression model. CRC, advanced adenoma, IBD and angioidsplasia were considered as relevant pathology. Positive and negative predictive values, sensitivity and specificity were calculated. MedCalc software was used for the ROC curve analysis.

Results: 171 patients (42.7% female; median age 62 years, IQR: 51–68) had relevant colonic pathology. The most frequent indications for colonoscopy were previous episode of rectal bleeding in 71 (42%) patients, change of bowel habits in 28 (16%) and anaemia in 22 (13%). Diagnostic accuracy of FOBT, FCP and combination of both are summarized in table 1.

AuROC curves for relevant colonic pathology were 0.777 (95% CI: 0.708–0.837; P < 0.0001) for FOBT, 0.692 (95% CI: 0.617–0.760; P = 0.0005) for FCP and 0.848 (95% CI: 0.785–0.898; P < 0.0001) for combination of both tests respectively. Combination of both tests have a significant better diagnostic accuracy compared to either test alone (P = 0.043 vs FOBT and P = 0.002 vs FCP) with a higher NPV. No significant difference was observed between FOBT and FCP (P = 0.221).

Conclusion: Our model based on combination of FOBT and FCP has a better diagnostic accuracy performance compared to each test alone for the detection of relevant colonic pathology. Because of high NPV, performing FOBT and FCP in all patients before colonoscopy could be a feasible strategy in order to avoid unnecessary procedures.

Introduction: The success of colonoscopy depends on the quality of the bowel preparation, which is estimated to occur in as many as 25% of colonoscopy procedures. The MOTUS GI Pure-VuTM System (Tirat Carmel, Israel) is an FDA cleared device designed to improve visualization in an inadequately prepared colon by facilitating intra-procedural cleaning. Adverse events were reported. The Pure-Vu significantly increased the number of inappropriate polypectomy technique for polyps ranging 4 to 5 mm in diameter.

Aims & Methods: This study aims to evaluate the performance of the Pure-Vu System in colonoscopy with an inadequately prepared colon which may help to improve the overall quality of colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1803 THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY KEY PERFORMANCE MEASURES FOR COLONOSCOPY IN THE POLISH COLORECTAL CANCER SCREENING PROGRAM
M. Bugajski1, P. Wieszczyc2, M. Rupinski3, J. Regula4, M.F. Kamiński5

Contact E-mail Address: marek.bugajski@gmail.com

Introduction: Recently, the European Society of Gastrointestinal Endoscopy (ESGE) published guidelines on key performance measures for colonoscopy (1). We analyzed feasibility of monitoring these measures and whether the proposed standards were met in the Polish Colonoscopy Screening Program (PCSP).

Aims & Methods: We analyzed database records for 40,644 participants aged 55 to 64 years, who between 2014 and 2015, underwent screening colonoscopy in 24 centers of population-based PCSP. We used the ESGE guideline definitions to calculate values of all seven key performance measures. We compared key performance measures within the PCSP against proposed standards on the program and center level. Data on adequacy of bowel preparation was routinely assessed with the Boston Bowel Preparation Scale, whereas data on patient experience with the validated GastroNet questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

Results: Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–39.1%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality was 0.02% (9 cases). GastroNet questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 7.6%-81.8%), with painful colonoscopy rate of 19.2%. No minimum standard is set, however target standard of 90% of procedures with measured patient’s experience was not met. Appropriate post-polypectomy surveillance, based on the European guidelines, was proposed in 95.4% of cases (range 84.9-99.7%). Target standard of 95% was met in 15 centers, the minimum standard is not set.

Conclusion: Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries. PCPS meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging 4 to 5 mm in diameter.

Conclusion: Our findings showed that the F-PAR with only five questions can be considered sufficient to provide clinical evidence of treatment failure. The use of standardized process to investigate the efficacy of treatment may reduce the time and improve the quality of managing for the chronic constipation patients.

OESOPHAGEAL, GASTRIC AND DUODENAL DISORDERS III - HALL 7...

P1806 ADHERENCE WITH TRANSMAL IRRIGATION USING THE NAVINA SYSTEM IS ASSOCIATED WITH PSYCHOLOGICAL TREATS EVEN WHEN THERE IS IMPAIRED HAND FUNCTION

V. Passannanti, J. Storrie, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassannanti@gmail.com

Introduction: Transanal irrigation has become a key therapeutic modality in managing patients with neurological diseases who experience constipation and/or faecal incontinence. Such neurogenic bowel dysfunction (NBD) complicates over three quarters of patients with spinal cord injury (SCI) and multiple sclerosis (MS). Approximately 60% of patients who start TAI continue with long-term treatment. A common cause of treatment cessation is impaired hand [1]. Training of the patient is a key aspect of TAI therapy and requires patients to be willing to manage their health themselves: self-efficacy.

Aims & Methods: We wished to study whether use of a novel TAI system, Navina™, which has an electronic pump component allows patients with impaired levels of hand function, to adhere to TAI therapy. We also wished to identify if there were physiological or psychological correlates of adherence. Twenty-eight consecutive patients (19 SCI and 9 MS; 17 male, mean age 42) were studied. All patients scored greater than 18 on the Cochin Hand Function questionnaire which was completed to assess anxiety/depression and locus of control respectively. Anorectal physiology (manometry, sensation and rectal compliance) was undertaken at baseline. Training in TAI was undertaken by the same experienced nurse, with weekly follow up until a stable regime was established. Adherence with therapy at 12 weeks was identified.

Results: At 12 weeks, 16/28 (57%) of patients were still using Navina TAI, similar proportions with SCI (11/19) and MS (5/9). There was no difference in baseline scores for HAD-anxiety (6.7 ± 3.9 vs 7.3 ± 2.9; p = 0.37) and HAD-depression (8.6 ± 3.9 vs 8.8 ± 4.2; p = 0.46) and were similar in both those who were and were not still using TAI (mean ± SD respectively). The Rotter score for non-adherers was significantly greater than adherers (14.2 ± 6.7 vs 10.6 ± 5.9 respectively; p = 0.008). There was no difference in any of the anorectal parameters between those who did or did not adhere with TAI.

Conclusion: Navina Smart TAI is an effective therapy in 57% of NBD patients with significant hand dysfunction. Anorectal physiology, anxiety and depression scores do not predict likelihood of treatment adherence. An external locus of control, reflecting a belief that health events occur because of outside forces (such as fate, chance, or powerful others), is associated with reduced treatment success. The results suggest that future studies of TAI should consider locus of control as an important potential predictor of outcome.

Introduction: The microbiota inhabiting the gastrointestinal (GI) tract plays an essential role in gut health. Although mucosal biopsies are increasingly used for microbiota studies, these are subject to variations introduced through sampling technique and patient preparation. The impact of bowel preparation on the microbiota/associated microbiota (MAM) is of particular interest given it results in complete emptying of bowel contents via laxative ingestion. Although bowel preparation does not appear to induce long term changes to stool microbiota [1], it can induce short-term changes to the colonic MAM [2]. While improvements in clearance of the small intestine after bowel preparation have been reported [3], the impact on the upper GI microbiota is currently unknown. Given patients may undergo both upper GI endoscopy and colonoscopy consecutively, a subset of endoscopy patients will have consumed bowel preparation prior to their procedure, representing a potential bias in MAM analyses. Therefore, this study aimed to assess the impact of bowel preparation on the duodenal MAM.

Aims & Methods: Individuals undergoing upper GI endoscopy, with or without concurrent colonoscopy, were recruited consecutively with ethical approval. Individuals who underwent upper GI endoscopy following overnight fast (n = 58), or both upper endoscopy and colonoscopy following polyethylene glycol bowel preparation (n = 48). Participants were undergoing screening for iron deficiency anaemia or GI symptoms with no evidence of mucosal disease/inflammation (n = 58), or with diagnosed Crohn’s disease (n = 18). Duodenal biopsies were obtained and gDNA extracted. Amplicon libraries of the 16s rRNA gene were sequenced (Illumina MiSeq). Sequencing of reagent controls enabled exclusion of...
non-duodenal sequences. Bioinformatics and statistics were performed in QIIME and Calypso.

Results: A diverse microbiota was observed in duodenal mucosal samples from all subjects, following overnight fasting or bowel preparation. Overall the duodenal microbiota was dominated by the genus Streptococcus, followed by Prevotella, Veillonella and Neisseria. Microbial diversity within samples was not significantly different with and without bowel preparation (Chao1 metric). Principal coordinates analysis (weighted UniFrac) revealed substantial overlap between the two groups, and no significant clustering was observed (ADONIS) based on whether patients had undergone overnight fasting or bowel preparation. Similar findings were obtained when these analyses were repeated with exclusion of the Crohn’s disease population.

Conclusion: This study reveals a diverse duodenal MAM is retained following bowel preparation. The comparison of overnight fasting and bowel preparation indicates these differences in patient preparation do not substantially alter the duodenal MAM. Thus patients undergoing concurrent upper GI endoscopy and colonoscopy can be included in study cohorts investigating the upper GI MAM without risk of a substantial confounding effect.

P1808 PERFORMANCE OF GLASGOW-BLATCHFORD, ROCKALL, AND AIMS65 SCALES TO PREDICT OUTCOMES AND TO IDENTIFY THE LOW-RISK GROUP AFTER UPPER GI BLEEDING IN PATIENTS WITH CANCER

M. C. Franco1, S. Jang2, B. D.C. Martins3, T. Stevens4, V. Jairath5, R. Lopez2, J. J. Varg6, A. Barkun2, F. Maluf-Filho1

Contact E-mail Address: mcavalkanteo@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) in patients with cancer presents a unique and difficult challenge as these patients are at higher risk for rebleeding and mortality.1 Currently available prognostic scoring systems for UGIB for the general population have produced variable accuracy in their validation studies.2 An effective method of stratification for cancer patients to identify the high-risk group for early hospital-based intervention and death could enhance the outcomes of this specific population.

Aims & Methods: The primary aim of this study was to compare the Glasgow-Blatchford scale (GBS), Rockall score (RS) and AIMS65 score for predicting ICU admission, blood transfusion, hemostatic therapy, rebleeding, and in-hospital mortality in cancer patients with UGIB. The secondary aim was to assess the above cited scales in correctly identifying low-risk patients that can be effectively managed as an outpatient. An IRB-approved, prospective study was conducted at the Cancer Institute of Sao Paulo, Brazil. Consecutive patients with known cancer admitted with UGIB were enrolled. Pre-endoscopic clinical parameters pertinent to the scoring systems, hemostasis techniques, and outcomes were collected into a prospective registry. Patients were followed for at least 30 days or until the day of discharge, whichever was longer. The low-risk group was defined as those without blood transfusion, hemostatic therapy (by endoscopy, radiotherapy, angiography or surgical intervention), rebleeding or mortality in 30 days. Multiple logistic regression with receiver operating characteristics analysis was done to assess the predictive ability of each scoring system for the above outcomes.

Results: From April 2015 to May 2016, 394 consecutive patient cases were screened, while 259 patients met the inclusion criteria. A total of 243 patients were considered for the final analysis, after excluding 16 patients due to missing data or lost to follow up (Table 1). Predicting outcomes: The AIMS65 score (area under curve [AUC] 0.85) was significantly better for predicting ICU admission than the GBS (AUC 0.79; p = 0.04), both the total and clinical RS (AUC 0.71 and 0.66; p < 0.001 for both). The GBS best predicted the need for blood transfusion (AUC 0.82, sensitivity 71% and specificity 80% for GBS ≥ 12) compared with the other prognostic scores. All scores performed poorly in predicting the need for hemostatic therapy and risk of rebleeding. The AIMS65 score best predicted in-hospital mortality (AUC 0.84) compared to the GBS (AUC 0.75; p = 0.004), both the total and clinical RS (AUC 0.70 and 0.69; p < 0.001 for both). Among patients with bleeding at EGD, there was no difference in 30-day mortality if the etiology of bleeding was tumoral or non-tumoral disease (38.1% vs 31.9%; p = 0.46). Identifying low-risk group: With GBS score of 0 as the cut-off value, its specificity was 100% with sensitivity of 5.8%. When GS ≤ 2, its specificity was maintained at 100%, while sensitivity was increased to 23.5%. This change increased the proportion of the patients from 1% to 5% without erroneously discharging high-risk patients. In comparison, when an AIMS65 value of 0 was chosen as definition for low-risk, this tool misclassified 20 patients who needed hospital interventions (specificity of 53% and sensitivity of 89.5%). Finally, head-to-head comparison between GBS vs. RS, and GBS vs. AIMS65 scoring system revealed GBS to be superior to both the clinical RS (p < 0.001) and AIMS65 (p = 0.001) in correctly identifying low-risk patients.

</tr>
</tbody>
</table>

Conclusion: The AIMS65 score was superior to other scoring systems in predicting in-hospital mortality and ICU admission in patients with cancer and UGIB, whereas the GBS was superior for predicting the need for blood transfusion. All scores performed poorly in prediction of hemostatic therapy and rebleeding. The GBS was superior in accurately identifying low-risk patients. Furthermore, the cut-off ≤2 in GBS score displays increased sensitivity without compromising specificity, effectively increasing the number of patients who can be safely managed as an outpatient.

Introduction: Endoscopists are more frequently performing endoscopic resection (ER) in patients on antplatelet or anticoagulant therapy and nowadays patients have increasingly started taking direct oral anticoagulant (DOAC) therapies, including direct anti-Xa and thrombin inhibitors. Major guidelines recommend the cessation of anticoagulants before ER and heparin bridging therapy (HBT) for high thrombotic risk cases, although these are still controversial. A recent study has suggested that HBT may be associated with a higher post-endoscopic resection bleeding (PEB) rate in patients on anticoagulants.

Aims & Methods: This study aimed to evaluate the effect of anticoagulants on PEB rate. This was a retrospective study based on medical records from three centers. PEB was defined as bleeding that occurred 6h to 10days after ER, which required endoscopic hemostasis. We reviewed 108 gastric tumors including adenoma and early cancer in 97 patients on anticoagulant therapy who underwent endoscopic submucosal dissection (ESD) in our hospitals between June 2008 and February 2016. Further, we reviewed 69 colorectal polyps including adenoma and early cancer in 69 patients on anticoagulant therapy who underwent ER in our hospitals between October 2013 and September 2016. ER included polypectomy, endoscopic mucosal resection (EMR), and ESD. Patients were divided into two groups: those prescribed warfarin and patients prescribed DOAC. The management of antithrombotics was based on the Japanese Gastroenterological Endoscopy Society guidelines published in 2005 and 2012. The anticoagulants used during the study period were warfarin, dabigatran, rivaroxaban, apixaban, and edoxaban. Warfarin was discontinued 4–5 days before ER, whereas the others were stopped 24–48h prior to the procedure. For patients at a high thrombotic risk, intravenous unfractionated heparin was administered after ceasing anticoagulants.

Results: Warfarin and DOAC were prescribed to 73 (75%) and 24 (25%) patients, respectively. Apixaban was administered to 1 (1%), dabigatran to 12 (12%), rivaroxaban to 11 (11%) patients. There were no significant differences between the DOAC and warfarin groups in terms of clinical characteristics or

United European Gastroenterology Journal 5(5S)
PBET rate. Overall, 57 patients (78%) in the warfarin group underwent HBT, and 29 patients (43%) in the PBET group compared to the patients who did not undergo HBT in the warfarin group (36% vs. 0%, p < 0.05). Although there was no significant difference in the PBET rate between the group that did and did not undergo HBT in the DOAC group, the PBET rate was higher among rivaroxaban recipients (45% vs. 0%, p < 0.05). Multivariate analysis revealed that HB, rivaroxaban, and anticoagulants plus antiplatelet therapy were associated with PBET (P < 0.05). Warfarin and DOAC were prescribed to 72 (57%) and 54 (43%) patients, respectively. Dabigatran was administered to 16 (13%), rivaroxaban to 18 (14%), apixaban to 18 (14%), dabigatran to 2 (1.6%) patients. Patients underwent polypectomy (n = 50), EMR (n = 62), or ESD (n = 10). PBET occurred in 5 (4.0%) patients (one polypectomy and four EMRs). Among them, warfarin was prescribed to one patient (1.4%) who also underwent ESD. Aspirin and apixaban were prescribed to two patients (11%) each. PBET rate was higher in the DOAC group than in the warfarin group (7.4% vs. 1.4%).

Conclusion: Patients on HB, rivaroxaban, and anticoagulants plus antiplatelet therapy are at an increased PBET risk after ESD for gastric tumors. In patients who underwent ER for colorectal polyps, PBET was more common in DOAC than that in warfarin recipients. That was the difference between ER for colorectal polyps and ESD for gastric tumors. We suggested that the PBET rate differs among DOACs because each drug has its own blood concentration and metabolism. Most clinicians have a limited knowledge on PBET during DOAC therapy because these are relatively new drugs, and because PBET has a low prevalence. Therefore, comparative data on larger patient series are needed to address this issue.

P1811 CLINICAL FEATURES OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS IN HIGH-RISK AND LOW-RISK PATIENTS
Gastroenterology, Osaka General Medical Center, Osaka/Japan
Contact E-mail Address: takatakakkun@gmail.com

Introduction: Antithrombotic drugs are administered to patients undergoing endoscopic treatment at high risk for thromboembolism. However, antithrombotic drugs have been also known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of post-polypectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.

Aims & Methods: The aims of the present study are to investigate the risk factors of delayed bleeding after gastric ESD and to clarify the clinical features of delayed bleeding in high-risk and low-risk patients. Patients with heparin bridge therapy who underwent ESD for gastric neoplasms in Osaka General Medical Center between January 2009 and December 2016 were retrospectively investigated. Independent risk factors of delayed bleeding were analyzed by using a multivariate analysis by logistic regression model, and three predictors of delayed bleeding were selected. Patients were categorized into a high-risk group or low-risk group for bleeding, and the clinical features of post-procedural bleeding in each group were investigated.

Results: A total of 717 patients with 781 gastric neoplasms were identified. Mean age was 74.6, and 71.6% was male. With regard to comorbidity, the proportion of hypertension, diabetes, chronic liver disease, and hemodialysis was 50.2%, 19.2%, 7.7%, and 6.1%, respectively. Total 188 patients (6.8%) experienced delayed bleeding after gastric ESD. Hospital stay was significantly longer in bleeding cases than in non-bleeding cases (median hospital stay (range) 11 (3–20) vs. 9 (9–25), p<0.007). A univariate and multivariate analysis showed heparin bridge therapy, antiplatelet therapy, and hemodialysis as risk factors for delayed bleeding. Delayed bleeding occurred in each group.

Conclusion: Delayed high-risk patients with heparin bridge therapy, antiplatelet therapy, and hemodialysis should be carefully observed after gastric ESD while early hospital discharge is acceptable for bleeding low-risk patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are few studies of the efficacy of parenteral ferric carboxymaltose (FCM) treatment in acute gastrointestinal bleeding (GIB) of different origins. Few data are available on its use to treat anemia post-acute haemorrhage.

Aims & Methods: To determine the efficacy and safety of FCM treatment in patients with acute GIB not associated with portal hypertension. A retrospective descriptive 3-year-study of patients with acute GIB (anemia with evident bleeding and/or hemodynamic instability) treated with FCM as part of our hospital’s habitual clinical practice.

Results: Analysis of 84 patients admitted with acute GIB (69.0% male, mean age 68.0 years [SD 6.9]), with a Charlson index ≥3 in 67.1% of cases (≥5 in 31.6%). 15.5% had previously suffered acute GIB due to peptic ulcer. There were 86 hospital admissions for acute GIB; 93.8% were upper GIB (above the angle of Treitz). The most frequent clinical presentation was melena, in 76.7% of cases. 23.6% presented hemodynamic instability at admission. The mean Glasgow-Blatchford index score was 16.1 (SD 2.7) and the mean Rockall score post-endoscopy was 4.2 (SD 1.7). The most common causes of bleeding were: 36.0% duodenal ulcer, 29% gastric ulcer, 9.3% gastritis/erosions, and 7.3% angiodysplasia of the colon. The mean Hb at admission was 9.0 g/dL (SD 2.2)
P1814 NOVEL EUS-GUIDED TREATMENT OF GASTRIC VARICES WITH A LIQUID NON-ADHESIVE NEUROVASCULAR EMBOLIZATION AGENT
Hospital de Clínicas Caracas, Caracas/Venezuela

Contact E-mail Address: albertainbaptista@gmail.com

Introduction: Endoscopic Injection of adhesive agents such as N-Butyl-2-Cyanoacrylate (NBC) is an accepted option for the management of gastric varices. Recently the combination of NBC and coils has been used with endoscopic ultrasound (EUS) assistance. Nevertheless adhesive properties of the polymer may cause blockage of instrumentation material and damage to endoscopes. Sometimes the ulcers, vascular wall necrosis, rebleeding and distal embolism. Ethylene-vinyl alcohol (EVOH) has been extensively used in interventional radiology to treat cerebral arteriovenous malformations and has the advantage of being radiopaque.

Aims & Methods: We aimed to demonstrate a novel gastric varices embolization therapy with EUS-guided injection of a composite non-adhesive endovascular liquid agent EVOH combined with Dimethylsulfoxide (DMSO) as a primer. Five cases of EUS-guided Injection under fluoroscopic vision with EVOH is described in 5 men and 2 women, aged 50–65 years with gastric fundus varices, portal hypertension, Child-B hepatic cirrhosis and previous episodes of bleeding. The endoscopy was advanced to the gastroesophageal junction. The selected gastric varix was punctured using a 22 Gauge needle. EVOH injected volume ranged between 1.5 and 3cc. Vascular flow promptly and obliteration was real time monitored by EUS. Ceftriaxone was intravenously administered during the procedure. Patients were discharged on the same day. The mean follow-up was 6 months.

Results: All patients presented mild epigastric pain during the first 12 hours effectively managed with oral analgesics. The obliteration of variceal flow was achieved in all patients in a single session. There were no new episodes of bleeding or complications related to the technique.

Conclusion: EUS-guided embolization of gastric varices with EVOH can be considered as an efficient alternative. The procedure promises effective advantages in terms of number of sessions required, local or systemic adverse events and endoscopic aspect of ulcer. A comparison of cases and cost evaluation against coils alone or combined with NBC are required.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: dmatei68@gmail.com

Introduction: Peptic ulcers are the most frequent cause of upper gastrointestinal bleeding. In different population based surveys regarding all-cause UGIB, mortality ranges between 3% and 14%.

Aims & Methods: The aim of this study was to assess in-hospital mortality in patients with peptic ulcer bleeding and to evaluate the risk factors associated with mortality. In this prospective study we enrolled all patients diagnosed with peptic ulcer bleeding in a tertiary medical center over a period of 24 months (January 2015- December 2016). Patients were divided into two groups - those who died and those who survived - and the following parameters were compared: age, signs of hemodynamic instability (hypotension, tachycardia), evidence of coagulopathy as defined by Charlson index, the number of cases and cost evaluation against coils alone or combined with NBC are required.

Results: The study included 431 patients. In-hospital mortality rate was 7.9%. The following differences have been observed by comparing patients who died and those who survived: age > 75 years 41.2% vs 23.4% (p = 0.036); hypotension 17.6% vs 2.3% (< 0.001); anemia 47.1% vs 21.4% (p = 0.001); one or more comorbidities 94.1% vs 63.5% (p = 0.001); high risk endoscopic stigmata 79.4% vs 62.2% (p = 0.070); multiple ulcers 41.2% vs 33.5% (p = 0.473); Rockall score ≥5 points 94.1% vs 46.9% (p < 0.001); Blatchford score ≥10 points 91.2% vs 66.2% (p = 0.005); hemoglobin < 9.5 g/dl 70.6% vs 41.1% (p = 0.002); INR ≥2.5 17.6% vs 5.8% (p = 0.022); creatinine ≥1.5 mg/dl 38.2% vs 10.8% (p = 0.001); rebleeding 20.6% vs 12.1% (p = 0.123); need for blood transfusion 82.4% vs 56.4% (p = 0.006); need for surgery 11.8% vs 3.5% (p = 0.063). In most cases (88.2%), the cause of death was other than hemorrhagic shock. Using multivariate analysis, three out of these factors were identified as representing independent factors significantly associated with in-hospital mortality: tachycardia (OR = 2.83, 95%CI:1.21–6.58, p = 0.016). Rockall score ≥ 5 (OR = 6.65, 95%CI:1.46–30.16, p = 0.014) and creatinine ≥1.5 mg/dl (OR = 1.25, 95%CI:1.25–7.73, p = 0.014).

P1816 ANAEMIA AND UPPER GI BLEEDING: A LOCAL EXPERIENCE

M. Ding, R. Prawiradilja, Z. Arasta, H. Sabri, M. Smith
Gastroenterology, Royal shrewsbury hospital, Shrewsbury/United Kingdom

Contact E-mail Address: Michuudd@gmail.com

Introduction: There has been significant research recently on the use of blood transfusions in upper GI bleeding (UGIB) [1] with recent evidence advocating a restrictive approach to blood transfusions as well as the use of iron therapy[2] for anemic patients. Our team conducted a local retrospective analysis of patients admitted with UGIB over a six month period and analysed the use of blood transfusions at our trust which consists of two District General Hospitals. Patient data over a period of up to 12 months post discharge was collected to monitor their anaemia.

Aims & Methods: Our aim was to monitor the appropriateness of transfusions in Upper GI Bleeding as well as monitoring the response to iron therapy following discharge. All inpatients that had an Upper GI endoscopy for UGIB were analysed.

Results: There were 148 patients, 81 male and 67 female. The mean age was 69.3, minimum 20 and maximum of 98. The average Hb on admission was 103.6 g/L (min = 32 g/L, max = 178 g/L). 78 out of 148 (52.7%) patients presenting with UGIB received a blood transfusion. The mean amount of blood received for those transfused was 3.7 units. 48 out of 78 (61.5%) of blood transfusions were given when Hb was below 70 g/L. 30 of 78 (38.5%) were transfused with Hb above 70 g/L. 80.7% of patients presenting with UGIB received a blood transfusion. The mean amount of blood received for those transfused above 70 g/L was 7.6 units.

Conclusion: The data obtained supports a restrictive transfusion policy (mortality rate of 13.5% vs 10.4%). 58.5% of patients who were anaemic on discharge did not receive any iron therapy. On follow up, there was a statistically significant rise in Hb level in the group discharged on iron (p = 0.005) follow- up versus those who did not receive it (n = 62). The anaemia readmission rates were similar for patients discharged on iron or not (91.5% vs 4 vs 9.7% vs 6)

Introduction: The interaction between gut microbiota and enterodendocrine cells alterations is believed to play an important role in the pathophysiology of irritable bowel syndrome (IBS). The densities of the duodenal enterodendocrine cells are abnormal in IBS patients, which appears to be caused by a reduced stem cell density and their differentiation into endocrine cells (1). Aims & Methods: The aim is to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into enterodendocrine cells as detected by neurogenin 3, the stem cells as detected by Musashi 1 and the enterodendocrine cells in the duodenum of patients with IBS. The study included 16 IBS patients according to Rome III criteria and four patients were excluded. The remaining patients (n = 12, 4 females and 8 males, age range 20–44 years) were divided according to the cause of IBS into PI-IBS patients (n = 6) and idiopathic IBS (n = 6) and received FMT donated from their relatives. The patients completed the IBS-symptom severity scoring system (IBS-SSS) before and 3 weeks after FMT. The patients underwent gastroscopies with biopsies taken from the descending part of the duodenum at baseline and 3 weeks after FMT. The biopsies were immunostained for neurogenin 3, Musashi 1 and all types of duodenal enterodendocrine cells, and quantified by computerized image analysis.

Results: The score of IBS symptoms as assessed by IBS-SSS was significantly reduced 3 weeks after (240.2 ± 33.6) compared to before (326.6 ± 22.3) receiving FMT, P = 0.0009. The scores of IBS-SSS before and 3 weeks after FMT for PN-IBS were 300.8 ± 27.8 and 210.2 ± 41, respectively (P = 0.025), and for idiopathic IBS are 352 ± 34 and 270.3 ± 54, respectively, (P = 0.034). The densities of neurogenin 3, Musashi 1 and enterodendocrine cells in the duodenum of IBS patients before and 3 weeks after receiving FMT are presented in Table 1.

Conclusion: Faecal microbiota transplantation improved the symptoms in IBS patients, both PI and idiopathic. This improvement was associated with a change in the enterodendocrine cell density. The changes in the enterodendocrine cell density does not appear to be caused by changes in the stem cells or their early progenitors, but rather by changes in the differentiation progeny as detected by changes in neurogenin 3.

P1817 THE RELATIONS AMONG SERUM GHELIN, MOTILIN, CIRCULATING ANTIMYENTERIC ANTIBODIES AND GASTRIC EMPTYING FUNCTION IN AUTONOMIC NERVOUS SYSTEM FUNCTION IN PATIENTS WITH AUTOIMMUNE GASTRITIS

C. Kalkan, F. Karakaya, I. Soykan
Gastroenterology, Ankara University, Ankara/Turkey

Contact E-mail Address: mfkarakaya@yahoo.com

Introduction: Autoimmune gastritis (AGI) is an organ-specific autoimmune disease of the stomach marked by autoantibodies directed to hydrogen-potassium-ATPase and intrinsic factor. Gastric emptying of solids is delayed and autonomic nervous system function is decreased in patients with autoimmune gastritis. This may be a cause of symptoms and also there is a close relationship between autonomic nerve dysfunction and delayed gastric emptying. As ghrelin and motilin are putative regulators of gastric emptying and, some autoimmune gastritis patients may have delayed gastric emptying leading up to gastrointestinal symptoms.

