secreted by cancer cells may be involved in occurrence of tumor metastasis [6, 7]. In a study by M. V. Kruchinina et al., the authors found that HMGB1 secreted by the primary tumors had an apoptotic effect on the Kupfer cells which promoted development of liver. [6, 7]. Furthermore, some researchers showed that increased levels of c-IAP2 and pERK, the downstream effector molecules of HMGB1 are found in tumor tissues. The investigation of 55 metabolites may be useful for diagnosis and treatment of CRC. However, whether HMGB1 has any role in the development of CRC metastasis is not clear. In this study, we investigated the effects of HMGB1 on CRC, and the possible underlying mechanisms were examined.

Aims & Methods: In this study, we investigated the relationship between high-mobility group B1 (HMGB1) and colorectal cancer (CRC) and the probable underlying pathogenic mechanism. In this prospective study, patients with CRC undergoing primary surgery and healthy subjects (control group) were included from July 2013 to December 2014. Serum HMGB1 concentration was determined using ELISA and HMGB1 mRNA expression was detected by RT-PCR method. Immunohistochemical analysis was performed to determine HMGB1, pERK and c-IAP2 protein expressions in the cancer tissues. Results: 114 patients with CRC and 50 healthy subjects underwent serum HMGB1 testing. Resected specimen of 50 patients were used for HMGB1 mRNA and protein expression analysis. Serum HMGB1 levels in CRC patients were higher than that of the control group (6.82 ± 1.79 µg/L, p < 0.05). Preoperative serum HMGB1 concentrations were significantly higher than the postoperative values (8.42 ± 6.57 vs. 1.64 ± 1.89 µg/L, p < 0.05). Serum HMGB1 levels in CRC patients with distant metastases were significantly higher (13.32 ± 6.12 vs. 7.57 ± 5.17 µg/L, p < 0.05). HMGB1 mRNA and protein expression in CRC tissues was significantly higher than in the adjacent normal mucosa. HMGB1 protein expression positively correlated with the lymph node metastasis. There was positive correlation between HMGB1 and c-IAP2 (r = 0.457, P < 0.01), HMGB1 and pERK (r = 0.461, P < 0.05) as well as pERK and c-IAP2 (r = 0.399, P < 0.05).

Conclusion: HMGB1 expression in CRC correlates with distant and lymph nodal metastasis. It may inhibit apoptosis by inducing activation of pERK and c-IAP2.

Introduction: Accumulating data indicate that some microRNAs (miRNAs or miRs) function as tumor suppressors or oncogenes in cancer development. We previously reported that certain miRNAs (miR-143, -145, -7a, and -34a) were differentially expressed in samples of tumors and paired non-tumorous samples taken from the same patients with colorectal tumors, and there was a relation close to adenoma-carcinoma sequence for these miRNA expressions. Aims & Methods: In this study, we examined the mRNA expression profiles of multiple colorectal adenomas comparing between sporadic colorectal adenoma and familial adenomatous polyposis (FAP). We examined the miRNA expression profiles (miRs-143, -145, -7, and -34a) and morphological appearance of 102 sporadic colorectal adenomas (SA), 27 tumors of multiple colorectal adenoma (over 10 adenomas/one patient, MA), 21 tumors of FAP and 114 sporadic cancer (SC).

Results: The expression levels of miR-143 and -145 were reduced in all tumors compared with the paired non-tumorous samples in the same patient. Especially, these miRNAs were significantly reduced in MA (P = 0.042 and P = 0.004) and FAP (P = 0.027 and P = 0.022) compared with SA. The expression levels of miR-7 were significantly up-regulated in cancers compared with adenomas (P < 0.001). The expression levels of miR-34a were significantly down-regulated in CA (P < 0.001), MA (P < 0.001), and FAP (P = 0.006) compared with SA.

Conclusion: These findings suggest that the malignant potential of MA and FAP was higher than SA, therefore MA needs strict follow-up like FAP.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Results: MPV, PCT, NLR and PLR were significantly higher in Group III compared to Group I (Table 1). However, only MPV was significantly lower in Group II compared to group I (8.6 ± 1.1 vs 8.2 ± 1, p < 0.001). The cut-off value of MPV in predicting CRC from patients with normal colonoscopy findings was 9.15 fL with a sensitivity and specificity of 80% and 91% respectively (r = 0.892).

MPV and PCT were also significantly higher in patients with neoplastic polyps compared to patients with non-neoplastic polyps (MPV: 8.7 ± 1.1 vs 8.4 ± 1, p < 0.001 and PCT: 0.23 ± 0.07 vs 0.19 ± 0.05, p = 0.003).

Conclusion: MPV and PCT may have a role as useful and simple markers in the diagnostic work-up of patients with colorectal cancer from patients with normal colonoscopic findings. In the clinical settings, these simple markers may be useful in selecting older patients for colonoscopy examination.

Contact E-mail Address: doenja.lambregts@gmail.com

Introduction: Rectal cancer patients with clinical evidence of a complete response after chemoradiotherapy may be selected for watchful waiting instead of surgical resection (although currently mainly within the scope of clinical trials). The clinical selection of potential candidates for watchful waiting to date is mainly based on morphological features seen on endoscopic images performed post-surgery (normal/teleangiectatic, ulcer, polypoid) was assessed. Additionally, the likelihood for a complete response was re-scored by the expert team according to updated selection criteria and classified as (1) residual tumour or (2) near (3) CR.

Results: 41 patients with ypT0 after surgery were identified: 9/41 (22%) had ypT0N0, 32 (78%) were true complete responders (ypT0N0). Upon reassessment by the expert team, 20/32 ypT0N0 patients (63%) were still deemed to have residual tumour (non-CR group), the remaining 12 (37%) were deemed to be possible clinical complete responders (cCR-group). In the non-cCR group vs the non-CR group patients more often showed heterogeneous signal on T2W-MRI (75% vs.25%, p = 0.01), massive/spicular fibrosis (90% vs.58%, p = 0.007) and residual high signal on DWI (58% vs.27%, p = 0.11). On endoscopy the majority of patients still had mucosal abnormalities (see Table 1). Eight ypN0 patients were still overstaged as being N+ at reassessment, mainly based on irregular nodal morphology.

Table 1: Endoscopic features of patients with ‘missed’ complete response (pCR after surgery)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Present in (%) of patients</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gross residual tumour</td>
<td>33%</td>
</tr>
<tr>
<td>Polypoid tissue</td>
<td>38%</td>
</tr>
<tr>
<td>Ulcer with irregular border</td>
<td>29%</td>
</tr>
<tr>
<td>Flat ulcer</td>
<td>25%</td>
</tr>
<tr>
<td>White scar (with telangiectasia)</td>
<td>33%</td>
</tr>
</tbody>
</table>

Conclusion: Main reasons for missing a complete response after CRT are heterogeneous T2W-MRI signal, massive/spicular fibrosis, residual diffusion-signal, ypN+ disease and residual mucosal abnormalities at endoscopy. Knowledge about these features may serve as a teaching reference to help improve the selection of patients for watchful waiting in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In patients with locally advanced rectal cancer (LARC) that show a very good response to neoadjuvant treatment, organ-preserving treatments such as watchful waiting may be a good alternative to surgical resection and can improve functional outcome and quality of life. If we can predict upfront (i.e. before commencement of CRT) how patients will respond to treatment this may create opportunities to further personalize and optimize the neoadjuvant treatment to enhance the chance of a good response, thereby ultimately offering more patients the chance of organ preservation. A promising new tool in this regard is Radiomics. Radiomics refers to a collection of analytical methods to convert images into high dimensional data via a set of quantitative descriptors called “features”. These features have the potential to uncover disease characteristics that cannot be detected by means of conventional (visual) imaging evaluation.

Aims & Methods: We aimed to assess the Radiomics signature of patients with LARC and evaluate its potential value for pre-treatment prediction of the response to neoadjuvant chemoradiotherapy.

We retrospectively assessed the primary staging MRIs (1.5T) of 124 LARC patients treated with CRT. The standard MRI protocol included T2W (T2W) and diffusion-weighted imaging (DWI) sequences, as well as quantitative apparent diffusion coefficient (ADC) maps derived from the DWI scans. For each patient, the whole volume of the rectal tumour was delineated on pre-treatment MRI, providing complete tumour regression (ypT0) versus residual tumour (ypT1-4) using histology and/or long-term FU as the standard of reference.

Results: Out of 3802 initially identified Radiomics features, 1853 proved stable across different readers/delineations. For the four manual delineations ±300/ 3802 features per reader remained significantly performant after FDR correction. However, these features did not sustain after FDR correction for the fully automated segmentation. A final subset of 266 features remained stable and performant across all five readers/delineations. These features resulted in a mean AUC of 0.67 (range 0.64-0.73) to predict a complete response and a mean ICC of 0.81 (range 0.75-0.95). Best results were obtained for textural features measuring the heterogeneity of the tumor on DWI (all top 20 features). In contrast, more ‘common’ radiological features such as volume showed inferior performance (highest rating 56) Results derived from delineations performed by the two expert radiologists and non-expert readers resulted in comparable diagnostic performance.

Conclusion: 1) Various Radiomics features extracted from pre-treatment MRI correlate to neoadjuvant treatment response and may be used as imaging biomarkers to predict the response to chemoradiotherapy in rectal cancer.

2) Best results are obtained for textural features (representing tumour heterogeneity) derived from diffusion-weighted MR sequences.

3) Features extracted from semi-automated (software generated) delineations show inferior performance compared to features extracted from manual delineations, emphasizing the need for adequate tumour delineation. Interestingly, however, delineations from expert and non-expert readers rendered similar good results, suggesting that the selected features are robust and do not necessarily require highly expert input.

P0456 CORRELATION OF ELECTRICAL AND VISCOELASTIC PARAMETERS OF ERYTHROCYTES WITH FATTY ACID COMPOSITION OF THEIR MEMBRANES AND SERUM IN PATIENTS WITH COLORECTAL CANCER

I. Prudnikova
Institution of Internal and Preventive Medicine, Federal State Budgetary and Scientific Institution, Novosibirsk, Novosibirsk; Russian Federation

Contact E-mail Address: dr.prudnikova@mail.ru

Introduction: An analysis of the efficient implementation of the guidelines for screening colorectal cancer (CRC) in patients with first diagnosed CRC (according to the archival case histories of the two medical institutions in Novosibirsk) was performed in 2013-2016, and leading reasons of late CRC diagnostics were identified.

Aims & Methods: We aimed to investigate the correlation of the electrical and viscoelastic parameters of erythrocytes with the fatty acid composition of their membranes and blood serum in patients with colorectal cancer (CRC) of different stages. 46 patients (median age of 53 + 9 years old) with CRC of various localizations and stages and 16 conditionally healthy patients were examined. Electrical and viscoelastic parameters of erythrocytes have been studied by direct electrophoresis. Fatty acid composition of erythrocyte membranes and serum has been studied using GC/MS system triple quad Agilent 7000B (USA).

Results: Erythrocytes of patients with CRC were characterized by an increasing the proportion of deformed cells with reduced strain amplitude and surface charge (low levels of cell velocity to electrodes and dipole moment) (p < 0.001-0.05). Metastasis was associated with an increase in the cell electrical conductivity, a sharp decrease of polarizability, and an increase in the tendency to hemolysis (p < 0.0001-0.03). Saturated fatty acids prevailed in composition of erythrocyte membranes in patients with CRC; omega 6/omega 3 fatty acid index was decreased, while the level of linoleic acid was significantly increased as related to oleic acid in serum of the patients with CRC compared to the healthy people (p < 0.01-0.04). The observed shifts correlated with a disease stage (r=0.04; p=0.04). The erythrocyte strain amplitude was associated with the level of unsaturated fatty acids in erythrocyte membranes (r=0.58; p<0.05), as well as with summarized viscosity (r=0.47; p=0.03) and rigidity (r=0.41; p<0.05). While the analysis of distribution of fatty acids of erythrocytes and their tendency to aggregate correlated with the level of lysofatty acids of fatty acids (r= 0.54, p=0.04; r= 0.42, p < 0.05). The surface charge of erythrocytes more closely correlated to the level (C16:2 and C18:1) in the blood serum (r = 0.42; p=0.04). There was a slight increase in the crossover frequency to the high-frequency range (r=0.03), a decrease of the cell capacity (p < 0.01), and a decrease of polarizability at high frequencies (106, 0.5 x 106 Hz) (p=0.02-0.03), as well as a decrease of C18:3, C20:2, C20:5, C20:5 and C22:6 levels in erythrocyte membranes (but not in blood serum) of CRC patients.

Conclusion: Revealing changes in the parameters of erythrocytes and fatty acid composition in blood serum associated with a stage of the disease can be promising for diagnostics and the case follow-up of patients with CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0458 POST-INVESTIGATION COLORECTAL CANCER RATES INCLUDING POST COLONOSCOPY COLORECTAL CANCER RATES IN A DISTRICT GENERAL HOSPITAL: THE POOLE EXPERIENCE MARCH 2015 TO FEBRUARY 2017

S.D. Parry, T. Deacy, E. J. Williams
Dept. Of Gastroenterology, Poole Hospital NHS, Poole Dorset/United Kingdom

Contact E-mail Address: sally.parry@poole.nhs.uk

Introduction: Post-colonoscopy colorectal cancer (PC-CRC) rates are proposed as an important measure of quality of colonoscopy service. Extrapolating PC-CRC rates is important but important to assess local practice and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT (Colonoscopy + abdomen) CRC rate at Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study1

Aims & Methods: Retrospective audit of all patients diagnosed with CRC during the initial period 1st March 2015-28th February 2017 included identified via the Somerset Cancer registry database for Poole Hospital using Crystal software. Previous colonoscopy and CT Colonoscopy (CTC) or CT abdomen results in the 3 years preceding the diagnostic investigations were reviewed across two neighbouring hospitals sharing the same electronic patient records. If patients had multiple surveillance colonoscopies the latest was counted as false negative as in previous studies2

Results: 416 patients were identified, 67 were excluded (39 non adenocarcinoma, 3 out of area, 12 patients where earlier decision was best supportive care, 6 patients diagnosed at laparotomy, 2 patients with abnormal PET scans and 6 with incomplete datasets). 348 patients were included for analysis. Colorectal cancer was diagnosed by colonoscopy in 200 patients and by CTC or CT for the remaining 148 patients in 148 cases. In the colonoscopy diagnosed group, 55 were via Bowel Cancer Screening Programme (BCSP), 138 via the symptomatic service and 7 from the surveillance programme. In the BCSP group 1 patient had a preceding colonoscopy within the previous 3 years. In the symptomatic service groups there were 7 preceding colonoscopies and in the surveillance group there were 5 preceding (“false negative”) colonoscopies within the previous 3 years. The overall PC-CRC rate was 6.5 (+3.6, +2.2 %) (90% confidence interval). In the BCSP diagnosed group, 1 patient with a preceding BCSP colonoscopy and the symptomatic service 4 from the surveillance group underwent CT scans within the preceding 6–36 months. All bar one of these 15 patients had undergone preceding CT abdomen scans with one elderly patient from the symptomatic service group having undergone a CT colonoscopy. The post CT-CRC rate was 10.2 (+5.0, +3.2 %) and the overall combined post investigation colorectal cancer (PI-CRC) rates during this two year period was 8.0 (+2.8, +2.0 %).

Conclusion: Our findings offer the opportunity for further review of individual patients to clarify their clinical course. The method of calculating PI-CRC rates needs ratification as well as more robust IT systems to capture and analyse the data if it is indeed a measure that is to become part of endoscopic quality assurance. Finally our numbers are small and methods suitable for retrospective observational population based studies may not transfer to assessing quality indicators at a local level.

RISK OF DETECTION OF GASTROINTESTINAL NEOPLASMS AND DEATH IN SYMPTOMATIC PATIENTS WITH A POSITIVE FECAL IMMUNOCHEMICAL TEST WITHOUT COLORECTAL CANCER

N. Pin, M.J. Iglesias, D. Remedios, P. Vega, J. Cubiella
Servicio De Aparato Digestivo, Complejo Hospitalario Universitario de Ourense, Ourense/Spain

Contact E-mail Address: noel.pin.viejo@sergus.es

Introduction: The fecal immunochemical test (FIT) has a high diagnostic accuracy for the detection of colorectal cancer (CRC) in symptomatic patients. However, we do not know the risk of other gastrointestinal neoplasms associated with a false positive test.

Aims & Methods: To calculate the risk of detection of gastrointestinal tract tumors (GITT) and death in symptomatic patients with a positive FIT determination and without a CRC in a complete colonoscopy with an adequate bowel preparation. We designed a prospective cohort study with follow-up. Patients from the COLONPREDICT study with complete colonoscopy without CRC were included. Two cohorts were defined: FIT positive and negative according to the ≥20ng/hemoglobin/g feces threshold. We performed a descriptive analysis of factors detected during follow-up and mortality. We estimated the differences in the risk of GITT detection and mortality between the two cohorts by logistic regression and proportional hazards after adjusting for age, sex, and significant colonic lesions (CSL) detection at baseline colonoscopy.

Results: We included 1061 patients without CRC and a complete baseline colonoscopy; 320 (30.2%) with a positive FIT and 741 with a negative FIT. The median follow-up was of 36.0±8.9 months with no difference between both groups (p=0.2). There were significant differences regarding age (67.5±12.7 years vs. 64.8±13.5 years, p=0.004) and sex (45.9% vs 52.0% females, p=0.04) between both cohorts. We detected a GITT in 14 (4.4%) patients with a positive FIT: 5 CRC, 6 gastric, 1 small intestinal lymphoma and one patient with a CRC and a small intestine adenocarcinoma; and in 12 (1.6%) with a negative FIT: 4 CRC, 2 small intestine adenocarcinoma, one esophageal, and one patient with a gastric and a CRC. Patients with a positive FIT had a non-significant increase in the risk of GITT detection (OR 2.1, 95% CI 0.9–4.8) after adjusting for age, sex and SCL. The overall risk of death in both groups was 8.8% and 6.7%, respectively, with no significant differences between both groups in the survival analysis (HR 1.3, 95% CI 0.8–2.1). However, the risk of death due to a GITT was 3.1% (10 deaths) in the positive FIT group and 0.8% (6 deaths) in the negative FIT group, with a significant difference after adjusting for age, sex and SCL (HR 3.2 95% CI 1.2–8.9).

Conclusion: Symptomatic patients with a positive FIT and complete colonoscopy without CRC are at increased risk of death due to GITT regardless of age, sex or the presence of SCL.

Introduction: Self-expandable metallic stent placement for malignant colorectal obstruction has been widely used; however, factors affecting the technical difficulty of stenting remain unclear.

Aims & Methods: The aim of this study was to clarify the factors associated with the technical difficulty of stenting for malignant colorectal obstruction. We established the Colonic Stent Procedure Research Group to provide instructions on how to perform stenting and to conduct this prospective, single-arm, observational, multicenter clinical trial between October 2013 and May 2014 in Japan. Thirty-two facilities participated in this study. A double-wire venous uncovered stent was placed by using a standard through-the-scope colonoscopic placement technique in each patient. Stent deployment time was defined as the time from reaching a lesion with a colonoscope to finishing the technical difficulty of stenting. Technically difficult cases of stenting were defined as independent factors associated with the technical difficulty of stenting by univariate and multivariate analyses.

Results: A total of 205 consecutive patients were enrolled in this study. Nine patients including 3 patients with technical failure of stenting, 5 patients with non-stenting and 1 patient with stenting for benign lesion were excluded. The remaining 196 patients were succeeded in stenting. Of these, 100 were men (51%) and the median age was 72 years old (interquartile range (IQR), 62–82 years old). One hundred eleven patients (57%) underwent stenting as a bridge to surgery, and 85 (43%) underwent stenting for palliation. The technical and clinical success rates were 98.5% and 97.0%, respectively. None of the patients experienced colorectal perforation. The median total procedure time in the cohort with technical success was 30 minutes (IQR, 18–42 minutes). The median deployment time was 21 minutes (IQR, 11–31 minutes). Forty-nine patients with a deployment time longer than 31 minutes were regarded as technically difficult cases of stenting. The following factors were identified as independent factors of the technical difficulty of stenting: presence of ascites (odds ratio, 2.483; 95% confidence interval [95%CI], 1.17–5.29; p=0.02), placement of >1 stent (odds ratio, 4.80; 95%CI, 1.10–21.1; p=0.04).

References
1 Int J Cancer 2014; 136: E359–86.
Conclusion: At this mid-study follow-up, paclitaxel-eluting stents appear to be efficacious for the three study groups.

Days 15 and 30 were selected to allow initial drug elution and to compare drug release to drug elution, respectively. At both 30 and 60 days post-implant, no persistent clinical symptoms were observed in any animal. Bile duct dilation and increased tissue overgrowth in all stent groups, which was expected to occur in the bare metal stent group, was not observed. A 4 cm length uncovered, laser-cut nitinol stent was coated with a polymer matrix allowing slow release of paclitaxel. Naïve Yucatan swine were assigned to each of the three study groups: control (n = 3, no polymer), standard dose paclitaxel (n = 6, 149.4 µg paclitaxel) and challenge dose (n = 3, 538.0 µg paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group. One stent was placed proximal to the papilla. Stents were assessed for migration via digital radiographs for the first 2 weeks and then monthly via endoscopy using SpyGlass™ DS cholangioscopic and cholangiography with a targeted 6 month study endpoint. Results: At 30 days post-implant, no significant tissue reaction to any stent was observed. However, all animals displayed mild biofilm formation and increased intraductal mucous production. Substantial dilation of the common bile duct was observed in 5/11 animals with no apparent relationship between drug coating and bile duct dilation. At 60 days post-implant, moderate mucus and biofilm formation was observed within the stent, however in only 3 animals bile duct dilation persisted and in the majority of stents were fully apposed to the duct wall. Although some animals displayed minimal tissue hyperplasia at the proximal end of the stents, no tissue overgrowth or stent embedding was observed in any animal. Up to 60 days post-implant, no persistent clinical symptoms were observed in any animal. Reduced dose animals were removed from the study between days 15 and 30, while all animals continued to be observed. At 60 days post-implant, no increase in number of dilated ducts between days 30 and 60, we expect increased rate of in vivo drug release rates in the bile duct over a 30 day period. Future cholangioscopic and histopathological assessment of these swine will further clarify the safety and effectiveness of paclitaxel stent coatings to mediate bile duct tissue ingrowth.