Aims & Methods: The aims of this study were to: (i) compare serum levels of ghrelin and motilin in patients with delayed normal gastric emptying and (ii) investigate whether circulating antimyenteric antibodies, serum levels of ghrelin and motilin are related to autonomic nervous system function. Forty-one patients with AGI were included into this study. Autoimmune gastritis was diagnosed depending upon histopathological findings in gastric biopsy specimens. Non-invasive cardiovascular reflex tests were used in order to evaluate autonomic nervous system function. Sympathetic nerve function was evaluated with two tests: blood pressure response to standing and handgrip test. Parasympathetic nerve function was evaluated with three tests: valsalva manoeuvre, heart rate response to deep breathing (E/I ratio) and orthostatic blood pressure testing. Dysfunction was considered to exist if at least two tests were positive. Gastric emptying time was evaluated by a standard 2-hour scintigraphic test using a solid meal. A half-time of longer than 110 minutes was chosen in the present study to further investigate patients with delayed gastric emptying. Serum ghrelin and motilin levels were tested by ELISA and circulating antimyenteric antibodies were tested by IFA.

Results: Forty-one patients (27 women), mean age 56.61 ± 11.79 years with AGI were included into the study. Overall, 22 (53.6%) patients showed delayed GE and 19 patients showed normal GE (GET ≥); 241.19 ± 190 ± 90 mins, p = 0.001). Serum ghrelin and motilin levels of patients with delayed GE were significantly decreased compared to patients with normal GE, respectively (67.5 ± 8.81 vs 126.79 ± 25.81 pg/mL, p = 0.001 and 279.59 ± 111.12 vs 500.42 ± 155.95 pg/mL, p < 0.001). In all, 26 (63.4%) patients showed autonomic nervous system dysfunction and, 15 (36.5%) patients had normal autonomic nervous system test findings (total autonomic test score: 0.8 ± 0.25 vs 5.65 ± 1.74, p < 0.001). Serum ghrelin and motilin levels of patients with deranged autonomic nervous system function were significantly decreased compared to patients with normal autonomic nervous system function (67.5 ± 8.81 vs 28.46 ± 127.79 ± 28.06 pg/mL, p < 0.001 and 316.92 ± 160.47 vs 490.20 ± 141.02 pg/mL, p < 0.001). In a multivariate analysis, plasma motilin level was found as an independent factor that affected serum ghrelin level (r = 0.43, p = 0.019). However, serum ghrelin (r = 0.623, p < 0.001) and gastritis (r = 0.70, p < 0.001) levels were found as independent factors that affected plasma motilin level. We also investigated the presence of antimyenteric antibodies, however all the patients were negative by means of antimyenteric antibodies therefore, no further relationship was sought.

Conclusion: Mean fasting serum ghrelin and plasma motilin levels in autoimmune gastritis patients with delayed GE and deranged autonomic nerve function were significantly decreased. Nearly all patients in our study were affected by circulating antimyenteric antibodies. These decreased serum ghrelin and plasma motilin levels in patients with autoimmune gastritis suggest a potential role for ghrelin and motilin in explaining the finding of the delayed gastric emptying in autoimmune gastritis patients. We believe that these new observations supply more insight into the pathophysiology of autoimmune gastritis.

P1819 THE EFFECT OF ESOPHAGEAL ACID EXPOSURE ON NMDA RECEPTOR SUBUNITs EXPRESSION AND D-SERINE IN PREFRONTAL CORTEX AND HIPPOCAMPUs

Introduction: Neuronal plasticity has been reported to develop following nociceptive emotional experience in prefrontal cortex (PFC) and hippocampus. The N-methyl-D-aspartate receptor (NMDAR) and D-serine, the endogenous co-agonist of NMDAR1, may mediate the neural plasticity. However, whether the neural plasticity participates in the mechanism of esophageal visceral hypersensitivity is little known.

Aims & Methods: This study aims to investigate the expression of NMDAR and the alteration of D-serine after neonatal and adult esophageal acid exposure. All rats were exposed to esophageal acid or saline at postnatal days 7-15(P7-P15), and most rats underwent acute acid or saline exposure again at adult time (P60).All rats were randomly distributed to 5 groups, including P7S, P7H, P60S, P60H and P7S þ P60H (P7: postnatal 7–15 days; P60: adult at postnatal 60 days; P: 0.1 M HCl infusion; S: saline control). The tissue harvest was conducted at P60. We examined the expression of subunits of NMDAR (including NR1, NR2A, NR2B, and NR2B), and c-fos, and serum racemase in PFC, dorsal hippocampus(DH) and ventral hippocampus(VH). We also determined the D-serine and L-serine in PFC and hippocampus by LC-MS analysis. Statistical comparisons were performed by General Linear Model and one way ANOVA in SPSS.

Results: In PFC, compared with adult saline treatment (AS, including P7H þ P60H and P7S þ P60H group) and without adult treatment (A-, including P7S and P7H group), adult acid exposure (AHE) increased the expression of NR1 (P = 0.052, P = 0.298), NR2B (P = 0.035, P = 0.045), and serum racemase (P = 0.022, P = 0.017) significantly. In ventral hippocampus, compared with adult treatment absence, adult acid exposure caused increasing expression of NR2B (P = 0.012) and NR1 (P = 0.024) significantly. In PFC, the expression of c-fos in the P7S þ P60H group was obviously higher than that of other groups (P = 0.008). See Table1. In dorsal hippocampus, the expression of c-fos was also increased (P = 0.008, AS vs A-: P = 0.042, AH vs AS: P = 0.081) and L-serine(AH vs A-: P = 0.008) decreased in the AH and AS group, comparing with A- group.

The expression of serine Racemase and c-fos in VH

Conclusion: Acute esophageal acid exposure may increase the expression of NMDAR in PFC and ventral hippocampus. We also found that the first acid exposure at adult stage may enhance the expression of serine racemase in PFC and c-fos in ventral hippocampus, but this phenomenon may be absent in those rats having the experience of acid exposure in early life. Those long-term and transitional molecular alterations may mediate the development of acid exposure related esophageal visceral hypersensitivity.

Reference
To the best of our knowledge, our findings are the first to establish an association between SLC6A4 gene polymorphism and globus pharyngeus.

Aims & Methods: 84 patients diagnosed with globus according to Rome III and 160 healthy controls were genotyped for 5-HTTLPR polymorphism by PCR amplification and agarose gel electrophoresis. All globus patients were studied with single water swallow resolution manometry pre-therapy. Globus patients were randomized into paroxetine group; amitriptyline group for 6-week treatment, and were asked to complete the following questionnaires pre- and post-therapy: Glasgow Edinbrough Throat Scale (GETS), Pittsburgh Sleep Quality Index, Hamilton Rating Scale Anxiety/Depression. Treatment response was defined as a > 50% reduction in GETS scores.

Results: The significant difference was shown in globus performed S/S genotype with anxiety when compared to without (X2 = 14.579, P = 0.006). The S genotype showed a significant difference between high upper esophageal sphincter pressure (>104 mmHg) and non-high upper esophageal sphincter pressure patients (X2 = 14.433, P = 0.006). There was significant association between the S genotype and the response to antidepressants treatment, while patients with sleep disorders or depression had lower rates.

Conclusion: A significant association was observed between S/S genotype of SLC6A4 polymorphism and globus pharyngeus, suggesting that SLC6A4 is a potential candidate gene involved in the pathogenesis of globus pharyngeus.

Disclosure of Interest: All authors have declared no conflicts of interest.

4University of Alberta, Edmonton/Canada

Contact E-mail Address: hasak.s@wustl.edu

Introduction: Multiple rapid swallows (MRS) and rapid drink challenges (RDC) are provocative tests that can enhance the diagnostic value of esophageal HRM. The discriminatory characteristics of these provocative tests were evaluated in symptomatic patients referred for esophageal HRM.

Aims & Methods: Consecutive patients presenting for esophageal HRM were a 2-month prospective cohort where provocative testing with MRS and RDC in addition to the standard manometric protocol. Integrated relaxation pressure (>15 mmHg) identified outflow obstruction; those without outflow obstruction were further analyzed for imaging software tools (IRP, distal contractile integral, DCI; intrabolus pressure, IBP) for peristaltic reserve (MRS or RDC DCI > mean DCI from wet swallows), and obstruction (IBP > 30 mmHg during MRS or RDC). All patients completed symptom questionnaires addressing reflux symptoms (GERD-Q), dysphagia (Mayo Dysphagia Questionnaire, MDQ) and global symptom severity (GSS) on a 100 mm visual analog scale (VAS). Univariate and multivariate analyses were performed to evaluate overall yield (proportions with MRS/RDC findings not seen with the standard HRM protocol) and to assess association of presenting symptoms with results of MRS and RDC in patients without outflow obstruction.

Results: 149 patients (55±1.2yr, 68% F) fulfilled inclusion criteria and had no outflow obstruction on HRM. Of these, 91 (61%) had peristaltic reserve on MRS, 19 (12.6%) on RDC (p < 0.001), only 10 were concordant. Obstruction was noted in 16 (9.8% on MRS, 8 (4.9%) on RDC (p = 0.09), and 5 were concordant; of these, only 2 patients had panoesophageal compartmentalization of pressure, and only 1 had elevated IRP during provocative measures. Within ineffective esophageal motility, peristaltic reserve was noted in 59.3%. Within dysphagia presentations, obstruction was noted in 7.7%, and absent peristaltic reserve in 50%. Thus, the overall yield of MRS was 80.5%, and RDC 19.8% (p < 0.001). 131 patients had adequate questionnaire data. Findings on provocative tests did not predict presenting symptoms (GERD-Q or MDQ). Obstruction on RDC predicted higher GSS (odds ratio 5.56, 95% CI 1.04-29.72).

Conclusion: MRS identifies peristaltic reserve better than RDC and has higher sensitivity measured in THIN patients. The variation of findings between the databases likely results from differences in coding practice and marginally different population structures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Prevalence of Achalasia in England in Two National Databases

Introduction: Achalasia is an uncommon condition of failed lower oesophageal sphincter relaxation. Data regarding the incidence and prevalence are limited. The aim of this study was to provide accurate, contemporary epidemiological data utilising two national databases.

Aims & Methods: Hospital Episode Statistics (HES) includes demographic and diagnostic data for all English hospital admissions. The Health Improvement Network (THIN) database includes primary care records of 7% of the UK population, representative of national demographics. Both were searched for incident cases and THIN for prevalent cases of achalasia.

Results: There were 10,509 and 711 new achalasia subjects in HES and THIN respectively. The incidence per 100,000 person years in THIN was 1.99 (95% CI 1.87-2.11) and 1.53 (1.42-1.64) per 100,000 person years in THIN. The prevalence measured in THIN was 27.1 (25.4-28.9) per 100,000 population.

Conclusion: The incidence of oesophageal achalasia was approximately 15 to 20 per 1 million population. There were approximately 17,500 patients with achalasia in the UK in 2013. The incidence rate increased by 1.8% in 2015. The prevalence measured in THIN was 27.1 (25.4-28.9) per 100,000 population.

Introduction: Resistance to bolus flow across the lower oesophageal sphincter (LES) is a hallmark of achalasia. Presently the gold standard of diagnosis is by high-resolution manometry (HRM) demonstration of raised integrated relaxation pressure (IRP) following ten 5 mL water swallows; however, this does not rule out normal swallowing behavior. It has been demonstrated that the addition of adjunctive tests improves sensitivity of identifying relevant dysmotility. Such tests include multiple water swallows (MWS; 200 mL water drunk freely) and solid swallows. In addition, the timed barium esophagum (TBE) measures esophageal emptying. This study describes a cohort of patients who have been treated as having achalasia based on resistance to flow not exhibited with single water swallows.

Aims & Methods: Inclusion criteria were all patients between October 2014–2016 with normal mean and median IRP with 5 mL water swallows but considered to have achalasia due to resistance to flow demonstrated by pan-oesophageal pressure surpression (PEP) during MWS or solid swallows and/or a persistent column at 5 minutes during TBE. Outcome following treatment was based on the Eckardt symptom score (ES).

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: 14 patients (9 male) fulfilled inclusion criteria. 7 were treatment-naive and 7 treatment-experienced (3 myotomy, 4 dilatation). Mean resting LES pressure was 14.6±4.7 mmHg. In all patients, and median IRP values for ten 5 mL water swallows were non-raised (mean 9.1±4.3 and 8.7±4.5 mmHg respectively). Of the 7 treatment-naive patients, 5 demonstrated PEP on MWS, 3 on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experience patients, 5 had PEP on MWS, 1 on solid swallows and all had a positive TBE. Of the 13 who had resistance to flow on TBE, 10 (77%) also had resistance on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experienced patients, Achalasia type III (n = 22), achalasia type IV (n = 17) and achalasia type V (n = 5) patients have (so far) undergone therapy based on these findings: one or more endoscopic myotomy and 7 pneumatic dilations. The median baseline ES was 7.5 (IQR: 5-8). The median ES at 3 minutes (range 3-15 months) following treatment was 1 (IQR 0-0.9; P < 0.001 cf. baseline). Similarly, there was significant improvement in TBE findings post-therapy (mean 5-minute column height 3.5±4.1 cm; P = 0.04 cf. baseline).

Conclusion: A normal IRP for water swallows does not preclude a diagnosis of achalasia. The addition of free drinking/solids during HRM or the TBE can identify pathology that might have been missed with standard 5 mL water swallows alone as normal, clinically relevant swallowing behavior is reproduced. Patients treated based on this algorithm exhibit excellent treatment outcomes, validating this approach. Further, the close correlation of HRM adjunctive testing with TBE supports its routine inclusion in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1824 200ML RAPID DRINK CHALLENGE DURING HIGH RESOLUTION MANOMETRY PREDICTS OESOPHAGOGASTRIC JUNCTION OBSTRUCTION IN DYSPHAGIA AND IS CORRELATED WITH SYMPTOM SEVERITY IN ACHALASIA

S. Gabieta-Sonmez1, P. Woodland2, J. Arguero3, J.L.S. Ooi4, K. Nakagawa1, E. Glasmiović1, E. Yazaki1, D. Sifrini3

Introduction: In patients with dysphagia, the identification of obstruction at the OGJ level determines the need for further endoscopic or surgical therapy. Timed barium esophagogram (TBO) is regularly used to detect impaired oesophageal emptying in dysphagia and achalasia. "Volume loading" the oesophagus with a 200ml rapid drink challenge (RDC) has recently been shown to help with the diagnosis of oesophageal motility disorders. We predict that this test can evaluate OGJ efficiency at HRM without the need for further TBO study. As such we hypothesised that RDC can predict pathological barium column at TBO, and associates with symptom severity in achalasia.

Aims & Methods: 39 patients with untreated dysphagia (mean age 55yr) were evaluated. All patients underwent HRM with standard protocol plus RDC, followed by TBO. In patients with achalasia, the Eckhardt score (ES) was calculated by reviewing HRM findings. Analysis of HRM followed the Chicago Classification v3 algorithm. A normal IRP for water swallows does not preclude a diagnosis of achalasia. The addition of free drinking/solids during HRM or the TBE can identify pathology that might have been missed with standard 5 mL water swallows alone as normal, clinically relevant swallowing behavior is reproduced. Patients treated based on this algorithm exhibit excellent treatment outcomes, validating this approach. Further, the close correlation of HRM adjunctive testing with TBE supports its routine inclusion in clinical practice.

Introduction: The timed barium esophagram (TBE) is an objective measurement of esophageal (3 myotomy, 4 dilatation) used in the assessment of achalasia. Post-therapy resolution of the maximum height of the residual barium column has been found to correlate imperfectly with short-term symptomatic outcomes, but carries long-term prognostic implications. We hypothesise that the surface area (SA) of the barium column might be more accurate than height, firstly, by showing a more pronounced improvement in esophageal width that often occurs post-therapy, but also by correcting for artificially higher height values due to esophageal (longitudinal) contraction occurring during a single image. We aim to compare the correlation of TBE outcome measures of height and SA with symptom improvement post-therapy.

Aims & Methods: Inclusion criteria were achalasia patients who underwent therapy between August 2015-6 and had TBE and Eckardt score (ES) performed at baseline and 6 months post-treatment. With TBE upright single images were acquired at 1.2, and 5 minutes following ingestion of 100-200 mL of low-density barium sulfate. Barium height was measured between the gastro-esophageal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES to ≤ 3. On TBE, metrics of adequate emptying evaluated were i) post-therapy column height < 5cm, ii) > 50% reduction in column height from pre to post-therapy and iii) > 50% reduction in column SA from pre to post-therapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson's correlation (R). Paired t-tests compared TBE measures before and after therapy.

P1826 NUTRIENTS ENHANCE BELCHING AND REDUCE INTESTINAL PROPULSION OF GASTRIC GAS IN HEALTHY VOLUNTEERS

E.N. Caballero De Garcia, B. Benslaiman Seyid-Jebari, J. Serra Pueyo

Contact E-mail Address: noe caballero s uarez@gmail.com

Introduction: During meal intake, large volumes of gas can be ingested together with nutrients, and patients with gas-related abdominal symptoms often refer symptom exacerbation by meals. Previous studies have shown that under fasting conditions gastric gas is rapidly eliminated from the stomach, either via gas belching or via belching. Nutrients have several effects on gastric and intestinal motor function that could modulate gas transport and symptoms.

Aims & Methods: We aimed to determine the effect of gastric nutrients on transport of gastric gas, and its relationship with abdominal symptoms. In 7 healthy volunteers without gastrointestinal symptoms (4 women and 3 men, age-range 21-25 yrs), a mixture of non-absorbable gases was infused into the stomach, 5 cm caudal to the lower margin of the LES, at 25 mL/min during 60 min (Total gas infused: 1500 mL). In each subject two gas infusion tests were performed on separate days, with simultaneous infusion of nutrients (Nutridrink 1.5 Kcal/ml, total 315 Kcal) or saline. Belching, by an esophageal multilumen impedance manometry catheter, rectal gas evacuation, via a rectal tube connected to a barostat, and epigastric and abdominal symptoms, by specific questionnaires (from 0–6), were continuously recorded from the start of gas infusion until 30min after gas infusion stopped. (Total recording time: 90 min).

Results: During saline infusion, participants evacuated via the rectum virtually all the infused gas (1631±87 ml), with exceptional belching (1.1±0.8 belches) and mild epigastric perception (score 1.7±0.6 at the end of infusion), that decreased during the 30 min following infusion stop (score 1.1±0.4; p = 0.051 vs infusion
PI827 MODIFICATIONS OF THE ECKARDT SCORE PARAMETERS AFTER PERORAL ENDOSCOPIC MYOTOMY

M. Barret1, S. Lebano1, M. Gaudric1, M. Guillaumot1, A. Ouditi2, M. Dhogue1, V. Abitbol1, A. Chrysostolis1, R. Coriat3, S. Chassande4, F. Prat1

Contact E-mail Address: maximilien.barret@aphp.fr

Introduction: Peroral endoscopic myotomy (POEM) is a recently developed technique or the treatment of lower esophageal sphincter achalasia. POEM could be as efficient as surgical Heller myotomy, while associated with lower morbidity.

Currently, the Eckardt score is the clinical score that is the most widely used to assess the postoperative effect of the treatment of achalasia, clinical success being defined by a score below 4. However, POEM might not equally improve all four parameters of the Eckardt score.

Aims & Methods: All consecutive patients undergoing POEM for achalasia at our institution were performed by 3 operators with at least 6 months follow-up were prospectively included. Demographic, clinical, procedural, manometric and radiologic data were collected.

Results: Between March 2013 and July 2016, 62 POEM procedures were performed on 59 patients (Male/female 33/26; Median age ± SD – 54 ± 13, range (15–77)). Median (IQR) follow-up time was 8 (3–13) months. Achalasia was diagnosed for a median (IQR) of 24 (13–62) months, and 42% of the patients had a previously received treatment, by botulinum toxin injection (8%), pneumodilation (32%), or Heller myotomy (7%). Achalasia subtype were type I/II/III in 37%/47%/15% of cases. Median Eckardt score and integrated resting pressure varied from 2 (1–3) to 0 (0–1) and 1 (0–1) (p = 0.0001). Dysphagia score varied from 5 (3–7) to 3 (1–5) and 2 (0–3) (p = 0.0001), while regurgitations varied from 2 (1–3) to 0 (0–1) and 1 (0–3) (p = 0.0001), chest pain varied from 1 (0–2) to 0 (0–1) and 0 (0–1) (p = 0.0006), and weight loss from 2 (1–3) to 0 (0–0) and 0 (0–0) (p < 0.0001). At three months, median (range) drop of the integrated resting pressure varied from 16 (6–22) mmHg after 1-st procedure up visit, 86% of the patients still had clinical success, and 31% reported gastro-esophageal reflux symptoms.

Conclusion: Our results confirm the efficacy of the POEM as a first line or rescue treatment for a low complication rate. POEM is most effective on dysphagia and weight loss, while chest pain and regurgitations tend to persist after treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Achalasia is a chronic condition presenting with dysphagia, regurgitation, chest pain and/or weight loss. Management options include Heller’s myotomy, Botox, pneumatic dilatation and Per-Oral Endoscopic Myotomy (POEM). Treatments carry risks of bleeding and perforation. Concomitant portal hypertension with varices is very rare and achalasia treatment in this context has only been described in single case reports.

Aims & Methods: Experience from physicians/surgeons treating these disorders was sought through the International Manometry Working Group.

Results: 13 patients with portal hypertension from 6 international centres have been collected; mean age 61 ± 9 years. The median pre-therapy Eckardt score was 7 (IQR 6–9); 9/13 (69%) patients had a barium swallow and 12/13 (92%) had oesophageal physiology studies performed. There were 3 Type I, 6 Type II, 2 Type III achalasia and 2 with oesophago-gastric outflow obstruction. Varices had been identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 3 grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, cryptogenic in 2 and 1 had hepatitis C cirrhosis. 75% were Child-Pugh A and 25% were Child-Pugh B. Patients had diverse treatments for their achalasia. 4 were treated with Botox injections (1 with EU5, 4 had dilation alone, 3 received a POEM, another had POEM then dilation and 1 patient had Botox followed by Heller’s myotomy. 3 patients underwent variceal eradication in advance; all had banding first but in 2 patients superficial eradication was followed by a transjugular intrahepatic portosystemic shunt (TIPSS) before endoscopic dilation. All patients had symptomatic improvement with median Eckardt score post intervention = 1 (IQR 0–2) < 0.0001 compared to baseline. A matched group of 20 patients who underwent treatment for achalasia (all subtypes) but without varices had no complications of bleeding or perforation; however both patients who had TIPSS had transient hepatic decompensation.

Conclusion: This report 13 patients from international centres who have had interventions for achalasia on the background of oesophageal varices. None had bleeding complications despite only 3 having had variceal eradication. Symptom response mirrored those who undergo standard achalasia therapy,
PI830  THE NATURAL HISTORY OF ACHALASIA: EVIDENCE OF A CONTINUUM-THE PATTERN-EVOLUTIONARY STAGING THEORY
Dept. Of Surgical, Oncological And Gastroenterological Sciences, University Hospital of Padova, Padova/Italy

Contact E-mail Address: m.costantini@unipd.it

Introduction: Esophageal achalasia is classified into three clinically relevant patterns at High Resolution Manometry (HRM) and according to Chicago Classification. Currently, it is unclear whether they represent distinct entities or are part of a disease continuum.

Aims & Methods: The aims of this study were: a) to test the hypothesis that the three manometric patterns represent different stages in the evolution of esophageal achalasia and b) to investigate whether manometric patterns change after Laparoscopic Heller-Dor (LHD). We evaluated the patients who had a diagnosis of achalasia and underwent LHD as first treatment from 1992 to May 2016. Symptoms were scored using a detailed questionnaire for dysphagia, food-regurgitation, and chest pain; barium swallow, endoscopy, and esophageal manometry (conventional or High Resolution technique) were performed, before and 6 months after surgical treatment. All conventional manometric tracings, before 2010, were reviewed and re-classified according to the manometric-pattern classification, whereas after 2010 the HRM data were prospectively collected.

Results: Five-hundred and eleven consecutive achalasia patients (M:F = 283:228) represented the study population. Based on their manometric findings, 231 patients (45.2%) were classified as having pattern I, 241 (47.2%) had pattern II, and 39 (7.6%) had pattern III. Demographic and clinical data showed that pattern III cases had a shorter duration of symptoms, a more incidence of chest pain, and a less dilated gullet (p < 0.001). Further, all patients with a sigmoid-shaped mega-esophagus (radiological grade IV) had pattern I achalasia. One patient with diagnosis of pattern III achalasia, who refused any treatment evolved to pattern II at a follow-up manometry performed for a progressive worsening dysphagia after 36 months. At a median follow-up of 30 months (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%).

The only predictor of final outcome was the preoperative manometric pattern (p < 0.001). All patients (42) whose surgical treatment failed underwent one or more endoscopic pneumatic dilations using Rigiflex balloons (30, 35 or 40 mm).

The overall success rate of the combined treatment (LHD plus endoscopic dilations where necessary) was 98%. All patients with pattern I preoperatively had the same pattern after LHD, whereas more than 50% of patients with pre-treatment pattern III had patterns I or II after surgery. There were no cases showing the opposite trend (Table 1). Five patients showed signs of a partial recovery of peristalsis (all patients had a pattern II before LHD).

Table 1: Changing manometric patterns after LHD. *5 patients had a recovery of peristalsis (all patients had a pattern II before LHD).

<table>
<thead>
<tr>
<th>Pattern 1</th>
<th>Pattern 2</th>
<th>Pattern 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pattern 1</td>
<td>159 (100%)</td>
<td>0</td>
</tr>
<tr>
<td>Pattern 2</td>
<td>65 (29.5%)</td>
<td>149 (67.7%)</td>
</tr>
<tr>
<td>Pattern 3</td>
<td>7 (24.1%)</td>
<td>8 (27.6%)</td>
</tr>
</tbody>
</table>

Conclusion: The data of this study strongly support the hypothesis/theory that the different manometric patterns of achalasia could represent different evolutionary stages of the disease - where pattern III is the earlier stage, pattern II an intermediate stage, and pattern I the end stage.

Introduction: The development of non-invasive methods to detect the presence of H. pylori, and to estimate the extent and severity of gastritis, have reduced the need for diagnostic endoscopy in asymptomatic individuals. However, it is not known whether the use of non-invasive diagnostic methods is effective in dyspepsia patients.

Aims & Methods: To use a non-invasive blood test with four stomach-specific biomarkers to assess the prevalence of different stomach conditions: gastroesophageal reflux disease (GERD), H. pylori (HP) infection, chronic atrophic gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 36%, mean age 44.0 yrs, range 6-95) was selected in a primary care population and examined with a panel of biomarkers [Pepsinogen-I (PG-I) and -II (PG-II), anti-Helicobacter pylori (anti-Hp), and Hp IgG and Hp IgA] (Biohit, Finland). A standard questionnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination.

Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five categories: healthy stomach (H), GER, HP, HP+CAG, and PPI therapy.

Conclusion: The combination of data on the levels of PG-I, PG-II, G17 and HP IgG allow to diagnose different pathological conditions such as HP- and non HP-related gastritis, the appropriateness of PPI administration, GERD and CAG, a precautionary condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI832  SUSTAINED TREATMENT EFFECTS OF MENTHACARIN ON SYMPTOMS AND QUALITY OF LIFE IN PATIENTS WITH FUNCTIONAL DYSPEPSIA 8 WEEKS AFTER THE END OF A 4-WEEK PLACEBO-CONTROLLED TRIAL

Introduction: Functional dyspepsia (FD) is one of the most common functional gastrointestinal disorders characterised by chronic or relapsing symptoms with no structural or biochemical abnormalities that can be identified in the routine clinical setting. Thus, treatment targets symptoms. Very little is known about prolonged treatment for more than 4 weeks. Fifty-four of them participated in the optional follow-up phase and received Menthacarin (34) or placebo (20) for further 8 weeks according to their original randomization. The results of these 54 patients are reported here.

Aims & Methods: The aim of the additional data analysis of a previous randomized placebo-controlled trial was to explore post-treatment effects that occurred after continuation of therapy after a 4-week randomised placebo controlled treatment with Menthacarin with regard to disease-specific symptoms and QoL in FD patients. After the 4-week randomised placebo-controlled treatment period, patients were allowed to continue the treatment. The treatment was given in a double-blind fashion and allocation of treatment followed the initial randomisation. 114 adult FD outpatients were initially treated and received twice a day one enteric-coated Menthacarin capsule or a matched placebo capsule for 4 weeks. Fifty-four of them participated in the optional follow-up phase and received Menthacarin (34) or placebo (20) for further 8 weeks according to their original randomization. The results of these 54 patients are presented here. Outcomes were assessed utilising the validated self-rating Nepean Dyspepsia Index (NDI). Intra-individual differences between baseline and week 4/week 12 for NDI sub-scores for pain (sum of the NDI items ‘pain or ache in upper abdomen’), ‘burping and flatus’ and ‘food-avoidance’ were calculated.