A328 United European Gastroenterology Journal 5(5S)
Aims & Methods: In this prospective study, we evaluated the overall survival (OS) of low rectal cancers with chemoradiotherapy and those with inappropriate first-line chemotherapy group based on CD-DST. Moreover, we evaluated additional effects of EGFR (Cetuximab; Cmab, Panitumumab; Pmab) to FOLFOX/FOLFIRI using CD-DST. Between Mar. 2008 and Aug. 2016, we obtained tumor specimens from 131 CRC patients without preoperative chemotherapy. Informed consent for measurement of individual chemosensitivity was obtained from all patients in writing. Approval for the present study was obtained from the Tobu Chikhi Hospital Institutional Review Board (No: 02.03.29. #1). The growth inhibitions were determined by CD-DST. The regimens were as follows: FOLFOX, FOLFIRI, Cmab, Pmab, and FOLFOX/FOLFIRI + Cmab. The incubation conditions were as follows: FOLFOX, 5-FU and 1-OHP (6.0 and 3.0 μg/ml, respectively) for 24 h. FOLFIRI, 5-FU and SN-38 (6.0 and 0.2 μg/ml, respectively) for 24 h. FOLFOX, Cmab and Pmab for 144 h. Pmab; Pmab 200 μg/ml for 144 h. FOLFOX + Cmb; Cmb 250 μg/ml for 120 h after FOLFOX/FOLFIRI incubation process. The cumulative distribution of IR values under each condition was evaluated on the basis that the clinical response to chemotherapy is equivalent (approximately 50%). The OS between the group treated with appropriate first-line chemotherapy and the group treated with inappropriate first-line chemotherapy were evaluated Kaplan-Meier method. Additional effects of Cmab to FOLFOX/FOLFIRI were also evaluated. Results: There was strongly relationship between the IR% of the FOLFOX and FOLFIRI regimen (R² = 0.7415). The median of the IR% with the FOLFOX and FOLFIRI regimen were 58.6 and 69.1, respectively. FOLFOX responder, FOLFIRI responder, dual responder, and poor responder were 8, 10, 53, and 60, respectively. There were 42 unresectable CRC patients with chemotherapy. The FOLFOX responder, dual responder, and poor responder were 58.6 and 69.1, respectively. FOLFOX regimen were 58.6 and 69.1, respectively. FOLFOX, FOLFIRI, Cmab and that of Pmab (R² = 0.686). Additional rates (%) of Cmab to FOLFOX between poor responder and other responder were 19.81 and 5.46, respectively (P=0.020). Additional rates of Cmab to FOLFIRI between poor responder and other responder were 16.50 and 1.29, respectively (P=0.005). There was significantly more additional effect of Cmab to FOLFOX/FOLFIRI in poor responder than in other responders.

Conclusion: Administration of the recommended first-line regimen using CD-DST is an effective strategy for CRC patients. Moreover, especially in poor responder, Cmab should be administrated to FOLFOX/FOLFIRI regimen.

P04608 LONG-TERM COLONOSCOPIC SURVEILLANCE BETWEEN PATIENTS WITH UNRESECTED DIMINUTIVE POLYPS AND THOSE WITH COLORECTAL ADENOMAS > 5MM IN SIZE RESECTED AT INITIAL COLORECTAL CANCER SURGERY.
S. Kimura1, M. Tanaka2
1Gastroenterology And Endoscopy, Aomori Rosai Hospital, Hachinohe/Japan
2Pathology And Laboratory Medicine, Hiroaki Municipal Hospital, Hiroaki/Japan

Contact E-Mail Address: saint4road@gmail.com
Introduction: A long-term risk of colorectal advanced neoplasia among patients having diminutive polyps at initial colonoscopy has been unknown. The present study aimed to compare the risk of metachronous advanced neoplasia during follow-up between patients with untreated diminutive colorectal polyps and those with small or large adenoma resected at baseline colonoscopy.

Aims & Methods: A total of 1595 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, B, and C as follows: A group (mean age 64.7 yr, M:F = 2.37:1) with low-grade adenoma colonoscopically resected at baseline, 245 in group B (66.1 yr, 2.31:1) with high-grade adenoma or intramucosal cancer colonoscopically resected at baseline, and 388 in group C (65.1 yr, 1.54:1) with invasive cancer resected at baseline. During follow-up colonoscopies detected metachronous neoplasms were resected and pathologically evaluated into non-inferior lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative incidences of metachronous colorectal neoplasms were compared with each other using Logrank test.

Results: Median follow-up periods and frequencies of colonoscopy were 64.3 months and 3.7 times in group A, 52.0 months and 3.5 times in group B, and 74.6 months and 3.9 times in group C, respectively. The cumulative incidences of metachronous non-index lesion were 24.5% (109 patients with 299 low-grade adenomas) in group A, 26.1% (64 with 184) in group B, and 19.3% (75 with 229) in group C, respectively. The prevalence of metachronous non-index lesion was lower in group B compared to that in group A (p = 0.07), and group C compared to that in group B (p = 0.05). Logrank test revealed that the cumulative incidence of metachronous non-index lesion in group B, 31 (31 patients with 3 high-grade adenomas or cancers) in group A, 6.9% (17 with 17) in group B, and 12.3% (48 with 55) in group C, respectively. The prevalence of metachronous index lesion was higher in group C compared to that in group A (p < 0.05) and group B (p < 0.05). The cumulative incidences of metachronous invasive cancer were 0.9% (4 patients with 4 invasive cancers) in group A, 1.2% (3 with 3) in group B, and 3.6% (14 with 14) in group C, disclosing highest prevalence in group C (p < 0.05). Logrank test revealed that the cumulative incidence of metachronous non-index lesion was highest in group C, and significantly different differences were observed compared to those in group A and B.

Conclusion: Significant higher prevalence of metachronous index lesion including invasive cancer and, in contrast, significantly lower prevalence of metachronous non-index lesion were observed in patients after resection of colorectal cancer compared to those after endoscopic resections of colorectal adenoma and intramucosal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.
incidences of metachronous colorectal neoplasms were compared with each other group. Log rank test.

Results: Median follow-up periods and frequencies of colonoscopy were 61.9 months and 3.6 times in group A, 61.6 months and 3.4 times in group B, and 72.3 months and 2.7 times in group C, respectively. The cumulative incidences of metastatic colorectal cancer were 24.1% (30 patients with 375 low-grade adenomas) in group A, 14.7% (73 with 168) in group B, and 6.6% (34 with 56) in group C, respectively. The prevalence of metachronous non-index lesion was highest in group A followed by those in group B and C, with significant differences observed between group A and B (p < 0.0005), and B and C (p < 0.05). The cumulative incidences of metachronous invasive cancer were 1.0% (6 patients with 6 invasive cancers) in group A, 1.4% (7 with 7) in group B, and 0.2% (1 with 1) in group C. No significant differences were observed, and logrank test revealed that the cumulative incidence of non-index lesion was highest in group A, and statistical significances were observed between group A and B (p < 0.0001), and between group B and C (p < 0.00001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group A, and statistical significances were observed between group A and B (p < 0.005), and between group B and C (p < 0.005).

Conclusion: The results of a longer colonoscopic follow-up disclosed a significantly higher prevalence of metachronous advanced neoplasms in patients with adenoma >5mm in size resected at baseline compared to those with diminutive polyps left untreated at baseline. Persons with no polyps at baseline colonoscopy were at very low risk of advanced neoplasia within five years during follow-up.

P0470 A NEW SCORING MODEL FOR PREDICTING ADVANCED COLORECTAL NEOPLASMS IN ASYMPTOMATIC SCREENING POPULATION AND COMPARISON WITH THE MODIFIED ASIA-PACIFIC COLORECTAL SCORING SCORE

M. Sekiguchi1, T. Matsuda2, Y. Kakugawa3, M. Matsumoto2, Y. Saito2

Introduction: Colorectal Cancer (CRC) is one of the major causes of death even in countries with a CRC screening program, indicating the need for improved screening methods. Risk-stratification of populations is one strategy that might satisfy this requirement. Currently, in the Asia-Pacific region, the use of the modified Asia-Pacific Colorectal Scoring (APCS) score [age 50–59: 1 point, age ≥60: 2, male sex: 1, presence of a first-degree relative (FDR) with CRC: 1, current or past smoker: 1, body mass index (BMI) ≥23kg/m²: 1] has been proposed for risk-stratification.1,2 However, further validation studies are required to approve the proposed model and considering the reported limited discriminatory capability of the score for advanced colorectal neoplasia (ACN), the development of a more useful scoring model is expected.

Aims & Methods: The aim of this study was primarily to develop and validate a new scoring model for predicting ACN in an asymptomatic screening population that is more useful than the APCS score. We externally validated the APCS score in a Japanese screening population and compared its discriminatory capability with that of our new scoring model. Data were reviewed from 5218 consecutive asymptomatic screened individuals who underwent colonoscopy for their first time at the Cancer Screening Center, National Cancer Center Hospital, Tokyo between February 2004 and March 2013. Multivariate logistic regression was used to investigate the associations between clinical variables and the presence of ACN in the subjects, and then a new scoring model was developed based on these associations. Scores were weighted according to the beta coefficient obtained from the logistic regression model. Thereafter, the discriminatory capability of the new model was assessed using the c-statistics in the development set. Performance of the new model was internally validated using bootstrapping with 1000 replicates. The discriminatory capability of the modified APCS score in the 5218 subjects was also assessed using the c-statistics. The value obtained was weak positively correlated with threshold for first RS (r = 0.03).

Conclusion: An 8-point scoring model to predict ACN in asymptomatic screening population that might have a higher discriminatory capability than the modified APCS score was developed and internally validated in this study. Our simple scoring model could stratify the screened population into low-, moderate-, and high-risk groups. Of the detected ACN, a substantial number were proximal or flat; therefore, primary screening with total colonoscopy may be advisable for high-risk individuals.

Introduction: Previous studies have shown that increase of threshold for first rectal sensation can be a predictor of fecal incontinence. However, significance of the entire range of rectal inhibitory reflex (%)RAIR in development of this disease remains unknown.

Aims & Methods: To determine association between %RAIR and threshold for first rectal sensation in healthy adults and its significance in development of fecal incontinence. 26 asymptomatic healthy volunteers (18 women, 8 men) median age was 35.03 years (19–59) were studied. We performed a high-resolution anorectal manometry (HRAM) using a 20 channels silicone water-perfused catheter (Solar GI, MMS, Netherlands). The following HRAM parameters were analyzed: threshold for RAIR and %RAIR (automatically calculated as the ratio of the amplitude of the relaxation of the anal sphincter (AS) to the basal pressure AS *100%), threshold for first rectal sensation (RS) and for desire to defecate. The statistical analyses were performed using Statistica for Windows 6.0 (StatSoft Inc.).

Results: Threshold for RAIR and %RAIR were 22.3 ml (10.0; 30.0), 7.44% (38; 99.5) respectively. Threshold for first RS was 30.07 ml (11.1; 58.3) and desire to defecate – 65.12 ml (33.5; 182.0). Threshold for RAIR was not associated with threshold for first RS (r = 0.00005), and for desire to defecate (r = 0.02). %RAIR was weak positively correlated with threshold for first RS (r = 0.26) and was not associated with threshold for desire to defecate (r = -0.03).

Conclusion: Threshold for RAIR and %RAIR are not associated with first rectal sensation. So, these parameters of RAIR cannot be predictors of fecal incontinence.

Introduction: Trait neuroticism and the DeLong et al. questionnaire consistently found to be associated with more severe functional gastrointestinal (GI) symptoms (1). One explanation for this is that high neuroticism predisposes individuals towards avoidant coping by leading them to view negatively-valenced situations as catastrophic (2) and, therefore, unsolvable (3). Avoidant coping, in turn, increases the risk of developing GI discomfort because over-reliance on “flight” strategies in stressful situations overstimulates the sympathetic nervous system at the expense of parasympathetic activity necessary for digestion (4). Evidence for this proposed chain of events is substantiated by findings of relationships between each pair of the chain’s components: neuroticism and avoidant coping (e.g., 3), and avoidant coping and higher GI symptom burden (e.g., 1). Across two studies, this paper integrates these findings, while also exploring the role of somatisation. Somatisation is consistently observed in people suffering from functional GI Conditions (e.g., 1) and refers to a subtype of avoidant coping - avoidant coping and GI symptoms are connected would need to be expanded to

Conclusions: Avoidant coping is significantly linked to higher GI symptom burden, and this effect is mediated by trait neuroticism. The role of somatisation in these findings needs to be considered in further studies.
predict that somatisation has deleterious consequences for GI conditions - possibly because it encourages reduced physical activity (7). Aims & Methods: In Study 1, 147 undergraduate students completed measures of neuroticism, 14 coping styles (including avoidant styles such as denial and disengagement), somatisation and GI symptom burden. In Study 2, where participants were undergraduates and hospital outpatients (pooled N=250), the variables investigated in Study 1 were measured alongside hypochondriasis, which was included to measure the aspect of somatisation that involves worry independently of any actual physical symptoms. Statistical analysis was based on path modeling. It involved fitting a model to test a priori hypothesised indirect relationships between neuroticism and GI symptom severity via the selected coping styles and somatisation. Direct effects were also estimated, meaning that the path analysis provided information regarding the significance of any indirect effects once a range of direct effects were accounted for. Only six coping styles found to correlate significantly with any actual physical symptoms. Statistical analysis was based on path modeling. Results: Significant standardised path model coefficients involving neuroticism across the two studies. In Study 1, neuroticism exerted indirect effects on symptom burden through substance-use-based coping and somatisation, as well as through disengagement-based coping and somatisation. In Study 2, neuroticism affected GI symptom burden through denial-based coping and somatisation, as well as through denial-based coping and hypochondriasis. An indirect effect of neuroticism through self-blame and somatisation, with the two intermediary variables relating negatively to each other, was observed in Study 1. (Note: *p < .05, **p < .01, ***p < .001). (n.s. denotes non-significant coefficients). Conclusion: Somatisation and hypochondriasis were found to be intervening variables in the relationship between neuroticism, avoiding coping (through substance-use, disengagement and denial) and GI symptom burden. Two interpretations of the findings are: (1) avoidance reduces the impact of neuroticism on reduced physical activity, which can interfere with digestion; and (2) GI symptoms are among the wide range of functional somatic symptoms that can arise from avoidance coping. These findings open new avenues for multidisciplinary treatment of FGIDs. Disclosure of Interest: All authors have declared no conflicts of interest.

P0473 POTENTIAL REGULATORY EFFECTS OF CORTICOTROPIN-RELEASING FACTOR ON TIGHT JUNCTION-RELATED INTESTINAL EPITHELIAL PERMEABILITY ARE PARTIALLY MEDIATED THROUGH CK8 UPREGULATION
Y. Hu, B. Li
1Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China

Contact E-mail Address: jiyueqingxuan@163.com

Introduction: This study aimed to investigate the regulatory effects of corticotropin-releasing factor (CRF) on the permeability of human intestinal epithelial cells through CK8-mediated tight junction. Aims & Methods: The expression of CRFR1 and CRFR2 on HT29 cell surfaces were upregulated by immunostaining (7). Results: CRF treatment with 100 nM CRF for 72h, the transmission of FITC-labeled Dextran was measured by a transwell chamber; the structural changes of tight junctions were observed under transmission electron microscopy; the expression and function of tight junction protein occludin were detected by immunoblotting and immunofluorescence. The activity of RhoA was detected by immunoprecipitation. Furthermore, effects of CRF on intestinal epithelial permeability were examined in CK8-silenced HT29 cells, which were constructed by shRNA interference. Results: CRF treatment increased FITC-labeled Dextran permeability, caused opening of tight junctions, induced increased fluorescence intensity of CK8 and decreased intensity of ZO-1, claudin-1, and occludin, together with structure destruction. The expression and function of tight junction protein occludin were downregulated. RhoA activity peaked at 30 min after CRF treatment. The increased permeability and the downregulation of claudin-1 and occludin induced by CRF treatment were not blocked by CK8 silencing. Nevertheless, CK8 silencing blocked the effects of CRF with regard to decrease in the expression of F-actin and ZO-1 and increase in RhoA activity. Conclusion: CRF may increase intestinal epithelial permeability by upregulating CK8 expression, activating the RhoA signaling pathway, promoting intestinal epithelial actin remodeling, and decreasing the expression of the tight junction protein ZO-1. Other CRK8-independent pathways may lead to decreased expression of claudin-1 and occludin, which also contributes to increased intestinal epithelial permeability. Disclosure of Interest: All authors have declared no conflicts of interest.

P0474 REGULATING EFFECTS OF TONGXIE-YAOFANG FORMULA ON COLONIC MUCOSAL INFLAMMATION IN RATS WITH DIARRHEA-PREDOMINANT IRRITABLE BOWEL SYNDROME

Introduction: Diarrhea-predominant irritable bowel syndrome (D-IBS) is a chronic functional gastrointestinal disease. Its clinical manifestations are characterized by diarrhea and abdominal pain or discomfort in the absence of a structural basis. D-IBS is not self-limiting and is often accompanied by demonstrable pathology. The diagnosis of D-IBS is based on symptom assessment and the Rome III Diagnostic Criteria. According to an epidemiological study, D-IBS mainly affects young adults of 20–40 years old, and the quality of their lives is seriously affected. The pathogenesis of D-IBS has not been clarified. Consequently, the usual treatment of the disease in Western medicine involves symptomatic therapy, which is unsatisfactory for patients while simultaneously increasing the use of health-care resources. Because traditional Chinese medicine (TCM) can significantly improve patients' symptoms and quality of life, increasing numbers of patients have begun to seek treatment with TCM. A series of randomized, double-blind, placebo-controlled trials had shown that Tongxie-YaoFang (TXYF) formula can significantly improve the clinical symptoms, such as diarrhea and abdominal pain or discomfort, of patients with IBS and improve the quality of their lives. However, the specific mechanism of it has not been completely elaborated. The purpose of this paper is to observe the regulating effects of TXYF-formula on colonic epithelial secretion via relevant indices.

Aims & Methods: To investigate the pharmacological effect of Tongxie-YaoFang (TXYF) formula, a Chinese herbal formula, on Diarrhea-predominant irritable bowel syndrome (D-IBS) rats. The effect of neonatal maternal separation plus restraint stress (NMS+RS) model of D-IBS, male Sprague Dawley rats were randomly divided into two groups (NMS+RS group and TXYF-formula group) with no handlings were used as controls (NH group). Starting from the postnatal day 60, rats in TXYF-formula group were administered TXYF-formula (4.92g/100g bodyweight) orally twice a day for 14 consecutive days while NH group and NMS+RS group were given distilled water. Using short-circuit current technology, we observed 5-HT-induced changes of current across ion channels, as such as cystic fibrosis transmembrane conductance regulator (CFTR) Cl channel, epithelial Na channel (ENaC), Ca2+-dependent CI channel (CACC), Na+-K+-2Cl co-transporter (NKCC), and Na+-HCO3 co-transporter (NBC), in the colonic epithelium of three groups after exposure to D-IBS for 14 days. The expression of CRFR1 and CRFR2 on HT29 cell surfaces were examined with immunostaining, and the permeability of human intestinal epithelial cells through CK8-mediated tight junction was measured by a transwell chamber; the structural changes of tight junctions were observed under transmission electron microscopy; the expression and function of tight junction protein occludin were detected by immunoblotting and immunofluorescence. The activity of RhoA was detected by immunoprecipitation. Furthermore, effects of CRF on intestinal epithelial permeability were examined in CK8-silenced HT29 cells, which were constructed by shRNA interference. Results: CRF treatment increased FITC-labeled Dextran permeability, caused opening of tight junctions, induced increased fluorescence intensity of CK8 and decreased intensity of ZO-1, claudin-1, and occludin, together with structure destruction. The expression and function of tight junction protein occludin were downregulated. RhoA activity peaked at 30 min after CRF treatment. The increased permeability and the downregulation of claudin-1 and occludin induced by CRF treatment were not blocked by CK8 silencing. Nevertheless, CK8 silencing blocked the effects of CRF with regard to decrease in the expression of F-actin and ZO-1 and increase in RhoA activity. Conclusion: CRF may increase intestinal epithelial permeability by upregulating CK8 expression, activating the RhoA signaling pathway, promoting intestinal epithelial actin remodeling, and decreasing the expression of the tight junction protein ZO-1. Other CRK8-independent pathways may lead to decreased expression of claudin-1 and occludin, which also contributes to increased intestinal epithelial permeability. Introduction: Stressful life events may trigger the symptoms of irritable bowel syndrome (IBS). Preclinical chronic stress models have been developed in animals to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silicate clay, is an adjuvant widely used for the treatment of several gastrointestinal diseases, mainly diarrhoea but also the functional abdominal pain experienced in chronic IBS. However, the effect of diosmectite treatment on IBS visceral hypersensitivity has never been investigated.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. For this purpose, visceral hypersensitivity (CVH) was induced by colonic injection of 0.5% acetic acid (AA) in 10-day old rats while control (NS) induced with 0.9% NaCL (CVH-NS). A group of control with no stress but with WAS (Con-sham) was used as another AWR was assessed, and the hippocampus and prefrontal cortex (PFC) and its metabolism were measured.

Introduction: DA-9701, a newly developed prokinetic agent formulated with Pharmacognomon and Corydalis, has been shown to effectively treat functional dyspepsia. Recently, it has also been suspected to improve gastrointestinal motor function. Aims & Methods: The aims of this study were to assess the effect of DA-9701 on colonic transit time (CCT) and symptoms of functional constipation. We prospectively enrolled 33 patients with functional constipation based on the Rome III criteria. The patients received 30 mg DA-9701 three times a day for 24 days. CCT was estimated initially and at the end of treatment. We also analyzed symptoms such as spontaneous bowel movements (SBMs), straining, stool form, feeling of incomplete emptying and anorectal blockage, abdominal discomfort and pain, overall defecation satisfaction, and incidence of adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0477 NEGATIVE EFFECTS OF BIFIDOBACTERIUM BIFIDUS ON THE RAT WITH COLONIC VISCERAL HYPERSENSIVITY INDUCED BY ACETIC ACID PERFUSION

X. Wang, W. Zhang, K. Wang, L. Zhang, Q. Sun, L. Duan
Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 15035126210@163.com

Introduction: Bifidobacterium with appropriate doses has been suggested to be an effective therapy for the treatment of IBS. But the impacts of Bifidobacterium on visceral sensation have never been reported. The negative effect of Bifidobacterium has been rarely studied and reported.

Aims & Methods: We aimed to study the effects of gavage administration with Bifidobacterium bifidus for two weeks on the visceral hypersensitivity of rats. Colonic visceral hypersensitivity (CVH) was induced by colonic injection of 0.5% acetic acid (AA) in 10-day old rats while control (NS) induced with 0.9% saline. The abdominal withdrawal reflexes (AWR), induced by colorectal distention (CRD), was used to quantify the level of colonic sensitivity in adult rats. The CRD in 42-day old were treated by gavage administration with Bifidobacterium bifidus (1*107 CFU/day) for two weeks (CVH-Bifi). Other CRD were treated with 0.9% NaCL (CVH-NS). A group of control with normal sensitivity was treated with sham gavage (Con-sham). In day 56th, another AWR was assessed, and the hippocampus and prefrontal cortex (PFC) were separated and used to analyze the c-fos, NMDAR 2A, NMDAR2B with western-blot.

Results: After two-week gavage, the CVH-Bifi presented lower volume than that of CVH-NS in CRD, though without significant difference (2.35 ± 0.28 vs.2.40 ± 0.23; p = 0.11). No significant difference was found between CVH-Bifi and Con-sham as well. In hippocampus, c-fos of CVH-Bifi was higher than that of Con-sham (1.04 ± 0.22 vs. 0.51 ± 0.16; p = 0.055). In PFC, the expression of c-fos of NMDAR2A in CVH-Bifi was significantly higher than that of CVH-NS (0.63 ± 0.14 vs. 0.21 ± 0.05; p = 0.004) and Con-sham (0.63 ± 0.14 vs. 0.20 ± 0.07; p = 0.011).

Conclusion: We reported the negative effects of Bifidobacterium bifidus gavage, which induced higher activation of c-fos and higher expression of NMDAR 2A in hippocampus and PFC. The roles of Bifidobacterium bifidus and its metabolites on visceral sensitivity needs further study to clarify.

Disclosure of Interest: All authors have declared no conflicts of interest.
**Results:** Twenty-seven patients completed the study. DA-9701 was associated without a significant CTT from 14.9 ± 6.8 to 3.7 ± 1.7 hours (P = 0.001). Significant CTT also significantly decreased after treatment (right CTT: from 14.0 ± 8.2 to 7.5 ± 4.7 hours, P = 0.001; rectosigmoid transit time: from 14.2 ± 11.9 to 9.5 ± 10.9 hours, P = 0.021). In addition, all constipation-related subjective symptoms, including SBM frequency, significantly improved compared to those before treatment. Serious adverse events did not occur.

**Conclusion:** DA-9701 accelerates colonic transit and safely improves symptoms in patients with functional constipation. Therefore, we suggest that this novel agent could help to treat patients with this condition.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

(continued)
The quality of referrals of patients with clinically suspected FGIDs do not result in long waiting lists and poor patient outcomes. New models of care are needed to translate specialist knowledge of functional gastrointestinal disorders (FGID) into primary care practice.

Aims & Methods: This study aimed to evaluate the safety and performance of an algorithm-based approach to the diagnosis and management of FGID. Consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over 2 years, with non-specific GI symptoms (no alarms) were randomised to waitlist control or intervention (2:1). Intervention patients were screened for alarms and abnormal blood/stool tests without an in-person consultation, to exclude organic disease (full blood count, C-reactive protein, biochemistry, thyroid function tests, iron studies, coeliac serology, H. pylori serology, faecal calprotectin and elastase) and classified according to the Rome III criteria. Information from patients with clinical alarm or a gastroenterology consult on board was judged appropriate, a prompt GE appointment offered. Elsewise patients received a letter stating that diagnosis and management options. Referrals were analysed for quality according to clinical triage practices.

Results: 89 intervention patients (61% female, mean 42, [SD 14]) and 21 control (75% female, mean 42, [SD 16]) y patients completed intake. 35 intervention patients warranted prompt GE review after active screening. Organic disease was diagnosed in 10 (diagnosed: 19 FGID, 2 IBD, 1 neoplasm, 1 pancreatic insufficiency, 1 reflux esophagitis, iron deficiency, 1, 7 did not attend), and 4 had additional clinically significant findings (polyps, iron deficiency). 45 were diagnosed with a FGID (9 had another non-urgent diagnosis). At follow-up (mean 2.7 y [SD 0.5yrs] post-referral), none of the 45 patients diagnosed with FGID had needed a gastroenterology consult based on the original referral (six received a specialist appointment via duplicate referrals within the system).

Conclusion: Among individuals who meet Rome IV criteria for IBS in the general population, those who are older, have more frequent bloating, have greater concern about their bowel function, and who are more socially affected by their bowel symptoms, are more likely to consult doctors about their bowel symptoms. In contrast, IBS consultants and non-consultors do not differ in their abdominal pain severity or extra intestinal symptom burden. Support: The Rome Foundation.

Introduction: Irritable bowel syndrome (IBS) affects 5–15% of adults in the general population, and is characterized by chronic recurrent abdominal pain, discomfort and associated with altered bowel habits. The pathophysiology of IBS is complex and not fully understood. Hence, treatment is often based on symptomatology rather than underlying physiological aberrances.

Aims & Methods: We retrospectively reviewed, via electronic records, all the patients seen at the Scottish Gut Motility Disorder Clinic between January and December 2016 included, focusing on original referral, diagnosis and treatment to evaluate the need for specialist input.

Results: In 2016, 378 patients attended the Motility Clinic total of 459 visits: 333 female, mean age was 51.4 (range: 16 to 95 years), 60% of referrals originated via secondary care (40% GI, 50% Surgery, 10% other disciplines). The commonest reason for referral was IBS (40%); IBS-Constipation (58%), IBS-Diarrhoea (21%) or IBS-MixType (21%). 16% were referred with faecal incontinence and 37% with chronic constipation. 35% of patients didn’t receive any therapy at time of referral. 44% were prescribed treatment but not followed up for assessment of successful response to therapy prior to referral to the specialist clinic. In 28% of patients the diagnosis changed following Motility clinic assessment. Diagnosis at clinic is based on RomeIII questionnaire, depression and anxiety score, thorough history taking and physical examination (including per rectum exam), ad hoc psychiatry input and referral to specialist investigation. In 30% of patients referred with chronic constipation the diagnosis was changed to IBS-Constipation. 8% changed from IBS-D to IBS-M, 8% referred with faecal incontinence had Obstructive Defecation Syndrome, 6% referred as IBS-M were diagnosed with IBS-C, 5% referred as IBS-D were diagnosed as IBS-M, 3% referred with IBS-D had bile acid malabsorption. 56% of patients underwent specialist investigations including uncorrelated physiology (70%), 33% of patients attending the Specialist clinic received 1st -line therapy and life style advice, albeit 57% of them, who received 2nd -line treatment, having failed 1st-line management.

Conclusion: The above data indicate the need for education and expansion of resources available in primary care to optimise patients’ management. Furthermore, it highlights the necessity for the introduction of a formal Neurogastroenterology curriculum in the general Gastroenterology training.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-Mail Address: francesca.moroni@sbs.net

Introduction: IBS is common worldwide. In UK it exceeds the 20% of the population. 1. Burden of Irritable Bowel Syndrome (IBS) on UK healthcare has been estimated around 1800£per patient per year. NIC guideline IBS provides a systematic approach to symptoms and therapies available to GPs and general gastroenterologists. This creates a good asset to minimal referrals to tertiary centres and address costs.

Aims & Methods: We retrospectively reviewed, via electronic records, all the patients seen at the Scottish Gut Motility Disorder Clinic between January and December 2016 included, focusing on original referral, diagnosis and treatment to evaluate the need for specialist input.

Results: In 2016, 378 patients attended the Motility Clinic total of 459 visits: 333 female, mean age was 51.4 (range: 16 to 95 years), 60% of referrals originated via secondary care (40% GI, 50% Surgery, 10% other disciplines). The commonest reason for referral was IBS (40%); IBS-Constipation (58%), IBS-Diarrhoea (21%) or IBS-MixType (21%). 16% were referred with faecal incontinence and 37% with chronic constipation. 35% of patients didn’t receive any therapy at time of referral. 44% were prescribed treatment but not followed up for assessment of successful response to therapy prior to referral to the specialist clinic. In 28% of patients the diagnosis changed following Motility clinic assessment. Diagnosis at clinic is based on RomeIII questionnaire, depression and anxiety score, thorough history taking and physical examination (including per rectum exam), ad hoc psychiatry input and referral to specialist investigation. In 30% of patients referred with chronic constipation the diagnosis was changed to IBS-Constipation. 8% changed from IBS-D to IBS-M, 8% referred with faecal incontinence had Obstructive Defecation Syndrome, 6% referred as IBS-M were diagnosed with IBS-C, 5% referred as IBS-D were diagnosed as IBS-M, 3% referred with IBS-D had bile acid malabsorption. 56% of patients underwent specialist investigations including uncorrelated physiology (70%), 33% of patients attending the Specialist clinic received 1st -line therapy and life style advice, albeit 57% of them, who received 2nd -line treatment, having failed 1st-line management.

Conclusion: The above data indicate the need for education and expansion of resources available in primary care to optimise patients’ management. Furthermore, it highlights the necessity for the introduction of a formal Neurogastroenterology curriculum in the general Gastroenterology training.

Aims & Methods: The aim of this study was to compare the expression of membrane transporters in mucosal biopsies of healthy subjects, IBS patients and post-infectious (PI)-IBS patients. Mucosal biopsies were obtained from the unprepared sigmoid colon in 18 IBS patients, 9 PI-IBS patients and 10 healthy subjects. Total RNA was isolated and prepared for gene expression analyses using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). We compared the expression of genes encoding membrane-spanning transporters, using GAPDH as a reference gene, and by using the comparative \( 2^{-\Delta\Delta Ct} \) method.

Results: Colonie expression of SLC7A5 and SLC3A2 (together comprising the amino acid transporter LAT1 + 4F2hc) was significantly lower in IBS patients, but not in PI-IBS patients, compared to healthy controls (P < 0.001). The expression of SLC7A8 (LAT2) tended to be lower in IBS patients compared to controls (P = 0.08). Mucosal gene expression of the short chain fatty acid transporter SMCT1 (SLC5A8) was lower in both IBS-patients and PI-IBS patients compared to healthy subjects (P < 0.01).

Conclusion: The amino acid transporters LAT1 and LAT2 appeared to be affected in IBS patients, but not in PI-IBS patients, compared to healthy subjects, suggesting a possible alteration in amino acids transport in this patient group. Furthermore, our results suggest a lower uptake of short chain fatty acids in both IBS- and PI-IBS patients. Altered expression of these transporters may be involved in the pathophysiology of IBS as well as being a potential biomarker of this aberration, and therefore deserves further study in IBS.

**P0489 DIVERTICULITIS IN THE SIGMOID COLON HAS THE HIGHEST RISK FOR INTESTINAL COMPLICATION OF COLONIC DIVERTICULITIS IN JAPANESE PATIENTS**

Gastroenterology And Hepatology, Karpushu Central Hospital, Karpushu/Japan

Contact E-mail Address: h7.takayama@gmail.com

**Introduction:** Most colonic diverticulitis can be conservatively treated, but some need surgical intervention due to intestinal complications. Cholestyramine associated with complications of diverticulitis have been reported mainly from Western countries, but few from Asian countries including Japan.

**Aims & Methods:** In this study, we aimed to determine risk factors for complications of colonic diverticulitis in Japan. Ken Haruma et al. characterized Colonic Diverticulitis Factors and Factors Associated With Complications: A Japanese Multicenter, Retrospective, Cross-Sectional Study. Diseases of the Colon & Rectum 2015;58:1174–1181.

**Aims & Methods:** The aim of this study was to compare the expression of membrane transporters in mucosal biopsies of healthy subjects, IBS patients and post-infectious (PI)-IBS patients. Mucosal biopsies were obtained from the unprepared sigmoid colon in 18 IBS patients, 9 PI-IBS patients and 10 healthy subjects. Total RNA was isolated and prepared for gene expression analyses using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). We compared the expression of genes encoding membrane-spanning transporters, using GAPDH as a reference gene, and by using the comparative \( 2^{-\Delta\Delta Ct} \) method.

**Results:** Of the 282 patients, 183 (64.9%) patients had right-sided diverticulitis, and 70 (24%) had complications; perforation (n = 53), fistula (n = 8), abscess (n = 5) and stenosis (n = 4). The rate of complication was highest in sigmoid colon (88.6%) when compared with other locations; ascending colon (10%), transverse colon (1.4%), and descending colon (0%). Multivariate analysis identified the location of sigmoid colon (odds ratio 62.2, 95% confidence interval 21.8–178.0) as a significant independent factor for complications of diverticulitis. Among 70 patients with complicated diverticulitis, 55 (78.6%) patients underwent emergent surgery; most of them (54 patients, 98.2%) were with diverticulitis in the sigmoid colon. The rate of complication associated with complications of diverticulitis (uni- and multivariate analysis)

**Conclusion:** The sigmoid colon was a significant risk factor for complication of colonic diverticulitis in Japanese patients. Acute colonic diverticulitis in the sigmoid colon should carefully be treated with surgical interventions in mind.

**Introduction:** Although symptoms occur in only 20% of patients harboring diverticula, Diverticular Disease (DD) of the colon DD represents the 8th disease as burden in USA. Several treatment are currently advised in managing those patients, but their impact on the burden of the disease is unknown. The recent DICA endoscopic classification has been developed and validated for the classification of DD, founding that treatment of DICA 1 and DICA 3 patients did not impact significantly in terms of acute diverticulitis occurrence/recurrence and surgery occurrence. Our aim was to assess the impact of using DICA classification on the burden of DD in Italy.

**Aims & Methods:** We assessed retrospectively the overall and the cost/year of treatment (or rifaximin, or any other treatment, including probiotics, fibers, systemic antibiotics and spasmoletic) in DICA 1, DICA 2 and DICA 3 population. Analysis of diverticulosis prevalence was estimated according to data population provided by Italian Institute of Statistics (ISTAT). Cost of treatments was calculated according to data on drugs’ consumption collected during the DICA study.

**Results:** According to 2015 ISTAT population data, we estimated that > 8 million of Italian people > 60 years may have diverticulosis. According to our endoscopic estimated that about 75% of diverticular population are on DICA 1, about 30% on DICA 2, and about 13% on DICA 3. According to the drugs’ consumption recorded during our study, we estimated that overall about 679 million of euros could be spent in Italy in treating those patients. In particular, > 357 million of euros are spent in DICA 1 population, > 205 million of euros in DICA 2 population, and > 88 million of euros in DICA 3 population. Considering that medical treatments did not show any significant advantage when treating DICA 1 and DICA 3 people in terms of prevention of acute diverticulitis recurrence and surgery occurrences, we can estimate that > 475 million of euros could be spent in Italy without any significant benefit for DD population.

**Conclusion:** DD has a significant burden for National Health System in Italy. DICA endoscopic classification may have a significant impact of this burden, helping to select DD people who effectively need treatments in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Fecal microbiota and metabolome may be altered in patients with Symptomatic Uncomplicated Diverticular Disease (SUDD). In particular, we found that Akkermansia muciniphila species were significantly increased in SUDD patients when compared with asymptomatic diverticulosis and healthy people, as well as PLS-DA analysis of NMR-based fecal metabolomics showed significant discrimination between HC and AD patient. Our aim was to assess the effect of current treatments for SUDD on fecal microbiota and fecal metabolic profiling in those patients.

**Aims & Methods:** Thirteen consecutive female patients, living in the same district and suffering from SUDD, were studied. Patients were treated with a 2-week course of 30g/day fiber supplementation (3 patients), 1.6 grams/day of mesalazine (3 patients), 900 billion/day of probiotic mixture VSL#3 (currently available in Europe as VivotinX®), 3 patients), and 800 mg/day of rifaximin (4 patients). Stool samples were collected at entry (T0), at the end of the 2-week course of treatment (T1), and after 30 (T2) and therefore after 60 days at the end of the therapeutic course (T3). Real-time PCR was used to quantify targeted microorganisms. High-resolution proton nuclear magnetic resonance (NMR) spectroscopy associated to Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabolite data set.

**Results:** The overall bacterial quantity did not differ before and after treatment (p = 0.449). The overall abundance of Akkermansia muciniphila species was significantly reduced at T1 (p = 0.017) and T2 (p = 0.026), while at T3 it became similar to that of T0 (p = 0.09). The amount of Lactobacillus group was increased in all groups but not significantly at T1 and T2, while at T3 it became similar to that of T0. Treatments showed the same results except for probiotic group, who had higher and persistent amount of Lactobacillus up to T3, PLS-DA analysis of NMR-based fecal metabolomics showed significant changes at T1 and T2, while at T3 it became similar to that of T0. All treatments were showed the same behaviour in influencing fecal metabolome except for rifaximin group, in which we did not find any metabolic change neither at the end of treatment nor during the washout period.

**Conclusion:** This preliminary study confirms that Akkermansia muciniphila may play a pathogenetic role in the occurrence of SUDD. We found also that current treatments for SUDD patients are able to influence metabolic activity in those patients except for rifaximin.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Natural history of colonic diverticulosis and diverticular disease (DD) is poorly known, and available data derived mostly from retrospective cohort studies.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

---
Aims & Methods: Aim of this study was to assess, in a cohort of patients with colon carcinoma, the incidence of new cases of symptomatic uncomplicated diverticular disease (SUDD) and diverticulitis, and recurrence of diverticulitis after 1-year of follow-up. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Register of Diverticular Disease) a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. Each center enrolled at least 20 consecutive patients during a period of two months. Inclusion criteria were: informed consent; age ≥18 years and endoscopic/radiological-confirmed colonic diverticulitis. Outpatient/telephone visits were scheduled every 6 months. Two retrospective data (patients' characteristics and habits, characteristics of DD, comorbidities and therapies) collected by participating centers were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients' features associated with new occurrence of SUDD and diverticulitis.

Results: Out of the overall, at baseline 1217 (55.8%) female, median years 67 (28–95), BMI 25.6kg/m² (16.2–43.4), patients were enrolled: 707 (58.1%), 300 (24.7%), and 210 (17.3%) with diverticulosis, SUDD, and PD, respectively. At 12 months, 922 patients (53.1%, 29.8%, and 17.1% with diverticulosis, SUDD, and PD) were followed, and 27.4% of patients were lost at follow-up. In the 12 months follow-up, 33 (6%) and 4 (0.7%) of diverticulosis patients developed SUDD and acute diverticulitis, respectively; 4 (1.6%) of SUDD patients developed acute diverticulitis, and in 14 (9.4%) of PD patients a new episode of acute diverticulitis occurred. Overall, only 3 patients developed a complication, without need of surgery. One year of follow-up logistic regression, showed that only female gender was associated with subjects who changed subgroup from diverticulosis to SUDD or PD (OR 2.26, 95% CI 0.97–5.22). No specific features associated with recurrence of diverticulitis could be identified.

Conclusion: These preliminary data suggested that, during an observation period of one year, progression from diverticulosis to SUDD occurred in less than a tenth of patients, and was associated with female gender. Overall incidence of diverticulitis and PD (2.3%), whereas recurrent diverticulitis was not higher. These data showed that, with respect to diverticulosis, female gender and presence of GI comorbidities are associated with SUDD, whereas younger age, family history for DD and female gender are associated with PD. Furthermore, patients with diverticulitis have higher physical and mental scores compared both to patients with SUDD and PD, suggesting that SUDD PD and reduced QoL of the affected patients.

Disclosure of Interest: R. Cuomo: Speaker and consultant for Alfa Wassermann G. Barbara: Speaker and consultant for Alfa Wassermann F. Pace: Speaker and consultant for Alfa Wassermann B. Annibale: Speaker and consultant for Alfa Wassermann All other authors have declared no conflicts of interest.

Introduction: Patients with symptomatic uncomplicated diverticulitis disease (SUDD) and those with diverticulitis share similar clinical patterns characterized by abdominal pain or change of bowel habits. In clinical practice, differential diagnosis between the two conditions may be useful in the diagnostic approach and therapeutic management.

Aims & Methods: Our aim was to assess the features of abdominal pain in patients with SUDD and PD. After a 6-months interval, patients were categorized according to the following criteria: i) diverticulitis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). In each center, patients were allowed to continue their therapy for DD, if any. T test was used to compare QoL scores. Logistic regression was performed to identify patients’ features associated with the presence of subtypes of DD. A p value <0.05 was considered statistically significant.
filled in long-lasting pain questionnaire. Abdominal pain lasting <24h was reported by patients with SUDD (86.1%) and 119/154 with PD (77.3%; p = 0.026). Symptom severity score was higher in PD group than in SUD group, but this difference was not statistically significant (5.5 ± 2.4 vs. 5.1 ± 2.2 cm; p = 0.130). Patients with PD had short-lived pain located more frequently in the left lower abdomen (50.6% vs. 29.6%; p = 0.002), whereas abdominal pain was more prevalent in patients with SUD (29.6% vs. 20.8%; p = 0.058). Pain lasting >24h was more prevalent in PD group compared to SUD group (62.1% vs. 52.6%; p = 0.029). Pain severity was higher in patients with PD and AD in comparison with CTR (28.4% vs. 20.5%; p < 0.001), confinement to bed (35.7% vs. 18.6%; p = 0.002), medical consultation (38.6% vs. 23.7%; p < 0.001), need for therapy (42.9% vs. 19.2%; p < 0.001), and hospitalization (28.6% vs. 8.3%; p < 0.001).