Results: Overall, there was a significant improvement in NDI pain score (p = 0.0001) and NDI symptom score (p = 0.0001) at week 12 compared to baseline (p = 0.0001). The 50% responder rate at week 12 is 57% (50% response rate at week 4). The NDI symptom score improved by 30% (p = 0.0001) at week 12.

Conclusion: Menthacarin was significantly effective for the treatment of functional dyspepsia for up to 8 weeks. Further studies are warranted to investigate the clinical relevance and cost-effectiveness of this approach.

Disclosure of Interest: None declared.

Abstract No: P1831
after 4 weeks of randomised double-blind, placebo-controlled therapy, the score had declined by 3.7 \pm 2.1 points during active therapy as compared to 5.4 \pm 2.1 points during placebo treatment (p = 0.003). For the 12-week therapy, the score had declined by 3.7 \pm 2.5 points and 1.3 \pm 2.6 for Menthacarin and placebo, respectively (p = 0.0014). Overall QoL improvement was better for active medication for 4 and 12 weeks as compared to placebo.

Conclusion: After 4 weeks of randomised double-blind, placebo-controlled treatment with either Menthacarin or placebo, patients who received active medication are more likely to opt for a continuation of therapy as compared to patients on placebo. The gain over placebo remained significant even after 12 weeks of treatment. Menthacarin is a proprietary combination of essential oils of specified quality from Menth\textsubscript{a} piperita L. (90 mg Peppermint oil WS\textsubscript{e} 1340) and Carum carvi (50 mg Caraway oil WS\textsubscript{e} 1520).

Introduction: The introduction of proton pump inhibitors (PPIs) into clinical practice has revolutionized the management of acid-related diseases. Studies in primary care and emergency settings suggest that PPIs are frequently inappropriately prescribed or used in clinical conditions with little benefit.

Aims & Methods: To evaluate the role of Gastropanol in relation to the appropriateness of PPI-therapy prescription. 2833 dyspeptic patients (male 36\%, mean age of 44.0 yrs, range 6-95) with no alarm symptom (i.e., dysphagia, anemia, weight loss and vomiting) from a primary care population were included in the study. For each patient a blood sample was collected for serum Pepsinogen I (PG-I) and II (PG-II), Gastrin 17 (G-17) and IgG HP (Biohit, Oyj, Finland); moreover, a clinical questionnaire searching for symptoms and presence of HP, and PPI therapy were filled out. We have evaluated the following serological profiles: HP infection, chronic atrophic gastritis (CAG), response to PPI therapy. The results obtained were used to evaluate the appropriateness of PPI-therapy prescription.

Results: 1015/2583 (39.3\%) received PPI therapy up to three months before serum sampling and were included in the study. Among 1015 patients under PPI therapy, 294 (29.0\%) received half-dose PPIs, 709 (69.8\%) full-dose PPIs and 12 (1.2\%) an exceeding-dose PPIs. Patients under PPIs therapy (3.7\%) showed a serological status compatible with body CAG (the definitive diagnosis was confirmed histologically). 68 (6.7\%) presented HP infection. Table 1 shows the values of PG-I and G-17 values according to the response to PPI therapy.

Conclusion: An appropriate prescription of PPI should be preceded by the assessment of gastric functional status. In particular, patients with HP infection should be eradicated before PPI therapy, while CAG patients should not receive PPI therapy because they are no responders. Patients who do not respond to PPI therapy should be further investigated (compliance, diagnosis).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastric acid secretion is believed to decrease in the aging stomach, but the number of elderly patients on proton pump inhibitor (PPI) therapy is...
increasing. Pepsinogen I (PG1) <30μg/L, PG1/PGII <3 and gastrin-17 (G17) >10μmol/L are non-invasive serological markers to surrogate to evaluate gastric function, with a negative predictive value for chronic atrophic gastritis (CAG) of 96%.

**Aims & Methods:** Aim of the study was to evaluate gastric function by means of serology (PG1, PGII, G17 and IgG-antibodies against Helicobacter pylori) in very elderly patients, including centenarians. A total of 379 patients were prospectively enrolled (M=126, F=253, mean age=83.6±6.7, range 70-106). They were divided in four groups: 132 subjects with an age between 70 and 79 years (first group), 107 subjects between 80 and 89 (second group), 76 subjects between 90 and 99 (third group) and 25 subjects between 100 and 106 (fourth group). Demographics and drug intake, particularly the PPI intake, were collected. For all patients, serological markers were determined in fasting blood. PPI was determined by using Gastropanel® (Biohit Oy, Finland; normal values: PG1: 30-120μg/L; PG2: 2-15μg/L; PG1/PGII ratio: >3; G17: 1-9μmol/L; H.p.-IgG: <30 EU).

**Results:** In the first group (age 70-79), 18.2% of the subjects showed H. pylori infection (PG1 >80μg/L, IgG against H.p. >50 EU), 22.7% had CAG (PGI <30μg/L and PG1/PGII <3) and 53.8% were under PPI therapy. 16.9% of the patients on PPI therapy had CAG. In the second group (age 80-89), 32.9% of the patients showed H. pylori infection, 8.9% had CAG and 48.6% were under PPI therapy, 8.5% of the patients on PPI therapy had CAG. In the third group (age 90-99), 22.4% of the patients showed H. pylori infection, 10.5% had CAG and 48.7% were under PPI therapy. 8.1% of the patients on PPI therapy had CAG. In the fourth group (age 100-106), 46.0% of the patients showed H. pylori infection, 16.0% had CAG and 72.0% were under PPI therapy. 16.7% of the patients on PPI therapy had CAG.

**Conclusion:** Acid secretion is preserved in most of the elderly and very elderly subjects, even in centenarians. Serological markers may be useful to identify patients affected by CAG in which the administration of PPI is inappropriate, especially in the elderly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** duanlp@bjmu.edu.cn

**Introduction:** Reflux hypersensitivity (RHV) was lately defined as a functional heartburn in patients with a negative response to either on the different technology (3-D VS two-dimensional) or in the new contractile parameters (i.e.: DCI and DL) introduced by the two HRM systems. This is particularly relevant in the evaluation of the LES resting pressure and abdominal length may rely on the different technology (3-D VS linear transducers) or on the different algorithms and threshold used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new semisolid manometric system. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
With PPI-REE before and after a course of PPI therapy

**Introduction:**

Information on the effect of PPIs in improving high resolution manometry (HRM) documented that patients with PPI-REE present frequently motility abnormalities, mostly weak peristalsis and hypotension. Eosinophilic esophagitis (EoE) is a condition characterized by symptoms of esophageal dysfunction associated with eosinophilic infiltration in the esophageal wall. EoE is mainly found in children, however, recent studies document that EoE is also prevalent in adults. The prevalence of EoE has increased in recent years, and this increase is likely due to a combination of factors, including increased awareness of the disease, improved diagnostic techniques, and more accurate reporting of symptoms. The disease is characterized by dysfunction in the distal esophagus, which is presented by esophageal dysfunction and histologically characterized by predominance of eosinophilic infiltration. The presentation of esophageal symptoms directly linked to esophageal infiltration (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE had higher median EGJ resting pressure [baseline 11 (1–34) vs. post-PPI therapy, 9 (1–25) mmHg, p<0.001].

**Results:**

Eighty-two patients [23M:5F; mean age 33] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were included in this study. After a course of PPI therapy, patients with symptomatic suggestive of EoE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on esophageal biopsies at mid/proximal esophagus and, therefore, treated with twice-daily PPIs for at least 8 weeks. Therefore, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients with PPI-REE underwent HRM at the time of the diagnosis (off-PPI) and after the course of PPIs (on-PPI). Pathologies with achalasia and absent peristalsis were excluded (Chicago Classification v.3).

**Conclusion:**

Eosinophilic esophagitis is a chronic immune disease of the esophagus characterized by predominance of eosinophilic infiltration. In inducing motor dysfunction and related symptoms. Disclosed of interest: All authors have declared no conflicts of interest.

**Introduction:**

Eosinophilic Esophagitis (EoE) is a chronic immune disease of the esophagus characterized by predominance of eosinophilic infiltration. EoE is mainly found in patients with atopic conditions. However, recently an association with IgG4 but not with IgE has been reported. Gastroesophageal reflux disease (GERD) is the most important differential diagnosis of EoE. In this study we measured systemic serum IgG4 and IgE levels of EoE patients before and after a topic steroid therapy, correlated them to esophageal IgG4-positive plasma cells and compared them to GERD patients.

**Disclosure of Interest:**

---
A794
Aims & Methods: Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day).
Biopsies were taken from the esophagus before and after therapy for histological
and immunhistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken a as control group.
Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after
eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken
from the esophagus before and after therapy for histological and immunhistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken a as control group.
Results: Serum IgG4 levels of EoE patients were significantly higher than in
GERD patients (mean: 121.0 mg/dL vs. 71.2 mg/dL, p ¼ 0.034). In contrast, no
significant difference of IgE levels in EoE and GERD patients was observed. In
EoE patients, the number of eosinophilic granulocytes in histology was decreased
at a significant level after topic steroid therapy (mean: 51.9 eosinophiles/high
power field (hpf) vs. 6.4 eosinophiles/hpf p 5 0.001). After therapy lower levels
of IgG4-serum-levels could be measured (mean: 121.0 mg/dL vs. 104.2 mg/dL
p ¼ 0.019), whereas IgE levels did not show a significant difference.The esophageal biopsies of EoE patients showed a high number of IgG4-positive plasma
cells (mean expression of 27.4 IgG4-positive plasma cells of 46.4 stromal plasma
cells/hpf).
Conclusion: EoE patients show higher systemic IgG4- but not IgE-serum levels
compared to GERD-patients. These elevated levels normalize under effective
topic steroid therapy. Additionally high local expression of IgG4- positive
plasma cells can be seen in EoE patients. These findings might be further evidence for a possible IgG4-association of EoE.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1841 SYSTEMATIC REVIEW: HEALTH-RELATED QUALITY OF
LIFE IN CHILDREN AND ADULTS WITH EOSINOPHILIC
ESOPHAGITIS: MEASURE INSTRUMENTS AND DETERMINANT
FACTORS
Dept. De Gastroenterologia, Hospital General de Tomelloso Dept. of Digestive
Health Dept. of Gastroenterology, Tomelloso/Spain
Contact E-mail Address: alucendo@vodafone.es
Introduction: Measurement of Health-related quality of life (HRQoL) with generic or specific intruments has been increasingly used in patients suffering from
EoE to support both research and clinical care. Generic instruments aim at
measuring the overall HRQoL of patients across several conditions, being
useful to compare HRQoL across different disease states and for evaluating
health economics outcomes. Disease-specific instruments assess domains specific
to a given disease and are considered more sensitive to changes in the patient’s
health state. An up-to-date systematic review will provide a useful resource for
researchers and EoE specialists to ensure they can select an appropriate HRQoL
measure for patients in their practice in order to identify correctable factors
determining an impaired perception and to improve treatment outcomes.
Aims & Methods: We aim to systematically review the current HRQoL measures
for patients with EoE and to appraise their measurement properties using a
robust evaluation methodology checklist. We also sought to identify diseasespecific determinant factors for HRQoL in children and adults with EoE, and
the effect of investigations and interventions for EoE on HRQoL. A search
strategy was designed to identify and retrieve all documents dealing with the
relationship between HRQoL and EoE in children and adults. This systematic
literature search was performed in 5 major databases (PubMed, EMBASE,
Scopus, PsycInfo and Web of Science) for the period up to March 2017. The
measure properties of each specific EoE instrument identified and their performance properties were assessed using the quality properties checklist proposed by
Terwee et al. Levels of the HRQoL measure establishment or use in literature: we
used Cohen’s criteria. Cohort studies, case series and case reports were evaluated
for the risk of bias with the aid of the Joanna Briggs Institute critical appraisal
checklist. A descriptive summary with data tables was produced to summarize
the literature. Quantitative pooling of data was not meaningful so a narrative
synthesis of the data was undertaken.
Results: Of the 596 references identified, data was collected from 34 studies
including a total of 1,842 individual patients. Three disease-specific HRQoL
measures in EoE covering different aspects of patients’ lives and developed in
English were scored positive regarding measurement properties. Respectively, the
PedsQL inventory (including parent and child report forms) and the Peds-QoLä
EoE module were the generic and specific instruments respectively used in children, while the SF-36 and EoE-QoL-A were the most used questionnaires in
adults. EoE significantly impairs HRQoL of affected children and adolescents,
which manifests in the normal development of their daily activities, their physical
health and their mental status, with parents generally underestimating the impact
of the disease regarding children declared HRQoL. Regarding determinant factors, age was not associated with HRQoL. Number and severity of symptoms
negatively correlated with child-reported and Parent proxy-reported PedsQL
score and family impact score. Disease duration was identified as a risk factor
for a low SF-36 score. EoE impacts on a number of domains including frustration, embarrassment or fear about the disease outcomes. No significant differences in the overall QoL score were found in adult patients managed with dietary
or pharmacological therapy, with specific treatment modalities having a negligible influence on overall EoE-specific QoL. Symptoms scores determined exerted
an increased impact on swallowing anxiety and emotional impact subscales.
Female gender negatively influenced QoL scores. Disease activity, as expressed
by endoscopic findings, were also significant determinants of QoL. A higher
educational level was also found to be a strong determinant for a worse QoL.

United European Gastroenterology Journal 5(5S)
Emotional impact was the only dimension with a significantly worse score in
patients under dietary restrictions.
Conclusion: HRQoL is a relevant outcome that should be considered in clinical
practice and research of EoE. Further validation studies in several languages and
populations are required to support the use of disease-specific HRQoL measures.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1842 TREATMENT SATISFACTION OF ADULT EOSINOPHILIC
ESOPHAGITIS PATIENTS

Introduction: Available treatment options for adult EoE patients include drugs
(proton-pump inhibitors [PPI], swallowed topical corticosteroids [STC]), food
elimination diets, and esophageal dilation. Knowledge about patients’ view
regarding the different therapeutic options is very limited.
Aims & Methods: We aimed to systematically assess adult EoE patients’ satisfaction with different EoE-specific treatment modalities. We first created a questionnaire that included items that queried general demographic characteristics (7
items), EoE-specific patient history and presence of atopic disease (8 items), past
and present EoE-specific therapy (9 items), concomitant medication use (7 items),
important considerations for choice of therapy (2 items), as well as treatment
satisfaction with various therapies recalled over a period of 12 months (assessed
using the validated ‘‘Treatment Satisfaction Questionnaire for Medication’’
[TSQM], 52 items). The TSQM consists of 14 items falling into 4 scales: effectiveness (3 items), side effects (5 items), convenience (3 items), and overall satisfaction (3 items). The score for each TSQM scale ranges from 0 (dissatisfied) to
100 (satisfied). In analogy with other conditions, a score above 66.6 and 83.3
identifies patients that are ‘satisfied‘ and ‘very satisfied’ with therapy, respectively. The psychologist-guided focus groups with adult EoE patients were conducted to inform the content and the structure of the questionnaire and ensure
that patient understand the items, instructions, and response options. The questionnaire was sent to 148 patients in Switzerland. Data were double-entered by
two researchers into an EpiData database (version 3.1, the EpiData Association,
Odense, Denmark). Dataset was then imported into Stata (version 13, College
Station, Texas, USA) for analysis.
Results: Patient response rate was 73.5% (108/147). Mean patient age at inclusion was 46.3  15.9 years, 85/108 (78.8%) of patients were male, and mean
disease duration (from the time of diagnosis to the time of enrollment) was
6.8  5.1 years. In the last 12 months, 11.1%, 48.1%, 10.2%, and 28.7% of
patients reported to have suffered from symptoms of asthma, rhinoconjunctivitis,
eczema, and food allergy, respectively. In the last 12 months, 25.0%, 3.7%,
77.8%, 1.9%, 19.4%, and 13.0% were treated with PPI, STC in the form of a
syrup, STC in the form of a powder, STC in a form of a spray, diet, and
esophageal dilation, respectively (37.0% patients received more than one treatment; 7.4% of patients did not receive any treatment). Patients identified the
following considerations as important for the choice of therapy: the effect of the
treatment on the symptoms (88.9%), the effect of treatment on esophageal
inflammation (75.9%), possible side effects (69.4%), ease of therapy use
(58.3%), recommendation of the physician (50.0%), and compatibility of therapy
with lifestyle (46.3%). When asked about single most important criterion for the
choice of therapy, 48.5%, 33.7%, 11.9%, 3.0% and 2.0% of patients chose the
effect of treatment on symptoms AND esophageal inflammation, the effect of the
treatment on the symptoms, the effect of treatment on esophageal inflammation,
compatibility of therapy with lifestyle, possible side effect, and recommendation
of the physician, respectively, as deciding factor. The TSQM scales scores as well
as average TSQM values for patients on PPI, STC, and diet are shown in Table 1.
Conclusion: Adult EoE patients consider both effect of medication on symptoms
as well as inflammation as most important criteria, when choosing EoE therapy.
EoE patients appear to be ‘satisfied’ with PPI, STC, and dietary therapy and
‘very satisfied’ with STC, if the therapy is taken twice daily.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: For technical reasons, the histologic characterization of eosinophilic (EoE)-specific alterations is almost exclusively based on those found in the esophageal epithelium, whereas little is known about subepithelial abnormalities.

Aims & Methods: In this study, we aimed to systematically assess the nature of subepithelial histologic alterations, analyze their relationship with epithelial histologic findings, endoscopic features, and symptoms, and evaluate the diagnostic impact of subepithelial eosinophil counts in patients with an epithelial eosinophil count of <15/hpf. We prospectively included in this cohort study adult EoE patients who underwent assessment of clinical, endoscopic, and histologic disease activity using scores.

Results: We included 200 EoE patients (mean age 43.5 ± 15.7 years, 74% males) with a median peak count of 36 intraepithelial eosinophils/hpf (IQR 14–84). The following histologic features were identified in the subepithelial layer: eosinophil infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrosis (82%), and lymphoid follicles (56%). Peak intraepithelial eosinophil counts were higher, identical, and lower when compared to the subepithelial layer in 62.5%, 7%, and 30.5% of patients, respectively. Subepithelial histologic activity correlated with epithelial histologic activity (rho 0.331, p < 0.001), endoscopic severity (rho 0.208, p = 0.003), and symptom severity (rho 0.179, p = 0.011). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of <15/hpf.

Conclusion: In one third of patients subepithelial peak eosinophil counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophil counts can aid in diagnosing EoE in additional 40% of patients with epithelial eosinophils <15/hpf.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1844 GASTROESOPHAGEAL REFUX DISEASE PATIENTS REFUXATE TYPE INFLUENCE ON MACROPHAGE PHENOTYPE

S. Lyamina1, S. Kalish1, A. Paraskevova2, O. Soronovaya3, S. Pirogov3, A. Ponomares4, D. Rumyantseva2, A.S. Troukhmanov2, V. T. Ivashkin5

Aims & Methods: To systematically assess the nature of refluxate pH on macrophage phenotype we recruited 68 patients with different forms of gastroesophageal reflux disease (GERD), endoscopic findings, and symptoms, and evaluated the diagnostic impact of refluxate pH on macrophage phenotype. Pooled analysis of patients refluxate type influence on macrophage phenotype showed the prevalence of M1 phenotype in groups: 2.49 ± 0.15 (II) vs 1.29 ± 0.12 (III) (p < 0.05). Th2 cytokine macrophage production increased with increasing pH, and most significantly changed in II (0.84 ± 0.13 pg/mL in group I vs 27.7 ± 8.65 pg/mL in group III [p < 0.05]). The expression of surface M1/M2 macrophage CD markers significantly varied depending on the acidity of refluxate. Mild-alkaline pH (III group) resulted in increasing expression of M2 markers CD163/CD206, respectively performed by flow cytometry (Beckman Coulter FC500).

Results: Analysis of cytokine macrophage production revealed the prevalence of Th1 and Th1/Th2 bivalent (IL-17, IL-6) cytokines as compared to Th2. The most significant changes due to the influence of refluxate pH were observed in Th1 cytokine IL-8, TNFα and TNFβ. Increasing of pH resulted in 2 times-fold and 3.5 times-fold fall of these cytokines production respectively (p < 0.05). Th2 cytokine macrophage production increased with increasing pH, and most significantly changed in II (0.84 ± 0.13 pg/mL in group I vs 27.7 ± 8.65 pg/mL in group III [p < 0.05]). The expression of surface M1/M2 macrophage CD markers significantly varied depending on the acidity of refluxate. Mild-alkaline pH (III group) resulted in increasing expression of M2 markers CD163/CD206, respectively performed by flow cytometry (Beckman Coulter FC500).

Conclusion: Pooled analysis of GERD patients refluxate type influence on macrophage phenotype showed the prevalence of M1 phenotype in groups: 2.49 ± 0.15 (II) vs 1.29 ± 0.12 (III) (p < 0.05). Th2 cytokine macrophage production increased with increasing pH, and most significantly changed in II (0.84 ± 0.13 pg/mL in group I vs 27.7 ± 8.65 pg/mL in group III [p < 0.05]). The expression of surface M1/M2 macrophage CD markers significantly varied depending on the acidity of refluxate. Mild-alkaline pH (III group) resulted in increasing expression of M2 markers CD163/CD206 as compared to M1–CD80/CD25, but changing M1/M2 index of CD163/CD206 to CD80/CD25 in definite trend of increasing expression of CD1 M2 markers and increased production of Th2 cytokines as compared to the other refluxate types. Analysis of MDM phenotype showed the prevalence of M1 phenotype regardless of refluxate pH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: p.woodland@qmul.ac.uk

Introduction: The pathophysiology of heartburn perception in gastro-esophageal reflux disease (GERD) remains unclear. The degree of reflux-induced epithelial change seldom predicts symptom severity, as evidenced by the greater symptom burden seen in non-erosive reflux disease (NERD) compared to patients with Barrett’s esophagus (BE). Existing models of acid hypersensitivity are inadequate to explain this discordance.

Aims & Methods: To test the hypothesis that differences in peripheral esophageal nerve fiber distribution may be relevant, we studied the distribution of mucosal nerve fibers in patients with NERD and BE and compared the results with that of healthy subjects. 13 patients with NERD undergoing reflux testing and 16 patients with BE undergoing endoscopic surveillance were prospectively recruited. Biopsies were obtained from the proximal and distal esophageal mucosa. Contact E-mail Address: sylvia@qmul.ac.uk

P1847 BELeching PATTERNS IN PATIENTS WITH ISOLATED PATHOLOGICAL UPRIGHT REFLUX AND PATHOLOGICAL BIPOZATIONAL REFLUX
Gastroenterology, Maastricht UMC, Maastricht/Netherlands
Contact E-mail Address: j.conchillo@mumc.nl
Introduction: Belching is a commonly occurring symptom in patients with gastroesophageal reflux disease (GERD). Belching may reflect reflux. It is unknown whether GERD patients with isolated pathological upright reflux (UP) have belching patterns that are different from GERD patients with pathological bipositional reflux (BIP).
Aims & Methods: Aim of this study was to therefore examine the belching patterns of UP reflux patients as compared with BIP reflux patients. We included 50 consecutive patients with pathological reflux and typical symptoms who underwent 24-h pH-impedance monitoring at the Maastricht University Medical Centre from 2015 to 2017. Patients referred for excessive belching were excluded.
A group of 25 UP reflux patients (10 male, mean age 52.9 years (range 22–77)) and 25 BIP reflux patients (11 male, mean age 47.9 years (range 18–77)) were enrolled. All 24-h pH-impedance tracings were analysed manually. We classified belches according to: a) physiological mechanism: supragastric vs. gastric; and b) their temporal relationship with a liquid reflux episode: isolated belch, preceding or during a liquid reflux episode. Symptoms-assocation analysis was performed to assess a relationship between reported symptoms and reflux episodes.
Results: BIP patients showed higher acid reflux time (17.8 ± 2.4% vs. 7.3 ± 0.6%, p < 0.001) and higher number of total reflux episodes (121 ± 9 vs. 97 ± 8, p = 0.05) than UP patients. Notably, both the proportion of reflux episodes with belches of any type and the proportion of belches preceding liquid reflux were higher in UP patients than in BIP patients (51.7 ± 3.6% vs. 32.1 ± 3.7%, p < 0.001 and 27.3 ± 3.1% vs. 17.8 ± 2.9%, p = 0.03, respectively). No difference was found in the proportion of both supragastric and gastric belches between groups. During 24-h pH-impedance monitoring UP patients reported more symptoms (21.6 ± 6 vs. 12.4 ± 3, p = 0.16) and had more positive symptoms with belches (60.2 ± 7.1% vs. 39.0 ± 6.6%, p = 0.03) than BIP patients. Of the total number of belches that were detected using 24-h pH-impedance, more belches were symptomatic in UP patients than in BIP patients (24.8 ± 6.4% vs. 11.1 ± 3.2%, p = 0.06).
Conclusion: In our study, GERD patients with isolated pathological upright reflux had more often (symptomatic) belches than GERD patients with pathological bipositional reflux. Therefore, examination of belching patterns can assist diagnostic and therapeutic strategic planning in GERD patients who are refractory to medical therapy.

P1848 TREATMENT WITH PROTON PUMP INHIBITORS (PPI) DOES NOT REDUCE ACIDIC LARYNGOPHARYNGEAL REFLUX (LPR) DESPITE REDUCING DISTAL ACIDIC GASTROESOPHAGEAL REFLUX AND IMPROVING SYMPTOMS IN PATIENTS WITH LPR

Introduction: PPI improve LPR symptoms in many patients. It is implicitly assumed that this effect is due to reduction of acidic LPR by PPI. Here we tested this assumption. We evaluated LPR and distal gastroesophageal reflux by using simultaneous pH/impedance monitoring in laryngopharyngeal segment and in distal esophagus before and after PPI treatment.
Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux finding score (RFS) > 7, determined by ENT physician) and/or positive reflux symptom index (RSI > 13) and at least one acidic LPR episode during 24-h pH-impedance study were enrolled. The RSI, RFS and dual pH/impedance study of LPR and distal reflux were done both before and after 3 months therapy with PPI twice a day. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was positioned 4–6 cm above LES. By definition each LPR event was preceded by reflux detection in the distal esophagus.
Results: 18 patients (11M/7F, 51 ± 10yrs) completed the study. In this group the PPI treatment substantially improved the symptoms of LPR. Reflux finding score (RFS) was decreased by 40% from 9/1 ± 5/1 ± 1 (P < 0.01). The number of distal acidic reflux episodes was reduced from 17 ± 2 to 3 ± 1 (P < 0.01). Surprisingly, acidic LPR was not decreased by PPI treatment. The number of LPR with pH < 5.0 was 2 ± 0.5 vs. 3 ± 1, P = NS, and the number of LPR episodes with pH < 4.0 was 0.7 ± 0.1 vs. 0.6 ± 0.2, P = NS. Surprisingly, the number of acidic LPR episodes with pH = 5.0–6.0 was even increased (14 ± 2 vs. 21 ± 3, P < 0.05) leading to an increase in the overall number of LPR episodes by approximately 50% from 16 ± 2 to 24 ± 3 (p < 0.05). PPI treatment did not decrease laryngopharyngeal time the pH with a normal oesophageal index (RSI) did not decrease laryngopharyngeal reflux (LPR = NS).
Conclusion: Proton pump inhibitor treatment does not reduce acidic laryngopharyngeal reflux despite substantially improving symptoms in patients with objectively established LPR. This suggests that PPI treatment influences some aspects of pathogenesis of LPR symptoms that are not readily detected by laryngopharyngeal pH/impedance monitoring.

The aim of the study was to evaluate the effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the certain components of esophageal motility. 13 healthy volunteers with at least 30 days without PPI treatment were used to quantitatively assess the impact of menthol on the esophageal peristalsis and LES tone.

Aims & Methods: The effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the certain components of esophageal motility. 13 healthy volunteers without esophageal sphincter were enrolled. High-resolution manometry with a thin silicon tube attached was placed transanally so that the distal end of the tube was 5 cm above the LES. After a 5 min. adaptation period the measurement was performed in the supine position according to the protocol as follows: recording 10 min. after 10 ml of 5 ml and 3 ml water swallows of 10 and 15 ml and after that a 20 min. infusion challenge with 3 mM menthol 8 ml/min. was carried out and subsequently the water swallows in order described above were repeated. HRM tracings were manually analyzed using ManoScan software and parameters used in the Chicago classification (v3.0) were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows were obtained. These were compared before and after the menthol infusion. Paired test was used for statistical analysis.

Results: None of the subjects had any motility disorder defined by the Chicago Classification v3.0. Few volunteers reported only mild cold sensation during infusion presumed to be of the esophageal origin. The nadir LES pressure before and after menthol infusion was 7.5±0.8 mmHg vs. 7.3±0.7 mmHg, respectively (p > 0.7). IRP of 5 ml swallows was 2.8±0.6 mmHg vs. 2.1±0.5 mmHg showed significance (p = 0.01). However, difference of IRP of 10 ml and 15 ml swallows was not significant (p > 0.1, p > 0.5, respectively). Averaged IRP of 10 ml swallow [5±1.8 vs. 6.3, respectively, p = NS], for the distal swallows 814±2.1 vs. 116.2 mmHg before and after menthol infusion, respectively (p > 0.5). We found no difference in DCI in 10 ml and 15 ml swallows before and after menthol infusion. Menthol seemed to have had only a marginal insignificant effect on IRP and DCI in rapid swallow flow.