Conclusion: PD patients show some peculiar clinical features of abdominal pain. SUD patients frequently complained abdominal diffuse and short lasting pain. In contrast patients with PD frequently complained pain located in the left lower abdomen lasting for more than 24h. Our results suggest that these features are useful indicators to distinguish patients with SUD and PD and should be carefully assessed in clinical work-up of diverticular disease.

Introduction: Colonic diverticulitis, as well as diverticular disease, is a multifactorial condition that can be characterized by an inflammatory and fibrotic state, impaired contraction, inflammation and fibrosis. Mesenchymal smooth muscle cells (SMC) are able to switch from a contractile phenotype to a less mature synthetic phenotype, characterized by a loss of differentiation with decreased expression of contractile markers as well as synthesis and release of several pro-inflammatory cytokines. Different organ specific pathways have been demonstrated to induce this mesenchymal transition. Renal fibrosis is driven by transforming growth factor β (TGF-β) through inverse regulation of Smad2/3. In SMC, whole fibrosis by PDGF-β-mediated downregulation of marker gene Trb3 expression.

Aims & Methods: Aim of this study was to determine, both in human uninvolved and involved tracts of asymptomatic diverticulitics (AD; AD) and in stenotic segments of diverticulitis patients, the incidence and severity of muscular alterations, impaired contraction, inflammation and fibrosis. Circular and longitudinal smooth muscle strips and cells (SMC) were isolated separately from surgical colon specimen of 18 patients (5 29, 80 years) submitted to surgery for cancer (6) (CTR). Contraction was tested in response to carbachol and relaxation in response to VIP, qPCR analysis, expressed as Relative Quantification, was performed for transcription of mRNA encoding for TGF-β, fibromodulin, and for SMC phenotypic switch molecules (Collagen I, -SMA, TGF-β, PDGF-β, Trb3, Smad2/3). Data were normalized to β-actin mRNA and expressed as mean ± SE. In addition, the activation of inflammasome complex was indirectly tested through quantification of IL-18 secretion by commercial ELISA kit.

Results: In both muscle layers, AD- and AD- SMC, compared to CTR, showed an overall increase in inflammatory gene expression, with a trend of decrease from AD to AD, the lowest expression been observed in CDD. This inflammation was associated with an increase in IL-1β secretion in SMC layer medium compared to CTR and a progressive inhibition of contraction to carbachol, already in AD in circular strips and SMC. In contrast relaxation in response to VIP resulted significantly decreased only in AD both on strips and SMC with no alteration in AD and CDD. Peculiarity of circular SMC was a progressive increase in Coll1 expression from AD to CDD compared to CTR (3 hundred fold increase) parallel to about 50% decrease in the contractile protein α-SMA. Differently, longitudinal SMC, both in AD and CDD, pre- sented a homogenous increased Coll1 expression, decrease in α-SMA and reduction of contraction. VIP-induced relaxation was significantly decreased in CDD. Phenotypic switch was only observed in CDD, driven in circular layer, by a TGF-β-dependent pathway (increased expression for TGF-β: 2.88 ± 0.6 and Smad2/3; 0.39 ± 0.11) compared to Smad2/3 and PDGF-β-dependent pathway (increase of PDGF-β: 2.27 ± 0.44 and parallel decrease of Trb3: 0.58 ± 0.13).

Conclusion: Intrinsic myogenic alterations are present in colon asymptomatic diverticulitics and complicated diverticular disease, both in the circular and longitudinal layers characterized by a myogenic pro-inflammatory state and an impaired contractile activity that, in complicated diverticular disease, ended in a muscular synthetic pro-fibrotic switch.

Introduction: Aberrant Notch activation has been implicated in multiple malignancies, including gastric cancer (GC). However, the clinical significance of Notch receptors and their functional role in gastric carcinogenesis remain unclear.

Aims & Methods: We aim to delineate the dysfunctional Notch signaling in GC and comprehensively reveal its activation by silenced microRNAs (miRNAs) in gastric carcinogenesis. The expression clinical relevance of NOTCH1-4 in GC were achieved from online available dataset. The mRNA and protein expression of NOTCH3 was examined by qRT-PCR and Western blot. The biological function of NOTCH3 in GC was demonstrated by MTT proliferation, monolayer colony formation, cell migration and invasion assays through siRNA-mediated knockdown. The expression of miR-491-5p/miR-875-5p in GC tissues was determined by microRNAs expression microarray.

Results: NOTCH3, but not NOTCH1, 2, 4, is uniformly up-regulated and significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 in AGS and MKN28 cells exhibited significant anti-oncogenic effect in vitro. NOTCH3 downregulation suppressed cell proliferation, reduced monolayer colony formation, and inhibited cell invasion ability. Moreover, NOTCH3 knockdown significantly increased cleaved caspase-3 and cleaved-PARP expression induced by cisplatin, which was further revealed by the gene set enrichment analysis (NCBI/GEO/GSE57303 and NCBI/GEO/GSE57303 database). NOTCH3 was confirmed to be a direct target of tumor-suppressive miR-491-5p and miR-875-5p. The functional downstream targets of NOTCH3 were identified by gene expression microarray.

Conclusion: NOTCH3 is over-expressed and plays an oncogenic role in gastric carcinogenesis through its direct downstream miR-875-5p. The activation of NOTCH3 in GC is partly due to the silence of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. These findings comprehensively revealed the activation of Notch signaling pathway and provided clinical translational potential for GC.

Introduction: We found that tumor suppressor gene FOX2 was silenced in gastric cancer (GC) through promoter hypermethylation. Restoration of FOX2 suppressed GC tumorigenesis through inhibition of canonical Wnt

Disclosure of Interest: All authors have declared no conflicts of interest.
signaling pathway. However, the molecular mechanism of FOXX2 in GC is still unknown.

Aims & Methods: We hypothesize that FOXX2 transcriptional upregulates a novel E3 ligase that targets β-catenin for degradation. We aim to investigate the molecular mechanism of FOXX2 in GC and identify such E3 ligase by PCR-Sequencing. Immunoprecipitation (ChIP) assay and luciferase assay.

Results: FOXX2 significantly increased both nuclear and cytosolic levels of β-catenin in a GSK-3β independent manner and promoted β-catenin degradation via ubiquitin-proteasome pathway in gastric cells. Using Human Ubiquitin Ligase RT1 Profiler PCR Array and western blot, we identified that IFR2B8L was upregulated upon FOXX2 overexpression and was a promising E3 ligase for β-catenin. Overexpression of IFR2B8L suppressed the TOP-flash luciferase reporter and reduced Wnt target gene c-myc expression in GC cells. Overexpression of IFR2B8L significantly increased β-catenin ubiquitination and reduced β-catenin protein without alteration of its mRNA level. Conversely, knockdown of IFR2B8L significantly decreased endogenous β-catenin ubiquitination. Immunoprecipitation assay suggested that IFR2B8L interacted with β-catenin. Therefore, IFR2B8L is a potential E3 ligase that targets β-catenin for degradation. To investigate whether FOXX2 directly regulates IFR2B8L transcription, we performed ChIP assay and found that FOXX2 bound on to the IFR2B8L promoter region. We cloned the IFR2B8L promoter region (-2700 bp to TSS) into pGL3-plasmid and performed a luciferase activity assay. Wild-type FOXX2 but not the mutant ΔFOXX2 significantly activated the lucerase reporter in AGS and 293 F cells, suggesting that FOXX2 directly activated IFR2B8L transcription. Moreover, FOXX2 significantly increased the level of HIK27Ac (a marker to distinguish active from inactive enhancer element) on the 5′-flanking region of IFR2B8L gene, suggesting that FOXX2 positively regulated IFR2B8L gene transcription. In addition, IFR2B8L mRNA was downregulated in human GC tissues compared to the adjacent normal tissues (N = 30, P < 0.01) by real-time PCR analysis. IFR2B8L mRNA showed a positive correlation with FOXX2 in gastric cancer in a Chinese cohort (N = 30, Spearman’s rho = 0.42, P < 0.05) and in the TCGA cohort (N = 245, P = 0.38, P < 0.001).

Conclusion: We reported a novel FOXF2-IRF2B8L-β-catenin signaling axis in gastric cells. FOXX2 is a critical tumor suppressor in gastric carcinogenesis through promoting β-catenin degradation by transcriptionally upregulating E3 ligase IFR2B8L.

Introduction: Gastric adenocarcinoma with enteroblastic differentiation (GAED) is a rare variant of gastric carcinoma. It is well known that GAED is associated with poor prognosis [1, 2]. However, the clinicopathological and molecular biological features of GAED and to find new therapeutic targets.

Among 1003 patients with primary gastric cancer who underwent surgery or endoscopic resection in our hospital between April 2008 and February 2017, we enrolled 52 cases (early:17, advanced:35) of GAED defined as having tubular to papillary or solid structure with clear cytoplasm and immunohistochemical positivity for at least one of the following antibodies: AFP, Glypican-3 and SALL4. NGS was performed for 24 cases of formalin-fixed paraffin-embedded samples (early: 2, advanced: 22) using Ion PGM system with cancer hotspot panel v2 targeting 50 genes (Thermo Fisher Scientific). All authors have declared no conflicts of interest.

Results: Twenty-five out of 53 (47%) FIGC families harbored germline variants, and co-occurrence of germline moderate-risk alleles was found in ten families. From these ten families, seven harbored one pathogenic or likely pathogenic variant combined with one or more unclassified novel variants. The remaining three families carried solely clusters of novel unclassified variants. Moderate-risk alleles of BRCA2, MAP3K6, MSH6, MSR1, SDHB and SDHD were the most frequently found in this cohort. In addition, tumours arising in these 10 families were enriched in somatic variants within DNA repair genes and often displayed microsatellite instability phenotypes.

Conclusion: The clinical homogeneity and relatively high number of FIGC families herein allowed studying the hypothesis that FIGC may be a hereditary polygenic syndrome caused by moderate-risk alleles in gastrointestinal cancer-associated genes.

**Aims & Methods:**
For understanding the therapeutic effects of obestatin/GPR39 system, we investigated the morphological and histological features of the human oral mucosal epithelial cell sheets, in addition to the cellular gene and protein expressions. From a small biopsy of human volunteer donors' oral mucosa, oral muco-sal glandular epithelial cells, which were then fabricated into transplantable cell sheets using a previously described procedure. The cell sheets were examined by immunohistochemistry (IHC) and electron microscopy as well as the gene and protein expression analysis by RT-PCR, with a DNA array. Furthermore, the culture supernatant obtained immediately before the transplantation, were analyzed with a cytokine array.

**Results:**
Histological and morphological analyses revealed that tissue-engineered stratified epithelial cell sheets have an apical-basal polarity, and that the junctions between the basal cells of the sheets were significantly loose, due to dissociating desmosomes, which were also fewer in numbers. IHC showed that the expression levels of E-cadherin and desmosomal cadherins were downregulated in the epithelial cell sheets, but mesenchymal markers (N-cadherin, vimentin, and fibronectin) were upregulated. Taken together, these findings implied that epithelial mesenchymal transition (EMT) was induced in the basal cells. The results of the cytokine array showed that the cell sheets secreted EMT effectors with pro-inflammatory factors (progranulin and eprigen) and antimicrobial proteins (b-defensin).

**Conclusion:**
The EMT of the basal cell layer of epithelial cell sheets may contribute to the improved engraftment after cell sheet transplantation. The secretion of antibacterial peptides and various growth factors from the cell sheets would exhibit anti-inflammatory effects, and promote wound-healing compared to reinforcement of esophagus with absorbable synthetic materials such as polyglycolic acid and polylactic acid.

3Tropical Medicine & Gastroenterology, Faculty of Medicine Al-Azhar university, Cairo/Egypt

**Contact E-mail Address:** doctor_gemy@yahoo.com

**Introduction:** Endoscopic variceal band ligation (EVL) is an effective procedure to control and prevent variceal bleeding in patients with liver cirrhosis. Although EVL has some complications, yet these complications are related to post-EVL ulcers. Few data exist regarding therapy of post-ligation ulcer and treatment been mostly empirical with drugs used for peptic ulcer disease.

**Aims & Methods:** We aimed to compare between the efficacy of rebamipide, sucralfate and pantoprazole in treatment of post banding variceal ulcers. Seventy-five patients with esophageal varices eligible for elective band ligation represented the population of the study. The patients were allocated into three groups; rebamipide group, they received rebamipide 100 mg 3 times daily; pantoprazole group, they received pantoprazole 40 mg/day orally at morning; sucralfate group, they received sucralfate 1 gm every 6 hours, for 14 days beginning at the next day of band ligation. Subjects underwent EGD 14 days after banding.
Primary outcomes included the size and number of ulcers and the subjects' rebleeding, dysphagia, chest pain and vomiting.

Results: At follow-up endoscopy, the number of patients with post-band ulcers and size of ulcers were similar in the three groups. However, the number of ulcers for each patient was statistically significant less in rebamipide group when compared to pantoprazole and sucralfate (P < 0.01). Chest pain, dysphagia and vomiting scores were not significantly different. Dysphagia was by far the most common symptom with no case of bleeding was reported in all patients of the studied groups.

Conclusion: Rebamipide is effective in decreasing the post banding complication and reducing size of ulcer as well as the number of ulcers with no significant effect on post banding ulcer formation. Rebamipide can be used routinely in settings of post-VEL as a good alternative to pantoprazole and sucralfate.

Introduction: A potential pump inhibitors (PPIs) has been widely used for the treatment of endoscopic submucosal dissection-induced gastric ulcers. However, post-operative bleeding is still one of the most important adverse side effects.1, 2 Vonoprazan (VPZ), a potassium-competitive acid blocker, is a new class of acid-suppressing agents, and it is expected to reduce bleeding after gastric endoscopic submucosal dissection (ESD) by strongly inhibiting gastric acid secretion compared with PPIs.3

Aims & Methods: We compared the incidence of bleeding after gastric ESD between patients who were treated with VPZ and those treated with esomeprazole (EPZ). Data for 101 patients who underwent gastric ESD from December 1, 2014 to December 31, 2016 in Osaka City General Hospital and started to take VPZ (n = 22) or EPZ (n = 79) by the day before ESD was reviewed. Twelve of them (3 in the VPZ group, 9 in the EPZ group) were excluded for simultaneous resection in any of these patients. There were no reported immediate or delayed complications from the treatment.

Results: Gender, age, resected specimen diameter, oral antithrombotic drug administration, and dialysis were not significantly different in both groups. Two of the 19 patients in the VPZ group (10.5%) and 6 of the 70 patients in the EPZ group (8.6%) had Post-ESD bleeding (Table). In addition, 6 patients in the VPZ group (31.6%) and 37 patients in the EPZ group (52.9%) had next-day hemostasis. There was no significant difference in both groups regarding post-ESD bleeding (p = 0.678) and next-day hemostasis (p = 0.197). However, next-day hemostasis was somewhat higher in the EPZ group than that in the VPZ group. That is possibly because EPZ or VPZ was first administered mostly from 2 to 4 g/dl of Hemoglobin within 4 weeks after ESD was defined as “post-ESD bleeding”. In addition, we perform second-look endoscopy on the day after ESD. A case in which active bleeding or exposed vessels were observed on the bottom of ulcers with hematemesis, melena or a drop of not less than 2 g/dl of Hemoglobin within 4 weeks after ESD was defined as “post-ESD bleeding”.

Table: Incidence of post-ESD bleeding and next-day hemostasis

<table>
<thead>

P0511 RISK FACTORS OF GASTROINTESTINAL BLEEDING IN PATIENTS RECEIVED DUAL ANTIPLATELET THERAPY

W. Yingyongthawat1, A. Pulsombo1

1Department Of Medicine, Faculty of Medicine Ramathibodi Hospital, Bangkok/Thailand
2Department Of Medicine, Faculty of Medicine Ramathibodi Hospital, Bangkok/Thailand

Contact E-mail Address: Dr.worapongth@gmail.com

Introduction: Current guidelines suggest dual antiplatelet therapy (DAPT), clopidogrel or ticagrelor with aspirin, for patients with acute coronary syndrome. Other indications of DAPT include recurrent ischemic stroke and peripheral vascular disease. Gastrointestinal bleeding (GIB) is one of the most common adverse effects of DAPT, potentially causing hospital admission and death. Scanty information regarding safety of DAPT in Thailand is available.

Aims & Methods: The objectives were to determine cumulative incidence and risk factors of GIB in patients received DAPT, clopidogrel with aspirin or ticagrelor with aspirin among Thai patients.

A retrospective cohort study was conducted. We reviewed the medical records of patients received cloppedregel or aspirin or ticagrelor with aspirin between January 2013 and June 2015 at Ramathibodi hospital. In patients with GIB, the endoscopic finding with stigmata of recent hemorrhage was also recorded.
In 213 patients with GI bleeding, 31 patients received VKA (14.5%) and each on the above mentioned NOACs. Use of proton pump inhibitor and frequencies. These real-life results were then from emergency department of the University Hospital Erlangen were analyzed. Their data manifesting with a GI bleeding under anticoagulation in 2014. All patients who had a rectal bleeding (0%). During NOAC therapy, a similar distribution was found with 71% and 17%, but the proportion of rectal bleeding was higher with 10%.

Conclusion: Risk of GI bleeding is almost two times higher among patients received clopidogrel with aspirin compared to those received ticagrelor with aspirin. Closed monitoring patients who had duration of DAPT < 180 days and previous GI bleeding might be minimized the risk of GI event after receiving DAPT.

Disclosure of Interest: All authors have declared no conflicts of interest.

3. Department Of Internal Medicine 1, University Clinical Center Erlangen, Erlangen/Germany

Contact E-mail Address: martin.raithel@waldkrankenhaus.de

Introduction: Non-vitamin K direct oral anticoagulants (NOAC) are increasingly used in thromboembolic disorders due to an efficacy at least equally as vitamin K antagonists (VKA) and/or significantly higher safety for intracerebral bleeding or major bleedings of any source. In the approval studies, there was no generally increased bleeding rate for all types of bleeding, but different gastrointestinal bleeding (GIB) rates for apixaban, dabigatran, edoxaban and rivaroxaban. Received ticagrelor with aspirin were recruited. Mean ± standard deviation age was 66.2 ± 11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs.100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 vs. 231. days, respectively (p = 0.216). There were 20 (10.1%) GIB events in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44% in clopidogrel group vs. 66.7 % in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.84 (95% confidence interval [CI] 0.95–3.7, p = 0.093). By multivariate logistic regression analysis, duration of DAPT < 180 days (RR 3.26; 95% CI 1.89–5.69, p < 0.001) and history of previous GIB were associated with GIB events (RR 10.35; 95% CI 6.04–17.71, p < 0.001).

Conclusion: The frequency of GIB in everyday life is approximately 10% higher than reported from the controlled NOAC studies, irrespective of the type of anticoagulation used. NOACs were associated with a non-significantly lower bleeding rate compared with VKA, but major GIB rates were similar. VKA with a bioavailability of 100% after oral ingestion showed a tendency of higher rates of upper GIB, while NOACs with a reduced GI absorption rate of 7–68% were found to occur more frequently at lower GIB sites. Thus, prior to any anticoagulation, a pre-therapeutic risk analysis for the occurrence of GIB is still required. Certain patient groups (anemia, aortic valve stenosis, renal insufficiency, NSAIDs, etc.) can benefit from proton pump inhibitor therapy, early endoscopy with intervention, or NOAC differential therapy.

P0514 CLINICAL CHARACTERISTICS OF FUNCTIONAL DYSPEPSIA PATIENTS DEPENDING ON WHETHER THEY ARE CHEMOSENSITIVE OR NOT

V. Hammer, K. Hammer, M. Führer, J. Hammer
Department Of Gastroenterology And Hepatology, Medical University of Vienna, Wien, Austria

Contact E-mail Address: jcapsaicin@yahoo.com.au

Introduction: Augmented chemosensitivity to capsaicin has been demonstrated in functional dyspepsia patients, but the relevance of these findings is still under debate. The oral capsaicin capsule test (Hammer et al, 2008) was used to determine whether there is a clinical significance of oral capsaicin sensitivity in dyspepsia patients.

Aims & Methods: Aims of the study was to determine clinical characteristics of FD patients with and without chemical hypersensitivity at baseline and after capsaicin ingestion for 4 weeks. N = 49 outpatients with confirmed FD received an oral capsaicin sensitivity test with 0.75 mg capsaicin at two occasions, before and after ingestion. Patients were designated to capsaicin positive (p < 0.05) when positive in both tests and capsaicin negative (p > 0.05) when negative in both tests. Symptom diaries for upper and lower gastrointestinal symptoms (visual analogue scales) were completed in the week before and during capsaicin ingestion and weekly aggregate symptom scores were calculated. Results are given as median; 25%/75%, p < 0.05 was considered significant.

Results: 53% of FD patients had a positive capsaicin test. Basic clinical characteristics (age, gender, FD subtype, medication, psychological profile) were comparable in capsaicin positive and negative FD, but median daily average upper gastrointestinal symptoms scores were significantly higher in capsaicin positive (median: 9.4; 5.4/11.7) than in capsaicin negative patients (6.6; 4.1/8.1) (p < 0.05). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients (p > 0.05). On the contrary, capsaicin negative patients had significantly lower scores for satiety (p < 0.001) and epigastric bloating (p = 0.01) than capsaicin positive patients. Lower abdominal symptoms were comparable in capsaicin positive and negative patients at baseline (NS). After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by –3.3 (–4.9/–1.9; p < 0.001) and epigastric bloating (p < 0.01) than capsaicin positive patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by –1.0 (–1.8/–0.1; p < 0.05) in capsaicin positive but not significantly altered (–0.6; –1.7/+0.9; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of chemosensitive patients (p < 0.01).

Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion.

Introduction: Gastro-oesophageal reflux disease (GERD) is one of the most common disorders encountered in clinical gastrointestinalology. GERD patients can be categorised as having erosive oesophagitis or non-erosive reflux disease (NERD), with the latter being more frequently encountered in clinical practice. In NERD, even though the endoscopic presentation of the oesophageal mucosa appears visibly normal, histological changes within the oesophageal epithelium such as dilated intercellular spaces and basal cell hyperplasia are present, which are indicative of a sensitised epithelial barrier (Toby et al 1996).

Aims & Methods: Here, we have investigated the expression and activity of key barrier function proteins present in the oesophageal epithelium of proximal and distal biopsies derived from 13 patients with typical GORD symptoms. We compared this to erosive oesophagitis. Nuclear loricrin (LOR), with its stage specific nuclear localization, was the first of the tight junction proteins to be described by the TGM-1 enzyme function to reinforce barrier function through its ability to crosslink and INV in tissue terminal differentiation in epithelial tissues at the cellular membrane. Analysis of TGM-1 enzymatic activity was performed in all NERD patients with and without chemical hypersensitivity at baseline and after capsaicin ingestion for 4 weeks. Nuclear LOR was significantly increased in capsaicin positive patients (5.4/11.7) than in capsaicin negative patients (6.6; 4.1/8.1) (p < 0.05). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients (p > 0.05). On the contrary, capsaicin negative patients had significantly lower scores for satiety (p < 0.001) and epigastric bloating (p < 0.01) than capsaicin positive patients. Lower abdominal symptoms were comparable in capsaicin positive and negative patients at baseline (NS). After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by –3.3 (–4.9/–1.9; p < 0.001) and epigastric bloating (p < 0.01) than capsaicin positive patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by –1.0 (–1.8/–0.1; p < 0.05) in capsaicin positive but not significantly altered (–0.6; –1.7/+0.9; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of chemosensitive patients (p < 0.01).

Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion.

P0516 INFLUENCE OF PRUCALOPRIDE ON SECONDARY PERISTALISIS IN REFLUX PATIENTS WITH INEFFECTIVE ESOPHAGAL MOTILITY

Introduction: Prucalopride, a high-affinity 5-hydroxytryptamine 4 receptors agonist, is useful in the treatment of chronic constipation by improving colon motility. Prucalopride also promotes secondary peristalsis in healthy adults (Clin Transl Gastroenterol, 2016).

Aims & Methods: We aimed to determine whether prucalopride would augment secondary peristalsis in reflux patients with EIM. After a baseline recording of primary peristalsis, secondary peristalsis was stimulated by slow and rapid mid-esophageal injections of air in 15 patients. Two separate sessions with 4 mg oral prucalopride or placebo were randomly performed.

Results: Prucalopride significantly increased primary peristaltic wave amplitude (68.1±10.0 vs. 55.5±8.8mmHg, p = 0.02). The threshold volume for triggering secondary peristalsis was significantly decreased by prucalopride during slow (9.3±0.8 vs. 12.0±0.8mL, p = 0.04) and rapid air injection (4.9±0.5 vs. 7.1±1.0mL, p = 0.01). Secondary peristalsis was triggered more frequently after application of prucalopride (55% [43–70%]) than placebo (45% [33–50%]) (p = 0.008). Prucalopride didn’t change pressure wave amplitudes during slow air injection (84.6±1.8 vs. 57.4±13.8mmHg, p =0.19) or pressure wave amplitudes during rapid air injection (84.2±8.6 vs. 69.5±12.9mmHg; p = 0.09).

Conclusion: Prucalopride enhances mechanosensitivity of secondary peristalsis and promotes motor properties of primary peristalsis in EIM patients. Our study suggests that prucalopride could be a therapeutic option in the management of GERD patients with significant esophageal hypomotility. Disclosure of Property: All authors have declared no conflicts of interest.

Introduction: Symptoms compatible with diabetic gastroparesis (DG) affect up to 1 in 5 patients with type I diabetes mellitus. Those affected suffer postprandial
nausea, vomiting, abdominal pain and impaired gastric control. Repeated hospital admissions are common. Endoscopic normal is most patients. Impaired gastric function is thought to cause the condition. DG does not respond reliably to intensive insulin regimens or prokinetic medications. Jejunal nutrition (JN) is an option in patients that cannot maintain their weight. The benefits are thought to follow improved nutrition and glycemia; however, we have observed that some DG patients eat normally during and after JN (i.e. a quasi-pharma-
cological effect). An explanation could be that DG represents a failure of oral nutrition to “switch” the stomach from the fasted to the fed state. According to this hypothesis, nutrients delivered directly to the small bowel triggers the release of peptide hormones that induce normal gastric function.

Aims & Methods: The study tests the hypothesis that JN prior to a test meal improves postprandial symptoms (primary outcome) and gastric function. Diabetic patients with severe symptoms (gastroesophageal cardiac symptom index (GCSI) > 27), diabetic controls (GCSI < 14) and healthy controls entered a randomized, double blind, controlled trial. An insulin/glucose infusion controlled (GCSI) improves postprandial symptoms (primary outcome) and gastric function. Aims & Methods: In this study we aim to compare the safety and efficacy of POEM in treatment native (TN) cases versus prior treatment (PT) failure cases. The data of consecutive patients with AC who underwent POEM at a single tertiary care center from (January 2013 to November 2016) was analysed retro-
spectively. A comparative analysis was performed between TN and PT failure cases. Technical and clinical success, adverse events (AE), operative time (OT) for POEM were compared between TN versus PT failure cases.

Results: Overall, 502 patients with AC underwent POEM during the study period. 260 patients (51.8%) were TN and 242 (48.2%) patients had PT. Type II AC was the most common subtype in both the groups (TN -63.5% vs PT – 57.8%) followed by type I and type III. There was no significant difference with regards to AC subtypes between the two groups. The distribution of patients according to prior treatment history is as follows – PHD (205), LHM (23), LHM and PBD both (7), botulinum toxin injection (4) and POEM (3). Significantly more patients in the PT group had sigmoid oesophagus (47 vs 18). Mean OT was significantly more in the PT group when compared to the TN group (PT vs TN -74.9 ± 30.6 vs 67.0 ± 27.1 min; P = 0.002). On multivariate analysis- type of AC, dilated esophagus (> 6 cm) and type of knife used were significant predictors of OT. Technical (98.1% vs 97.1%, P > 0.05) and clinical success (94.9% vs 91.9%) of POEM were similar in TN and PT cases. Gas related events and mucosotomies were equal in both groups (TN-35.7% vs PT-33.1%; p=0.57). Objective evidence of gastroesophageal reflux was found in 17/53 patients (32.1%) in PT group as compared to 11/44 (25%) in TN group (p=0.50).

Conclusion: POEM is equally efficacious and safe in treatment native and prior treated cases. POEM should be considered in treatment failure cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Partial recovery of esophageal peristalsis has been reported in up to 95% of achalasia patients treated by myotomy (either per-oral endoscopic myotomy (POEM) or laparoscopic Heller’s myotomy) in several rather small studies. The aim of our study was to assess motility patterns focusing on possible “recovery” of esophageal peristalsis in a large cohort of patients after POEM.

Aims & Methods: We performed a retrospective analysis of prospectively collected data of patients undergoing POEM at our tertiary referral center. All patients in whom high-resolution manometry (HRM) studies were performed prior to and 3 months after POEM and who completed at least 6-month follow-up were included. All HRM studies were reviewed and the Chicago Classification (CC) v3.0 of motility disorders was applied to characterize both pre- and post-POEM motility patterns.

Results: From 192 patients who underwent POEM since 2012, 127 patients met the inclusion criteria. The initial CC diagnoses before POEM were as follows: type I achalasia – 20 pts (16%), type II achalasia – 100 pts (79%), type III achalasia – 5 pts (4%), other (esophageo-gastric junction outflow obstruction (EGJOO) and Jackhammer) – 2 pts (1%). Only 6 patients (5%; type III achalasia – 4, other – 2) had had signs of esophageal contractility before POEM. After POEM, peristaltic fragments were present in 28/127 patients (22%) - 9x ineffective esophageal motility, 5x fragmented peristalsis, 2x distal esophageal spasm, 5x EGJOO, 7x type III achalasia. Thus, the partial “recovery” of esophageal peristalsis was observed in 22/121 patients (18%) and it only occurred in patients with type II achalasia; contractile activity was not detected in any patient with type I achalasia after POEM (22/120 vs. 0/20, p = 0.023). Panesophageal pressurization completely resolved in 88 patients (88%) with...
achalasia type II. The mean integrated-relaxation pressure (IRP) decreased from 27 (±13) mmHg to 13 (±5) mmHg (p < 0.001). The presence of partial peristaltic recovery was neither associated with normalization of IRP (IRP normalized in 17/28 (61%) patients with peristaltic recovery and in 72/99 (73%) patients without, p = 0.25), nor with overall treatment success of POEM (Eckardt score < 3).

Conclusion: In this so far largest case-series investigating the rate of peristaltic recovery after POEM this was present in 18% of patients, therefore, the rate may be lower than previously reported. Peristaltic recovery seems to have no clinical impact on post-POEM symptomatology. Esophagealcontractility after POEM was not observed in any patient with achalasia type I.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peroral endoscopic myotomy (POEM) has gained trust by proven safety and short-term efficacy and at present, it is considered to be a standard method for treatment of esophageal achalasia. However, long-term data concerning the efficacy and safety especially with regard to post-POEM reflux are still awaited.

Aims & Methods: The aim of this prospective single-center case series was to assess the long-term clinical outcome of POEM with emphasis on post-POEM reflux evaluated by pH monitoring, endoscopy findings, reflux symptoms and use of proton pump inhibitors (PPIs). Since 2012, a total of 192 patients with achalasia underwent 202 POEM procedures. Follow-up visits at 3, 12, 24 and 36 months were completed in 160, 116, 70 and 27 patients. Upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH monitoring were performed 3 months after POEM, endoscopy was then repeated between 24–36 months. Main outcomes were treatment success defined as Eckardt score < 3, recurrence rate and post-POEM reflux.

Results: At 3, 12, 24 and 36 months, treatment success was achieved in 97% (95% CI: 94–100), 95% (CI 91–99), 88% (CI 82–95) and 81% (CI 69–93) of patients. A total of 14 patients experienced treatment failure (n = 5) or recurrence (n = 9). The recurrences occurred most often in patients with HRM type I achalasia (4 out of 26, 15.4%) followed by type II (3 out of 113, 2.6%) vs. none in type III achalasia (0 out of 10, 0%); p = 0.022. At 3 months, reflux esophagitis was diagnosed in 63/160 patients (39.4%; severe esophagitis LA C or D in 8 patients). Abnormal acid exposure on pH-metry studies was detected in 58/146 (39.7%). At 24–36 months, endoscopy was performed in 41 patients and reflux esophagitis was present in 9 patients (21.9%; none of the patients has been treated with PPIs). At 3 and 24M, a proton pump inhibitor was administered to 33.5% and 31.4% of patients.

Conclusion: POEM is effective treatment modality for achalasia with treatment success around 90% at 2 years, slightly dropping down to 81% at 3 years. Generally mild reflux esophagitis and abnormal esophageal acid exposure are diagnosed in about 40% of patients 3 months after POEM but are successfully manageable with proton pump inhibitors. Occurrence of reflux esophagitis tends to decrease with time.

Introduction: Rumination syndrome is a functional gastrointestinal disorder characterized by effortless, post-prandial regurgitation of food. In addition to regurgitation, a large proportion of patients report functional dyspepsia (FD) symptoms including post-prandial discomfort, early satiety and nausea (1, 2). Recently, duodenal eosinophilia has been described both in adult and pediatric patients with FD (3, 4). Because of the significant symptomatic overlap between FD and rumination syndrome we hypothesized that histological changes similar to those described in FD might exist among patients with rumination syndrome. Aims & Methods: We therefore aimed to assess histology of duodenal biopsies from patients with rumination syndrome and compared these to healthy controls. Rumination syndrome was diagnosed with post-prandial esophagogastric high resolution impedance manometry (HRIM) and/or fulfilled ROME II/III criteria. This study was approved by the Institutional Review Board. We included persons aged 18 and above with a diagnosis of rumination syndrome in whom we had also obtained 4–6 duodenal biopsies from diagnostic upper endoscopy. Normal controls were aged 18 and above without any gastrointestinal symptoms in whom 4–6 duodenal biopsies were obtained for research purposes. Cases and controls with a personal history of an eosinophilic disorder, gastric or esophageal surgery, recent (within 30 days) intake of NSAIDS and pregnant and/or lactating females were excluded. Duodenal biopsies obtained were routinely processed to formalin fixed paraffin-embedded tissue blocks which were cut at 3 μm, stained with H&E and scanned to digital images (Aperio). The pathologist, blinded to the case-control status, analyzed de-identified digital images of the biopsy specimens and assessed for eosinophil counts/mm² in sections. Individual sections were also assessed for the presence of Brunner’s glands (BG) and intraepithelial lymphocyte counts (IEL) 100 enterocytes. This was done in order to distinguish the first part of the duodenum with Brunner’s glands (BG1) and the second part generally without BG, (DG2) and intraepithelial lymphocyte counts (IEL) 100 enterocytes.

Results: Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. Controls (10) had a mean age of 34.3 (range 19–69) and 80% were female. The mean eosinophil counts/biopsy fragment +/− Brunner’s glands (BG), showed no difference in counts in the sections +/− BG (D1 vs D2), p=0.8. No overt pathology was noted, but IEL counts were significantly higher in rumination patients (mean 15, range 8–29, and 2 cases had lymphocytic duodenitis) vs controls (mean 11, range 11–18), p=0.02. Compared to controls, there was a significant increase in the mean eosinophil count among the patients with rumination syndrome rumination, 26 pm² (range 16–42), vs 18 pm² (range 10–28), p=0.006.

Conclusion: These findings demonstrate that patients with rumination syndrome have duodenal eosinophilia and increased IEL counts compared to healthy controls. To our knowledge, histopathological changes among patients with rumination syndrome compared to controls have not previously been described. Therefore, a potential role of duodenal immune mechanisms in the pathophysiology of rumination syndrome warrants further enquiry.

Introduction: Rumination syndrome is a functional gastrointestinal disorder characterized by effortless, post-prandial regurgitation of food. In addition to regurgitation, a large proportion of patients report functional dyspepsia (FD) symptoms including post-prandial discomfort, early satiety and nausea (1, 2). Recently, duodenal eosinophilia has been described both in adult and pediatric patients with FD (3, 4). Because of the significant symptomatic overlap between FD and rumination syndrome we hypothesized that histological changes similar to those described in FD might exist among patients with rumination syndrome. Aims & Methods: We therefore aimed to assess histology of duodenal biopsies from patients with rumination syndrome and compared these to healthy controls. Rumination syndrome was diagnosed with post-prandial esophagogastric high resolution impedance manometry (HRIM) and/or fulfilled ROME II/III criteria. This study was approved by the Institutional Review Board. We included persons aged 18 and above with a diagnosis of rumination syndrome in whom we had also obtained 4–6 duodenal biopsies from diagnostic upper endoscopy. Normal controls were aged 18 and above without any gastrointestinal symptoms in whom 4–6 duodenal biopsies were obtained for research purposes. Cases and controls with a personal history of an eosinophilic disorder, gastric or esophageal surgery, recent (within 30 days) intake of NSAIDS and pregnant and/or lactating females were excluded. Duodenal biopsies obtained were routinely processed to formalin fixed paraffin-embedded tissue blocks which were cut at 3 μm, stained with H&E and scanned to digital images (Aperio). The pathologist, blinded to the case-control status, analyzed de-identified digital images of the biopsy specimens and assessed for eosinophil counts/mm² in sections. Individual sections were also assessed for the presence of Brunner’s glands (BG) and intraepithelial lymphocyte counts (IEL) 100 enterocytes. This was done in order to distinguish the first part of the duodenum with Brunner’s glands (BG1) and the second part generally without BG, (DG2) and intraepithelial lymphocyte counts (IEL) 100 enterocytes.

Results: Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. Controls (10) had a mean age of 34.3 (range 19–69) and 80% were female. The mean eosinophil counts/biopsy fragment +/− Brunner’s glands (BG), showed no difference in counts in the sections +/− BG (D1 vs D2), p=0.8. No overt pathology was noted, but IEL counts were significantly higher in rumination patients (mean 15, range 8–29, and 2 cases had lymphocytic duodenitis) vs controls (mean 11, range 11–18), p=0.02. Compared to controls, there was a significant increase in the mean eosinophil count among the patients with rumination syndrome rumination, 26 pm² (range 16–42), vs 18 pm² (range 10–28), p=0.006.

Conclusion: These findings demonstrate that patients with rumination syndrome have duodenal eosinophilia and increased IEL counts compared to healthy controls. To our knowledge, histopathological changes among patients with rumination syndrome compared to controls have not previously been described. Therefore, a potential role of duodenal immune mechanisms in the pathophysiology of rumination syndrome warrants further enquiry.

P0527 CHRONIC POSTSTROKE OROPHARYNGEAL DYSPHAGIA IS ASSOCIATED WITH IMPAIRED CORTICAL ACTIVATION TO PHARYNGAL SENSORY INPUTS

Introduction: The role ofafferent sensory pathways in the pathophysiology of post-stroke oropharyngeal dysphagia (OD) is not known [1]. We hypothesized that chronic post-stroke patients with OD (PSD) would show impaired sensory cortical activation in the affected hemisphere.

Aims & Methods: We studied 28 chronic unilateral post-stroke patients (17 PSD and 11 non-dysphagic [PSnD]) and 11 age-matched healthy volunteers (HV). ES was used to assess event-related sensory evoked potentials to pharyngeal stimulation (pSEP) and sensory thresholds with a naso-pharyngeal catheter with two electrodes passed through the nostrils 14–15 cm until the pharynx (Gaeltec Ltd, Dunvegan, Scotland) [2]. We analyzed pSEP peak-latency and amplitude (N1, P1, N2, P2) and neurotopographic stroke characteristics from brain MRI.

Results: HV presented a highly symmetric bi-hemispheric cortical pattern of brain activation at centro-parietal areas (N1-P1, N2-P2) to pharyngeal stimulation. In contrast, an asymmetric pattern of reduced ipsilesional activation was found in PSD (N2-P2; p = 0.026) but not in PSnD. PSD presented impaired safety of swallow (Penetration- Aspiration score: 4.3 ± 1.6) and delayed laryngeal vestibule closure (360.0 ± 70.0 ms), and higher NIHSS (7.0 ± 2.3 vs. 1.9 ± 1.4; p = 0.001) and Fazekas scores (3.0 ± 1.4 vs. 2.0 ± 1.1; p = 0.05) than PSnD. pSEP showed a unilateral delay at stroke site exclusively for PSD (peak-latency inter-hemispheric difference vs. PSnD: N1: 6.5 ± 6.7 vs. 1.1 ± 1.0 ms; N2: 32.0 ± 15.8 vs. 4.5 ± 4.9 ms; p = 0.05).

Conclusion: Chronic post-stroke OD is associated with stroke severity and degree of leukoaraiosis. Impaired conduction and cortical integration of pharyngeal sensory inputs at stroke site is a key feature of chronic PSD. These findings highlight the role of sensory pathways in the pathophysiology of post-stroke OD and offer a potential target for future treatments.

Introduction: Gastroperis is characterized by abnormal gastric motor function with delayed gastric emptying in the absence of mechanical obstruction. In our tertiary referral centre, patients are treated with a stepwise approach, starting with dietary and lifestyle advice and prokinetics followed by pyloric botulinum toxin. When these initial measures fail, the presence of malnutrition, one of the following interventions are considered: three months nasoduodenal tube feeding with ‘gastric rest’ and placement of a percutaneous endoscopic gastrostomy with jejunal extension (PEG-J). Our primary aim was to evaluate the effect of nutritional interventions in patients with gastroparesis who fail previous treatments, on weight and symptoms.

Aims & Methods: Prospectively collected data of all referred gastroparesis patients between 2008 and 2016 were reviewed.

Results: A total of 101 gastroparesis patients (71 female, 20-86yrs, mean 55yrs) with ‘gastric rest’ and maintenance (72%), jejunal extension (27%) and surgical (7%) were reviewed. Of the 101 patients, 51 patients had adequate responses to dietary advice and prokinetics, not requiring further therapeutic interventions. For the remaining 50 patients, various treatments were used. Half with respect to nutritional interventions, 36 patients were treated with three months of gastric rest via complete nasoduodenal tube feeding. Enteral tube feeding was well accepted, occlusion occurred in 8% of patients. Mean weight gain in symptom responders was 3.5% (2.4 kg, p = 0.02), in non-responders 3.7% (2.4 kg, p = 0.1). These 19 patients with insuficient symptomatic response after 3 months gastric rest continued treatment with enteral feeding through PEG-J. A significant weight gain of 8.2% was seen (mean 5.0 kg, range –6% to +29%, p = 0.003) within 3-6 months after PEG-J placement. Thereafter only 3 patients (10%) were able to return to complete oral intake, the PEG-J was removed after a mean treatment time of 11 months. In 84% of patients the PEG-J is still in use, with a mean treatment time of 894 days. Over 75% of patients report adequate effect on symptoms. Most frequent complication was ligation of the jejunal extension to the stomach (32% of patients). Other complications were peristomal infection (11% within 30 days, 16% after 30 days) and buried bumper (16%).