Conclusion: We quantified the effect of menthol on the esophageal function and LES pressure in healthy volunteers using high resolution manometry. The analysis of HRM tracings revealed that menthol has no effect on particular parameters of the esophageal peristalsis and esophageal motility.

P1850 ANALYSIS OF THE RELATIONSHIP BETWEEN GLOBUS PERCEPTION AND ACIDIC LARYNGOPHARYNGEAL REFLUX BY DUAL PHARYNGEAL AND ESOPHAGEAL 24-HOUR pH/IMPEDANCE MONITORING
L. Bubernakova, M. Durecik, P. Banovcin, R. Hyrdel Internal Gastroenterological Clinic, Jessenius Faculty of Medicine, Martin/Slovak Republic

Contact E-mail Address: lenka.bubernakova@gmail.com

Introduction: Globus is considered to be related to the gastroesophageal reflux disease/laryngopharyngeal reflux (LPR). However, a substantial part of subjective and self-perception of globus sensation which is impossible to measure objectively makes this symptom difficult to study. Visceral hypersensitivity and/or altered functional state of the afferent nerve endings in the hypopharynx resulting from reflux have been suggested responsible for the development of globus. We hypothesized differences in the reflux burden and esophageal/pharyngeal symptoms between the patients with LPR symptoms with globus compared to the patients with LPR symptoms without globus.

Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux symptom index (RSI > 15) and at least one acidic LPR episode during 24 h pH/impedance study were enrolled. We recruited patients that were at least 30 days without PPI treatment. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was positioned 4-6 cm above LES. For each LPR event we determined the maximal difference of pH on the pH index determined between globus positive (tick 4–5 in the RSI) and globus negative (tick 0–1 in the RSI).

Results: 19 (13M/6F) completed the study. The number of globus positive and negative patients was 11 and 8, respectively. There were no major differences between groups. Disregarding these differences there was a significant difference between the globus positive and negative group (25±2 vs. 21±2, respectively, p = NS). As for the reflux in distal esophagus, we observed no difference in the acid exposure time between the globus positive and negative patients (11.1%, respectively, p = NS). We therefore assumed differences in the results from the hypopharyngeal pH sensor. However, the number of LPR events with pH drop to <5.5 showed no significant difference between the globus positive and negative patients, either for the number of events (92±5.6 vs. 86±4.2, respectively, p = NS) or for the pharyngeal acid exposure time (45±14 vs. 88±4.2, respectively, p = NS). We speculated that more acidic LPR events (pH drop to <5.5) might be of greater relevance. However, no significant difference was found between the globus positive and negative patients either in terms of the number of these LPR events (10±2 vs. 1±1, respectively, p = NS), or the pharyngeal acid exposure time (16±6.9 vs. 42±3.6, respectively, p = NS).

Conclusion: We found no significant difference in the reflux burden in the distal esophagus/hypopharynx between the groups of symptomatic LPR patients with and without globus using 24h dual channel pH/impedance. Other factors, e.g. visceral hypersensitivity might play a role in the development of globus symptoms, even in patients with objectively established LPR.

Introduction: Sliding hiatal hernia (HH) is a frequent diagnosis during upper endoscopy (UE) in patients with GERD-related symptoms. Recently, high resolution manometry (HRM) allowed an accurate evaluation of the esophago-gastric junction (EGJ) and its sub-types (Chicago Classification V3.0; CCv3). Few data are available comparing the diagnostic accuracy of HRM and UE to detect HH.

Aims & Methods: The aim of this study was to compare the prevalence of HH obtained with UE and HRM and to determine the role of this finding by diagnosing gastroesophageal reflux disease (GERD) on the basis of impedance and pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH diagnosed with UE. After UE, all patients underwent HRM and MII-pH to investigate GERD. All tests were performed previous a 20-day wash-out from antireflux therapy. GERD was diagnosed in patients with gastroesophageal reflux symptoms with GERD and those with functional heartburn (FH), classified by means of upper GI endoscopy and impedance-pH (MII-pH) monitoring off-medication. We also aimed to develop a predictive model for distinguishing FH from GERD by using the prevalence of these HRM features. Consecutive patients with heartburn and/or regurgitation and a recent endoscopic assessment were enrolled. All patients underwent HRM to assess the EGJ and 10 single water swallows to evaluate esophageal peristalsis and EEJ function and their motility pattern were measured. Moreover, all patients underwent MII-pH off-therapy. We measured the esophageal acid exposure time (AET), mean of total impeded reflux events and symptom-reflux association analysis using both symptom association probability (SAP) and symptom association index (SI).

Results: Overall, 68 patients (39 F/29 M, median age 42.3 years) underwent HRM and MII-pH. HRM findings stratified according to MII-pH positivity for GERD are provided in Table 1. At univariate analysis, statistical differences were found in EGI pressure, EGJ-CI, mean DCI and MRS DCI/mean DCI ratio between GERD and FH. Based on logistic regression analysis and according to Hosner’s purposeful selection of covariates, a predictive model based on HRM variables was built by logistic regression analysis. The model was tested for discriminative performance by computing the area under ROC curve (AUROC), and calibration was assessed by Hosmer-Lemeshow goodness-of-fit test. The bootstrap resampling method was used to evaluate the internal validity of the model and to correct for over-fitting.

Results: Overall, 68 patients (39 F/29 M, median age 42.3 years) underwent HRM and MII-pH. HRM findings stratified according to MII-pH positivity for GERD are provided in Table 1. At univariate analysis, statistical differences were found in EGI pressure, EGJ-CI, mean DCI and MRS DCI/mean DCI ratio between GERD and FH. Based on logistic regression analysis and according to Hosner’s purposeful selection of covariates, a predictive model based on HRM variables was developed a predictive model which ultimately encompassed in HRM variables, a HRM mean DCI/mean DCI ratio (OR 1.614, 95% CI 0.993–2.895) and EGJ-CI (OR 0.952, 95% CI 0.913–0.985). The model had a fair discriminative performance (AUROC: 0.798, 95% CI 0.650–0.894) between MII-pH positivity and negativity for GERD and was well calibrated according the Hosmer-Lemeshow goodness-of-fit test (p = 0.769). The internal validation of the model by bootstrap method showed AUROC = 0.797. Considering that the predicted cut-off of the predicted probability of MII-pH for GERD which maximized sensitivity and specificity (i.e. 67.4%), sensitivity and specificity of the predictive model in predicting GERD against FH were 80.8% and 76.2%, respectively.

Introduction: Randomized controlled trials report about 30% of GORD patients complain of bothersome remaining symptoms (heartburn, regurgitation) despite PPI. The LOPA (Lost Patients) I Study of 333 GORD patients seen in general practice revealed 46% of patients experienced heartburn or regurgitation symptoms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recommended other options (<10%).

Aims & Methods: The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked the duration of their PPI therapy, satisfaction with their current condition, frequency of symptoms in the last week, whether they had previously received diagnostic evaluation or surgical consult related to GORD, whether they plan to consult a reflux specialist for further diagnostics, and reasons for dissatisfaction with their current medication treatment. “Lost Patients” were defined as those with a satisfaction score of 0 or 2 on a 5-point Likert scale (1: very dissatisfied; 2: dissatisfied; 5: very satisfied).

Results: 510 consecutive patient responses were collected within one year. Patients suffered from GORD an average of 9.6 years and prescribed PPI therapy for an average duration of 7.9 years. 70% were dissatisfied or very dissatisfied with their PPI therapy (satisfaction score of 1 or 2). 83% reported heartburn or regurgitation at least 2 days in the prior week (53% 4-7 days). 49% reported using additional medication other than their prescribed PPI at least 2 days per week (34% 4-7 days). In patients dissatisfied on PPI, most cited insufficient symptom control (78%). Reasons for dissatisfaction included: 31% cited concerns with long-term use of drugs and 27% the need for daily medication. 92% of patients had an upper endoscopy, 12% had a prior pH-meter, 7% manometry, and 9% received prior surgical consult for GORD. Of patients who never received diagnostic evaluations, 48% were not aware of any surgical anti-reflux methods, 25% were concerned about possible complications, 18% felt their condition is not serious enough, 6% were recommended against anti-reflux procedures by their doctor.

Conclusion: Chronic GORD patients who are dissatisfied with their PPI therapy are rarely offered specialized GORD diagnostic procedures or treatment alternatives. Half of the patients took medication in addition to PPI to control their symptoms. In addition to persistent symptoms, concerns of long-term PPI use and burden of daily medication play a role in patient dissatisfaction with PPI therapy.

Introduction: Autoimmune gastritis (AIG) is characterized by corpus-predominant atrophy with consequent hypo-acchlorhydria. In AIG patients dyspepsia is frequent but acid reflux symptoms are uncommon, with few data available regarding gastroesophageal reflux disease (GERD) in AIG.

Aims & Methods: Our study was aimed to define the prevalence of reflux symptoms in AIG patients, to evaluate the serological, histological and clinical differences in AIG patients with or without reflux symptoms and to investigate the pathophysiology behind these symptoms. One hundred and fifty AIG outpatients were evaluated and 87 were included in the study: 29 AIG patients with reflux symptoms (AIG-R) and 58 without (controls), selected with similar age and gender distribution. AIG-R underwent a pH-impedance (pH/I) and high resolution manometry (HRM). Serum biomarkers, EGDS, histology and anamnestic data were evaluated in both groups. Statistics was performed as indicated.

Results: AIG-R were 19% overall and 28% of them showed endoscopic esophageal lesions, with more frequent hiatal hernia than in controls (p < 0.02). pH/I diagnosis acid reflux, esophageal hypersensitivity and a normal pattern in 7%, 28% and 66% patients, respectively. The number of non-acid reflux (NAR) was higher when compared with acid ones (p < 0.0001), moreover NAR and NAR proximal extension were associated with endoscopic lesions (p < 0.03 and p < 0.05, respectively). HRM revealed normal pattern in 62% of patients, minor peristaltic disorders in 24%, and outflow obstruction in 14%. According to the new Rome IV criteria, 55% of patients presented “functional esophageal disorders” (Rome IV-IN). No differences were detected in serological marker and clinical presentation. AIG-R presented lower antrum gastritis (p < 0.07) and a trend towards lower corpus gastritis (p = 0.07) when compared with controls. The two patient with acid GERD were an OLGA 0 with mild gastrin increase and an OLGA I with short segment Barrett’s esophagus. Lower OLGA stages, lower corpus atrophy (p < 0.02) and more frequent response to PPI (p < 0.05) were associated with Rome IV-OUT status.

Conclusion: AIG-R patients are not uncommon despite the hypo-acchlorhydria. Acid reflux is rare in AIG, while motility and “functional” disorders are frequent. Lower corpus atrophy and OLGA stage in Rome IV-OUT patients, with an at least partly preserved secretion, is likely related to the presence of symptoms. Treatment should consider use of proton pump inhibitor drugs only in specific patients.

Introduction: Gastroesophageal reflux disease (GERD) is a common disorder commonly overlapping with several functional or allergic/immunological disorders, whose symptoms are related to food intake. Awareness of health care costs and potential side effects of long-term acid suppression has increased the attention in non-pharmacologic treatment for alleviating reflux symptoms.

Aims & Methods: The aim of our prospective study was to evaluate the non-inferiority of a controlled diet compared to antacid compounds in relieving reflux symptoms in patients suffering from mild GERD. We considered 500 consecutive patients referred to the Division of Allergy and Clinical Immunology of Azienda IST IRCCS San Martino of Genova for gastrointestinal symptoms associated to food intake. Patients with a clinical and instrumental diagnosis of food allergy, food intolerance, Irritable Bowel Syndrome (IBS) and Small intestinal Bacterial Overgrowth (SIBO) were excluded. Patients with a diagnosis of GERD based on clinical history represented our study population. Basal metabolic rate and calories needs of patients was assessed by means of Harry-Benedict equation corrected for their physical activity. Patients were asked to take antacids for one month. Subsequently patients discontinued medication consumption and followed an elimination diet of food commonly associated to eliciting reflux symptoms, based on their calories need. Efficacy of the two treatments was evaluated by means of a validated symptomatic questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month). A treatment was considered effective if a 50% improvement in the symptom score was recorded.

Results: After investigations 261 patients out of 500 (52.2%) were excluded because of IBS (146), celiac disease (6), nickel allergy (25), lactose intolerance (60), SIBO (10), and allergy to other foods (20). The remaining 239 patients were diagnosed as affected by mild GERD (median age 47; BMI 24; 123F/107M; no erosive reflux disease) and were included in our interventional prospective study. All patients, antacids treatment was effective in 198 cases (75.3%). Symptoms relief was reported by 220 patients (92.1%) after diet based on calories need. No differences were noted between responders and non responders in terms of BMI, age and gender. Diet was more effective than antacids treatment in relieving reflux symptoms in mild GERD (p = 0.01)

Conclusion: A structured diet regimen, tailored on the metabolic need of the patients, appears more effective than antacids alone in relieving reflux symptoms in patients with mild GERD. Further controlled studies are mandatory to confirm these preliminary data.

Introduction: Safety and efficacy of electrical stimulation of the lower oesophageal sphincter (LOS) using the EndoStim® LOS Stimulation System (Nijmegen, The Netherlands) has been demonstrated in clinical trials up to >5 years. Data on outcomes in routine clinical practice is growing.

Aims & Methods: An ongoing, prospective international multicenter web-based registry, collecting data in patients with refractory GERD symptoms, treated with ES-LOS in clinical practice. Data is collected at baseline and at routine follow-ups for 5 years. Demographics, adverse events, GORD symptoms, GORD related quality of life (GORD-HRQL) scores, use of proton pump inhibitors (PPI), and physiological data (oesophageal pH,manometry) are collected when available.

Results: 180 patients at sites in Europe and Latin America have been enrolled. Follow-up data up to 2 years is available. Median (IQR) age at the time of implant was 51 (41–60), 57% were male. All patients were taking prescription PPI at baseline. At their last follow-up between 6 and 24 months post op, 70% (84/121) were completely off PPI (p < 0.001). Median (IQR) composite GORD-HRQL score improved from 23 (17–29) preoperatively to 8 (4–15) at 6 months, 7 (2–12) at 12 months, and 5 (4–15) at 24 months (p < 0.001 at all time points, n = 154, 121, 66, 33 at baseline, M6, M12, M24, respectively). Oesophageal pH testing post-op was performed by a few sites either as standard of care or in particular situations. Median (IQR) 24-hour oesophageal acid exposure improved from 8.2% (4.6–18.4) at baseline to 4.7% (1.4–14.5) at 6 months (p = 0.26) and 3.6% (1.0–5.8) at 12 months (p = 0.04) at 12 months, 39, 10 at baseline, M6, M12, respectively). The proportion of patients with moderate to severe regurgitation decreased from 64% at baseline to 22.5% after 6 and 13.4% after 12 months. Extra-oesophageal symptoms (recurrent cough, pneumonitis, shortness of breath) and sleep disturbances also decreased substantially. Overall, dysphagia and gas were less common at 12 months than preoperatively. Four serious adverse events were reported in one patient. One myocardial infarction related sudden death at 11-month post-op, not related to the device or procedure; 1 event of asymptomatic electrode erosion into the oesophagus detected during routine endoscopy and the device safely removed during laparoscopic fundoplication; and 2 events of gastroparesis in 1 patient requiring hospitalization, possibly related to the device, were reported.

Conclusion: ES-LOS is safe and effective in treating patients with refractory GERD symptoms despite PPI in routine clinical practice. ES-LOS should be considered as a treatment option for these difficult to treat patients.

P1681 LONG-TERM RESULTS OF RADIOFREQUENCY ABLATION (RFA) IN PATIENTS WITH BARRETT'S ESOPHAGUS RELATED NEOPLASIA

J. Krajciová1, J. Malusková1, M. Kollar2, Z. Vackova1, J. Spicak1, J. Martinek1
1Department of Digestive Endoscopy, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: krajiojikem.cz

Introduction: Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is an established endoscopic treatment of early Barrett’s esophagus (BE) related neoplasia (BORN). After successful treatment, follow-up is still required as recurrences may occur. The aim of this prospective single-center case series was to assess the long-term efficacy of endoscopic treatment (RFA with or without ER) for BORN. Main outcomes were complete remission of neoplasia (CR-N) and intestinal metaplasia (CR-IM) and recurrence of IM (R-IM) and neoplasia (R-N).

Aims & Methods: A total of 99 consecutive patients with BORN have been treated with RFA and/or ER in our center (media 64 years, range 22–91), 57 patients (57.5%) had no prior therapy and 42 patients completed the treatment and were included into this analysis. The patients had been followed up during 296 patient-years (mean 3.4 years, range 0.5–6). Thirty-three patients were diagnosed with adenocarcinoma (38%), 24 patients with high-grade dysplasia (28%) and 30 patients with low-grade dysplasia (34%). Prior to RFA, ER for visible lesions was performed in 57 patients (66%). Mean length of the Barrett’s esophagus (BE) was 4.6 cm (range 1–13 cm). After treatment, the patients have undergone regular endoscopic surveillance with multiple biopsies. Recurrence of complete remission of IM (CR-IM) and complete remission of neoplasia (CR-N) were attained in 54 patients (54.3%, 65.1%; 95% CI 54.3–74.5) and 82 patients (98.8%; 95% CI 92.8–99.9), respectively. All patients who did not achieve CR-IM had macroscopic normal neo-Z-line without visible abnormality. The only one patient who macroscopic eradication of BE was not achieved due to giant hiatal hernia and who was referred for anti-reflux surgery. During the follow-up, 18 patients (13.3%, 18/134 pts) experienced a recurrence of IM and 3.8% (3/79 pts) had a recurrence of neoplasia (LGD 2x, HGD 1x). We did not encounter any patient with a subsquamous neoplasia. All recurrences occurred at the level of neo-Z-line and 6 patients with recurrent IM had also macroscopic recurrence of BE. A total of 13 patients underwent endoscopic retreatment: 7x probe-based re-RFA, 5x escape argon plasma coagulation (APC) and 1x ER. After retreatment, we achieved 100% CR-N and 54% (7/13 pts) CR-IM. Treatment-related adverse events occurred in 22 patients (25%): 12x chest pain and 10x stricture. Two patients with a stricture had to undergo surgical resection - first patient due to perforation during balloon dilatation of a post-RFA stricture, the second because of refractory post-RFA stricture after 20 sessions of dilatation.

Conclusion: RFA combined with ER for patients with BORN achieves a high success rate of CR-N with durable results. Recurrence of IM occurs in approxi- mately one-third of patients and supports continuous endoscopic surveillance even after complete eradication. Nonetheless, the majority of recurrent IM occurs within a normally appearing neo-Z-line with questionable clinical relevance.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Barrett’s Esophagus (BE) is a premalignant condition, in which prolonged gastroesophageal reflux results in intestinal metaplasia, leading to an annual risk of adenocarcinoma 0.12%/year1. The current standard of treatment is Endoscopic Resection (ER) of visible nodular lesions and Radiofrequency Ablation (RFA) that Barrett’s, which has a success rate of 92%2. For refractory cases, wide field ER, cryotherapy and other methods are used, but may have higher adverse events. We hypothesize that thicker Barrett’s tissue is less likely to respond to RFA and have developed methods to precisely measure mucosal thickness with Volumetric Laser Endomicroscopy (VLE). These methods may facilitate future studies, correlating tissue thickness with response to therapy and prediction of optimal treatment.

Aims & Methods: We performed a nested cohort study from the U.S. VLE Registry (which comprises 1000 patients) of patients with BE, who had a baseline VLE scan, followed by RFA ablation and had at least one follow up exam. We excluded patients who had any ablative therapy prior to baseline VLE. The primary outcome was the percentage reduction of Prague length after the first treatment. Secondary outcomes were: 1. complete remission of intestinal metaplasia (CRIM) during 12 months after baseline procedure, 2. complete remission of dysplasia (CRD) during 12 months after baseline procedure, and 3. number of RFA treatments necessary for complete response of intestinal metaplasia.

Results: We included 92 patients with BE (at least COM1), who had a baseline VLE scan, followed by RFA, and had no prior ablative therapy. These patients were divided into three patient groups: without prior EMR and treated with only RFA (n = 53, mean Prague length(M) = 5.396, SEM = 0.520), with prior EMR treated with combined EMR and RFA at baseline(n = 3, mean Prague length(M) = 6.67, SEM = 1.67), with prior EMR and RFA at baseline (n = 19, mean Prague length (M) = 3.816, SEM = 0.616). After determination of gastro-esophageal junction (GEJ) location on VLE, we measured mucosal thickness in 8 segments at 0.5 cm intervals from GEJ to the top of the Barrett’s tissue. The mean amount of selected cross sections in the scan for the first 40 patients was 6.33 (SEM = 0.50, n = 40). The measurements of thickness, using the subjective and objective protocol in one patient is shown in Table 1.

Conclusion: We developed an algorithm, that automatically adjusts raw VLE images in order to recognize superficial layers of the esophageal wall and measure the thickness of these different layers in Barrett’s tissue. We performed both subjective and objective methods for thickness calculation. This is the first step to the production of a biomarker for the prediction of treatment response in patients with Barrett’s Esophagus. Further research is needed to demonstrate whether one of these two measurement protocols can predict the response to RFA and ER.

Disclosure of Interest: G. Tearney; Tearney G is the co-inventor of the VLE scan; he contributed VLE expertise to be able to do the measurements. The measurements itself were done by Iris Levink.

S. Schlachter; Schlachter, S is an employee at Ninepoint Medical and manages the data of the Ninepoint registry. Schlachter, S had no influence on the outcome of the measurements. The measurements were done by Levink, I.

All other authors have declared no conflicts of interest.

Introduction: Radiofrequency ablation (RFA) of Barrett’s oesophagus (BE), with or without prior endoscopic resection (ER) of focal lesions, results in complete eradication of intestinal metaplasia (CE-IM) and complete eradication of neoplastic tissue in 96–100%, respectively.

Aims & Methods: The aim of this study was to assess if the excellent results after successful RFA for BE with high-grade dysplasia (HGD) or early cancer (EC) are sustained on the long term. We screened all patients treated with RFA, and EC were excluded. Patients were included if they were previously enrolled in 5 consecutive cohort studies in a tertiary referral center in the Netherlands. All patients who had reached endoscopic and histologically confirmed NE neo-SCJ and CE-IM after RFA were included for evaluation of long-term follow-up (FU). Primary outcome: recurrence of HGD/EC; recurrence of endoscopically visible Barrett’s mucosa. Secondary outcomes: Buried Barrett’s glands; IM in biopsies obtained distal to a normal appearing neo squamos-columnar junction (neo-SCJ); need for retreatment; sustained CE-IM and neo-SCJ at last FU.

Results: 68 patients were included (55 men, median 64 yrs, median BE C5M6). In 53/68 patients ER was performed (worst pathology: low-grade dysplasia (LGD)).

Conclusion: With 7-years of follow-up, this study presents the longest published follow-up data on RFA for BE with HGD/EC to date. Our long-term outcomes show that after successful RFA recurrence of HGD/EC is rare (3%). Recurrence of endoscopically visible BE was found in 32% of patients, however it was confined to small islands or tongues <1 cm in the vast majority of patients.

Table 1: A 14-point based questionnaire which was used to check the understanding amongst patients with Barrett’s Oesophagus (BE–Barrett’s Oesophagus; OAC–Oesophageal adenocarcinoma; PPI–Proton pump inhibitor).

<tr>
<td>12. Does or has anyone in your family suffered with BE or OAC?</td>
<td>36 (35)</td>
<td>68 (65)</td>
</tr>
<tr>
<td>13. Do you feel or have you ever felt anxious about your diagnosis of BE?</td>
<td>53 (51)</td>
<td>51 (49)</td>
</tr>
<tr>
<td>14. Do you think it would be useful for your understanding or reduce your anxiety if you either sat down with someone in clinic or spoke to someone over the phone regarding your BE?</td>
<td>82 (79)</td>
<td>22 (21)</td>
</tr>
</tbody>
</table>

Conclusion: We have demonstrated that patients with BE have a relatively poor understanding of their diagnosis and the treatment options that are available to them. Further efforts need to be made to address this and help empower a group of patients who are understandably anxious about their diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

BARRETT’S ESOPHAGUS IS ASSOCIATED WITH TOTAL SERUM ADIPONECTIN IN WOMEN, BUT NOT WITH OTHER INFLAMMATORY OR METABOLIC MARKERS

M. Jovani1, Y. Cao1, D. Fekanich2, B. C. Jacobson3, A. T. Chan1
1Clinical And Translational Epidemiology Unit, Massachusetts General Hospital, Boston/United States of America/MA
2Channing Division Of Network Medicine, Department Of Medicine, Brigham and Women’s Hospital and Harvard Medical School, Boston/United States of America/MA
3Boston University Medical Center and Boston University School of Medicine, Boston/United States of America/MA

Contact E-mail Address: manol.jovani@email.harvard.edu

Introduction: Data on the association between inflammatory and metabolic biomarkers and Barrett’s oesophagus (BE) are scant and conflicting.

Aims & Methods: We aimed to study the association between circulating inflammatory biomarkers (interleukin-6 [IL-6], high-resolution C-reactive protein [hsCRP], intra-cellular adhesion molecule [ICAM], tumor necrosis factor receptor-2 [TNF-R2]) and metabolic biomarkers (leptin, adiponectin, C-peptide, insulin-like growth factor 1 [IGF-1], and insulin-like grow factor binding proteins -1, -2 and -3 [IGFBP1, -2 and -3]) with BE. This was a case-control study, nested within two female-only prospective cohort studies (Nurses’ Health Study 1 and 2) and one male-only prospective cohort (Health Professional Follow-up Study). Participants of provided biennial detailed information on demographic, lifestyle, dietary and medical factors, including endoscopy use. Overall, 80,437 participants enrolled in these cohorts provided a prediagnostic blood specimen between 1989 and 1995. Among these participants, through 2012, we identified 283 cases of BE (163 females and 120 males). Two study physicians, blinded to biomarkers results, reviewed the medical records of patients reporting BE. We matched BE cases to controls in a ratio of 1:2 by sex and year of birth. A total of 1044 controls were identified.

Results: In women, plasma adiponectin was significantly associated with BE (p-value = 0.01). When compared to the lowest quintile (Q1), the tetra latent odds ratio (OR) for the highest quintile (Q5) of adiponectin was 0.39 (95%CI 0.17, 0.88). This association was not materially altered after further adjustment
Conclusion: There was little evidence that pre-diagnostic inflammatory or metabolic biomarkers are associated with risk of BE. Only adiponectin was associated with a decreased risk of BE in women but not in men. These findings may serve to inform future clinical risk assessment for BE and shed light on potential mechanisms of its pathogenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1866 OUTCOMES OF TREATMENT OF PATIENTS WITH EARLY-STAGE ADENOCARCINOMA OF THE ESOPHAGUS WITH INCipient SUBMUCOSAL INVASION, RETROSPECTIVE ANALYSIS OF 19 CASES FROM A TERTIARY REFERRAL CENTER IN THE UK

B. Eros1, C. Clishby2, C. Gordon3
1Gastroenterology, Royal Bournemouth Hospital, Bournemouth/United Kingdom
2Endoscopy, Royal Bournemouth Hospital, Bournemouth/United Kingdom

Contact E-mail Address: xeroxal@yahoo.co.uk

Introduction: Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early neoplasia, but not enough data exists regarding the use on the patients, in whom the EMR’s histologic assessment identifies early-stage adenocarcinoma of the oesophagus with incipient submucosal invasion (pT1b smI).

Aims & Methods: We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BE, who underwent EMR from October 2010 to December 2016. We investigated the size of the EMRs, the complication rates of the EMRs, the histological features and the resection margins of the EMR specimens and also the outcomes with the mortality.

Results: A total of 99 patients underwent 134 EMR procedures, and the histology identified early adenocarcinoma with incipient invasion of the submucosa in 25 patients. 23 (92%) were male, the mean age at the EMR was 71 years (SD: 8.1). In all 25 EMR 9 (36%) patients had a single piece, 7 (28%) patients had a 2 piece, 7 (28%) patients 3 piece and 4 (16%) patients 4 piece EMR. The median length of the circumferential and maximum extent of the BO segments were 2 and 5 cm respectively (interquartile range (IQR) 2-4). We observed 6 (24%) intra-procedural bleedings and 2 (8%) patient needed admissions with post procedural bleeding and 1 (4%) of them required transfusion. Stricture was endoscopically detectable but not causing any symptoms in 1 (4%) patient and another patient (4%) had slight dysphagia post EMR, but did not need dilatation. Histology showed lymphovascular invasion in 6 (28%) patients and vascular invasion in 1 (4%) patient. Of all 25 early adenocarcinomas 7 (28%) were reported as poorly differentiated, 11 (44%) as moderately differentiated and 3 (12%) as well differentiated. In 4 (16%) cases differentiation was not reported. All resection margins were reported as being clear from dysplasia or cancer. There were 2 (8%) cases, radial resection margins were reported with dysplasia in 3 (12%) cases and with cancer in 15 (60%) cases, but this included the multiple piece EMRs. The deep margin was reported as being clear in 18 (72%) cases, with dysplasia in 1 (4%) case and with cancer in 6 (24%) cases. There were 5 (20%) patients with carcinoma on the radial and/or deep margin of the EMR specimen, of these patients 9 (60%) had oesophagectomy and in the histologic assessment of these specimens, lymph node involvement was observed in 2 cases (22.2% of all oesophagectomies and 9.5% of all surviving and currently cancer-free patients). There was no residual cancer in 3 (33.3%) of the surgical specimens. Radical radio-chemotherapy was given in 1 (6.7%) patient and 3 (33.3%) patients did not have radical treatment for clinical reasons. There were 10 (40%) patients without cancer invasion of the EMR resection margins, of these 4 (40%) had oesophagectomy and 1 (10%) radical radio-chemotherapy. The histologic assessment of these surgical specimens showed residual cancer in 3 (30%) cases and high-grade dysplasia in 1 (10%) case. Of the 25 patients 5 (20%) met the criteria and had radio frequency ablation of the residual Barrett’s oesophagus. Of the 13 (52%) patients who had oesophagectomy 1 (7.7%) patient died of the deterioration precipitated by the oesophagectomy, and sadly in this case the oesophagectomy specimen did not show residual cancer. Of the 12 (48%) patients who did not have oesophagectomy 3 (25%) died since their EMR, 1 (8.3%) of cardiac arrest, 1 (8.3%) of chronic obstructive pulmonary disease and 1 (8.3%) of advanced oesophageal cancer, 18 months after the EMR, and the 9 (75%) surviving patient are all cancer free on follow up investigations, one after radical chemoradiotherapy. The median survival of all 21 (84%) patients currently alive is 25 months (range: 2-68 months; SD: 22.2).