Conclusion: This study describes the sequelae of a large group of tertiary referral gastroparesis patients treated with PEG-J treatment. In gastroparesis patients who failed all previous treatment, PEG-J is an excellent option to regain and maintain adequate nutritional status with marked symptom control.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The prevalence and frequency of esophageal symptoms suggestive of a functional esophageal disorder according to the Rome IV criteria are unknown. This study aimed to describe the general population prevalence and risk factors for esophageal symptoms compatible with functional esophageal disorders.

Aims & Methods: Data from an online survey of 6300 individuals age ≥18 years in the United States, United Kingdom and Canada (2100 in each country) including the Rome IV diagnostic questionnaire for adults and demographic questions was used. Quota-based sampling ensured equal proportions of sex, age groups, and educational distributions across countries. Prevalence and frequency of esophageal symptoms in the past 3 months and putative functional esophageal disorders were retrieved from the Rome IV questionnaire. Symptoms were considered present if they occurred at least weekly for dysphagia, chest pain, and globus, and at least twice weekly for heartburn. Variables with a p < 0.1 in univariate analyses were entered into a multivariate analysis (logistic regression) to identify factors independently related to esophageal symptoms. As endoscopy and pH measurement are parts of the clinical diagnosis of esophageal disorders in the Rome IV criteria, we only describe esophageal symptoms compatible with functional esophageal disorders. Somatization was assessed with the Patient Health Questionnaire (PHQ)-12.

Results: Data from 5117 participants (47.8% female; mean age 46.7 (range 18–92) years; 1645 US, 1734 UK, 1798 Canada) were retained for analysis after 369 inconsistent responders and 754 previously diagnosed with gastroesophageal reflux disease (GERD) were excluded. Esophageal symptom prevalence was: feeling of a lump or something stuck in the throat (globus) 8.1% (n = 420), heartburn 6.5% (n = 334), dysphagia 4.5% (n = 233) and chest pain 5.2% (n = 269). Independent predictors for increased risk of esophageal symptoms included younger age, symptoms consistent with other FGIDs, using medications for gastrointestinal symptoms, somatization, cannabis use, and certain foods (see table 1). When individuals with GERD were included in re-analyses, GERD was ¼ separately associated with esophageal symptoms (up to 33 variables).

Variables with a p-value of 0.1 or less in univariate analysis were entered into a multivariate analysis (logistic regression) in order to identify factors independently associated with esophageal symptoms (up to 33 variables).

Conclusion: Esophageal symptoms compatible with a functional esophageal disorder are common in the Western population. Age and presence of other GI and non-GI symptoms are associated with reporting esophageal symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0531 DETERMINANT FACTORS OF QUALITY OF LIFE IN ADULT PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

A. J. Lucendo Villarin1, L. Arias-González2, J. Molina-Infante2, A. Arias3
1Dept. Of Gastroenterology, Hospital General de Tomelloso, Tomelloso/Spain
2Gastroenterology, Hospital San Pedro de Alcázar, Cáceres/Spain

Contact E-mail Address: ajlucendo@hotmail.com

Introduction: Eosinophilic esophagitis (EoE) affects children and young adults and has rapidly grown over the past decade, especially in developed countries. Presently, it represents the second leading cause of chronic esophagitis after gastroesophageal reflux disease (GERD) and the main cause of dysphagia in children and young adults. EoE affects health-related quality of life (HRQoL). Data on determinant factors and the influence of dietary interventions are scarce.

Aims & Methods: In this study we aimed (1) to determine for the first time the health-related QoL in a representative sample of Spanish adults with EoE, and (2) to identify determinants of impaired HRQoL, including the effect of dietary restrictions. Multicentre observational, cross-sectional study in eight Spanish centers attending adult EoE patients throughout several Spanish Regions. A validated Spanish version of the self-administered Adult Eosinophilic Esophagitis Quality of Life (EoE-QoL-A) questionnaire was used, as well as a survey of demographic and clinical data. Multiple linear regression was used to identify and quantify determinant factors of HRQoL.

Results: Responses provided by 170 patients were assessed (73.5% male; mean age 33.5 ± 11.4y). Overall mean score for the EoE-QoL-A index was 1.4 ± 0.8, with no differences between patients on dietary or pharmacological therapy (1.82 ± 0.8 vs. 1.62 ± 0.8; p = 0.132). Disease activity showed the highest. The mean score (2.13 ± 0.9 points), followed by choking anxiety 1.97 ± 1.1; social impact, 1.77 ± 1.1, and diet/eating impact 1.68 ± 0.9 points. Emotional impact had the lowest rating (1.15 ± 0.9), and the only with a significantly worse score in patients under dietary restrictions. Recurrent food impaction, a higher educational level, dietary interventions and symptom duration were all independent determinant factors significantly impairing HRQoL. Female gender and empiric elimination diets negatively influenced diet/eating impact.

Conclusion: HRQoL is impaired in adult EoE patients, especially disease and choking anxiety. Recurrent food impaction, dietary interventions and symptom duration are the most important factors influencing the perception of HRQoL in EoE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Several studies have provided information on the prevalence of different atopic conditions in adult EoE patients compared to other groups of control subjects. The findings indicate that, overall, EoE patients show a higher frequency of asthma, rhinoconjunctivitis, eczema, and food allergies than control groups; however, definitions for the associated atopic conditions have not been uniform and the study designs for the controls has not been such that they can be considered universally representative of the general population without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE. This systematic review was conducted in order to perform a meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both paediatric and adult EoE patients in comparison with the non-EoE control populations.

Aims & Methods: A highly sensitive search strategy was designed to identify and retrieve all documents dealing with the relationship between atopy and EoE in children and adults. This systematic literature search was performed independently (AA and AJL) and prospective throughout PubMed databases (PubMed, EMBASE, and Scopus) for the period up to March 2016. The search was not restricted with regard to the language of publication. A predefined protocol was used in accordance with the quality standards for performing meta-analyses of observational studies in epidemiology. Four reviewers (G-JC, AA, MM-MM, and AJL) independently extracted relevant information from each eligible study using a standardized data extraction sheet and then proceeded to cross-check the results. Estimates for the prevalence of each atopic manifestation in EoE patients and controls were summarized with the aid of a fixed- or random-effects meta-analysis, depending on intra-study heterogeneity, weighted for inverse variance following the method elaborated by DerSimonian and Laird. Summary estimates, including 95% confidence intervals (CI), were calculated for each season and month, whenever possible.

Results: Of the 2954 references identified, data was collected from 21 studies including a total of 33,542 EoE patients and 54,759 controls. The criteria for defining a diagnosis of atopy in either EoE patients or controls were not structurally considered in most of the studies. The frequency or prevalence of the different atopic manifestations among EoE patients was compared with that observed in several types of control populations, including series of patients with other upper GI tract diseases (GORD patients, patients with other GI diseases, patients, and healthy controls), all of whom were endoscopically assessed with a diagnosis of EoE specifically ruled out. In all cases, EoE was considered as independent from GORD and other upper GI tract diseases. Some studies included database-registered subjects as a diagnostic group among EoE patients and control subjects varied widely across the different studies, from self-reported/parent-reported atopic background to strict allergist/immunologist-provided diagnoses. Overall, allergic rhinitis was significantly more common among EoE patients as compared to control subjects (OR 5.4 [95% CI: 3.27, 9.53; I² = 86%]) as were bronchial asthma (OR 3.06 (95% CI, 2.01, 4.66; I² = 83.4%) and eczema (OR 2.86; 95% CI, 1.88, 4.36; I² = 57.2%). Food allergies and other atopic conditions were also assessed. No significant publication bias was observed while dealing with allergic rhinitis and eczema in EoE. Finally, our search uncovered two papers that reported on the frequency of drug allergy in EoE patients compared to controls, showing no significant differences between these two populations (OR = 0.981; 95%CI: 0.07, 14.72).

Conclusion: Our present study shows that an accurate diagnosis of allergy is lacking in most of the research evaluating the prevalence of asthma, rhinitis, and eczema among EoE patients. Still, the prevalence of these three conditions seems to be significantly higher in children and adults with EoE as compared to control subjects. More uniform definitions and criteria for defining atopy and other allergic diseases in the general population, based on independent research and use standard definitions of allergic rhinitis, asthma (including its severity and level of control), skin allergy, and food allergy (rather than mere self-reported/parent-reported atopic background to strict allergist/immunologist-provided diagnoses). Overall, allergic rhinitis was significantly more common among EoE patients as compared to control subjects (OR 5.4 [95% CI: 3.27, 9.53; I² = 86%]) as were bronchial asthma (OR 3.06 (95% CI, 2.01, 4.66; I² = 83.4%) and eczema (OR 2.86; 95% CI, 1.88, 4.36; I² = 57.2%). Food allergies and other atopic conditions were also assessed. No significant publication bias was observed while dealing with allergic rhinitis and eczema in EoE. Finally, our search uncovered two papers that reported on the frequency of drug allergy in EoE patients compared to controls, showing no significant differences between these two populations (OR = 0.981; 95%CI: 0.07, 14.72).

to steroids (64% vs 36%; p = 0.002). Specifically, the presence of strictures indicated a more likely clinical response to steroids compared to PPI alone. (p = 0.007).

Conclusion: A higher eos/hpf was found in patients with chronic EE features at index endoscopy than those with normal or acute endoscopic signs. In those with normal or acute EE changes and without dysphagia as a presenting complaint, a clinical response was noted with PPI therapy alone. In those with chronic EE changes or with dysphagia/FBO, steroids appear to be the preferred therapeutic option, although at 3 months follow up a clinical response might precede a histological one.

Introduction: Proton Pump Inhibitor-response esophageal eosinophilia (PPI-REE) is an emerging condition characterized by a constellation of clinical, endoscopic, and histopathologic features in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of proton pump inhibitor (PPI) therapy. A recent meta-analysis explored the role of different PPIs in inducing clinical and histologic remission in patients with PPI-REE. These data, although obtained in a small sample of patients, suggest that the pharmacokinetic and pharmacodynamic differences among these drugs do not affect their effect on PPI-REE patients.

Results: Twenty-eight patients [23M/5F; mean age 35] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. According to treatment allocation, 8 (29%) patients received esomeprazole, 9 (32%) rabeprazole and 11 (39%) pantoprazole. At baseline, demographic, allergy conditions and latency from diagnosis were similar (p = ns).

Aims & Methods: We aimed to prospectively compare the effect of different PPIs in inducing endoscopic and histologic remission in patients with PPI-REE. Consecutive patients with symptoms suggestive of EE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on esophageal biopsies at mid/proximal esophagus and, then, were treated with twice-daily PPI for at least 8 weeks. Patients were assigned to receive esomeprazole 20 mg bid, rabeprazole 20 mg bid or pantoprazole 40 mg bid in a 1:1:1 ratio. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf on esophageal biopsies at mid/upper esophagus mechanically (fluid, solids and gas).

Results: Twenty-eight patients [23M/5F; mean age 35] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. According to treatment allocation, 8 (29%) patients received esomeprazole, 9 (32%) rabeprazole and 11 (39%) pantoprazole. At baseline, demographic, allergy conditions and latency from diagnosis were similar (p = ns).

Endoscopic and histologic features at baseline and after PPI therapy are shown in the Table. Esomeprazole, rabeprazole and pantoprazole reached the same degree of efficacy in inducing endoscopic and histologic changes in PPI-REE patients (p = ns).

Table: Endoscopic and histologic features at baseline and after PPI therapy in PPI-REE

Conclusion: Esomeprazole, rabeprazole and pantoprazole administered at double daily dose were equally effective in determining endoscopic and histologic remission in patients with PPI-REE. These data, although obtained in a small sample of patients, suggest that the pharmacokinetic and pharmacodynamic differences among these drugs do not affect their effect on PPI-REE patients.

P0537 THE «GARD» (GASTRO-ESOPHAGEAL ANTI-REFLUX DEVICE): A NEW ENDOSCOPIC MEDICAL DEVICE TO DIAGNOSE, MANAGE AND TREAT GERD

N. Godin
Private Practice, Geneva/Switzerland

Contact E-mail Address: dr.godin68@gmail.com

Introduction: The « GARD» (Gastroesophageal Anti-Reflux Device) is an anti-reflux tubular valve placed in the lower esophagus under endoscopic control allowing normal ingestion of food and beverages but blocking all gastro-esophageal refluxate mechanically (fluid, solids and gas).

Aims & Methods: The « GARD» has an upper ring sized to the diameter of the patient’s esophagus with an accessory called the « calibration device » placed through the 2.8 mm working channel of a standard gastroscope. The GARD is held in place by pressure. The upper ring holds an anti-reflux thin-walled tubular valve moulded in one piece under the ring. After placement of a standard guidewire, the « GARD » is placed through the patient’s mouth and is released in the lower esophagus. The procedure is performed under sedation on an ambulatory basis in about 15 minutes when experienced. The « GARD » was placed in the esophagus of 8 pigs during 7 days to evaluate placement, feeding, weight gain, absence of migration as well as removal. Deployment of the « GARD » was easy, there was no migration in the stomach and removal of the GARD with the developed accessories was easily achieved. However, pigs have a strong lower esophageal sphincter and have no reflux so gastro-esophageal reflux could not be evaluated. In a human volunteer with very severe gastro-esophageal reflux who had previously failed anti-reflux surgery and had an unsatisfactory response to clinical and pH metric measurement under 80 mg of esomeprazole, the « GARD » was placed preoperatively. Hereafter are this patient’s pHometric results without PPIs (table 1); with the patient taking 80 mg/day PPIs (table 2) and after GARD placement and PPIs stopped for 10 days, table 3.

Results: Fig 1. First pH metric study (no PPIs for 10 days): The patient has very severe reflux with 63% of the time with a pH under 4 (normal less than 4% of the time at a pH under 4) after PPIs were stopped for 10 days. Fig 2. Patient is taking 80mg of esomeprazole a day. A pH metric measurement remains highly pathological at 23% of the time under pH 4 once PPIs have been resumed at 80 mg of PPIs daily. Fig 3. After placement of the GARD and PPIs have been stopped for 10 days, there is no longer any reflux measured. The pH tracing does not drop under the red line at pH 4.

Conclusion: a new medical device blocking GERD is presented. A first clinical trial is scheduled to start in 2018 to help diagnose and manage Refractory GERD. Further clinical indications are at the planning stage including treatment of Refractory GERD and LPR.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0538 SYMPTOM PATTERNS AND TYPES OF GASTROESOPHAGEAL REFLUXES SIGNIFICANTLY DIFFER IN GROUPS OF EROSIve ESOPHAGITIS AND NON-EROsiVe FORM OF GASTROESOPHAGEAL REFLUX DISEASE (GERD) PATIENTS

M. Konovalova, S. Morozov, V. Isakov
Gastroenterology And Hepatology, Federal Research Center of Nutrition and Biotechnology, Moscow/Russian Federation

Contact E-mail Address: sunnysister@mail.ru

Introduction: Patients with gastroesophageal reflux disease (GERD) demonstrate a range of different symptoms (esophageal and extraesophageal) however the relationship between symptoms and types of reflux was not evaluated.

Aims & Methods: The aim of the study was to assess the relationship between GERD patients’ symptoms with characteristics of refluxes obtained by 24-h esophageal pH-impedance. One hundred fifty eight GERD patients (68 men, 89 women, age (M ± m) 42 ± 4.8 yrs and 49 controls (22 men, 27 women, age (M ± m) 46 ± 6.7 yrs) were examined using 24-hour esophageal pH-impedance recordings (Ohmega, MMS, the Netherlands; 2pH-6 impedance channels catheters, UnisensorAG, USA) and validated GERD-Q questionnaire. According to baseline endoscopy 91 patients were classified as non-erosive reflux disease (NERD) and 67 as erosive reflux disease (ERD) patients. Patients’ symptoms were classified according to Montreal classification.

Results: Extraesophageal symptoms as well as weak acid gastroesophageal refluxes were found significantly more often in patients with NERD compared to ERD group (table 1). However higher number of acid refluxes, higher GERD-Q score and DeMeester score were present in ERD. The total number of gastroesophageal refluxes didn’t differ between ERD and NERD groups of patients.

Table 1: Results of the study

Introduction: Several clinical-based studies from Western countries have investigated the prevalence of extra-esophageal symptoms in various degrees of reflux erosive esophagitis. However, the independent factors related to the development extra-esophageal manifestations remain unclear.

Aims & Methods: Our aim was to assess the prevalence of extra-esophageal symptoms (laryngeal disorders and chronic cough) in adults with (cases) and those without (controls) erosive esophagitis in Albania, a developing Southeast European country. A case-control study was conducted at the Regional Hospital of Durres, the second main district in Albania, a transitional country in South Eastern Europe, including 289 patients with erosive esophagitis (aged 16–55 years) and 273 controls (aged 46± 16.0 years; response rate: 70%) enrolled during the period January 2013 – June 2014. Both cases and controls underwent upper endoscopy. Information on socio-demographic characteristics and lifestyle factors were also collected. Binary logistic regression was used to assess the association of erosive esophagitis and extra-esophageal symptoms.

Results: Patients with erosive esophagitis had a higher prevalence of excessive alcohol consumption, smoking, sedentariness and obesity compared to their control counterparts (9% vs. 5%, 70% vs. 49%, 31% vs. 17% and 22% vs. 9%, respectively). The prevalence of hiatal hernia was higher in cases than in controls (21% vs. 8%, respectively), whereas the prevalence of gastric-duodenal ulcer was similar in both groups (13% vs. 14%, respectively). Upon adjustment for all sociodemographic characteristic and lifestyle/behavioral factors, there was evidence of a strong association of erosive esophagitis with chronic cough (OR = 3.1, 95%CI = 1.7–5.7), and even more so with laryngeal disorders (OR = 4.4, 95%CI = 2.6–7.4). In all models, the association of extra erosive esophagitis with extra-esophageal symptoms was strong and remained significant after adjustment of the symptoms separately (fully-adjusted model: OR = 4.6, 95% CI = 2.9–7.3).

Conclusion: Our findings indicate that the prevalence of extra-esophageal symptoms is higher among patients with erosive esophagitis in a transitional country characterized conventionally by the employment of a Mediterranean diet. Therefore, the upper esophageal should be part of the evaluation in patients with suspected reflux-related chronic cough and laryngeal disorders.

4Department Of Bioanalytical Instrumentation, CEITEC Masaryk University, Brno/Czech Republic

Contact E-mail Address: stefankoneny@gmail.com

Introduction: Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological anti-reflux mechanisms and is the main cause of extraesophageal symptoms. Extraesophageal reflux (GER) is a condition where refluxate penetrate above the upper esophageal sphincter (UES) in to the oral cavity, pharynx, upper and lower respiratory tract and leads to pathological changes like e.g. chronic cough, globus pharyngis, laryngitis, pharyngitis, rhinosinusitis, otitis media, bronchial asthma, COPD, sleep apnea and noncardiac chest pain. Currently there is no suitable, non-invasive diagnostic method applicable for GERD in clinical practice. Exhaled breath condensate (EBC) and saliva are two easily obtainable samples that could be used in monitoring of patients suffering from extraesophageal symptoms of GERD. The aim of this study was to compare the pH and total ionic profile of EBC with 24-hour multichannel intraluminal impedance and pH monitoring (MII-PH) and salivary Peptest in a group of patients with reflux (pH < 4), weak and strong acid reflux (pH 4–7) and healthy controls.

Aims & Methods: A portable EBC sampler was used for collection of EBC. 10 µL sample aliquots of EBC were analyzed. For pH measurement, the CO2 from EBC was trapped with Na2 gas for 24 hours. The pH was measured with a pH microelectrode and total ionic profile (amions, cations, organic acids - NH4+, K+, Ca2+, Na+, Mg2+, Cl-, CO3-, NO3-, SO42-, acetate, lactate, propionate, butyrate) was analyzed by capillary electrophoresis in each sample. Saliva was collected using the commercial Peptest sampling containers, applied to the Peptest lateral flow devices and analyzed using the device reader. The data from EBC were compared with MII-PH and Peptest. In total the study comprised of 39 participants. The patients were divided by dominant findings from MII-PH to groups with acid reflux (n = 17), weakly acid reflux (n = 8) and without reflux (n = 14).

Results: The values of pH (after CO2 removal with Na2) were significantly higher in the group with acid reflux (p < 0.01), (mean pH 7.13, interquartile ranges 6.83–7.47) and in the group with weak acid reflux (p < 0.01) (7.37, (7.18– 7.57)) vs. healthy controls (6.8, (6.65–6.99)). Butyric acid (BA) was the second most significant parameter that was significantly elevated (p < 0.01) in both patient groups (acid reflux- mean BA 2.29 µM, weak acid reflux- mean BA 3.31 µM) compared to healthy subjects (mean BA 0.69 µM).

Further statistically significant differences were found in chloride ([Cl]−), nitrate ([NO3]−) and sodium ([Na+] ions concentration. CI− was elevated (p < 0.01) in group with acid reflux vs. healthy controls and NO3− and Na+ were elevated (p < 0.01) in the group with with weak acid reflux vs. healthy controls. For saliva sampling and peptin analysis showed no statistically significant differences within the groups. In the groups of patients with acid reflux, the incidence of high peptin concentration (above 75 ng/ml) was found only in 50% of the patients.

We found statistically significant difference in pH in selected ions from EBC between different groups of patients and healthy controls. The analysis of selected parameters in EBC could provide a fast and non-invasive diagnostic method for GERD patients with EER symptoms in the future. This can
Introduction: Impedance-pH testing is actually considered the gold standard diagnostic tool for reflux assessment. In fact, it allows to characterize any type of gastro-esophageal reflux (GER), namely acid and non-acid, and therefore permits – in presence of typical reflux symptoms – to diagnose functional heartburn (FH) based on the lack of abnormal acidic or non-acidic refluxate (i.e. normal number of reflux episodes and negative reflux-symptom association). Gastrin-17 (G17) has been proposed as a non-invasive marker of GERD, due to the negative feedback between acidic output and this hormone. Indeed, preliminary data showed that intermediate values of G17, between very low to normal levels, may identify GERD subjects with abnormal non-acid reflux.