Conclusion: This retrospective analysis we have found that the clinical outcomes are very difficult to predict for patients with early adenocarcinoma and incipient invasion of the submucosa. Clinical decision making remains very challenging and has to be individualised for all patient, until further in depth studies gives us more useful prognostic factors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1867 THE USE OF ENDOCYSTOSCOPY FOR THE EARLY DETECTION OF ESOPHAGEAL NEOPLASMS

S. M. Chan1, P. W.Y. Chiu1, A. Y.B. Yeoh3, H.C. Yip1, V. Wong1, E. Ng2, J.Y. Lau3
1Surgery, The Chinese University of Hong Kong, HK/Hong Kong PRC
2Institute of Digestive Disease Room 94020 7/F, Liut Che Woo Clinical Sciences Building, Prince of Wales Hospital, Shatin, N.T., Hong Kong/ Hong Kong PRC
3Pomerantz School of Medicine, The University of Pennsylvania, Philadelphia, PA, USA

Contact E-mail Address: shannonechan@surgery.cuhk.edu.hk

Results: From July 2015 to March 2017, forty-four patients were included in the study. Seventeen of the forty-four (38.6%) patients had histological confirmed cancer of the esophagus. There were sixteen patients who had normal finding and nine patients with epithasia. The positive predictive value for malignancy (ECA 4 and 5) was 89.5%; the negative predictive value was 100%. Sensitivity was 100% and specificity was 92.6%. Similar findings were noted with IPCL on magnifying NBI. The positive predictive value for malignancy (IPCL 4 and 5) was 100%; the negative predictive value was 99.7%. Sensitivity and specificity were also similar at 100% and specificity 92.6% respectively. To compare the diagnostic accuracy of endocystoscopy and magnifying NBI, the McNemar test was performed. The McNemar chi-squared statistic is NaN, meaning that the two tests have the same diagnostic accuracy.

Conclusion: Endocystoscopy had a high positive predictive value and sensitivity for esophageal malignancy. Its diagnostic accuracy was comparable to magnifying NBI. It may be helpful as an adjunct for better characterization of esophageal lesions. However, further studies on interobserver variability is required.

Introduction: Early detection of esophageal cancers can significantly reduce the mortality. The incorporation of endocystoscopy incorporating the endocystoscopy function into a magnifying endoscope has been designed. Previously, Inoue et al have published a pilot trial on evaluating the use of this endocystoscopy in various types of benign and malignant pathology. We aimed to evaluate clinicopathological findings and outcome.

Aims & Methods: All consecutive patients who had esophagogastroduodenoscopy (EGD) arranged for screening of the esophagus during the period July 2015 to March 2017 were included in the study. EGD with narrow band imaging and endocystoscopy were performed in these patients. During the procedure, the esophageal mucosa was stained with 0.5% methylene blue and then with crystal violet. The endocystoscopic findings were graded from 1 to 5 according to the Inoue’s ECA classification. The esophageal mucosa was also evaluated with narrow band imaging (NBI) and the findings were classified according to the Intrapapillary capillary loop (IPCL) pattern classification. These findings were compared against the gold standard of histopathological diagnosis which was based on the Lauren classification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1868 CLINICAL OUTCOMES OF ENDOCYSTOSCOPIC RESECTION FOR ACHALASIA-ASSOCIATED SUPERFICIAL ESOPHAGEAL CANCER

Gastroenterology, Showa University Koto-Toyosu Hospital, Tokyo, Japan

Contact E-mail Address: nishikawa6@med.showa-u.ac.jp

Introduction: Esophageal achalasia is considered to be a high-risk factor for superficial esophageal cancer. But there are few reports of endoscopic resection for this cancer, and the outcome is unclear. In our hospital, we have performed over 1300 Per-Oral Endoscopic Myotomy procedures for esophageal achalasia and related esophageal abnormalities. In this process, we diagnosed 10 superficial esophageal cancers in patients with achalasia. We performed endoscopic resection for all cases and report relatively long-term outcome.

Aims & Methods: We aimed to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. This is a case series study at our hospital. Between August 2010 and February 2017, 10 achalasia patients with superficial esophageal cancer underwent endoscopic resection. We performed in all cases upper gastrointestinal endoscopy using narrow’s solution and narrow band imaging. We included all patients that had early cancers that were eligible for endoscopic resection in this series. At 2 and 12 months after treatment, we performed follow-up endoscopy in all cases. After this, we performed long-term endoscopic follow-up every year. In the case that the tumor invasion depth is to the muscularis mucosae(MM) on histopathology, we performed endoscopic follow-up every 6 months and CT scan.

Results: There were 6 men and 4 women and their average age was 61.7 years. 8 patients were diagnosed with lesions before POEM. We performed endoscopic submucosal dissection (ESD/EMR;9/1) in all cases after POEM. None of the patients had a severe adverse event. The mean tumor diameter was 30mm (range: 5-80mm). The pathological diagnosis was 8 SCC, 2 high grade intraepithelial neoplasia. Out of the SCC cases, 7 were found with superficial lesion with depth of Tis-EP to T1a-LPM, and 1 with depth of T1a-MM, without lymphatic invasion(0) or venous invasion(0). Follow-up surveillance mean term was 32 months (range: 1–
only patient who had venous involvement was 92 years old, and followed up without an additional therapy. 6. Local recurrent rate was 0%. 7. LNM rate of EP and SEP was 0% and 5.7% (2/35), respectively. One of two patients who had LNM was a 76-year-old male. He had SEP SCC without lymph duct involve- ment. A cervical LNM was diagnosed 6 months after ESD. Lymph node dissec- tion (LND) and chemoradiotherapy (CRT) was performed for the patient. The patient died of other disease without recurrence of pharyngeal SCC. The other patient also had a cervical LNM and treated by lymph node dissection + CRT. The patient is alive without recurrence for 10 years after ESD. 8. Prognosis No patient died of pharyngeal SCC after ESD.

Conclusion: ESD is a safe and useful treatment for superficial pharyngeal SCC. However, surveillance of LNM is important for the patients who had SEP SCC.

Introduction: While definitive chemoradiotherapy (CRT) showed high efficacy for patients with high-risk early esophageal cancer (EEC), approximately 40% of patients develop local failure, resulting in poor long-term survival. However, there is no definitive biomarker which is useful to predict survival outcome after CRT for ESCC. Several studies have investigated the correlation of expression of CD24, cytokeratin 4 (CK4), or podoplanin (PDPN) with prognosis of various malignant tumors who underwent surgical resection. However, it remains unclear whether the expression of these proteins can predict the outcome of CRT for patients with EEC.

Aims & Methods: The aim of this study was to clarify the predictive values of expression of CD24, CK4, and PDPN for ESCC patients who received CRT. Among patients with ESCC who received CRT or curative esophagectomy with extended lymph node dissection (OPE) as an initial treatment between 2005 and 2015 at our institution, cohorts were selected based on the following criteria: clinical stage II, III (UICC-TNM classification 6th edition), age of 75 years old or younger, ECOG Performance Status 0–1, and no prior or concurrent other cancers. The method of immunohistochemistry (IHC) was utilized to examine the protein expression of CD24, CK4, and PDPN in pretreatment biopsy specimens of ESCC. The cut-off values for CD24, CK4, and PDPN expression were used hazard ratio for overall survival (OS). The prognostic factor of CD24, CK4, and PDPN expression were statistically analyzed. OS was calculated from the date of CRT or OPE to the date of death or last follow-up, using the Kaplan-Meier method. The survival predictors identified by univariate analysis was assessed by multivariate analysis using a Cox’s proportional hazards model.

Results: 148 ESCC patients (CRT group, n = 83; OPE group, n = 65) were analyzed. In the CRT group, 40 patients had stage II and 43 patients had stage III, and the 5-year OS was 52%. In the OPE group, 32 patients had stage II and 33 patients had stage III, and the 5-year OS was 66%. By univariate analysis, there were significant variables for OS in differences between CRT and OPE group. The cut off value for CD24, CK4, and PDPN expression were 20%, 10%, and 20%, respectively. While the expression equal to the cut off value or more was defined as strong, the expression less than the cut off value was defined as weak. The frequency of strong protein expression was 50% for CD24, 12% for CK4, 65% for PDPN, respectively. In the CRT group, the OS of patients with strong CD24 expression was significantly better than that of patients with weak CD24 expression (p = 0.015; strong/weak 5-year OS: 65%/43%). On the other hand, CD24 and strong CD24 expression was poorer OS comparing with patients with weak expression in the OPE group, however there was no significant difference (p = 0.286; strong/weak 5-year OS: 57%/74%). Strong CD24 expression was significantly different between CRT group and OPE group (p = 0.046), however there was no significant difference between CRT and OPE group in patients with weak CD24 expression (p = 0.009). There were also no significant differences of the OS based on expression of CK4 or PDPN between the CRT and OPE group, respectively. Multivariable analysis showed the strong CD24 expression in the CRT group (p = 0.012; HR = 2.787; 95% CI: 1.253–6.200) as an independent variable for favorable outcome.

Conclusion: CD24 expression was significantly associated with the survival outcome in EEC patients when used in combination with CRT. Furthermore, weak CD24 expression might be a useful predictive biomarker of poor outcome for CRT in EEC patients.

Introduction: Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland will culminate in a single duct. The esophageal submucosal gland ducts (ESMGDs) can traverse the subepithelial connective tissue and muscularis mucosa, and deliver the acinar secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement accompanied by early esophageal cancer (ESMUDG) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesion has not been reported widely. While since the 1990s, the esophageal lesions presumed to originate from ESMGDs had been described constantly in various case reports. Currently, in addition to the gold standard of histopathology, almost no useful modality could be applied to this lesion. In our study, we considered that the ESMUDG had a correlation with early esophageal cancer, and we noted that the ESMUDG had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESMUDG.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing ESMUDG accompanied by early esophageal cancer, which were suggested by conventional endoscopy or endoscopic ultrasonography (EUS). We included consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2016. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined Endoscopic Submucosal Dissection(ESED). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, all patients (371 males and 148 females, with a mean age of 67.5±4.5 years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESMUDG by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESMUDG, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESMUDG were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intraepithelial neoplasia. One case was diagnosed as ESMUDG in EUS, but confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESMUDG were 85.0% (34/40) and 99.8% (478/478) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/480).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lesion performed as a hypoechoic sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESMUDG as well as a high positive predictive value.

Introduction: Endoscopic treatment is a standard therapeutic approach for patients with Tla early esophageal cancer (EEC). In patients with ‘high-risk’ Tla EEC, the treatment of choice is endoscopic mucosal resection (EMR), whereas for patients with Tla early esophageal cancer (EEC), and in patients with any submucosal (sm) invasion (Tlb), surgery is recommended as a standard of care. However, recent data suggest, that endoscopic treatment might be curative in selected patients with ‘high-risk’ EEC. Aims & Methods: The aim of this study was to assess outcomes of endoscopic treatment in patients with ‘high-risk’ EEC. ‘High-risk’ cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of the following: poor differentiation (G3/G4), invasion to blood (A+) or lymphatic vessels (L+) and high tumor cell dissociation (TC3D). The main outcome measurement was tumor-free survival. A single-center, retrospective analysis of prospectively collected data. Patients with EEC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Based on histopathological staging, patients with ‘high-risk’ features underwent endoscopic submucosal dissection (ESD). Based on histopathological staging, patients with ‘high-risk’ features continued in endoscopic treatment consisting of further sessions of ER and/or radiofrequency ablation if necessary. The patients have been followed up for a median of 39 months (range 2–156).

Results: Of the total of 56 patients with ‘high-risk’ EEC underwent endoscopic treatment: 21 patients (41%) had Tla cancer with ‘high-risk’ features and 35 patients (59%) had Tlb cancer with sm invasion (sm1: 15; sm2: 9, sm3: 11); 45 patients had adenocarcinoma (EAC), 11 patients had squamous carcinoma (SCC); 19 (34.5%) were referred for surgery and 37 patients were referred for endoscopic treatment. Complete local remission (CLR) of neoplasia was achieved in 35/37 patients (95%). Two patients without CLR continued endoscopic therapy with palliative intent. Tumor generalization occurred in 2 patients (one of them achieved CLR) 24 months after endoscopic treatment (both patients had sm3 invasion, A+, L+ and these patients are undergoing oncological treatment. All remaining patients with CLR (n = 33) have experienced neither local relapse nor generalization. One patient had to undergo surgery due to esophageal related perforation. Tumor-free survival was 89% (CI 79–99%) in patients treated endoscopically and endoscopic related mortality was 0% (0/37). Among 19 patients who were referred for esophagectomy, one patient presented with tumor generalization revealed during the operation. The remaining 18 patients underwent esophageography; local residue of malignancy was present in 5/18 patients (28%). Lymph node (LN) metastases have not been detected in any patient among the 337 examined LNs. Surgery related mortality was 6% (1/18).

Conclusion: Endoscopic treatment provides long-term remission or cure in a considerable number of patients with ‘high-risk’ EEC and it may thus represent a valid alternative to surgery. Brodening of indications for radical endoscopic treatment of early EEC should be reconsidered.

Introduction: Preoperative Neutrophil to Lymphocyte Ratio (NLR) has been proposed as a prognostic marker in several solid tumors (Templeton 2014). A retrospective prospective study of 60 patients showed the prognostic relevance of NLR as a predictor of response in esophageal cancer patients treated with chemoradiotherapy. The aim of this study is to assess the NLR prognostic strength in a retrospective series of two high-volume centers.

Aims & Methods: A retrospective review of two prospective esophageal cancer database was conducted. Neutrophil to lymphocyte ratio was defined as the prochemoradiotherapy serum neutrophil count divided by lymphocyte count. We dichotomized the NLR data using as cut-off values 2.5 and 3 respectively. Univariable logistic regressions were performed to determine the effect of NLR on response after neoadjuvant treatment. Survival curves were constructed with Kaplan Meier method and compared with the long rank test.

Results: We included of 280 patients. The analysis of NLR as predictor of pathologic complete response (pCR) showed a OR of 0.963 (95% CI 0.531–1.746, p = 0.991) and 1.161 (95% CI 0.647–2.081, p = 0.617) considering as cut-off values 2.5 and 3 respectively. In our large series, NLR did not result as a predictive marker neither in terms of Overall Survival nor in terms of Disease Free Survival (p = 0.997 and p = 0.672 respectively).

Conclusion: Our results did not confirm NLR as a significant marker of pCR. Moreover, the survival analysis did not reveal significant differences using NLR as a preoperative predictive marker. The heterogeneity of treatments, the complexity of the disease, the absence of a validated and pre-defined NLR cut-off value in the available literature are the main limits to our analysis. Further studies are needed to assess the clinical relevance of NLR as a predictive marker of response to neoadjuvant treatment.

ACCELERATION OF HEALING OF PREEXISTING GASTRIC ULCERS BY CARBON MONOXIDE RELEASING MOLECULE -2 (CORM-2), INVOLVEMENT OF HEME OXYGENASE, OXIDATIVE STRESS AND PROINFLAMMATORY MECHANISMS

Physiology, Jagiellonian University Medical College, Cracow/Poland

Contact E-mail Address: kataryzyna.magierowska@uj.edu.pl

Introduction: Carbon monoxide (CO) is produced endogenously in the body as a by-product of heme degradation via activity of the enzyme heme oxygenase (HO-1). This gaseous mediator with multidirectional biological activity exerts anti-inflammatory, anti-fibrogenic, and immunomodulatory properties. The newly discovered class of compounds, named CO-releasing molecules (CORMs), is capable of releasing CO gaseous molecule that can be useful as pharmacological tool to assess the pathobiological role of CO under experimental conditions. CORM-2 was implicated in gastrointestinal protection against formation of acute gastric lesions but the contribution of CO to the mechanism of ulcer healing has not been fully elucidated.

Aims & Methods: We determined the effect of daily treatment with vehicle or CORM-2, on healing of preexisting gastric ulcers induced by serosal application of acetic acid (ulcer area = 28 mm²) in rats. Our second goal was to examine the mechanism of CO released from its donor by the determination of the CORM-2-induced alterations in gastric blood flow (GBF) at ulcer margin, the parameters of oxidative stress and the gastric mucosal expression of pro-inflammatory and anti-inflammatory factors. Groups of seventy rats with gastric ulcers (A-D) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 up to 10 mg/kg i.g., C) the HO-1 inhibitor, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinc protoporphyrin IX (ZnPPIX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNF-α and IL-1β levels were analyzed by ELISA and TNF-α, HO-1, HO-2, COX-1, COX-2, iNOS, eNOS mRNAs were analyzed by RT-PCR and Western blot. Gastric mucosal samples were collected for the assessment of MPO activity, level of reduced glutathione (GSH) and lipid peroxidation products (MDA + 4HNE) by spectrophotometric method.

Results: Treatment with CORM-2 significantly reduced the area of gastric ulcers and significantly raised GBF at ulcer margin. The dose accelerating ulcer healing up to 10 mg/kg (CORM-2) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 up to 10 mg/kg i.g., C) the HO-1 inhibitor, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinc protoporphyrin IX (ZnPPIX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNF-α and IL-1β levels were analyzed by ELISA and TNF-α, HO-1, HO-2, COX-1, COX-2, iNOS, eNOS mRNAs were analyzed by RT-PCR and Western blot. Gastric mucosal samples were collected for the assessment of MPO activity, level of reduced glutathione (GSH) and lipid peroxidation products (MDA + 4HNE) by spectrophotometric method.

Results: Treatment with CORM-2 significantly reduced the area of gastric ulcers and significantly raised GBF at ulcer margin. The dose accelerating ulcer healing up to 10 mg/kg (CORM-2) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 up to 10 mg/kg i.g., C) the HO-1 inhibitor, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinc protoporphyrin IX (ZnPPIX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNF-α and IL-1β levels were analyzed by ELISA and TNF-α, HO-1, HO-2, COX-1, COX-2, iNOS, eNOS mRNAs were analyzed by RT-PCR and Western blot. Gastric mucosal samples were collected for the assessment of MPO activity, level of reduced glutathione (GSH) and lipid peroxidation products (MDA + 4HNE) by spectrophotometric method.

Results: Treatment with CORM-2 significantly reduced the area of gastric ulcers and significantly raised GBF at ulcer margin. The dose accelerating ulcer healing up to 10 mg/kg (CORM-2) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 up to 10 mg/kg i.g., C) the HO-1 inhibitor, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinc protoporphyrin IX (ZnPPIX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNF-α and IL-1β levels were analyzed by ELISA and TNF-α, HO-1, HO-2, COX-1, COX-2, iNOS, eNOS mRNAs were analyzed by RT-PCR and Western blot. Gastric mucosal samples were collected for the assessment of MPO activity, level of reduced glutathione (GSH) and lipid peroxidation products (MDA + 4HNE) by spectrophotometric method.
CORM-2 was accompanied by a significant decrease in plasma levels of IL-1β and TNF-α when comparing to vehicle-control group. The expression of IL-1β, TNF-α, COX-2 and iNOS mRNA was strongly upregulated in vehicle-treated gastric mucosa but expression of these factors was significantly attenuated in CORM-treated animals. The increased mucosal expression of mRNA for HO-1 but not HO-2 was detected in vehicle control group and these effects were ameliorated by treatment with CORM-2. The gastric mucosal MPO activity and thermocanal content of MDA + 4HNE in gastric mucosa were elevated in vehicle-control group and these effects were significantly inhibited by CORM-2. Consumption of CORM is donor CORM’s specific property that decreases the levels of pre-existing gastric ulcerations by the mechanism involving an increase in gastric microcirculation at ulcer margin, the inhibition of inflammatory response as manifested by the attenuation of enhancing synthesis of the proinflammatory markers IL-1β, TNF-α, COX-2 and iNOS as well as by antioxidant properties of CORM-2 releasing CO limiting lipid peroxidation.

P1878 PROTON PUMP INHIBITORS INAPPROPRIATE USE IN PATIENTS ADMITTED IN A TERTIARY HOSPITAL AND IN THE COMMUNITY

Introduction: There is evidence of proton pump inhibitors (PPIs) misuse in the community and in the hospitals causing significant direct and indirect costs burden for the health care system.

Aims & Methods: We aimed to evaluate the frequency of inappropriate PPIs administration in hospitalized patients, to measure the direct in-hospital costs of PPI misuse and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, cardiac, psychiatric, obstetrics and day clinic admission were excluded) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and on discharge. Patient’s data was collected for patients prescribed PPIs overuse and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model.

Results: We included data from 470 patients aged 67 ± 19 yrs; 32.5% were pre-scheduled admission, 65.9% during hospitalization and 72.8% at discharge. PPIs overutilization was detected in 15.7%, 41.3% and 12.6% of the patients before, during and after the admission, while medications underutilization was detected in 10.2%, 8.1% and 9.5% of them, respectively. Adverse drug reaction and orthostatic hypotension was associated with the highest unadjusted ORs (1.68 [95% CI 1.63–1.72] and 1.68 [1.59–1.78]) for PPIs misuse, 80% of the 193 over treated patients received PPIs iv (80% of them od, 20% bid) while the rest were treated with PPIs per os (80% of them od, 10% bid) during hospitalization. This accounts for 140 PPI iv and 344 PPI per os doses inappropriately given during the observation period. Taking into account in our simulation model that there are 90 on-call days of our hospital’s activity, the cost of each PPI iv dose is 3.435 and 0.235 euros for iv and per os preparations and assuming a similar to that of our sample case distribution for the next 12 months, we calculated the direct hospital costs burden of inappropriate PPIs use at 154940 euros per year. Using the same model, 1200 patients would be at risk of UGI complications annually, due to under prescription of PPIs at discharge.

Conclusion: Hospitalization does not represent an opportunity for optimization of PPIs utilization. On the contrary, the frequency of PPIs inappropriate use during hospitalization is higher than that of outpatient admission, causing significant direct costs for the hospital and exposing patients to the risks of UGI complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1890 ENDOSCOPIC RESECTION OF ADVANCED AMPULLARY ADENOMAS: A SINGLE-CENTER 14-YEAR RETROSPECTIVE COHORT STUDY

Aim: To assess the technical success, complications and recurrence of endoscopic resection for treating patients with ampullary adenomas with intraductal extension (AIE), and patients with lateral spreading adenomas (LSA). Between January 2002 and November 2016, all patients were identified by using ENDOBASE and we provided a search in our local PALGA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists. Endoscopic success was described as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Methods: The aim of our study was to evaluate the technical success, complications and recurrence of endoscopic resection for treating patients with ampullary adenomas with intraductal extension (AIE), and patients with lateral spreading adenomas (LSA). Between January 2002 and November 2016, all patients were identified by using ENDOBASE and we provided a search in our local PALGA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists. Endoscopic success was defined as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Results: We included 84 patients, 56 patients (67%) had an adenoma confined to the ampulla (ACA), 17 patients (20%) had a LSA and 11 patients (13%) were treated for adenomas that demonstrated growth pattern with intraductal extension. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6 mm (range 0–80). The median follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–37) for IAE (P = 0.039). Complications occurred in 26 patients (30.9%), of which hemorrhage was most seen in 17.9%, followed by perforation in 5.9% of the patients. Complications were equally divided over these three groups (P = 0.775). The mean follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–37) for IAE (P = 0.036). Endoscopic resection was curative in 87.5% of patients with a localized adenoma, 82.3% in patients with a lateral spreading adenoma and in only 9.1% of patients with an intraductal extended tumor (P < 0.000). Recurrence occurred in 9 patients (10.7%), 5 of them had a localized adenoma, 3 patients with a lateral spreading adenoma and 1 patient with an intraductal extended adenoma (P = 0.875).

Conclusion: Endoscopic ampullactomy is a safe and successful treatment in patients with an adenoma with or without a lateral spreading growth pattern. In contrast, an intraductal extended adenoma endoscopic success rates are significantly lower.

P1879 CONTINUOUS INCREASE IN PREVALENCE OF FUNDIC GLAND POLYPS WITH THE LENGTH OF PROTON PUMP INHIBITORS USE. IS THERE ANY CLINICAL CONSEQUENCE?

R. Kroupa1, M. Dastych1, S. Konecný1, J. Dolins2

1Department of Internal Medicine and Gastroenterology, University Hospital and Faculty of Medicine Masaryk’s University, Brno/Czech Republic

Contact E-mail Address: kroupa.radek@ffbrno.cz

Introduction: Proton pump inhibitor (PPI) usage is associated with an increased risk of development of fundic gland polyps (FGP). The trend of change in the prevalence with increasing length of PPI exposure over 5 years is not known. Theoretical risk of FGP seems to be very low for clinical consequence in management.

Aims & Methods: To evaluate the relationship between the length of PPI use and risk of fundic gland polyps. Prospective cohort study in patients referred for upper gastrointestinal endoscopy between years 2015–2016 was performed. The length of PPI use was ascertained from direct patient interview and confirmed from medical records. The prevalence of FGP in history not continuing at the time of endoscopy was also queried. FGP were determined both endoscopically and histologically. Odds ratios for subsequent intervals of length of PPI use were calculated. Clinically relevant complications—dysplasia and bleeding from large polyps were recorded.

Results: During study period 1525 patients (mean age 59.2 years, 53% male) were included. Only 612 (40%) of patients had no history of any PPI use. Fundic gland polyps were identified in 170 patients (11%) and only 13 of them (7.6%) were without PPI use. The prevalence of FGP in subgroup of patients according to the length of PPI use was: 10.6% of 161 patients using PPI less than 1 year, 9.4% of 405 (1–4 years of PPI), 25.2% of 230 (5–9 years of PPI), 35.1% of 94 (10–15 years of PPI) and 47.8% of 23 patients using PPI more than 15 years. The approximate odds ratios were 57.6 (2.6–11.4), 4.8 (95% CI 8.5 (CI 8.3–29.0), 24.9 (CI 12.4–49.5) and 42.2 (CI 15.7–113.1) respectively, all with statistical significance (p < 0.001). Only 1 case of low grade dysplasia within FGP was observed in the patient with familiar adenomatous polyposis. Polyps larger than 15 mm with signs of bleeding determined as a case of sidereopenic anemia were diagnosed in 6 patients.

Conclusion: The prevalence of FGP is permanently growing during prolonged use of PPI. Complex source of informations regarding history of PPI use identified quite low proportion of patient with FGP and without prior PPI use. Rather rare complications like bleeding from FGP might be clinically significant in increasing number of long term PPI users. The requirement of repetitive endoscopies and therapeutic interventions may burden gastroenterologists and sources.

Introduction: There are few reports about the technical difficulty of gastric endoscopic submucosal dissection (ESD) which were investigated through the prospective trial.

Aims & Methods: The aim of this study was to evaluate the factors associated with the technical difficulty of ESD for early gastric cancer (GC) which met expanded indication criteria using data from JCGOG0607. The major inclusion criteria of JCGOG0607 was as follows: 1) histopathologically proven intestinal-type adenocarcinoma; 2) cT1aN0M0; 3) lesion without finding of ulcer (UL negative) and 4) age 20-75. ESD were performed by certified endoscopists or under the supervision of certified endoscopists. 162 cases (55%) had the studied 100 cases or more. The difficult case was defined that ESD took 120 minutes (min) or longer, and/or developed perforation during procedure. Multivariate analysis was performed to investigate the clinical factors associated with technical difficulty of ESD.

Results: Between June 2007 and Oct. 2010, a total of 470 patients (pts) (male/female: 385/85, median age 65y-o (range: 40–75)) were enrolled from 29 institutions. The difficult case was defined that ESD took 120 minutes (min) or longer, and/or developed perforation during procedure. Multivariate analysis was performed to investigate the clinical factors associated with technical difficulty of ESD.