Aims & Methods: We aimed to correlate various patterns of refluxate (i.e. predominant acidic refluxate, predominant non-acidic refluxate and no reflux at all), as assessed by impedance-pH, with different levels of G17 in endoscopy-negative subjects with heartburn. Thirty-five consecutive patients (19F/16M, mean age 47 years, range 31–56 years), all reporting heartburn since 6 months with at least 3 episodes/week, entered the study. All patients underwent upper endoscopy off-therapy and blood determination of G17. In the Group A, the mean value of G17 was 2.6 pmol/l, and, in the Group C was 5.1 pmol/l any kind of GER (Group C). In the Group A, the mean value of G17 was 2.6 pmol/l, and, in the Group C was 5.1 pmol/l. Results: The results of impedance-pH: a) Group A: subjects with increased number of acid reflux episodes and normal AET. In the Group B, levels of G17 were always low, but higher than in case of acid reflux pattern (Group A) (p < 0.05). Finally, when impedance-pH did not show any kind of abnormal reflux, suggesting a diagnosis of FH, G17 levels were always normal.

Conclusion: In this preliminary study, G17 levels well correlated with the three different categories of patients suffering of heartburn and included in the NERD umbrella (i.e. NERD patients with increased acid reflux episodes or abnormal AET, endoscopy-negative patients with increased non-acidic reflux and subjects with FH), suggesting its use as surrogate marker of NERD or non-acid reflux disease, without the need of performing invasive tests.

Disclosure of Interest: E. Savarino: Consulting fee from Medtronic, Sofar, Takeda, Abbvie, MSD. All other authors have declared no conflicts of interest.

Introduction: As a treatment for gastro esophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstream of medical therapy. Laparoscopic fundoplication is generally advised when symptoms are poorly controlled with PPIs and is regarded as a gold standard of treatment, with excellent control in the short- and midterm. Long-term results, however, remain equivocal. Following on from the principles of surgical fundoplication, a variety of endoscopic procedures for GERD have been proposed to achieve non-surgical control. Linx procedure, Stretta have been proposed as less invasive options.

Aims & Methods: We recruited all patients who had GERD refractory to standard medical therapy to see whether anti reflux mucosectomy prevents acid reflux into the esophagus. We screened all GERD patients who were refractory to proton pump inhibitors, hydrogen 2 receptor blockers and alginates and had an endoscopy suggestive of a lax cardia with mucosal flap valving grading of 1 to 5. We performed a baseline screening endoscopy to rule out a hiatus hernia and to exclude helicobacter infection. A GERDQ questionnaire was filled by all the patients indicative of severity of reflux All patients had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probe (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valving grade 1, 2 or 3 were selected for anti reflux mucosectomy.

Results: Technique: Crescentic ARMS of the esophagogastric junctional (EGJ) mucosa was conducted with the standardized technique of endoscopic mucosal resection (EMR) of at least 3 cm length in the stomach, with the length of mucosal resection at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal valve at gastric cardia. All the patients who underwent ARMS had a significant reduction in the DeMeester score, with predominant decrease in the recumbent acid reflux. 7/12 patients were able to discontinue all the medical therapy, PPI dose reduction was possible in the other patients with a mean reduction of 50%, all alginates were stopped in all patients and HRA were also discontinued.

Conclusion: Results suggest a potential anti-reflux effect of ARMS. The mechanism is presumed to be due to scar formation after healing of the mucosal defect. On the gastric side, this induces narrowing of the gastric cardia opening, while preserving and/or re-creating a robust his angle. After ARMS, the lesser curve of the gastric cardia takes on an almost “mechanically-stitched” appearance. The mucosal flap is robust and looks well-defined. Furthermore, the lesser curve side potentially reduce the diagnostic cost and avoid unnecessary invasive MII-pH testing in future. Unlike the EBC, pepsin analysis using Pepstep did not provide any diagnostic value.

</table>
of the EGI is shortened with scar formation, and greater curve of EGI (his angle is not mentioned) is noted, and therefore retained resectability as a mucosal flap valve. The quantity of mucosa to be resected to induce appropriate (“not too tight and not too loose”) scar formation is a key issue in this procedure. Total circumferential resection causes strictureing as demonstrated in previous studies, while subtotal dissection, which we have termed crescentic, produces better results in this regard, while still resulting in symptom control. Mucosal flap valve grading is not only a good predictor of reflux in these patients but also is a prognostic marker of effectiveness of ARMs, i.e. higher the grade worse the outcome. The extent and type of mucosal resection (4R vs. 4S) according to the mucosal flap valve grading may be a better predictor of outcome than a box standard procedure. This technique has a potential role in people with oesophageal dysmotility wherein Nissen’s fundoplication is relatively contraindicated.

Introduction: Observational and epidemiologic data have suggested an association between proton pump inhibitor (PPI) use and osteoporotic fractures. To evaluate potential mechanisms for this association, we measured bone turnover, except a small increase in CTX levels with DEX (0.12 ng/mL, 95% CI 0.03–0.23). The 26-wk median % increases in P1NP from baseline vs PBO (difference not significant (P = 0.05) increase in the pH in the esophagus for 120 minutes after ingestion [average pH values 6.04 ± 0.27 vs. 4.86 ± 0.23 during 0–60 min., and 5.93 ± 0.25 vs. 4.15 ± 0.26 during 60–120 min.]). In the gastric cardia (a typical place of formation of postprandial acid pocket) showed significant (P = 0.05) higher values for the first 60 minutes after intake of alginate [pH 4.3 ± 0.37 vs. 3.04 ± 0.25], during 60–90 min, pH values wasn’t significantly (P > 0.05) different [2.75 ± 0.45 vs. 2.43 ± 0.20]. In the stomach body no significant effect of the drug on pH was recorded [average pH values for stomach 2.56 ± 0.46 vs. 2.1 ± 0.18 during 1st postprandial hour and 2.29 ± 0.49 vs. 2.09 ± 0.18 during 2nd postprandial hour; P = 0.05].

Conclusion: Our findings demonstrate that raft-forming alginate is an effective antireflux treatment and is effective in the prevention of postprandial acid and gas reflux and to reduce the injurious effect of acid in the esophagus. At the same time alginate showed no effect on stomach content in the postprandial period, it means that the main mechanism of action is through the movement of postprandial acid contents from the lower esophageal sphincter, but not the neutralization of stomach acid, unlike nonraft-forming antacids and PPIs.

Introduction: S-isomer (S) pantoprazole is more bioavailable and less dependent on cytochrome 2C19 than is racemic pantoprazole.

Aims & Methods: We aimed to evaluate the efficacy and safety of 10 mg S-pantoprazole for treatment of non-erosive reflux esophagitis (NERD). This study was designed as a multicenter, randomized, double-blind, placebo controlled trial. NERD was defined as reflux symptoms and normal endoscopy findings. Patients were allocated to take either 10 mg S-pantoprazole or placebo once daily for 4 weeks, after which reflux symptoms were reassessed. Recurrence of symptoms was assessed at 4 weeks after cessation of medication. The efficacy endpoints were complete relief of symptoms, improvement of reflux symptoms, and safety.

Results: Eighty-eight patients randomly assigned pantoprazole group (25 males, 43.7 years old) and 86 to the placebo group (32 males, 43 years old), and 163 patients were subjected to a per protocol analysis. A higher proportion of patients in the S-pantoprazole group had complete symptom relief (33.6% vs. 14%, P < 0.001). In the both groups, symptoms of heartburn, acid regurgitation and epigastric discomfort significantly improved after treatment compared with baseline; however, improvement of all symptoms was greater in the s-pantoprazole group compared to placebo group. Therapeutic gains in controls of heartburn, acid regurgitation and epigastric discomfort were 66 to 80%.

The factors associated with poor symptom responses to PPI were older age, female sex, greater body mass index and symptom severity in both groups.

Conclusion: S-pantoprazole (10 mg) was more efficacious than placebo in providing reflux symptom relief in patients with NERD, especially acid regurgitation.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Refractory non erosive reflux disease (NERD) is defined by absence of clinical response to a 12-week course of proton pump inhibitors (PPI) at full dose in absence of esophagitis. It accounts for about 20% of all NERD cases. 24-hour multichannel intraluminal impedance (pH/MII monitoring) should give useful patient-specific information about refractory NERD. Therefore, our aim was to assess whether this technique could be useful to guide a “tailed” therapy to refractory NERD patients.

**Aims & Methods:** We retrospectively recruited patients undergoing pH/MII monitoring for refractory NERD. All patients had undergone upper endoscopy, and cases of esophagitis were excluded. No patient received PPI during pH/MII monitoring. Subjects were subgrouped into 3 categories according to Zerbib’s classification: i) Acid reflux (exposure to pH ≤ 4 for at least 1.1% of record time), ii) Non acidic reflux (symptom association probability to pH > 4 reflux episodes > 95%), and iii) Functional heartburn (no pathologic reflux with symptom association probability < 50%). MII-pH guided therapy was performed as follows: patients with acid reflux received PPI at double dose, patients with non acid reflux PPI at full dose plus alginates and patients with functional heartburn levosulpride 75 mg/day for 4 weeks. A visual analogue scale (VAS) ranging 0–100 was administered before and after such tailored therapy to evaluate overall symptomatology. Responders were defined by VAS improvement of at least 70%. Comparisons between continuous variables were performed by ANOVA or paired/unpaired t-test where required, and Fisher’s exact test was applied to categorical variables. Variables with statistical significance p < 0.10 at univariate analysis were entered into a binary multivariate regression analysis, aimed to investigate factors predictive of response to tailored therapy.

**Results:** Thirty-four patients with refractory NERD were selected (female:male ratio 20:14, mean age 47.4 ± 12.8). Twelve had acid reflux, 7 non acid reflux and 15 functional heartburn. Overall effectiveness of tailored therapy was 82.3% (26 out of 34), and it did not differ between subgroups (91.7% acid reflux, 71.4% non acid reflux, 80.0% functional heartburn, p = 0.31). At univariate analysis, therapy failure directly correlated with dysphagia (OR = 0.15, p = 0.10) and inversely with sensation of slow digestion (OR = 7.70, p = 0.05). However, at multivariate analysis, these parameters were not statistically significant. We found a mean VAS reduction of 30.2 ± 24.9, which was similar between acid reflux (36.7 ± 22.7), non acid reflux (30.0 ± 27.7) and functional heartburn (38.2 ± 25.7) p = 0.76.

**Conclusion:** A tailored approach to refractory NERD, guided by pH/MII monitoring, demonstrated to be effective, independently from disease subtype. Therefore it should be advised to patients who complain of symptom persistence despite PPI therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic reflux, a risk factor for the development of Barrett’s esophagus (BE), causes damage to the normal squamous epithelium of the esophagus, which eventually is replaced by a columnar type of epithelium. It has been shown that bile acids (BAs) play a role in the development of BE. The effect of different BAs in the refluxate has been poorly studied with respect to the pathogenesis of BE. Insights in the effects of the bile components in reflux can help provide more efficacious targets for preventing the development of metaplasia and the progression from BE to EAC. Before being released into the duodenum, BAs produced by the liver are conjugated with either taurine or glycine. BAs not only have detergent properties, but can also act as signaling molecules by activating the farnesoid X receptor (FXR) and G-protein coupled bile acid receptor (TGR5). Both receptors are upregulated in BE and EAC compared to normal squamous mucosa, suggesting a possible role in the progression of BE. (De Gottardi 2006; Hong 2010).

**Aims & Methods:** The aim of the study was to analyze refluxates of BE patients and evaluate the effect of these different bile components on metastatic gland development and bile receptor activation.

**Results:** Determination of the bile composition in refluxate of BE patients by HPLC showed the presence of both glyco-conjugated (67.6 ± 8.8%) and taurine-conjugated BAs (31.5 ± 9.1%). Only a low percentage of unconjugated BAs was found in the patient refluxates (0.5 ± 0.4%). Although unconjugated BAs were absent in our refluxates, they have shown their presence in GERD patients (Nehra 1999). Deoxycholic acid (DCA), a secondary bile, is formed through deconjugation by microbial enzymes present in the colon, but the increase in pH due to PPI use can cause gastric bacterial overgrowth, resulting in the presence of DCA in reflux (Theisen 2000). Each of the six conjugated bile components

**Introduction:** STW5, a herbal combination preparation of nine different plant extracts (Iberis amara (L.), Menthae piperitae (L.) Chamomilla recutita (L.), Glycyrrhiza glabra (L.), Angelica archangelica (L.), Carum Carvi (L.), Silybum marianum (L.) Gaertn. Melissa officinalis (L.) und Chelidonium majus (L.)), Glycyrrhiza glabra (L.), Angelica archangelica (L.), Carum Carvi (L.), Silybum marianum (L.) Gaertn. has been extensively studied for the treatment of gastrointestinal disorders resulting in an recommendation for the German therapy guidelines for both upper and lower functional gastrointestinal disorders (1). We investigated the mode of action of this herbal medicine on reflux esophagitis as the most common condition treated by gastroenterologists with possible long-term implications such as Barrett’s esophagus and esophageal adenocarcinoma.

**Aims & Methods:** We were especially interested in the tight junction proteins (TJ), which are multi-protein complexes in epithelial and endothelial cells known to contribute to the barrier-function, but recently discovered to play an important role in tumorigenesis (3). TJ proteins like ZO-1 and 2 participate in cell-cycle regulation, occludin (OCLN) regulates the mitotic entry via centrosome separation, claudin-4 increased cell proliferation (CDP), claudin-1 is responsible for increased proliferation of the crypt cells (3). CLDN 1, 3, 4, 5, 7, 10 and 16 have been found altered in various types of cancer and OCLC is regarded an anti -transformation protein (3).

**Results:** In the model, RE was induced by surgical methods and rats (n = 6 per group) were treated with STW5 (0.5 or 2 ml/kg) or the proton pump inhibitor (PPI) omeprazole (O) (30 mg/kg) as described earlier (2). RNA was isolated from defined tissue areas of the esophag. In the inflamed tissue we found a simulta-neous transcript down regulation of claudin 4 (p < 0.0001), compared to DCA treated or untreated animals. DCA was able to activate FXR, while the addition of all conjugated BAs did not result in a signal change. Both receptors are able to activate bile receptors we transfected primary mouse esophageal epithelial cells (ME10) with TGR5 and FXR, too. Transcripts of MarvelD1 and JAM 2 were increased. The down regulation of ZO1 was seen by Western Blot, too. HLPC showed the presence of both glyco-conjugated (67.6 ± 8.8%) and taurine-conjugated BAs produced by the liver are conjugated with either taurine or glycine. BAs not only have detergent properties, but can also act as signaling molecules by activating the farnesoid X receptor (FXR) and G-protein coupled bile acid receptor (TGR5). Both receptors are upregulated in BE and EAC compared to normal squamous mucosa, suggesting a possible role in the progression of BE. References:

Aims & Methods: Organoid cultures are widely used because they mimic in vivo differentiation of self-organizing stem cells and represent the perfect model to study stem cell interaction in basic and translational research. We developed an in vivo organoid model of human BE to investigate the potential to modulate the metaplastic process using an innovative anti-BMP2/4 llama-derived Dwarfbody™ (DB). Endoscopic BE biopsies were implanted into immunocompromised nude mice intramuscularly and grown for a period of three months with DB or control. These structures were assessed histologically and immunohistochemically (IHC) using panels of squamous, intestinal and stem cell markers.

Results: A clustering phenomenon is seen at the epithelial layer containing goblet cells and recapitulated the crypt and villous regions seen within BE glands. IHC validation confirmed that the xenograft structures were of human origin and expressed markers of intestinal differentiation (CKS, CDX2 and villin). In contrast, treatment with the BMP inhibitor lead to the formation of multi-layered squamous epithelium expressing both the stem cell marker p63 and the squamous marker CK5.

Conclusion: Preliminary results demonstrate that inhibition of BMP2/4 in this model can prevent development of squamous epithelium. These pre-clinical results may be translated to the clinical setting in order improve treatment of BE and as such prevent the development of esophageal adenocarcinoma.

P0550 GASTRIC CARDIA GLANDS MANIFEST APPARENT BROAD DIFFERENTIATION POTENTIAL, AS EVIDENCED BY HOXA13 EXPRESSION, IMPLICATIONS FOR THE ORIGIN OF BARRETT’S ESOPHAGUS

Introduction: Metaplastic phenomena in the upper gastrointestinal tract are still poorly understood. A prominent theory is that Barrett’s esophagus originates from gastric cardia glandular epithelium. However, in absence of evidence that the gastric stem cell has broad differentiation potential, this theory remains controversial. The gastroesophageal junction is a high prevalence area for metaplasia and subsequent cancer. Characteristic of this area are the gastric cardia glands which are only the most proximal part of the anatomic gastric cardia. Recent evidence from human and mouse studies has shown Barrett’s esophagus can originate from these gastric cardia glands. If it can be shown that gastric cardia glands contain elements associated with positional mis specification, this theory could be substantially bolstered. HOX genes are a family of transcription factors that convey positional information. The 3rd to 5th sequence of HOX genes corresponds to the sequence in which they act along the anterior to posterior axes of the gut. This property is termed collinearity and links clustering to function. In gastrointestinal physiology, HOX4.13, a 5’ member of the HOX 4 cluster, has an expression pattern restricted to the colonic epithelium. However, pathological metaplastic lesions of the esophagus and stomach are also characterized by HOXA13 expression. This in parallel with the similarities of these lesions with physiological embryonic morphology. Hence, investigating HOXA13 expression in gastric cardia glands appears a rational strategy in assessing the potential of this gastric cardia epithelium to serve as the origin of Barrett’s esophagus.

Aims & Methods: We aimed to determine HOXA13 expression in physiological gastric cardia glands. Firstly, strips of tissue from surgical specimens containing squamous esophageal epithelium, gastric cardia glands, and oxyntic stomach, were collected. These were continuous strips, from proximal to distal, to preserve morphological information. Material from three patients was selected, they suffered from either a neuroendocrine tumor, or decompensated achalasia, or an adenocarcinoma. Antibodies against HOXA13 were found not to be specific. Therefore, RNA in situ hybridization by RNA-scope was performed to visualize HOXA13 RNA. Secondly, a HOXA13GFP x C57BL/6J heterozygous mutant mouse model was used. In these animals, the cardiac glands were visualized directly for GFP expression using a fluorescence confocal microscope.

Results: All three patients showed HOXA13 expression of a portion of gastric cardia epithelial cells. The squamous epithelium, the oxyntic epithelium, and the cardia did not show any signal. The signal is located relatively close to the base of the crypts of the cardiac glands. The HOXA13GFP x C57BL/6J heterozygous mice showed GFP expression localized to the nucleus of some of the epithelial cells of the cardia gland. No nuclear signal was detected in the squamous or oxyntic epithelium. The colonic epithelium of the mouse showed nuclear GFP signal. Rectal squamous epithelium was negative as well as ileal epithelium, in accordance with HOXA13 colinearity in mouse and human. A littermate negative for HOXA13 was analyzed and showed no nuclear signal in either gastric cardia gland cells or in any intestinal cells.

Conclusion: Gastric cardia gland epithelial cells in both human and mouse exhibit HOXA13 expression. All other physiological upper gastrointestinal tract tissues are HOXA13 negative in line with HOX gene colinearity in the gut. This dichotomy proves positional information in these glands is discordant with their actual location. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett’s metaplasia in the gastric cardia and might be indicative of Barrett’s not being a true transdifferentiation.

Introduction: Barrett’s Oesophagus (BE) is an acquired condition resulting from of continuous reflux that causes chronic irritation of the Barrett’s metaplasia-dysplasia-adenocarcinoma sequence. Am J Gastroenterol 2013;108: 1082-93.

During progression from BE to EAC the infiltration of CD4+ cells was observed. The number of IL-22+ cells and IL-17A+ cells as well as the number of FOXP3+ cells/mg tissue increased in oesophageal cancer and in its peritumoral tissue as compared to healthy controls. The relative amounts of IL-22+ and IL-17A+ cells decreased while an increase of FOXP3+ cells was observed. Also more IL-10+ cells/mg tissue were observed in the tumours. In accordance to the latter finding high IL-10 mRNA expression levels were associated with poor survival in EAC patients. Interestingly, high mRNA expression levels of IL-10 in the non-malignant peritumoral tissue also correlated with poor survival.

Conclusion: During progression from BE to EAC the infiltration of CD4+ immune cells increases. While the relative amount of pro-inflammatory cells (CD4+ / CD8+ ) increases it is accompanied by a decrease of FOXP3+ regulatory T cells. Our results strongly suggest that especially regulatory T cells influence overall patient survival in EAC. Notably, high levels of IL-10 in the non-malignant peritumoral tissue also demonstrated to be unfavourable for patient survival. Thus, a pro-tumorigenic immune response is accompanied by increased IL-10 expression and high mRNA expression of IL-10 in BE patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0553 ANTI-INFLAMMATORY ENVIRONMENT CHARACTERISES BARRETT’S OESOPHAGUS ASSOCIATED ADENOCARCINOMAS AND INFLUENCES PATIENT SURVIVAL

Introduction: Barrett’s Oesophagus (BE) is a premalignant condition associated with an increased risk of adenocarcinoma. The potential for BE to progress to dysplasia and ultimately lead to oesophageal adenocarcinoma presents a significant clinical challenge. The identification of environmental factors that can progress to dysplastic lesions, which ultimately lead to oesophageal adenocarcinoma (EAC). The incidence of EACs is rising in the Western world and 5-year survival rates are below 20%. Hence, new diagnostic and prognostic markers are needed. Since elevated levels of interleukin (IL)-6 in BE producing cells are associated with a poor prognosis in colorectal cancer we wanted to investigate their influence in EACs.