Comparison of clinical characteristics and therapeutic outcomes between STER and EFTR

STER (n = 15) EFTR (n = 28) P
No. of clips for suture 5.8 ± 1.4 7.6 ± 1.6 0.001
Complications, % 6.7% (1/15) 14.3% (4/28) 0.643
En bloc resection, % 6.7% (1/15) 3.6% (1/28) 1.000
GIST/Liomomyoma/Schwannoma 11/4.0 25/2.1 0.173
Length of stay, d 6.1 ± 1.5 6.2 ± 2.0 0.856
Cost, USD 3260.0 ± 618.3 3237.5 ± 615.8 0.906
Follow-up time, mon 12.1 ± 12.2 22.8 ± 18.4 0.052

Conclusion: The treatment efficacy between submucosal tunneling endoscopic resection and endoscopic full-thickness resection for treating gastric fundus submucosal tumors was comparable, but submucosal tunneling endoscopic resection offers advantages over endoscopic full-thickness resection in terms of shorter surgery time and smaller number of clips needed to close the gastric wall defect.

P1884 COMPARISON OF THE DIAGNOSTIC YIELDS OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION FOR DUODENAL AND GASTRIC SUBEPITHELIAL LESIONS
K. Nakamura
Gastroenterology, St. Luke’s International Hospital, Chuo-ku/Japan

Contact E-mail Address: nakamen@lukaike.ac.jp

Introduction: The progress of diagnosis and treatment for gastrointestinal subepithelial lesions (SELs) have been remarkable by the wide use of Endoscopic Ultrasound-Guided Fine Needle Aspiration (EUS-FNA) and the development of Laparoscopy and Endoscopic Cooperative Surgery. EUS-FNA is used widely for SELs that occur in the digestive tract. There are many reports on gastric SELs, but there are no studies on a large group of patients focusing on duodenal SELs.

Aims & Methods: The aim of this study was to investigate the usefulness and safety of EUS-FNA for duodenal SELs, comparing them with gastric SELs. Cross-sectional study was conducted using 41 patients who underwent EUS-FNA at tertiary medical center in Tokyo between April, 2012 and February, 2017. We divided into 2 groups: 6 patients with duodenal SELs (group D) and 35 patients with gastric SELs (group G). Tumor location was not significantly different between the two groups. Median specimen was the same in both groups with no significant difference: 43 mm and 15 mm, respectively. The en bloc resection rates (96.3% and 97.8%) and the curative resection rates (82.5% and 84.6%) were not significantly different. The perforation rates were not statistically different (2.44% and 3.21%). However, the postoperative bleeding rate (5.28% vs. 2.72%: p = 0.05), postoperative delirium (2.0% vs. 0.25%; p = 0.009) and pneumonia (2.0% vs. 0.25%; p = 0.009) were significantly higher in the elderly group (30.9% vs. 17.0%: p < 0.0001.). Comorbidities were significantly higher in the elderly group including heart disease (24.8% vs. 10.5%: p < 0.0001), lung disease (13.6% vs. 7.4%: p = 0.002) and diabetes (13.3% vs. 1.0%; p = 0.009). Tumor location was not significantly different between the two groups.

Conclusion: Endoscopic ultrasound-guided fine needle aspiration biopsy of submucosal lesions including duodenal SELs can be applicable in elderly patients, and our results are expected to be useful in EUS-FNA study for duodenal SELs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is widely used as a standard treatment for superficial tumors in the GI tract and its safety has been established. Opportunities for elderly patients to undergo ESD for early gastric cancer is increasing due to the continued improvement in life expectancy. However, short-term and long-term outcome of ESD for elderly patients is still uncertain because of the high incidence of comorbidities and possible increased risk of complications related to ESD in this population.

Aims & Methods: Therefore, we investigated the safety, efficacy and short-term outcome of gastric ESD for patients over 80 years old. Additionally, we evaluated the long-term outcome of non-curative resections according to both age groups. 1056 lesions in 886 patients treated with ESD between January 2011 and December 2015 in our hospital were retrospectively reviewed. They were classified into two groups; elderly group > 80 years old (346 lesions in 201 patients) and non-elderly group > 79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delirium, pneumonia), were compared and we considered the safety, efficacy and short-term outcome of non-curative ESD, cases performed between 2011 and 2013 were assessed.

Results: The median age was 83 years old (range: 80–92) in the elderly group and 67 years old (range: 36–78) in the younger group. The ratio of female patients was significantly higher in the elderly group (30.9% vs. 17.0%: p < 0.0001). Comorbidities were significantly higher in the elderly group including heart disease (24.8% vs. 10.5%: p < 0.0001), lung disease (13.6% vs. 7.4%: p = 0.002) and diabetes (13.3% vs. 1.0%; p = 0.009). Tumor location was not significantly different between the two groups.

Conclusion: Concerning the long-term outcome of non-curative ESD, cases performed between 2011 and 2013 were assessed.

Disclosure of Interest: All authors have declared no conflicts of interest.
published guidelines regarding appropriate surveillance of patients with GIC and how to safely and efficiently perform and interpret follow-up biopsies. GIC is associated with a varying risk of progression to GC, and a genetic predisposition is a major risk factor. The goal of this study is to evaluate the risk of progression of GIC in family history GC and 887 (81.4%) did not have. Genotype of TGFB1 was obtained from surgery, endoscopic submucosal dissection (ESD), endoscopy, histology and outcomes were reviewed.

**Results:** 160 patients (including those with Barrett’s oesophagus, GIC and family history of gastric cancer) were enrolled on the surveillance programme. 42 patients with GIC were identified–20 females (47.6%) and 22 males (52.3%). The mean age at which GIC was first diagnosed was 60.6 years (range from 7.9 to 71.5 years). 15/42 patients (35.7%) had a co-existent Barrett’s oesophagus and Helicobacter pylori was identified in 6/42 (14.3%). The follow-up period ranged from 0.5 to 17.3 years. 27 patients had repeat gastroscopies following initial diagnosis. 15 patients are still awaiting a repeat gastroscopy. A large degree of variability in the number and frequency of follow-up gastroscopies was observed. The average interval of follow-up gastroscopies was 3.3 years per person. 14/27 patients (51.8%) had no evidence of GIC on most recent gastroscopy, 7/27 patients (26%) had repeat findings of persistent focal GIC, 5/27 patients (18.5%) progressed to extensive GIC. No cases of dysplasia were recorded but 1 patient (3.7%) developed gastric cancer.

**Conclusion:** This study suggests a low apparent risk of progression of gastric intestinal metaplasia in a small western cohort. Further studies may be necessary to address if the applicability of published surveillance guidelines can be generalised to regions with low gastric cancer prevalence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS) has to be described recently only in a few families worldwide (only one in Europe till now). Three different point mutations in promoter 1B of the APC gene were identified as causol (c.191T>C, c.192A>G, and c.195A>C). We diagnosed GAPPS in the second Czech white family (not related to that one published previously–ref. 1).

**Aims & Methods:** We diagnosed GAPPS across 3 generations in a new Czech white family. A genetic analysis of the family was performed.

**Results:** The Proband (a 43-year-old male) was endoscopically regularly surveyed from his 34 years of age because of fundic-gland polyposis with predominant involvement of the gastric fundus and body (with relative sparing of the lesser curve) and microcytic anemia. Polyposis slowly progressed with the intestinal differentiated low-grade dysplasia in polypyctomy specimens 10 years after the diagnosis. As the GAPPS criteria were fulfilled (ref. 2), he and his family underwent genetic testing and bi-directional Sanger sequencing of promoter 1B revealed a point mutation (c.–191T>C). The same type of mutation was described in his father (63 years old), sister (41 years old), nephew (son of his sister, 6 years old), uncle (father’s brother, 51 years old) and 2 cousins (uncle’s daughters, 23 and 27 years old), all have been asymptomatic. No gastric cancer in the family history was mentioned. The Proband underwent preventive total gastrectomy, histology of the surgical specimen confirmed severe involvement of gastric body with fundic gland polyps, low-grade and focal high-grade dysplasia. The microcytic anemia improved rapidly after surgery. The rest of family is scheduled for gastroscopy. The fundic-gland polyposis of similar distribution (with significantly lower number of polyps, without any dysplastic changes) was recently diagnosed in the 23-year-old cousin.

**Conclusion:** The second European family with GAPPS is presented. The recently described mutations in promoter 1B of the APC gene does not automatically mean a faster progression of the disease as suggested earlier. GAPPS can be presented with various phenotypes with a different course of disease, the prevalence can be higher than previously reported. Acknowledgement: The study was supported by the Research Project PROGRES Q40–15.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1889 ENDOSCOPIC TREATMENT FOR LATERAL SPREADING SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA

Introduction: ESD is the one of the options of treatment even for lateral spreading (size is over 5 cm) esophageal squamous cell carcinoma (ESCC). Endoscopic diagnosis is developed by magnified endoscopy, however accuracy of diagnosis for lateral spreading ESCC is not high. Some patients have to undergo additional treatment because tumor is invaded to submucosal layer or lymphvascular invasion. On the other hand, wide resection by ESD could cause the delay of additional treatment because of the treatment for esophageal stricture after ESD. Thus, treatment strategy for lateral spreading ESCC has to include additional treatment after ESD. Aim of this study is to evaluate our treatment strategy for lateral spreading superficial ESCC.

Aims & Methods: From January 2010 to December 2014, 49 cases of lateral spreading superficial ESCC were resected by surgery or ESD. Diagnosis, treatment methods and outcomes are evaluated. Our indications for additional treatment after ESD are the cases of over pT1b (SM2) or lymphvascular invasion. Results: In 49 cases of lateral spreading superficial ESCC, 32 cases were treated by ESD and 17 case were treated by surgery. All lesions of 32 cases are completely resected by ESD. Average size of tumor treated by ESD is 59.4mm(50-88mm). Accuracy of estimated depth of invasion by endoscopy for ESD cases was 65.7%. Four of 32 cases of ESD underwent additional therapy (3 for surgery and 1 for CRT) because of pT1b (SM2) or lymphvascular invasion, and one case has lymph-node metastasis. Rate of stricture after ESD was 20.0% for sub-circumferential ESD and 77.3% for circumferential ESD instead of steroid injection. Average time and duration for control of esophageal stricture by Baloon Bougie is 13.5 times and 18 weeks. In 17 surgical cases, all cases are treated by thoracoscopic esophagectomy. Average size of tumor treated by surgery is 76.5 mm (50-130 mm). Accuracy of estimated depth of invasion by endoscopy for EUS combined diagnosis was 97.1% (34/35), and the negative predictive value was 98.8% (478/484).

Conclusion: The esophageal submucosal gland duct involvement is a kind of endoscopic performed diagnosis pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESCMID as well as good sensitivity and specificity.

Introduction: miRNAs are a group of small non-coding RNAs that dysregulate in various types of cancers [1–3]. They play a pivotal role in several pathological processes. Growing evidence show that miRNAs can act as either tumour oncogenes or suppressors in different types of cancers. Previous studies revealed that miR-211-5p could suppress melanoma proliferation, migration, and invasion [4]. Aims & Methods: We aimed to investigate and characterize the biological roles of miR-211 in the development of gastric cancer. The expression level of miR-211-5p was measured in paired primary gastric cancer with corresponding adjacent nontumoral gastric mucosa by RT-PCR. Furthermore, we investigate the biological role of miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines in vitro. Results: The expression levels of miR-211-5p were significantly decreased in gastric cancer and low expression of miR-211-5p correlates with poor prognosis in gastric cancer patients. Ectopic expression of miR-211-5p suppressed proliferation, migration and induced apoptosis in gastric cancer cell lines in vitro. Bioinformatics and quantitative analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation and migration of gastric cancer cells and Overexpression of FoxC1 partly abrogated the inhibitory effects of miR-211-5p on gastric cancer cell proliferation and motility. Conclusion: We confirm that miR-211-5p acted as a tumour suppressor by targeting FoxC1 in gastric cancer and miR-211-5p might be a potential target for the treatment of gastric cancer.

associated, in our series, with a higher incidence of residual/recurrent adenoma, when compared to sporadic adenomas. These results are similar to those reported in the literature. Residual and recurrent duodenal adenomas were successfully retreated by EMR in all of them but one. Mortality related to NASDA was absent in our series after a median follow-up of 59 months (range 1–147). The incidence of interventional radiologists and surgeons with experience in retroperitoneal surgery. In our experience colorectal adenomas was correlated to NASDA (33.3%), colonoscopy is considered part of the pre-EMR assessment when NASDA is diagnosed. A recall system and patient’s compliance to endoscopic follow-up are mandatory to detect recurrences and their prompt treatment.

ACh on T (nicotinic receptor agonist, increased the number and size of T, while hexamethonium, a selective muscarinic receptor agonist, increased the number and size of T as compared to control conditions (p<0.001).

Results: ACh at concentrations of 0.1 and 1 μM significantly increased the number and size of T as compared to control conditions (p<0.001). Bathemonium, a selective muscarinic receptor agonist, increased the number and size of T, while hexamethonium, a nicotinic receptor agonist, significantly inhibited the stimulatory effect of ACh on T (p<0.001 as compared to ACh-stimulated cells). Interestingly, L-NAME, significantly inhibited the effects of ACh on the number of T. Conversely, SNP, at 1 and 10 μM, increased the number and size of T. Finally, ACh induced the expression of CSC markers (CD44, ALDH and EMT markers (Snail, ZEB1 and Vimentin)) on gastric cancer cells.

Conclusion: This study shows that ACh induces CSC properties of gastric cancer cells through type via activation of muscarinic and nicotinic pathways. It also shows that ACh effects are, at least in part, mediated by nitric oxide pathway. These results suggest that ENS may be a new actor in gastric carcinogenesis.

Aims & Methods: In this study, we investigated whether activation of gGlu-HMRG fluorescence detects a wild-type of H. pylori (WT) and a ggt gene disrupted mutant of H. pylori (ggt mutant). In addition, we investigated whether activation of gGlu-HMRG fluorescence was suppressed in H. pylori culture solution which was co-incubated with an inhibitor of GGT (GGsTop). Furthermore, we applied gGlu-HMRG to biopsy specimens which were taken from antrum and corpus of stomach in H. pylori positive patients (n = 13) and H. pylori negative patients (n = 14). We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J2 software (National Institutes of Health, Rockville, Maryland).2

Results: Activation of gGlu-HMRG fluorescence was detected in WT strain, but was not in ggt mutant strain. Activation of gGlu-HMRG fluorescence was inhibited by GGsTop. There was significant difference of the increase of fluorescence intensity between H. pylori positive and negative both in antrum corpus of stomach (antrum p = 0.0008, corpus p = 0.047).

Conclusion: GGT-activated fluorescent probe can be useful for H. pylori infection diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1903 SEROLOGICAL CHANGES AFTER EQUIVOCAL HELICOBACTER PYLORI-SEROLOGY TEST FINDINGS DEPEND ON THE GASTRIC SECRETING ABILITY

J.H. Kim, S. Lee, S.P. Lee, J.H. Kim, I. Sung, H.S. Park, C.S. Shim Internal Medicine, Gastroenterology, Konkuk University Hospital, Seoul/Korea, Republic of

Contact E-mail Address: kjhcess@gmail.com

Introduction: The serum anti-Helicobacter pylori (H. pylori) IgG and serum pepsinogen (PG) assays are widely used for gastric cancer screening. An equivocal serology test finding indicates IgG titre between the positive and negative test findings.

Aims & Methods: The study aim was to evaluate the long-term, follow-up result after an equivocal test finding on the serum anti-H. pylori IgG assay. Koreans above 18 years-old with an equivocal serum anti-H. pylori IgG assay finding were included. Subjects were excluded if they did not undergo H. pylori serology test, serum PG assay, and upper gastrointestinal (UGI) endoscopy on the same day at our center. Annual test findings were followed up using the same methods.

Results: Of the 7,178 subjects who underwent the serum assays and UGI endoscopy on the same day, 274 (3.8%) subjects showed an equivocal H. pylori serology test finding. Of the 98 followed-up subjects, 58 (59.2%) showed sero-positive finding at the mean follow-up period of 30.6±12.4 months. Subjects with seroconversion showed a higher initial serum PG I (p = 0.023) and PG II (p = 0.036) levels than the subjects without seroconversion.

Conclusion: An equivocal H. pylori serology test finding is not rare (3.8%) in Korean adults, and 60% of the equivocal subjects show seroconversion within 3 years. Higher seroconversion rates in the subjects with high PG I and PG II levels suggest that intact gastric secreting ability play a role for the survival of H. pylori. Therefore, equivocal subjects with increased serum PG levels should be considered as a potential seropositive subjects.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The diagnosis of Helicobacter pylori (H.p.) infection is currently made by means of non-invasive (Urea Breath Test or HpSA) or invasive (gastric biopsy or culture) methods. Serological assessment of H.p. infection by using levels of IgG is not recommended. Pepsinogen II (PGII) is validated in the literature as a non-invasive marker of gastric inflammation. Aim of the study was to assess in a population of dyspeptic patients the clinical availability of PGII determination in singling out subjects infected by H.p. in comparison with non-infected ones.

Aims & Methods: A cohort of 880 consecutive dyspeptic patients (F 439; mean age 55.5 yrs; range 29.83-93 yrs) were enrolled in the study. Exclusion criteria: previous surgery, previous H.p. eradication therapy, concomitant PPI. In all patients the diagnosis of H.p. infection was made by means of upper GI endoscopy and at least one of these two methods: UBT, HpSA. All patients underwent blood sample for determination of serum levels of PGII (Biobit Oyj; Finland; normal values: 2-15 μg/l). In a group of 670 pts a course of antibiotics (triple, concomitant or sequential therapy) to cure H.p. infection was performed and PGII levels were assessed at baseline (T0) and after two months (T1) from the end of the antibiotic therapy. The search for the most appropriate cut-off of PGII in diagnosis of H.p. infection was assessed by using the ROC curve method.

Results: 430 out of 660 dyspeptic patients (F 245;mean age 52.3 yrs; range 32-69 yrs) showed an H.p-related gastritis (group1) in comparison with 430 (F 261; mean age 57.3 yrs; range 38-74 yrs) resulted negative for H.p infection (group 2). The mean value of PGII in group 1 was 20.9±6.1 opposite to 7.2±1.7 in group 2; p<0.0001. 415 out of 670 patients treated with antibiotics schedules were cured from H.p infection, opposite with 255 non-eradicated ones. In the group of cured patients, the PGII values at T0 were 16.5 in comparison with 8.6 at T1; p<0.001. The cut-off for PGII in the diagnosis of H.p infection, by comparing the 430 H.p positive pts and the 430 negative ones with method of ROC curve identified the mean value of 10.6 μg/l, youden index J=0.997.

Conclusion: serum PGII levels seem able to perform diagnosis of H.p infection in dyspeptic patients, as well as the efficacy of antibiotics treatment for H.p eradi- cation, being 10.6 μg/l the best cut-off in singling out infected from non-infected subjects.

Introduction: The Urea Breath Test (UBT) is considered the gold standard non-invasive test for detection of Helicobacter pylori infection in Ireland. In Ireland, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. With this in mind, it is important to optimise management of H. pylori infection. It has been suggested that the DOB value is reflective of the amount of bacteria present in the stomach and could predict whether the infection is eradicated.

Aims & Methods: The aim of this study was to determine whether there is an association between DOB and eradication of H. pylori infection in an Irish cohort. Treatment naïve adult patients undergoing UBT were included. Patients were deemed to be H. pylori positive if a Delta Over Baseline (DOB) value of > 10% was obtained. Positive patients were categorised into low (< 16%), intermediate (16-35%) and high (> 35%) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at 8 weeks post-treatment to confirm eradication of H. pylori in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBT’s assessed (mean age 43.3 ± 15.2 years, 39% male), 289 (33.6%) were positive (mean age 43.1 ± 14.9 years, 41.9% male). Of the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of H. pylori. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between the groups (p = 0.06 for age, p = 0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p = 0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly lower than the DOB value compared to unsuccessful (p = 0.03, 95% CI 0.69 to 17.5). 46 (50.5%) patients were patients categorised for triple therapy for 7 days. When this subset of positive patients was categorised into low, intermediate and high UBT groups, eradication rates were 76.2%, 75% and 70% respectively. When these rates were compared to respective rates in those whose treatment was not known, no difference was observed. The subset was also categorised according to eradication status. When eradication was successful, the average DOB value was lower, at 22.0 ± 30.2% compared to 29.8% when eradication was unsuccessful (p = 0.03, 95% CI 0.69 to 17.5). Similarly, when these DOB values were compared to respective values in whose treatment was not known, no difference was observed.

Conclusion: As the DOB value increases in the UBT, the eradication rate of H. pylori decreases, regardless of treatment regimen. When categorised according to eradication status, the DOB value was significantly lower when eradication was successful (20.6% vs 29.8%, p = 0.03). The DOB value could be a useful value in stratifying patients with H. pylori infection; especially as histology and antimicrobial resistance information is unavailable in patients undergoing non-invasive testing for H. pylori infection.

P1908 COMPARISON OF THE EFFICACY BETWEEN BISMUTH AND ALTERNATING RIFAXIMIN ON SECOND-LINE QUADRUPEL THERAPY REGIMEN OF HELICOBACTER PYLORI ERADICATION

Dietetic Disease Center, Institute For Digestive Research, Soonchunhyang University College of Medicine, Seoul;Korea, Republic of

Contact E-mail Address: junspark@schmc.ac.kr

Introduction: Bismuth is a heavy metal which has antimicrobial activity through its inhibition of bacterial metabolism. Rifaximin has been confirmed as 92.7% (789/851, PPS) as the strongest HP eradication therapy in Japan. The aim of this study was to determine whether there is an association between DOB and eradication of H. pylori infection in an Irish cohort. Treatment naïve adult patients undergoing UBT were included. Patients were deemed to be H. pylori positive if a Delta Over Baseline (DOB) value of > 10% was obtained. Positive patients were categorised into low (< 16%), intermediate (16-35%) and high (> 35%) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at 8 weeks post-treatment to confirm eradication of H. pylori in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBT’s assessed (mean age 43.3 ± 15.2 years, 39% male), 289 (33.6%) were positive (mean age 43.1 ± 14.9 years, 41.9% male). Of the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of H. pylori. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between the groups (p = 0.06 for age, p = 0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p = 0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly lower than the DOB value compared to unsuccessful (p = 0.03, 95% CI 0.69 to 17.5). 46 (50.5%) patients were patients categorised for triple therapy for 7 days. When this subset of positive patients was categorised into low, intermediate and high UBT groups, eradication rates were 76.2%, 75% and 70% respectively. When these rates were compared to respective rates in those whose treatment was not known, no difference was observed. The subset was also categorised according to eradication status. When eradication was successful, the average DOB value was lower, at 22.0 ± 30.2% compared to 29.8% when eradication was unsuccessful (p = 0.03, 95% CI 0.69 to 17.5). Similarly, when these DOB values were compared to respective values in whose treatment was not known, no difference was observed.

Conclusion: As the DOB value increases in the UBT, the eradication rate of H. pylori decreases, regardless of treatment regimen. When categorised according to eradication status, the DOB value was significantly lower when eradication was successful (20.6 % vs 29.8%, p = 0.03). P1909 COMPARISON OF 10-DAY STANDARD TRIPLE THERAPY AND LEVOFLOXACIN BASED THERAPY FOR HELICOBACTER PYLORI ERADICATION: RANDOMIZED CONTROLLED TRIAL

M.K. Kang, S. Lee, M.C. Kim, K.H. Kim, K.O. Kim, B.I. Jang, T. Kim
Internal Medicine, Yeungnam University College of Medicine, Daegu;Korea, Republic of

Contact E-mail Address: kmggood111@naver.com

Introduction: Standard triple therapy (STT) has been widely used in Helicobacter pylori infection, but eradication rate is decreasing because of clarithromycin resistance. Recently, Levofloxacin-based therapy (LBT) has been evaluated to overcome the low eradication rate of standard triple therapy and reported eradication rate over 80%.

Aims & Methods: We compared the efficacy and safety of STT group and LBT group for Koreans. Between April 2014 and April 2016, 49 patients in the STT group (amoxicillin 1g bid, clarithromycin 500mg bid and esomeprazole 20mg bid for 10 days) and 48 in the LBT group(levofloxacin 500mg bid, amoxicillin 1g bid, PPI Rabeprazole (RPZ) b.i.d. for 7 days. The judgement of success or failure on eradication was done with UBT breath test on 3 months later after eradication therapy to avoid false negative results.

Results: Success rate of VAC 800 showed significantly high (416/428 = 97.2%, PPS) than VAC 400 (373/423 = 88.2%, PPS) (p < 0.001). The average eradication rate of VAC regimens was 92.7% (789/851, PPS). On the other hand, success rate of RAC 800 showed high (190/245 = 77.6%, PPS) rather than RAC 400 (140/198 = 70.7%, PPS) (p = 0.125). The average success rate of RAC regimens was 74.5% (330/443, PPS). The average success rate of VAC regimens was significantly higher than the average success rate of RAC regimens (330/443 = 74.5%) (p < 0.001). These results suggest that using high dose CAM with VPZ (P-CAB) plus AMX regimen might be the strongest H. pylori eradication triple therapy regimen to overcome CAM resistance.

Conclusion: High-dose CAM with Vonoprazan (P-CAB) plus AMX triple therapy regimen is the strongest H. pylori eradication therapy even if CAM resistance. We will be able to expect significantly high success rate (more than 97%) on HP 1st eradication therapy.
TREATING HELICOBACTER PYLORI INFECTION
WILL TAILORING THERAPY FIRST TIME EVERCOME INCREASING FAILURE OF STANDARD TRIPLE THERAPY?

D. Brennan, M. Hussey, D. Tighe, C. O’Morain, S. Smith, D. Menamara
Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland

Contact E-mail Address: dbrenn9@tcd.ie

Introduction: In Ireland, Helicobacter pylori infection has become increasingly resistant to commonly used antibiotics, such as clarithromycin. Concurrently, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. Aims & Methods: To compare eradication rates of standard clarithromycin-based triple therapy with that of tailored therapy based on antimicrobial susceptibility as a first-line treatment for H. pylori infection. Treatment-naïve adult patients undergoing endoscopy were prospectively recruited. Biopsies from H. pylori-positive patients (assessed by CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType HelicoDR assay (Hain). Results: To date 889 patients have undergone endoscopy and 186 (21%) were H. pylori positive. Infected patients were significantly younger (mean age 53 vs 49 years, p = 0.002) and tended to be male (43% vs 55%, p = 0.02). Of 186 H. pylori-positive patients, 112 (60%) were treatment naïve. Culture of H. pylori was successful in 75% (64/112) of samples and primary clarithromycin resistance was 47% (30/64) by E-test. Genotypic resistance data was available for 93% (92/99) of samples. The eradication efficacy of tailored therapy by intention-to-treat analysis was higher at 74% (40/54) compared to 67% (n = 30.45) for standard therapy (p = 0.5). The eradication efficacy for per-protocol analysis was also higher, at 82% (40/49) for tailored versus 70% (30/43) for standard therapy (p = 0.2). Patients in each arm were further categorised by clarithromycin resistance status, phenotypically by E-test and genotypically by the GenoType HelicoDR assay. Of note, in clarithromycin resistant patients, tailored therapy achieved a better eradication rate per protocol analysis than standard triple therapy (83% vs 57% per protocol, p = 0.09).

Conclusion: In those who are sensitive to clarithromycin, standard clarithromycin-based triple therapy achieves an acceptable eradication rate of approximately 81%. However, a high primary clarithromycin resistance rate of 24% was observed in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (57%, p = 0.09).

Disclosure of Interest: All authors have declared no conflicts of interest.
A. Benkirane1

the PPI side effect was 14.7% in the PPI group, 10.0% in the VPZ group and 19.1% in the MBM group, and there was no significant difference between 3 groups. Conclusions: This study shows that Concomitant therapy led to statistically significant higher eradication rates over sequential therapy. Both therapies showed excellent compliance and an acceptable safety profile. The use of quadruple therapy in this setting is not recommended; however, a combination scheme should be the adopted for first-line H. pylori eradication in Morocco.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1916 PROSPECTIVE COMPARATIVE STUDY OF TWO FIRST-LINE REGIMENS FOR HELICOBACTER PYLORI ERADICATION: 14-DAYS NON-BISMUTH QUADRUPLICATE OPTIMIZED CONCOMITANT THERAPY VERSUS 10-DAYS BISMUTH-CONTAINING QUADRUPLICATE THERAPY USING A TWO-ARM DESIGN

Department Of Digestive Diseases, Miguel Servert University Hospital, Saragossa/Spain

Contact E-mail Address: jalcedo@telefonica.net

Introduction: The Maastricht V/Florence Consensus Report recommends bismuth quadruple or non-bismuth concomitant therapies as first-line treatments for H. pylori infection, in areas where clarithromycin resistance is high (>15%). Head-to-head studies between both therapies are needed.

Aims & Methods: We aimed to compare compliance, efficacy and adverse effects of two first-line H. pylori eradication therapies in a high clarithromycin resistance
area, and in clinical practice. A prospective study was performed in a Spanish center recruiting consecutive naive adult patients, candidates to H. pylori eradication. Omeprazole 40mg, Clarithromycin 500mg, Amoxicillin 1g and Metronidazole 500mg, all drugs b.i.d, for 14 days (OCAM); or Omeprazole 20mg b.i.d and 3-in-1 capsule with Bismuth 140mg + Tetracycline 125mg + Metronidazole 125mg, 3 capsules q.i.d, for 10 days (3–1-OBMT) were prescribed according to physician criteria. Compliance was assessed by striking the consumed doses in a patient filled template, and adverse effects using a specific questionnaire with a 1–3 intensity scale. Efficacy was determined by 13C-urea breath test. A descriptive study and analysis of efficacy by intention to treat (ITT) were performed. Cases with poor therapeutic compliance (<80%) or no available data were excluded in per-protocol (PP) analysis. Chi2, Student’s t, and Mann-Whitney U tests with significance level p < 0.05 were applied. The primary endpoint was approved by the Ethics Committee.

**Results:** 216 patients (63.43% women; mean age 51.33 year 18–94 years-) were included. OCAM were prescribed in 103 and 3–1-OBMT in 113. No differences in sex, age and functional dyspepsia as indication to eradicate were observed between groups. Main indications for treatment were functional dyspepsia (39.35%), gastroduodenal ulcer (19.44%) and non-investigated dyspepsia (13.89%). Compliance was <80% in 11 patients and unknown in 7. The efficacy outcome was unavailable in 9 subjects. Compliance >80% was obtained in 91% with OCAM and in 93.53% with 3–1-OBMT (p = 0.064). The ITT rates were 82.52% vs 85.84% (p = 0.63), and PP 89.47% vs 96.04% (p = 0.13), for OCAM and 3–1-OBMT respectively. The outcomes of adverse effects (frequency, number, duration and intensity) are shown in the Table.

**Conclusion:** H. pylori infection management at primary care level is inappropriate with 30% on PCP compared to GS group (57.1% vs 81.1%; p < 0.0001) and eradication rates (78% vs 57.1%; p < 0.0001). The introduction of a specific counselling to PCP has significantly improved these outcomes. These data should encourage the implementation of interventional strategies in order to reduce the actual increase in antibiotic resistance.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1919 PREVALENCE OF CELIAC DISEASE AMONG RELATIVES OF CD PATIENTS IN ALGERIA**

**Introduction:** Celiac disease (CD) is an important health problem worldwide. It is characterized by a high prevalence (1%), non-specific morbidity, long-term complications and epidemiological progression. However, mass screening is not recommended. Currently, the strategy of 'Targeted screening,' defined as screening of high-risk groups, is widely practiced and recommended by learned Societies, in first-degree relatives of CD patients. In the world, targeted screening studies related to CD showed prevalence ranging from 4.2 to 42.5%. 

**Aims & Methods:** The main aim of our study is to determine the prevalence of CD in the first degree relatives in Algerian population. This was a descriptive-transversal study with prospective recruiting. This is a screening of first-degree relatives of patients known and treated for CD. Relatives are screened by using antitransglutaminase (tTG) antibodies in the serum. Upper digestive endoscopy and duodenal biopsy are performed in all sero-positive relatives and graded as per Marsh modified by Oberhuber classification to confirm the diagnosis. 546 first degree relatives of 107 families are included in our study.

**Results:** Among the 546 first-degree relatives, we have 18.5% of parents, 57.5% of siblings and 24% of children (8% sons and 16% daughters). The main parameter for the prevalence of CD among first-degree relatives is 8.1% with Confident Interval (CI) at 95% [5.8–10.4]. The prevalence of CD in first-degree relatives with positive serology and positive duodenal biopsy is 7.3% with CI at 95% [5.2–9.4]. The average age of screening cases is 31.8 years with CI at 95% [27.2 to 36.4] and extremes of [3–71] years. The mean duration of symptoms before diagnosis is 3.4 years, with CI at 95% [2.8 to 4.0] years. Among the 44 new cases detected by targeted screening, few cases [5 cases, 1.5 cases, Marsh IIIa, 27 cases Marsh IIIb and 3 cases Marsh IIIc. 44 patients are screened with CD: they are divided as follows: 9% Parents (4 mothers), 11% of children (son 3 and 5 girls) and 72% of siblings (brothers and sisters 23). The average age of screening cases is 31.8 years with CI at 95% [27.2 to 36.4]. The prevalence of CD in first-degree relatives is 8.1% with CI at 95% [5.8–10.4]. Our investigation supports the idea that the development of an extensive screening approach is needed to promote early diagnosis and prevent complications of CD in first-degree relatives. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** The present work entitled “Prevalence of celiac disease in relatives” is the first screening study of CD in the first-degree relatives carried out in Algeria. Among the 546 first-degree relatives, it is shown that 44 patients present positive serology which corresponds to the prevalence of CD in first degree relatives of 8.1% with CI at 95% [5.8–10.4]. Our investigation supports the idea that the development of an extensive screening approach is needed to promote early diagnosis and prevent complications of CD in first-degree relatives.

P1924 CIRCULATING EXTRACELLULAR VESICLES, A NOVEL MECHANISM OF ENDOCRINE CELLULAR CROSS-TALK, ARE INCREASED IN NEWLY DIAGNOSED CELIAC DISEASE PATIENTS

Contact E-mail Address: efkan78@gmail.com

Introduction: Extracellular vesicles (EVs) have been recently hypothesized to represent a major peripheral mechanism of cellular cross-talk. EVs carry surface receptors and proteins characteristic of their cells of origin and shuttle molecules (proteins, RNAs, microRNAs) potentially controlling physiological and pathological systemic processes. Recent studies have demonstrated an increased number of circulating EVs in a variety of conditions characterized by multi-organ impairment and/or damage such as insulin-resistance, atherosclerosis and obesity. Celiac disease (CD) is an immune-mediated inflammatory enteropathy, culprit by gluten ingestion in genetically susceptible individuals. It is frequently associated with a variety of systemic conditions both autoimmune and potentially immune-mediated in nature.

Aims & Methods: The aim of this study was to assess and characterize patterns of circulating EVs in newly diagnosed CD patients. We enrolled consecutive adult anti-ITG positive, biopsy proven CD patients. Circulating EVs were identified and quantified on whole blood samples by a no-lyse/no-wash method, combined with EVs volumetric count (FACSVerse, BD), based on a novel six-colour flow cytometry panel, in order to identify and enumerate both the whole EV compartment and different EV subpopulations. Data are expressed as mean ± SD and statistical differences were evaluated by means of T-test.

Results: We evaluated 12 CD patients (mean age 42.9 ± 19.1 vs. 40.8 ± 15.9 years, F:M = 4:1) at diagnosis and 12 age- and sex-matched healthy controls. Histology was considered positive for lesions of grade ≥B1 according to the Corazzi-Villanacci classification. Mean anti-ITG levels at diagnosis were 6.9 ± 3.1 times U/L. Mean number of total circulating EVs was significantly higher in CD than in controls (5985 ± 72482 vs 14383 ± 10018 EV/microL, p = 0.035). Subgroup analysis showed that EpCAM + EVs, of epithelial origin, and CD41 + platelet-derived EVs were not significantly different between CD and controls (894 ± 1004 vs. 548 ± 1237 and 3052 ± 1563 vs. 1734 ± 1810 respectively, p > 0.05). On the contrary, CD45 + EVs, of leucocyte origin, showed a significantly higher number in CD patients vs. controls (460 ± 492 vs. 119 ± 50 p = 0.026).

Abstract No: P1923

Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to treatment.
P1925 COELIAC DISEASE AND REPRODUCTIVE DISORDERS: IS THERE ANY CORRELATION

Contact E-mail Address: hanaeboutallafa@gmail.com

Introduction: The coeliac disease is an autoimmune enteropathy induced by the intake of gluten-containing foods (Corn, barley, rye), that occurs in people who are genetically predisposed primarily affecting the small intestine inducing atrophic lesions, which are regressive with a gluten-free diet. The classic form is actually a minority of patients. The extradigestive forms are currently the most found, with varied manifestations including reproductive disorders. The aim of our study is to evaluate the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Aims & Methods: It's a single-center, retrospective and descriptive study including 241 patients with coeliac disease enrolled within period of 17 years from 1995 to 2016 in the department of Gastroenterology « Medecine C » in Ibn Sina University Hospital.

Results: About 241 patients suffering from coeliac disease, 58 patients presented reproductive disorders, either 28.9%. Recruiting 53 women and 5 men, with a sex ratio M/F of 10.6:1. The mean age was 32.25 years ranging from 13 to 59 years old. The diagnosis of coeliac disease was based on: Histology (severe or partial Villous atrophy with intraepithelial lymphocytosis exceeding 30%), the antientomysial antibodies and/or antitransglutaminase antibodies positive. The reproductive disorders were never isolated but always associated with digestive or extradigestive signs at the time of the diagnosis of coeliac disease. These disorders were in our study: Amenorrhea in 11 cases (19%), secondary amenorrhea in 13 cases (22.4%), Metrorrhagia in 12 cases (20.6%), absence of development of secondary sexual characters in 8 cases (12.5%), spontaneous abortion in 7 cases (10.9%), menometrorrhagia in 4 cases (13.8%), primary sterility in 5 cases (8.6%), precocious menopause in 6 cases (10.3%), premature labour and/or IUGR in 3 cases (5%), primary amenorrhea in 2 cases (3.4%), and intrauterine Fetal death IUFD in one case (1.7%). All our patients benefited from a gluten-free diet. 15 patients were excluded from the study, 2 patients died, and 12 patients were lost to follow-up. Of the remaining patients stayed, the evolution of the reproductive disorders under gluten-free diet was good in 26 cases (90%), with normalization of the cycles in 15 cases. The cycle was returned in 6 cases, development of secondary sexual characters in 2 cases, fertility was returned in one case. A patient developed her cycle after primary amenorrhea, and one case was delivered a baby in term after a repeated premature deliveries. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrhea continued in 2 cases.

Conclusion: Reproductive disorders related to the coeliac disease were frequent and variable. In our study, these disorders well responded to the gluten-free diet in 90% of cases, and these disorders were reversible under gluten-free diet.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1926 SEVERITY OF MUCOSAL DAMAGE AND TISSUE TRANSGLUTAMINASE ANTIBODY LEVELS CORRELATE WELL IN ADULT CELIAC DISEASE IRRESPECTIVE OF CLINICAL FEATURES

R. Maxim1, A. Trifan2, A. Pleșu3, S. C. Oana Cristina1, I. Ciortescu1, I. Gîrlaun2, C. Stanciu1

Introduction: Celiac disease (CD) is a chronic imune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes ranges from classical gastrointestinal manifestations to only atypical signs, thus making the clinical diagnosis a challenge. The aim of our study was to investigate the relationship between duodenal histology, specific antibody levels and clinical presentation in adult CD Romanian patients.

Aims & Methods: The study group included 81 adult patients with a female: male ratio of 3:1. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients with anemia and Marsh 3b lesions (P = 0.001) and IgA anti-gladiol antibodies (IgA-AGA) levels (61.83 ± 69.41 u/mL vs 77.15 ± 71.02 u/mL, P = 0.001) correlated with intestinal villous atrophy (Marsh 3b and 3c) in CD patients by Spearman rank correlation. Among symptoms, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients with anemia with patients with elevated IgA-AGA levels (r = 0.516, P = 0.004), IgA-AGA (r = -0.301, P = 0.006) and Marsh 3b-c lesions (P = 0.004). Among biological markers included in the statistical analysis, low iron levels (cut off 30 mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3b lesions (P = 0.008) and elevated IgA-AGA titers (r = -0.384, P = 0.001). Coeliac disease (CD) IgA-AGA and AGA levels correlate with duodenal villous atrophy in adult CD patients. An IgA-AGA titer >160 was nearly always associated with severe CD histopathology. GI and non-GI symptoms are not reliable predictors of CD.

Introduction: Celiac disease is an immunologically-mediated enteropathy that triggered by the intake of gluten-containing foods in genetically predisposed individuals. It causes intestinal and extraintestinal manifestations. Extraintestinal findings are observed in many systems. The prevalence of extraintestinal findings in CD patients is controversial. Reports have shown that extraintestinal manifestations are more common in pediatric patients [1]. There is also no data in the literature regarding the association of patent foramen ovale (PFO) and celiac disease, which is 10–25% common in the general population. We performed an echocardiography study to determine the frequency of accompanying cardiac findings in our patients with celiac disease. In this article, we aimed to share the frequency of the PFO detected in celiac patients with high results.

Aims & Methods: Between May-June 2015, 65 patients who applied to the gastroenterology clinic of Derince Education and Research Hospital and followed up with celiac disease were identified. The sociodemographic characteristics, celiac disease diagnosis duration, symptoms and complaints, accompanying diseases, drug use histories, hemogram and biochemical parameters of these patients were recorded. The patients underwent saline contrast transthoracic echocardiography in the cardiology clinic. Patients' data were recorded. The obtained data were evaluated with appropriate statistical methods.

Results: Sixty-five celiac patients were included in the study. 21 (32.3%) male and 44 (67.7%) female. The mean age of our patients was 41.3 ± 14.1 years. PFO was detected in 39 (60%) of the patients. There was no difference in the incidence of PFO in between male and female patients. (61.9% and 59.1%, respectively, p=0.829). Compared with the frequency of PFO in the general population, the incidence of PFO in celiac patients was higher (25% and 60% respectively).

Conclusion: As a result, the incidence of PFO is more prevalent in celiac patients than in the general population. For this reason, the evaluation and treatment of this cardiac atrial septal defect in clinical follow-up of patients, are required. In addition, the high incidence of PFO in celiac patients suggests that celiac disease is a factor affecting the development of patients from intratuber period. Because our patients did not undergo transesophageal echocardiography, this rate may be less than real exist. For this reason, further evaluation is required with a wider patient group and by transesophageal echocardiography.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1928 USEFULNESS OF BULB BIOSPY SAMPLES IN CELIAC DISEASE DIAGNOSIS IN ADULTS

D.V. Balaban1, A. Popp2, J. Taavela2, K. Laurila2, M. Makii3, M. Jinga3

Introduction: Currently available celiac disease (CD) guidelines recommend sampling of both the bulb and distal duodenum for diagnostics. This has been reinforced by the recent data on ultra-short CD [1]. However, it has been previously shown in pediatric CD that bulb specimens are frequently of poor quality [2-4]. The aim of this study was to assess the usefulness of bulb biopsy samples in the clinical follow-up of celiac patients also, and it can lead to false-positive diagnoses [2]. Our aim was to address the same issue in adult CD, using the same validated morphometric methods [3].

Aims & Methods: We prospectively recruited cases of clinically recommended upper GI endoscopy; all patients also had signs and symptoms of CD and were checked for CD serology (serum tissue transglutaminase 2 antibodies and endomyosal antibodies) and biopsy sampled according with current
recommendations. Paraffin embedded biopsy samples were assessed for villous height (VH) and crypt depth (CD) and VH:CD ratio. The corresponding frozen duodenal samples were assessed for duodenal IgA deposits targeting transglutaminase 2 (TG2-IgA), density of CD3 (cut-off 37 cells/mm epithelium) and γδ T cell receptor bearing intraepithelial lymphocytes (IELs) (cut-off 4.3 cells/mm epithelium). The study was approved by the Local Ethical Committee.

**Results:** Altogether 41 patients, mean age 45.4±14.6 years, 61% female, were recruited. Among these, 21 were finally diagnosed as adult CD (mean TG 156 U/l, CD:50% and crypt hyperplastic mucosal lesion in distal duodenum) and the rest 20 were non-CD controls (serum negative and normal on distal duodenal biopsy). All patients were on a gluten-containing diet. Quality of bulk biopsy samples was unsatisfactory and unreadable in 67% of CD cases and 50% of controls, even after reorientations and reittings. All CD patients had, when measurable, VH:CD < 2 in the anatomical abundant (value 0.31, range 0.02-0.61). On the other hand also non-CD controls had a crypt hyperplastic diseased bulk mucosa in 80% of patients (average VH:CD 1.63, range 0.7–4.1), but the injury was not that severe compared to CD (p = 0.0006). The inflation was significantly higher in CD compared to controls (CD3 81.87 vs. 34.05, p < 0.01; γδ IELs 29.12 vs. 6.44, p < 0.01). Bulk IgA deposits were positive in all CD patients and were able to discriminate CD cases from disease controls.

**Conclusion:** As reported in previous, bulk biopsy samples in adults are frequently of poor quality and not reliable for accurate histological measurements. Also, interpretation of results from bulk samples should be done with caution, as non-CD patients may have mild injury in the bulk lining and could be misinterpreted as positive. Assessment of bulk TG2-IgA subepithelial is a powerful tool to confirm CD.

bleeding rate with or without treatment, the rate of anaemia exacerbation (hemoglobin ≤2.0 g/dL), 5 year overall survival rate (OS), and 5 year disease specific survival rate (DSS). Occult OGBD was defined as recurrent or persistent iron deficiency anaemia with or without a positive faecal occult blood test and no bleeding findings by esophagogastroduodenoscopy and colonoscopy. Results: The positive CE findings rate was 44% (157/357) and the detection rate of bleeding source lesions was 27% (95/357). All of the treated recurrent bleeding source lesions (Group A) were as follows: angioectasia 61 patients (Yamano-Yamamoto classification Type 1a 37 patients, Type Ib 24 patients), non-specific ulcer 22 patients, metastatic abdominal/rectal-anti-inflammatory drug-induced ulcer. In patients, hemangiomata 5 patients, Crohn’s disease 3 patients, primary cancer 2 patients, metastatic cancer 2 patients, gastrointestinal stromal tumour 2 patients, malignant lymphoma 2 patients, others 3 patients. Lesions that were not recognized as bleeding source without treatment (Group B) were as follows: angioectasia 25 patients (Type 1a without oozing 25 patients), erythema 31 patients, others 3 patients. There were no patients with overt bleeding in Group B. Although 6 patients (10%) had anaemia exacerbation in Group B, 1 patient (Type 1a) that was not a bleeding source lesion. OS in both Group A and Group B was 90%. DSS in Group A was 99% and in Group B was 100%. One patient in Group A died of a primary small-bowel cancer.

Conclusion: Long-term outcomes with occult OGBD patients were good except malignant tumor, because overt bleeding and/or anaemia exacerbation did not occur within the follow-up period. Thus, occult OGBD patients without bleeding source lesions, including Type 1a angioectasia without oozing, and erythema, are unnecessary to follow-up with CE in occult OGBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1932 A PILOT STUDY EXPLORING THE VALUE OF FAEAL IMMUNOCHEMICAL TEST (FIT) WHEN INVESTIGATING ANAEMIA OR OCCULT GASTROINTESTINAL BLEEDING WITH SMALL BOWEL CAPSULE ENDOSCOPY

2Department Of Clinical Chemistry, AMNCH Tallaght, Dublin/Ireland

Contact E-mail Address: donalitighe83@gmail.com

Introduction: Small bowel capsule endoscopy (SBCE) is a very useful method of investigating iron-deficient anaemia, or occult gastrointestinal (GI) bleeding. It can identify causes of anaemia or bleeding, such as angiodysplasia, small bowel Crohn’s disease, polyps, lymphoma, and malignant lesions. There is however a need to improve the diagnostic yield, particularly where resources and access to capsule endoscopy are restricted. Faecal immunochromestic test (FIT) has an established role, in investigating large bowel bleeding, and is incorporated into a number of bowel cancer screening programmes.

Aims & Methods: The aim of our study was to investigate whether FIT could help predict likelihood of small bowel bleeding or other significant pathology at time of small bowel capsule endoscopy. This was a prospective pilot study, performed at our centre from September 2016-April 2017. Indications for enrolment were patients referred for SBCE with the indication of anaemia or occult GI bleeding. Baseline patient characteristics were obtained including age, gender, history of recent GI disease, transfusion requirements and use of anti-platelet/anti-coagulants. Patient haemoglobin (Hb) level was checked on the day of capsule endoscopy where possible. Patients were asked to return one completed FIT for further analysis. A cut of 50 ng/ml was chosen as this is the standard cut-off used, in the Irish National Bowel Cancer Screening programme.

Results: A total of 40 patients were enrolled, mean age 55.4 years (range 18–77), 64% were female. A total of 27.6% of patients were on anti-platelet agents or anti-coagulants. 34% of patients had a blood transfusion within the last year. Mean Hb for the cohort was 12.8 g/dL (range 7.8–15.9 g/dL). The average FIT reading was 459 ng/ml (range 0–4246 ng/ml). 30% of patients had a FIT level >50 ng/ml. 46% of patients, had positive findings at SBCE. 9/12 (75%) of patients with a FIT level >50 ng/ml had positive findings at capsule endoscopy compared to 5/28 (17.8%) for FIT ≤50 ng/ml, p value = 0.002. 95% C.I. 0.29–0.86 O.R. 0.16. These included 4/12 (33%) new cases of Crohns, 3/12 (25%) angiodysplasia, 3/12 (33%) non-BD enteritis, 1/12 (16.7%) small bowel tuberculosis and 1/12 (16.7%) malena, with no clear source. In addition there was a good correlation between FIT and Haemoglobin levels. 60% of patients with FIT >50 ng/ml were anaemic (Hb <11.5 g/dL), compared to 17% with FIT <50 ng/ml, p value = 0.02 95% C.I. 0.09–0.76 O.R. 0.14. Combining Hb and FIT levels, was also informative and predictive of small bowel pathology. 83% of patients, who were anaemic and had a FIT >50 ng/ml had clinically significant findings at SBCE compared to 21% pick up rate in patients with normal Hb and FIT levels, p value = 0.05 95% C.I. 0.22–1.03 O.R. 0.05. Overall the sensitivity for a FIT >50 ng/ml for detecting small bowel pathology was 83% with a specificity of 92%, giving a positive predictive value of 83.3% (95% C.I. 56.9%-95%). Plateletpleatelet use was not predictive of a positive FIT, as 16.7% of patients with a FIT >50 ng/ml were on anti-platelet agents, compared to 83.3% who weren’t.

Conclusion: FIT is useful at predicting clinically significant small bowel pathology at the time of capsule endoscopy. It may help better identify and prioritise patients who would best benefit from referral.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: VCE detected small bowel lesions in 71% of our cohort. There is a high prevalence of PHE in patients with decompensated cirrhosis. Vascular lesions are the most common finding in the small bowel of this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Small-bowel capsule endoscopy (SBCE) have been useful in managing obscure gastrointestinal bleeding. We previously reported that the use of oxicams and diclofenac was associated with an increased risk of nonsteroidal anti-inflammatory drug (NSAID)-induced small-bowel injury (Aliment Pharmacol Ther 2014). However, the etiology and temporal development of drug-associated small-bowel bleeding (SBB) have not been well characterized.

Aims & Methods: The aim of this study is to determine the risk of drugs associated with overt SBB using a case-crossover design. The Japanese Association for Capsule Endoscopy developed a prospectively recorded database of outpatients and inpatients that underwent SBE at 18 medical centers in Japan, and for Capsule Endoscopy developed a prospectively recorded database of outpatients and inpatients who underwent SBCE at 18 medical centers in Japan, and to evaluate long-term outcomes and drug exposure in patients undergoing VCE for OGIB.

Results: Of 1052 patients with OGIB (male/female: 678/374, age of onset: 64±26, 455 with SBB (male/female: 291/164, age of onset: 66±20), 313 patients were on 134 drugs which could be identified 24 weeks before overt SBB were analyzed. ORs (95%CI) of enteric-coated aspirin, clopidogrel, and loxoprofen were identified as risk factors causing overt SBB during a relatively short period after administration.

Conclusion: Enteric-coated aspirin, clopidogrel, and loxoprofen were identified as risk factors causing overt SBB during a relatively short period after administration. Disclosure of Interest: All authors have declared no conflicts of interest.

P1935 META-ANALYSIS REVEALS SIMILAR REBLEEDING RATES AMONG EASTERN AND WESTERN POPULATIONS UP TO FIVE YEARS AFTER INDEX VIDEO CAPSULE ENDOSCOPY

EXAMINATION FOR OBSCURE GASTROINTESTINAL BLEEDING

G. Tzatzios, P. Gkolfakis, G. D. Dimitriadis, K. Triantafylou
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: Video capsule endoscopy (VCE) is the first-line diagnostic modality for obscure gastrointestinal bleeding (OGIB) investigation and different re-bleeding rates have been published among Western and Eastern studies.

Aims & Methods: Aim of this meta-analysis was to examine the differences in re-bleeding rates in patients with OGIB after index VCE, as measured in Western and Eastern studies. A comprehensive literature search in MEDLINE was conducted to identify all studies examining re-bleeding rate after VCE for OGIB. Meta-analysis assessed the pooled proportion of re-bleeding events after VCE for OGIB according to study’s origin (Western vs. Eastern) as the primary end point. Potential heterogeneity and publication bias were detected using Egger’s test and Begg’s test. Funnel plot asymmetry was analyzed by using the trim-and-fill method. Heterogeneity was measured using the I² statistic and publication bias risk was examined with Funnel plots inspection.

Results: Thirty-eight (14 Eastern and 24 Western) studies were included in the analysis with 5197 patients followed from 6 to 52 months. We detected significant heterogeneity with no evidence for publication bias in the meta-analyzed studies. While the overall, pooled rate of re-bleeding after VCE was 25(21–29)%, I² = 93%, similar re-bleeding rates were detected among Eastern and Western populations [22(16–28)%, I² = 71% vs. 25(21–29)%, I² = 95%]. The re-bleeding rate after positive compared to negative VCE index examination was higher [1.89(1.00–3.34), I² = 72%] in Eastern population studies, while a similar difference was not detected in the Western studies [1.46(0.72–2.94), I² = 88%]. When only studies with short-term follow-up were analyzed, the OR of re-bleeding after positive vs. negative VCE was 1.23(0.81–1.88), I² = 77% and 1.93(0.90–4.13), I² = 71% in Western and Eastern studies, respectively. For studies with long-term follow-up, no significant difference in the OR of re-bleeding after positive vs. negative index VCEs was detected either in the East [2.03(0.86–4.29), I² = 71%] or in the West [7.01(1.37–37), I² = 99%].

Conclusion: Our analysis shows that patients undergoing VCE for OGIB have similar re-bleeding rates in the East and in the West, regardless of the length of the follow-up. An increased re-bleeding risk after positive vs. negative index VCE was noted only in studies originating from the East.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1936 LONG-TERM OUTCOMES AFTER NEGATIVE DOUBLE-BALLOON ENTEROSCOPY FOR SUSPECTED OVERT SMALL BOWEL BLEEDING (OBSCURE-OVERT GASTROINTESTINAL BLEEDING)

R. Hashimoto1, T. Matsuda1, M. Nakohori1
1Dept. Of Gastroenterology, Sendai Kosei Hospital, Sendai/Japan

Contact E-mail Address: rinhashimoto@gmail.com

Introduction: There are very few reports about long-term outcomes in patients undergoing negative balloon assisted enteroscopy for suspected overt small bowel bleeding (obscure-overt gastrointestinal bleeding). Aims & Methods: The aim of this study is to evaluate long-term outcomes and risk factors of re-bleeding after negative double balloon enteroscopy (DBE) for suspected overt small bowel bleeding. We investigated 297 patients undergoing DBE for suspected overt small bowel bleeding between December 2004 and April 2016 at Sendai Kosei Hospital. Prospectively collected data were reviewed, and 83 patients (27.9%) showed negative results in the first antegrade and/or retrograde DBE. For these patients, letter and telephone interviews were conducted in April 2017. As a result, a cohort of 64 patients could be followed. The primary outcome measurement is overt rebleeding and necessity for clinical assessment after negative DBE.

Results: The rebleeding was observed in 19 of 64 patients (29.7%) with 76 months follow-up period. The mean period during the first DBE and the first rebleeding episode was 11.6 months (2day–48months). Three patients showed rebleeding after more than three years of the first DBE. At the time of rebleeding, emergent endoscopy including DBE (within less than 48 hours) and/or contrast-enhanced computed tomography (CECT) was performed in all patients. The bleeding source was identified in 17 of 19 patients (89.4%). The bleeding source were duodenum (n = 8), jejunoileum (n = 7) and colon (n = 2), respectively. One
patient died due to uncontrollable duodenal bleeding. Blood transfusion before the first DBE was associated with rebleeding (odds ratio 22.5, p = 0.0005), but total endoscopy rate, use of capsule endoscopy, use of anti-thrombotic agents and use of NSAIDs were not associated with rebleeding.

Conclusion: Rebleeding after negative DBE for suspected overt small bowel bleeding is lethal. Blood transfusion before the first DBE may predict rebleeding. Emergent endoscopy including DBE and concomitant CECT use could help in the diagnosis on re-bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
3 was superior to CapsoCam SV-1 (27 min. vs. 40 min, p = 0.01). 95% of the physicians were satisfied with each capsule system and evaluation software. The acceptance rate of the patients to retrieve the CapsoCam SV-1 was high. Adverse events/SAEs were 17.9%/1.3% with CapsoCam SV-1 and 16%/0% with PillCam SB 3. Re-bleeding rate was 28.75% within 3 months.

**Conclusion:** Both capsules allow high-quality imaging of the small bowel. CapsoCam SV-1 detected more lesions, however, relevant bleeding sources were visualized by both capsules. Physician’s satisfaction was high with both capsule systems and evaluation software. Patient’s acceptance with CapsoCam SV-1 was unexpectedly high. SAEs were 0% with PillCam SB 3 and 1.3% with CapsoCam SV-1.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic mesenteric ischemia (CMI) is the result of insufficient mucosal perfusion of the gastrointestinal tract, mostly caused by atherosclerotic stenosis of the mesenteric arteries. Other causes of CMI are vasculitis, median arcuate ligament syndrome or non-occlusive ischemia (NOI) due to decreased cardiac output or hypo-oxygenation. The diagnosis of CMI remains challenging as chronic abdominal pain is common and mesenteric artery stenoses are frequently observed in the general population but not necessarily related. Harki et al.(1) designed a score chart to predict the risk of CMI based on a cohort of CMI suspected patients. This score chart consists of patient characteristics (female 1 pt, weight loss 1 pt, cardio-vascular disease 1 pt) and radiologic evaluation (50–70% celiac artery (CA) stenosis 1 pt, >70% CA stenosis 4 pts, 50–70% superior mesenteric artery (SMA) stenosis 1 pt and >70% SMA stenosis 3 pts). A total score of 0–2 pts predicts an absolute risk of CMI of 0–21%, 3–6 pts a 22–91%, 7–9 pts a risk of 91–95% and ≥10 pts a risk of >95%. We aimed to validate this prediction model in a prospective large multicenter patient cohort.

**Aims & Methods:** Patients suspected of CMI referred to two Dutch specialized CMI centers were included consecutively from January 2006 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography or MR-angiography, and a mucosal ischemia test (visible light spectroscopy or tonometry), all patients were discussed in an expert based consensus diagnosis. All patients with a CMI consensus diagnosis were planned for treatment (revascularization or sclerotherapy or medication for NOMI). A definitive diagnosis of CMI was made if successful treatment resulted in durable symptom relief. The score chart to predict the risk of CMI was computed for each patient.

**Results:** A total of 246 patients were included and consensus diagnosis of CMI was made in 108 (44%) patients, which resulted in 96 (39%) patients with a definitive diagnosis of CMI after a positive response therapy. A definitive diagnosis of CMI, leading to an expert based consensus diagnosis. Patients with CMI, 107 (43.3%) patients were included were classified according to the score chart. The definitive ability of the score chart was strong (C-Statistic 0.87).

**Conclusion:** The score chart for CMI based on patient characteristics and anatomy is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** lvdandijk@erasmusmc.nl

**Introduction:** Isolated stenosis of the celiac artery (CA) or the superior mesenteric artery (SMA) is frequently detected in patients with abdominal complaints. These patients may suffer from chronic mesenteric ischemia (CMI) causing nonspecific abdominal complaints as postprandial pain, nausea or diarrhea. However, the exact role of single artery mesenteric ischemia is a topic of continuous clinical debate and reports on the effectiveness of single mesenteric artery revascularization are scarce. We evaluated the long-term clinical success rates for single CA or SMA revascularization in patients with gastrointestinal symptoms and confirmed mesocoeal ischemia.

**Aims & Methods:** Data were collected from all 97 consecutive patients with gastrointestinal symptoms and a single mesenteric artery stenosis referred to the outpatient clinic of our tertiary care institution for analysis of CMI between January 2006 and October 2010. All patients underwent a standardized diagnostic work-up for CMI at baseline consisting of medical history taking and physical examination, imaging of the gastrointestinal arteries with either CT- or MR-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy. All cases were discussed in a multidisciplinary meeting attended by a vascular surgeon, interventional radiologist and gastroenterologist, all specialized in CMI, leading to an expert based consensus diagnosis. Patients with consensus diagnosis of CMI underwent surgical or endovascular revascularization. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

**Results:** Consensus diagnosis of CMI was obtained in 62/97 patients and all consensus patients were revascularized. Isolated CA stenosis was present in 55/ 62 patients (89%) (31 vascular disease; 24 median arcuate ligament syndrome, MALS) and isolated atherosclerotic SMA stenosis in 7 patients. After a mean follow-up of 5.5 ± 3.0 years, 42/62 patients (68%) experienced sustained symptom relief. Responders to revascularization had a BMI increase during follow-up in contrast to the non-responders (+0.43 ± 2.5 versus −1.06 ± 2.4 kg/m², p = 0.033). Response to revascularization was not related to lesion localization (CA 67% versus SMA 71%, p = 0.825) or lesion etiology (MALS 63% versus vascular disease 71%, p = 0.483). See table.

**Conclusion:** The score chart for CMI based on patient characteristics and anatomy is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI.

We aimed to review various digestive manifestations of vasculitis for diagnosis. The other difficulty remains the interference of digestive side and granulomatosis is broad and can affect any segment of the digestive tract.

**Conclusion:** Revascularization of the CA or SMA provides long-term symptom relief in 68% of patients with chronic gastrointestinal symptoms and confirmed mucosal ischemia due to single mesenteric artery stenosis. This provides the opportunity to help patients with otherwise unexplained, refractory abdominal complaints.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1942 UNDERUTILIZATION OF ENDOSCOPIC ARGON PLASMA COAGULATION FOR TREATMENT OF BLEEDING GASTROINTESTINAL ANGIODYSPLASIAS: AN INTERNATIONAL MULTICENTRE COHORT STUDY**

K. Grooteeman1, M. Mathurewicz1, G. Holleran2, E. Van Geenen1, D. Meurom2, J. H. Dreij11

**Contact E-mail Address:** karingrooteeman@gmail.com

**Introduction:** Endoscopic argon plasma coagulation (APC) is the first-line treatment in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodysplasias. In the minority of patients active bleeding angiodysplasias are seen during endoscopy, but in contrast non-bleeding angiodysplasias can be an incidental finding. This can make the decision whether to treat endoscopically detected angiodysplasias with APC difficult.

**Aims & Methods:** The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodysplasias who were left untreated during the index endoscopy. We initiated an international, multicentre cohort study to collect clinical, laboratory and endoscopic data from angiodysplasia patients. Cases were identified through a systematic search in endoscopy reports from 2010–2015 with follow-up until July 2016. Inclusion criteria was endoscopic detection of angiodysplasia in the context of overt bleeding or iron deficiency anaemia. Exclusion criteria were other vascular anomalies and angiodysplasias as incidental finding.

The primary outcome was repeat endoscopy with APC.

**Results:** A total of 197 patients with proven angiodysplasia as cause for anaemia or bleeding were included (mean age 68 years, 58% male). Median follow-up was 37 months (range 18–57). In 52% of the cases (n = 103) APC treatment for bleeding angiodysplasia(s) was performed at the index endoscopy. Repeat endoscopy with APC was necessary in 17 patients (18%) in whom angiodysplasias were detected but left untreated during the index endoscopy. Median time between index and repeat endoscopy was 21 weeks. A total of 48 patients (51%) who received a purely diagnostic index endoscopy were in need of other treatment modalities (e.g. iron supplementation, blood transfusion, stop anti-coagulants). Anaemia and/or overt bleeding resolved spontaneously in 24 patients (26%).

**Conclusion:** A substantial proportion of patients with clinical symptomatic angiodysplasia bleeding do not receive APC at the index endoscopy and continue to be dependent on iron supplementation, blood transfusion or undergo repeat endoscopy with APC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1943 DIGESTIVE INVOLVEMENT IN SYSTEMIC DISEASES: A UNIVERSITY HOSPITAL EXPERIENCE**

W. Khamoussi1, K. Chhita1, H. Bachir2, G. Kharrasse1, A. El Mekkaoui1, H. Guerreiro1

3Hepatogastroenterology, CHU Med VI Oujda, Oujda/Morocco

**Contact E-mail Address:** wkhamoussi@yahoo.com

**Introduction:** Digestive manifestations in systemic diseases including vasculitis and granulomatosis is broad and can affect any segment of the digestive tract and related organs. The clinical symptoms are not specific and it can be challenging for diagnosis. The other difficulty remains the interfereance of digestive side effects of medication used

**Aims & Methods:** We aimed to review various digestive manifestations of systemic diseases. This was a retrospective study from Feb 2009 to Sep 2016 in internal medicine and gastroenterology departments. The exclusion criteria was incomplete data considering the diagnosis of the systemic disease.

**Results:** We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 21.6 ± 4.5 kg/m2. There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before
bariatric surgery, 52.3% of patients had VDD and 36.8% had VDI. After surgery, the number of VDD increased to 71.1% (p = 0.0079). The mean levels of 25(OH)D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL after surgery (p < 0.05). There was no correlation between the amount of weight loss and the changes in the levels of 25(OH)D in our study.

**Conclusion:** There is a high prevalence of vitamin D deficiency in obese patients eligible for bariatric surgery. The level of deficiency tends to increase after RYGB. This population of patients should, therefore, be offered an adequate level of vitamin D supplementation, especially after the procedure.

According to A. Scudero Sanches, 71.1% of patients experience nausea and 57.9% most common side effects after IGB implant.

**Introduction:**

Contact E-mail Address: sergio.barrichello@healthme.com.br

Endoscopic treatment of obesity and overweight with intragastric balloon (IGB), is a safe and effective option. Nausea and vomiting are the most common side effects after IGB implant. According to A. Scudero Sanches, 71.1% of patients experience nausea and 57.9% most common side effects after IGB implant.

**Aims & Methods:**

Evaluation of Frequency of vomiting and number of patients requiring intravenous hydration (HEV) after gastric balloon placement. This was a retrospective analysis of medical records of 340 obese and overweight patients requiring intravenous hydration to quell nausea and vomiting during the first day of the accessory use.

**Results:**

There were 340 patients treated with intragastric balloon between 2015 and 2016. The present study showed 74.41% vomiting until the third day after placement of the IGB, and it is in accordance with literature. Those 252 patients who had vomiting, 67.58% presents frequency of 0 to 5 times per day and 32.42% of the group 5 to 7.48% of the patients required intravenous hydration and there were no early explant.

**Conclusion:**

All other authors have declared no conflicts of interest.

P1951 FRUCTO-OligoSACCHARIDE EXACERBATES STRESS-INDUCED VISCERAL HYPERALGESIA AND GUT INFLAMMATION IN A MURINE MODEL
B. Chen, L. Du, H. He, J.J. Kim, N. Dai
1Department Of Gastroenterology, Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Introduction: Many factors contribute to the development of irritable bowel syndrome (IBS) including the altered visceral perception, intestinal low-grade inflammation and psychosocial factors. Recent research has revealed a relationship between intake of FODMAPS (Fermentable, Oligo, Lacto, and Poly) and abdominal complaints. A diet low in FODMAPs can reduce symptoms in patients with IBS but mechanisms were poorly understood.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) in stress induced IBS mice model. Fructo-oligosaccharide (FOS) as one of the most frequently exposed FODMAPs in daily life was used in this study. Intestinal mucosa of mice were subjected to water avoidance stress (WAS condition; 1 h/day for 10 days) or sham stress (basal condition; 1 h/day for 10 days) with an oral gavage of saline or saline solution containing FOS (8 g/kg) for 2 weeks. Then visceral sensitivity was measured by abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD) and histologic analyses were used to evaluate mucosal inflammation. Immunohistochemistry, reverse transcription, and scanning were used to estimate mucosal mast cell level, levels of cytokines (IL-6, IL-23, TNF-α, IL-10, IL-1β) and SCFA, respectively.

Results: Visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs in stress induced IBS mice model. Fructo-oligosaccharide (FOS) administration reduced visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) in stress induced IBS mice model. Fructo-oligosaccharide (FOS) administered mice compared with saline-administered mice. In WAS condition, increased visceral sensitivity and mucosal mast cell (12.3 ± 2.61 vs. 8.33 ± 3.55, P < 0.01) were observed in FOS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression were mediated by FOS with increased IL-23 (3.17 ± 2.11-fold, P < 0.05) in ileum and IL-1β (2.45 ± 1.55-fold, P < 0.05) in colon compared with saline. In addition, the average concentrations of acetate (2.48 ± 0.62 vs. 1.04 ± 0.10, P < 0.01), propionate (0.48 ± 0.09 vs. 0.33 ± 0.00, P < 0.01), and butyrate (0.19 ± 0.03 vs. 0.21 ± 0.03, P < 0.05) and total SCFA (3.61 ± 0.89 vs. 1.79 ± 0.17, P < 0.01) significantly increased in FOS-administered mice compared with saline-administered mice in WAS condition. In basal condition, no difference of visceral sensitivity, intestinal inflammation and SCFA were observed between mice treated with FOS or saline.

Conclusion: Oral gavage of FOS leads to both an increase in visceral sensitivity and gut inflammation in stress induced IBS mice. These effects are linked with the production of SCFA in the gut which involved in the regulation of sensitivity and intestinal immune activation. These findings support the hypothesis that visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs may be responsible for IBS symptom generation, and indicate an alternative mechanism of the efficacy of the low-FODMAP diet for IBS patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several formulations consisting of live lactic acid bacteria, including bifidobacteria, are marketed as probiotic products. However, these products are currently poorly understood in their effect in human beings. Fructooligosaccharides (FOS) are fermentation by probiotic bacteria, generating short chain fatty acids and providing prebiotic potential probiotic functions. Full sets of genes for the production of metabolites and bioactivities were identified in the VSL#3 product specification and showed the 8 strains of this multispecies probiotics. A number of studies have shown the potential probiotic functions. Many factors contribute to the development of irritable bowel syndrome (IBS) including the altered visceral perception, intestinal low-grade inflammation and psychosocial factors. Recent research has revealed a relationship between intake of FODMAPS (Fermentable, Oligo, Lacto, and Poly) and abdominal complaints. A diet low in FODMAPs can reduce symptoms in patients with IBS but mechanisms were poorly understood.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) in stress induced IBS mice model. Fructo-oligosaccharide (FOS) administration reduced visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) in stress induced IBS mice model. Fructo-oligosaccharide (FOS) administered mice compared with saline-administered mice. In WAS condition, increased visceral sensitivity and mucosal mast cell (12.3 ± 2.61 vs. 8.33 ± 3.55, P < 0.01) were observed in FOS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression were mediated by FOS with increased IL-23 (3.17 ± 2.11-fold, P < 0.05) in ileum and IL-1β (2.45 ± 1.55-fold, P < 0.05) in colon compared with saline. In addition, the average concentrations of acetate (2.48 ± 0.62 vs. 1.04 ± 0.10, P < 0.01), propionate (0.48 ± 0.09 vs. 0.33 ± 0.00, P < 0.01), and butyrate (0.19 ± 0.03 vs. 0.21 ± 0.03, P < 0.05) and total SCFA (3.61 ± 0.89 vs. 1.79 ± 0.17, P < 0.01) significantly increased in FOS-administered mice compared with saline-administered mice in WAS condition. Introduction: Disease prevention and public awareness are fundamental to reduce morbidity, mortality and health-related costs. Extensive research led to identification of causes of gastrointestinal (GI) diseases, nevertheless it is still difficult to get population involved. The goals of our pilot campaign are: (a) to raise awareness about GI diseases, risk factors, signs, symptoms, in order to convince people to change behavior and to prompt them with concerns to visit doctors as early as possible; (b) facilitate communication between healthcare providers and population; (c) to determine the knowledge of health personnel about the appropriate diagnostic investigations. Any information we can share may also benefit patients and their families, in recognition of the many people who suffer with the pain and discomfort caused by GI disorders.

Aims & Methods: We organized population-based events, out of health facilities during which: (a) giant inflatable anatomical models of GI organs that can be visited inside, were installed; (b) educational panels and brochures were set and exhibited both inside and outside the models; (c) videos illustrating endoscopy exams and histopathology examinations were projected and discussed; (d) clinical cases, also mimicking patient encounter, were simulated.

Results: We started an innovative strategy focused on the keywords: multidisciplinary team, scientific rigor but simple words, people attraction, inducing communication, in Parma and neighbouring Cities. Specialists in Gastroenterology, Anatomic Pathology, Radiology, Surgery, Biochemistry, Nutrition, together with pre- and post-graduate Students, discussed various aspects of the disease, in a friendly and informationally engaging way. Municipal and civil society were also involved to ensure organizational efficiency. The most discussed topics regarded dyspepsia, gastritis, helicobacter pylori infection, gastroesophageal reflux disease, alcohol abuse, cirrhosis, hepatitis, intestinal bowel disease, inflammatory bowel disease, IBS, Crohn disease, food allergy and intolerance, optimal nutrition in health and disease. The event performed in the main square of Parma lasted two full consecutive days and was attended by about 3,000 people, most of which also filled a questionnaire. A total of 120 ultrasound examinations were performed. In neighbouring Cities the events were organized for one day; as a consequence, the number of participants was lower in proportion, but very satisfactory.
Conclusion: The events were educational and enjoyable for all age groups. The interactive approach and the environment out of health-care centres facilitated population to feel comfortable and eager to learn, as well as clinical cases simulation provided a valuable entertaining experience. This strategy of raising public awareness of GI diseases seems promising, we are refining the model for a national campaign.

P1958 OPTIMAL NUTRITIONAL ROUTE FOLLOWING TOTAL GASTRECTOMY: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

S. Govil1, D. Chan2, T. Abdelrahman3, A. Folliak2, W. Lewis2, G. Clark2, G. Blackshaw2
1Cardiff University, Cardiff/United Kingdom
2General Surgery, University Hospital of Wales, Cardiff/United Kingdom

Contact E-mail Address: govils@cardiff.ac.uk

Introduction: Total gastrectomy can profoundly influence patients’ nutritional status and recovery, and controversy surrounds the various nutritional options available post-operatively, namely total parenteral nutrition (TPN), or enteral nutrition (EN) either via the nasojejunal (NJ) or feeding jejunostomy (JEJ). The aim of this review was to determine the optimal nutritional route after total gastrectomy for cancer.

Aims & Methods: PubMed, MEDLINE and the Cochrane Library (January 1985 to January 2017) were systematically searched for randomized controlled trials comparing various nutritional routes after total gastrectomy. The primary outcome measure was overall morbidity. The secondary outcome was time to morbidity.

Results: Six studies involving 353 patients (median age 62 years, 217 males, 170 TPN, 96 NJ, 87 JEJ) who underwent total gastrectomy were analysed. Overall morbidity was significantly greater in patients after TPN compared with EN (OR 1.95, 95% CI 1.16–3.28, p = 0.02). Time to morbidity was measured after 16 hrs. of food and 24 hrs. of water deprivation. Weight of faeces for 16 hrs. and transit time with charcoal were measured. Data was expressed as mean standard deviation, comparison between groups was done with two-way ANOVA.

Results:

- VAD increased body weight significantly (p < 0.05) during feeding period irrespective of fat content of the diet. Fat content and VAD had no effect on 1 hr food intake after food deprivation. HFD decreased water intake (p < 0.05), VAD blunted this effect (p < 0.05). Both HFD and VAD decreased faces weight significantly (p = 0.0001 and p < 0.05 respectively) but there was no change in intestinal transit. HFD impaired short-term memory (p < 0.02), whereas VAD compromised spatial learning (p < 0.04). HFD rats were more anxious in OFT (p < 0.01).

Conclusion: HFD-induced alterations in memory and anxiety were not affected by VAD but VAD blunted effect of HFD on water intake and faces weight, suggesting that their operating mechanisms are different. VAD by itself impaired spatial memory that requires further investigation.

Introduction: Patients on home parenteral nutrition (HPN) are exposed to a lifetime risk of catheter-related bloodstream infections (CRBSI), which threaten catheter and patient survival. Both taurodine 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurodine as CLS is superior to saline in preventing CRBSI in HPN patients.

Aims & Methods: We hypothesized that taurodine 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blinded trial randomly assigned HPN patients to use either the CLS taurodine 2% or saline 0.9% for one year. Primary outcome was the number of CRBSI/1000 catheter days. Secondary outcomes included time to CRBSI or catheter removal due to CRBSI, number of catheter removals due to CRBSI, exit-site infections, catheter occlusions, and (serious) adverse events.

Results: Of 105 randomized patients enrolled as modified intention-to-treat population. With taurodine, 5 CRBSI occurred during 15318 catheter days. In the saline arm CRBSI occurred over 12493 catheter days. CRBSI/1000 catheter days were 3.33±4.44 in the taurodine and saline groups, respectively. Relative risk, 0.23; 95% CI, 0.07 to 0.63; P = 0.002. The cumulative proportion of CRBSI-free patients after one year was 88% in the taurodine group and 49% in the saline group (P = 0.002). The number of catheter removals due to CRBSI was two (4%) in the taurodine group and eight (16%) in the saline arm (P = 0.049). The cumulative proportion of patients without a catheter removal due to CRBSI was higher in the taurodine group (P = 0.025). Exit-site infection and catheter occlusion rates were similar in both groups. Except for occurrence of CRBSI (P = 0.002), there was no difference in (serious) adverse events between groups. Drug-related adverse events were rare and generally mild to moderate.

Conclusion: Taurodine 2% decreased the risk for CRBSI by more than four times in HPN patients compared to saline 0.9%. Given its favorable safety profile and lack of evidence for altering microbial susceptibility, taurodine lock solution therefore seems a key strategy to prevent CRBSI.

P1960 REPAIR OF DAMAGED CENTRAL VENOUS CATHETERS SUBSTANTIALLY ALONGS DEVICED SURVIVAL IN PATIENTS ON HOME PARENTERAL NUTRITION

Y. Wouters1, R. Vissers1, W. Kiewit2, G. Wanten1
1Radboudumc, Nijmegen/Netherlands
2Radboud University Medical Center, Nijmegen/Netherlands

Contact E-mail Address: Yannick.Wouters@radboudumc.nl

Introduction: Patients with severe intestinal failure depend on life-long home parenteral nutrition (HPN) support. Repeated central venous catheter (CVC) loss due to complications, including mechanical damage, compromises vascular access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain vascular access.

Aims & Methods: The objective of this study was to characterize patients who underwent catheter repair and to evaluate effects on catheter survival and describe complications. This study concerns a retrospective analysis of all catheter repairs that were performed in HPN patients in the Radboud University Medical Center between January 2000 and May 2017. Primary endpoint was the difference in catheter survival in the presence or absence of catheter repair. To this end, a non-parametric survival analysis was performed. Secondary outcomes included localization of catheter damage and frequency of repair-related complications within 1 month after catheter repair.

Results: A total of 50 repairs in 38 CVCs of 32 HPN patients were included in the analysis. 16 CVCs (32%) were damaged at the distal end, near the screw thread of the catheter, 25 CVCs (50%) at the junction between the rigid and flexible part of the catheter, and 9 CVCs (18%) at the flexible part of the catheter. The mean time to catheter repair after placement was 2.2 years (95% CI = 1.55–2.89). The mean catheter survival after repair was extended by 1.4 years to 3.36 years (95% CI = 2.69–4.46; p = 0.01). No repair-related complications occurred within 1 month after catheter repair.

Conclusion: Repair of damaged CVCs significantly extends catheter life in HPN patients with previous vascular access. Catheter repair is a safe procedure.

Introduction: Catheter-related complications (CRCs) in home parenteral nutrition (HPN) patients are a threat to both catheter and patient survival. Taurine 2%, an antimicrobial catheter lock solution (CLS), is an effective agent in the prevention of catheter-related bloodstream infections (CRBSI).

Aims & Methods: The aim of this retrospective study was to evaluate long-term clinical outcomes of our HPN patient cohort that uses the CLS taurolidine. Between 2008 and 2016, all adult HPN patients requiring a central venous catheter (CVC) were included. CRBSI rates/1000 catheter days were described. Kaplan-Meier analysis was used to determine the time until a first CRC. Cox proportional hazard analysis was performed to identify risk factors for a first CRC.

Results: In 221 HPN patients, 658 CVCs (418 Hickmans, 172 PACs, and 28 non-tunneled CVCs) were inserted, comprising 261252 catheter days. Median survival for Hickmans, PACs and non-tunneled catheters was 175 (43–544), 310 (61–827) and 14 (7–19) days, respectively. During years eight follow-up, 176 CRBSI occurred and 50 catheter-related occasions (CRO). CRBSI and CRO rates/1000 catheter days were 0.74 and 0.34, respectively. In 47% and 32% of patients, at least one CRBSI or CRO occurred, respectively. Median time to a first CRBSI or CRO was 246 (54–817) and 215 catheter days (5–2070). Numerically, but not statistically, a lower CRBSI or CRO rate was associated with tauroline (RR 0.32). Twenty patients reported adverse events (5 grade 1, 13 grade 2 and 2 grade 3) or CRO was 246 (54–817) and 215 catheter days (5–2070). Numerically, but not statistically, a lower CRBSI or CRO rate was associated with tauroline (RR 0.32).

Conclusion: The study describes the largest cohort of HPN patients to date on long-term taurolidine 2% as CLS. Overall, CRC incidence rates were low when compared with the literature. We found no evidence for a decreased effect of taurolidine over time.

P1962 INTESTINAL DYSBIOSIS IN PATIENTS WITH SHORT BOWEL SYNDROME DEPENDENT ON TOTAL PARENTERAL NUTRITION IS REFLECTED BY ALTERED METABOLOME IN FAECES

Introduction: Patients with short bowel syndrome (SBS) exhibit substantial disturbances in gut microbiota composition, which implicates significant alterations of intestinal metabolism.

Aims & Methods: The aim of this study was to perform genetic and metabolomic analysis of stool samples collected from SBS patients totally dependent on parenteral nutrition (TPN). We compare the stool samples from 8 healthy individuals and 8 patients with SBS dependent on TPN. Faecal microbiota composition was assessed by sequencing of variable V4 and V3 regions of 16S rRNA gene using Illumina MiSeq TM platform. Library preparation, template and template sequencing was performed according to manufacturer’s protocol. Obtained data were filtered by quality and length and processed for alpha and beta diversity analyses using QIIME software package. SCFA profile was measured using solid phase microextraction (SPME) coupled to gas chromatography and high resolution mass spectrometry employing time of flight mass analyser (Pegasus GC-HRT; LECO, USA). D-lactate content was determined using Megazyme kit.

Results: Weighted Unfmac analysis revealed significant differences between control and TPN subjects. In healthy controls, most abundant phylum was Firmicutes (64.2±7.5%), followed by Bacteroidetes (22.5±9.1%) and Actinobacteria (8.9±4.5%). Proteobacteria were found in one control sample. In TPN group, Firmicutes represented 64.6±29% of microbiota but Bacteroidetes were absent and Actinobacteria significantly reduced (1.6±4%). Proteobacteria were found in all samples (23.6±15%). The most abundant metabolites in control stool samples were short - chain fatty acids (SCFA): acetate, propionate and butyrate. In the TPN group, lactate predominated significantly, while SCFA were absent in the intestinal content of these patients.

Conclusion: Long-term dependency on total parenteral nutrition results in dysbiosis of the intestine residuum characterized by extinction of Bacteroidetes and appearance of Proteobacteria. This metabolic change was reflected by the changes in the composition of prevailing metabolites in stool.

P1963 COMPARING RISKS OF ADVERSE EVENTS ASSOCIATED WITH PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) PLACEMENT BETWEEN THE MODIFIED INTRODUCER TECHNIQUE AND THE OVERTUBE ASSISTED PULL TECHNIQUE

Introduction: Techniques of percutaneous endoscopic gastrostomy (PEG) placement can be divided into two techniques, the pull technique or the introducer technique. Although the introduction of the pull technique has improved procedural safety for the gastrostomy placement, the pull technique, in which the PEG catheter is delivered through the oral cavity and the hypopharynx, inevitably contaminates the peristomal site. A series of studies directly comparing the newly developed modified introducer technique using a blunt cannula compared with the conventional pull technique demonstrated that the modified introducer technique was more preferable regarding procedure related adverse events. Meanwhile, use of an overtube while guiding the catheter into the stomach is expected to reduce the occurrence of the bacterial implantation. It is still unclear if the modified introducer technique or the overtube assisted pull technique would reduce risks of adverse events.

Aims & Methods: In this study, we retrospectively investigated risks of adverse events associated with the modified introducer technique and the overtube assisted pull method. Outcomes of patients who underwent the PEG placement from Jan 2013 to Oct 2016 at Jikei University Hospital were analyzed. The following data were collected from clinical records: age, gender, technique of PEG, reasons for PEG, lab tests and prognostic nutritional index (PNI).

Results: During the study period, 236 PEG placements were done in 234 patients. The average age was 69.3 ± 12.5. The modified introducer technique was applied in 167 procedures (70.8%) and the overtube assisted technique was applied in 69 procedures (29.2%). The nutritional index (PNI) of the PEG was placed aiming for a target PNI > 30.2%. Twenty patients reported adverse events (5 grade 1, 13 grade 2 and 2 grade 3) which were possibly related to the use of taudoline.

Conclusion: This study describes the largest cohort of HPN patients to date on long-term taurolidine 2% as CLS. Overall, CRC incidence rates were low when compared with the literature. We found no evidence for a decreased effect of taurolidine over time.

Disclosure of Interest: Y. Wouters: Previous financial support for prospective study from Geistlich Pharma AG. G. Wanten: Research Support from: Baxter, B. Braun, and Fresenius. patients required blood transfusion for the peristomal bleeding. In a univariate analysis, age, the rate of aspiration pneumonia as the reason for the PEG placement were higher in patients encountering adverse events (p < 0.05) (table 1). Also, serum platelet level, serum albumin and the rate of nutrition supports for cancer as the reason of the PEG placement was lower in patients encountering adverse events (p < 0.05). In a multivariate analysis, lower serum platelet level was solely recognized as a relevant predictive factor for adverse events (p < 0.05). The types of the technique used were not relevant to risks of adverse events.

Clinical backgrounds of patients with and without adverse events.

Conclusion: There was no significant difference in overall risks of adverse events between the modified introducer technique group and the overtube assisted pull technique group. However, the modified introducer technique may be associated with higher risks of severer adverse events. Especially, special care should be taken in patients with lower serum platelet level.