Aims & Methods: None of the patients enrolled in this study received chemoradiation therapy prior to surgery and all patients had pathologically confirmed BE. mRNA expression levels of interleukins in tumour tissue and non-malignant peritumoral specimens of 39 patients were measured. Immunohistochemical analysis was conducted to investigate interleukins during the progression from BE to EAC. Interleukins were investigated in formalin-fixed paraffin-embedded oesophageal cancer specimens and in their non-malignant peritumoral tissue (n = 11). During routine endoscopy samples from healthy volunteers were obtained and analysed by flow cytometry as controls (n = 5).

Results: During progression from BE to EAC an increase of CD4+ cells was observed. The number of IL-22+ cells and IL-17A+ cells as well as the number of FOXP3+ cells/mg tissue increased in oesophageal cancer and in its peritumoral tissue as compared to healthy controls. The relative amounts of IL-22+ and IL-17A+ cells decreased while an increase of FOXP3+ cells was observed. Also more IL-10+ cells/mg tissue were observed in the tumours. In accordance to the latter finding high IL-10 mRNA expression levels were associated with poor survival in EAC patients. Interestingly, high mRNA expression levels of IL-10 in the non-malignant peritumoral tissue also correlated with poor survival. 

Conclusion: During progression from BE to EAC the infiltration of CD4+ immune cells increases. While the relative amount of pro-inflammatory cells increases in BE it is accompanied by a decrease of FOXP3+ regulatory T cells. Our results strongly suggest that especially regulatory T cells influence overall patient survival in EAC. Notably, high levels of IL-10 in the non-malignant peritumoral tissue also demonstrated to be unfavourable for patient survival. Thus, a pro-tumorigenic immune response is accompanied by increased IL-10 expression and high mRNA expression of IL-10 in BE patients.

as genotypic evolution. Patients with dysplasia also show a significant increase in gland phenotype diversity (Shannon) per biopsy in adjacent to dysplasia glands compared with patients who do not have dysplasia.

**Conclusion:** BE is phenotypically diverse with a range of glandular phenotypes that are clonally related. An increase in phenotypic diversity may be a potential biomarker for assessment of patients progressing from BE to cancer with implications for diagnostic and surveillance policy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0555** A DEDICATED BARRETT'S OESOPHAGUS ENDOSCOPY LIST IMPROVES THE ACCURACY OF ENDOSCOPIC REPORTING AND QUALITY OF BIOPSY

H. Al-Hasani, T. Sharp, S.M. Ha, L. Matsuoka, N. Siddique

**Gastroenterology, Queen Elizabeth the Queen Mother Hospital, Margate/United Kingdom**

**Contact E-mail Address:** hannahalhas@gmail.com

**Introduction:** The importance of skilled endoscopic assessment of Barrett's oesophagus (BO) has been clearly established and forms part of the British Society of Gastroenterology guidelines. Use of Prague classification when reporting on areas of BO improves standardisation, and adherence to the Seattle biopsy protocol (quadrant biopsies every 2 cm) when sampling Barrett's mucosa is thought to improve dysplasia detection. In East Kent Hospitals NHS Foundation Trust we have created a dedicated nurse-led BO surveillance endoscopy list with the aim of improving compliance with guidelines and the quality of biopsies taken. Here we present a retrospective observational study of patients who underwent upper GI endoscopy on a general endoscopy (GE) list compared with the dedicated BO endoscopy (DBO) list.

**Aims & Methods:** We searched our endoscopy software for patients who had had an endoscopy documented by a consultant gastroenterologist who had an endoscopy on a GE list from 2012–2013. The same search was performed for patients who were scoped on the DBO list from 2014–2016. Endoscopy reports were reviewed to assess the use of Prague classification and determine numbers of biopsies taken. Biopsy results were reviewed on our electronic pathology database.

**Results:** One hundred procedures for BO surveillance on GE lists were audited, comprising 65% male patients with median age 68 years; 60% were performed by a consultant gastroenterologist and the remainder were performed by other operators including surgical consultants and gastroenterology registrars. Of the 105 procedures on the DBO lists, 63% of patients were male, median age 70 years. Prague classification was used in 94% of endoscopy reports on the DBO lists compared with 5% on the GE lists. The Seattle biopsy protocol was observed in 70% of cases on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) was similar in both groups: 8/105 (7.6%) on the DBO list and 6/100 (6%) in the GE group. All (100%) of the dysplasia detected on the GE lists occurred in procedures performed by consultant gastroenterologists.

**Conclusion:** Our comparison shows that observance of Prague classification is significantly higher on the DBO lists when compared with GE lists (94% vs 5%), and compliance with the Seattle biopsy protocol is similarly higher (74% vs 30%). These are indicative of higher quality endoscopic surveillance on DBO lists. However, this did not translate to a different dysplasia detection rate which appeared to be more influenced by the endoscopy operator since all of the dysplasia detected on GE lists was identified by consultant gastroenterologists. We believe that adding this additional familiarity of guidelines and possible greater experience of endoscopists regularly taking BO biopsies. We therefore recommend that all Barrett's oesophagus patients have their surveillance endoscopies performed on dedicated BO endoscopy lists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

2.Gastroenterology, University of Florida, Gainesville/United States of America

**Contact E-mail Address:** dennis.yang@medicine.ufl.edu

**Introduction:** Adherence to quality indicators and surveillance guidelines in the management of Barrett's esophagus (BE) promotes high-quality cost-effective care.

**Aims & Methods:** The aims of this study were to evaluate (1) adherence to standardized classification (Prague Criteria) and a systematic four-quadrant biopsy protocol, (2) identify predictors of practice patterns, and (3) to assess adherence to surveillance guidelines for non-dysplastic BE (NBDE).

This was a Single-center retrospective study of endoscopies (EGDs) performed for BE between June 2008 to December 2015. Data on patient demographics, procedure characteristics and histology results were obtained from a prospectively collected endoscopy database and chart review. Adherence to the use of Prague Criteria and systematic biopsy protocol were assessed based on operative report documentation. Guideline adherent surveillance EGD was defined as those performed within 6 months of the recommended 3–5 year interval. Uni- and multivariable analysis were performed to identify predictors of practice patterns.

**Results:** A total of 397 patients (66.5% male; mean age 60.1 ± 12.5 years) had an index EGD during the study period. Adherence to the use of Prague Criteria and systematic biopsies were 27.4% and 24.1%, respectively. Endoscopists who perform systematic interventions for BE were more likely to use the Prague Criteria (OR: 3.16; 95% CI: 1.47–6.82) than those who do not. Longer time in practice (in years) was positively associated with adherence to Prague Criteria (OR 1.07; 95% CI: 1.02–1.12; p < 0.01) but with a lower likelihood of performing systematic biopsies (OR 0.91; 95% CI: 0.85–0.97; p < 0.01). Nearly 41% of patients with NBDE (11/27) underwent surveillance EGD sooner (range 1–24 months) than the recommended interval.

**Conclusion:** Adherence to quality indicators and surveillance guidelines in BE is low. One major characteristic, including experience with endoscopic therapy for BE and time in practice predicted adherence to the use of Prague Criteria and systematic biopsies. Future efforts are needed to reduce variability in practice and promote high-value care.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0557** EXPRESSION OF TGF-B AND CD-44 IN AGE SPECIFIC SUBGROUP OF PATIENTS WITH ADENOCARCINOMA OF GASTRIC CARDIA

N. Lukavetsky, T. Fetschys

**Oncology Department, Lviv Medical University, Lviv/Ukraine**

**Contact E-mail Address:** lukavetskyy@ukr.net

**Introduction:** Adenocarcinoma near the esophagogastric junction is one of the most lethal GI malignancies known. Surgical treatment of these cancers stay determinative factors of patient survival. Older persons often differ from the younger adult population in terms of biological and functional perspectives; as such, they may have particular needs which require an interdisciplinary approach and intervention, especially when faced with a cancer diagnosis.

**Aims & Methods:** The aim of this study was to detected expression of TGF-B and CD-44 in age specific subgroup. The expressions of TGF-B and CD-44 were evaluated immunohistochimically in 23 patients with adenocarcinoma of gastric cardia who underwent curative surgery (RO) without any neo/adjuvant therapy. Additionally we analyzed control group of patients with non-cancer lesion or normal tissue of upper digestive tract (13 patients). We divided the patients into two groups. Group A consisted of 13 cancer patients and 7 control patients 65 years of age or older, while Group B consisted of 10 cancer and 6 control patients younger than 65 years of age. The two groups were comparable - there were no differences between the two groups regarding tumor stage.

**Results:** Elderly patients have statistically significant better survival (median 20.2 month) compared with younger patients (median 15.4 month) (p = 0.045). The median survival rate of patients without TGF-B and/or CD-44 expression was significantly lower (7 m) than that of patients with positive expression (>15 m) (p = 0.003). Regardless of patients age, CD-44 was significantly higher in the cancer tissue of elderly patients than in younger (p < 0, 035). But no significant difference was observed in the TGF-B expression between group A and group B cancers tissue (p = 0.005).

**Conclusion:** The biology of tumors may be different in elderly patients, leading to a lower rate of tumor-related mortality.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Barrett’s esophagus (BO) is considered a premalignant condition for oesophageal adenocarcinoma (OAC). Once diagnosed, interval endoscopic surveillance is recommended to promote early detection of dysplasia and cancer. Occurrence and incidence of dysplasia and cancer among BO vary across populations. Recent studies show BO patients mortality is mainly related to non-oesophageal cancer and cardiovascular morbidity.
### Aims & Methods:
In this cross-sectional study, our aims were to describe the local BO clinical, endoscopic and histologic profile in our tertiary referral centre, and discover whether the Prague classification reporting requirements are filled. We identified and included all consecutive patients with oesophageal intestinal metaplasia (identified by the presence of goblet cells) from March 2009 to May 2015. All endoscopies and biopsy reports were reviewed: BO segment length, use of the Prague classification, endoscopic abnormalities, treatment modality and, histologic findings of dysplasia. Participants were sent a clinical questionnaire, via which pertinent clinical data including personal and familial cancer history, were collected.

### Results:
Clinical profile: Our cohort consists of 406 patients, with a mean age of 60.9 ± 13.3 years, 69% were male. Endoscopic profile: Mean maximal BO length (Prague classification M) was 2.8 ± 1.9 cm (reported in 49.6% of endoscopies). Mean circumferential BO (Prague classification C) was 4.9 ± 3.1 cm (reported in 18.1% of endoscopies). Histologic profile: Low-grade dysplasia (LGD) was seen in 4.4% of patients, high-grade dysplasia (HGD) in 3%, intramucosal carcinoma (IMC) in 0.7%, and OAC in 2%. A subgroup of 250 patients underwent more than one endoscopy, allowing for prospective incidence analysis. They had 914 years of follow-up, with a mean number of endoscopies of 4.7 ± 3. The incidence rates of LGD, HGD, IMC, OAC per 1000 patient-years were 20.8, 15.3, 2.2, and 5.7 years. A personal history of non-oesophageal malignancy was reported in 15.4%. A family history of BO, OAC and non-oesophageal cancer were reported in 5.2%, 4.5%, and 35.4%, respectively.

### Conclusion:
Compared to the information gathered by Katz et al. (1), we demonstrated a lower rate of LGD, but comparable rates of HGD and OAC. The personal and familial history of non-oesophageal malignancy was higher than the oesophageal malignancy rates. Our findings may support the importance of age appropriate non-oesophageal malignancy screening in BO patients. Physician compliance in reporting BO according to the Prague classification is lacking. Factors associated with our local BO profile as well as the implication of family history requires further prospective studies.

**THE EFFICACY OF ENDOSCOPIC MUCOSAL RESECTION IN MANAGING EARLY NEOPLASIA IN BARRETT’S ESOPHAGUS, EXPERIENCES OF A TERTIARY REFERRAL CENTER IN THE UK**

**B. Eross**, C. Clisby, B. Foria, C. Gordon

1Gastroenterology, Royal Bournemouth Hospital, Bournemouth/United Kingdom

3Pathology, Royal Bournemouth Hospital, Bournemouth/United Kingdom

**Contact E-mail Address:** xerobal@yahoo.it

**Introduction:** Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early neoplasia. Our objectives were to demonstrate EMR’s efficacy in removing early neoplasia within BO and its usefulness in obtaining comprehensive histological specimens to accurately stage the early neoplasia and effectively deliver therapy.

**Aims & Methods:** We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We analysed the resection margins for both en bloc and piecemeal EMRs. We compared the original histology from the referral endoscopy to the histology obtained from the EMR, to analyse any deviation and to demonstrate the importance of histological staging of the early neoplasia in BO. We also investigated the three-year survival in patients, who have had their EMR longer than 3 years ago, along with causes of death. A total of 99 patients underwent 134 EMR procedures and 259 EMRs. 84% were male, the mean age at first EMR was 71 years (SD = 8.2). 24 patients underwent 2 EMR procedures, 2 patients underwent 3 EMR procedures and 2 patients underwent 4 EMR procedures. The median length of the circumferential and maximum extent of the BO segments were 3 cm and 4 cm, respectively (interquartile range (IQR) 2–4). 44 patients underwent 60 en bloc resections. After histologic assessment of these EMR specimens, 34 (56.7%) had clear deep and radial resection margins, 14 (23.5%) showed least low-grade dysplasia at the radial margin and 8 (13.4%) at both margins. 2 (3.3%) were clear at the deep margin, but due to thermal damage the radial margins were indeterminate. Following the 60 EMRs there was no visible residual early neoplasia on the follow up endoscopy in 37 cases (61.7%), 55 patients underwent 74 piecemeal EMRs, of which 52 (70.3%) had clear deep margins on histologic assessment and 38 (51.4%) had no visible residual neoplasia on the follow up endoscopy. Pre EMR histology was available in 82 patients and it showed high-grade dysplasia (HGD) in 49 (59.8%), mucosal adenocarcinoma in 24 (29.2%) and low-grade dysplasia in 9 patients (11%). However the EMR histology resulted in altered grading in 59 (72%) patients, with 47 (57%) upgraded and 12 (14%) downgraded from the pre EMR histology and unchanged only in 22 patients (28%). The EMR histologies in the 82 patients showed HGD in 16 (19.5%) patients, intramucosal adenocarcinoma in 33 (40.2%), adenocarcinoma with submucosal invasion in 20 (24.4%) and LGD in 13 (15.9%). The remaining 52 EMRs were performed for visible lesions within BO without pre EMR histology result, predominately for patients in the radiofrequency ablation program. The 3 year survival rate for 42 patients was 81%, 8 patients died, 5 due to cardiac failure, 1 due to a PE and 2 due to advanced oesophageal adenocarcinoma.

**Conclusion:** In this moderately sized retrospective study EMR has been proven to be an effective tool in managing early neoplasia within BO. It not only allows the potential complete resection of the visible early neoplasia (61.7% for en bloc and 51.4% for piecemeal EMR), but also gives a histologic specimen with a more accurate grading of the neoplasia (upgraded in 57%, downgraded in 14% and unchanged in only in 23% of all EMRs), both aspects culminating in more effective and precise patient treatment. In all patients managed and assessed by EMR we have seen 19% mortality of which only 4.8% was cancer related.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**ADHERENCE TO BARRETT’S ESOPHAGUS SURVEILLANCE GUIDELINES: A SYSTEMATIC REVIEW AND META-ANALYSIS**

1Department Of Gastroenterology & Hepatology, Erasmus University Medical Center, Rotterdam/Netherlands
2Department Of Medical Statistics And Bioinformatics, Leiden University Medical Center, Leiden/Netherlands
3Department Of Biostatistics, Erasmus University Medical Center, Rotterdam/Netherlands
4Department Of Public Health, Erasmus University Medical Center, Rotterdam/Netherlands

**Contact E-mail Address:** heather.rapoport@erasmusmc.nl

**Objective:** To determine the adherence to surveillance guidelines for Barrett’s oesophagus (BO) in different countries using a systematic review and meta-analysis of prospective cohort studies.

**Methods:** A systematic review of prospective studies was conducted using a predefined protocol. Studies were identified through a comprehensive search of Embase, PubMed and CINAHL databases until 2015. The primary outcome was the percentage of patients that adhered to surveillance guidelines, i.e. the percentage of patients that underwent at least two endoscopies within the recommended surveillance interval. Results were presented as a meta-analysis of proportions using a random-effects model.

**Results:** A total of 11 studies were included. The total number of patients in the studies was 10,824. The adherence to surveillance guidelines was 51% (95% CI: 43%–58%). A meta-analysis of the studies revealed a significant difference in adherence among the countries. The adherence was significantly lower in the Netherlands (41%, 95% CI: 33%–48%) compared to the United States (57%, 95% CI: 52%–62%) and Australia (64%, 95% CI: 57%–70%).

**Conclusion:** The adherence to surveillance guidelines for BO varies significantly among different countries. The Netherlands has the lowest adherence, while the United States and Australia have higher adherence rates. Further studies are needed to investigate the reasons for the differences in adherence among the countries.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
BE surveillance in non-dysplastic BE patients a prevalence ratio for adherence of
Results:
1 proportional hazard ratio of mortality for ESD compared with surgery was not
lymphovascular invation, submucosal invation, and ASA-PS, multivariate Cox
ESD compared with surgery has not been clarified.
54 lesions in the ESD group and 51 lesions in the surgery group met the
and surgery for cN0M0 relative indication lesions of ESCC. Between 2006 and
2016, patients with relative indication lesions of ESCC treated endoscopically or
surgically in Okayama University Hospital were retrospectively analyzed. We
and analysis of heterogeneity (I² statistic).
Results: From a total of 373 studies, 49 were eligible for this meta-analysis. For
BE surveillance in non-dysplastic BE patients a prevalence ratio for adherence of
percentage of mortality for ESD compared with surgery was not
lymphovascular invasion, submucosal invasion, and ASA-PS, multivariate Cox
Results: Eight FA subjects with a median age of 22.2 years at first endoscopy
(range 16–41) were identified. The median upper endoscopies number per patient
was 1.5 (range 2–14) with a median time of follow-up of 4.5 years (range 1–9
years). All subjects (100%) had an endoscopic evidence of reflux esophagitis: 3
(37.5%) had mild and 5 (62.5%) had moderate-severe reflux esophagitis. Three
subjects (37.5%) had complicated esophageal reflux disease (two subjects develop-
multiple squamous cell carcinomas). A retrospective cohort study had an endoscopic stente.
Two subjects (25%) developed esophageal squamous cell carcinoma during follow-
up, with interval time of 8 and 18 months from previous upper endoscopy. Both
had tumor expression of p16 protein suggesting human papilloma virus (HPV)
infection. The calculated standardized incidence ratio (SIR) for the development of
esophageal squamous cell carcinoma was 5.107.
Conclusion: FA patients are at an increased risk for developing esophageal cancer
and reflux esophageal disease with associated complications. Larger, prospective
studies are needed to determine the optimal interval for endoscopic screening in
these patients.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Multiple development of squamous cell carcinoma (SCC) in the
upper aerodigestive tract is known as the “field carcinization phenomenon,”
and alcohol is a definite carcinogen. Multiple dysplastic lesions in the esophagus
are a useful predictor of the risk for the field carcinization. However, what causes
the development of dysplastic squamous epithelium in the esophagus is still
unclear.
Aims & Methods: The aim of this prospective cohort study was to identify associa-
tions between patients’ lifestyle, including alcohol consumption, the genetic
trait of aldehyde dehydrogenase-2 (ALDH2), and the development of dysplastic
squamous epithelium in the esophagus. This is a post hoc analysis of the Japan
Esophageal Cohort (JEC) study (UMIN1676). Patients with superficial SCC
were carefully documented. To examine two single nucleotide polymorphisms included in the study. The drinking and smoking histories before and after ER for SCC of the oesophagus, based on a prospective study of 330 patients from 16 hospitals.

Aims & Methods: Between Sep 2005 and May 2010, 330 patients (M/F = 278/52) were registered. The proportions of the different grades of LVL were A = 50%, B = 52.7%, and C = 47.3%. After adjusting for sex and age, controls and the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), liking high-temperature food (4.6%, 19.6%, 20.8%, and 20.7%, respectively, p < 0.0001), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in moderate and heavy drinkers before ER (OR = 3.7; p < 0.0001) than non-temperate drinkers (OR = 2.3; p < 0.0001) and moderate and heavy drinkers after ER. Six of the seven patients had an inactive heterozygous ALDH2. We analyzed the 63 patients with inactive heterozygous ALDH2 and moderate and heavy drinkers before ER based on their temperance history and found 38 patients in the temperance group (light drinkers after ER) and 25 patients in the non-temperance group. The 3-year cumulative incidence of SCC was 3.4% in the temperance group and 16.2% in none. The 5-year cumulative incidence of SCC was 6.2% in 49.8%, respectively (p < 0.05). The 5-year cumulative incidence rate of a third SCC revealed an incidence of 0% vs 23.8%, respectively (p < 0.01). The 7-year cumulative incidence rate of a fourth SCC revealed an incidence of 0% vs 16.9%, respectively (p < 0.01).

Conclusion: The development of dysplastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0564 EVALUATION OF THE RISK OF METACHRONOUS SQUAMOUS CELL CARCINOMA OF THE OESOPHAGUS AND THE HEAD AND NECK AFTER ENDOSCOPIC RESECTION FOR SQUAMOUS CELL CARCINOMA OF THE ESOPHAGUS BASED ON THE GENETIC POLYMORPHISMS OF ADH1B AND ALDH2
Department Of Gastroenterology And Hepatology, Hokkaido University Graduate School of Medicine, sapporo/Japan

Contact E-mail Address: abik1082@gmail.com

Introduction: Metachronous multiple squamous cell carcinoma (SCC) of the oesophagus and the head and neck often occurs in patients who previously underwent endoscopic resection (ER) for SCC of the oesophagus. This has become a problem regarding the curability of ER. Katada et al reported that alcohol abstinence significantly decreased the risk of developing a secondary SCC of the oesophagus, based on a prospective study of 330 patients from 16 hospitals. However, there are few studies that have investigated the risk of developing a secondary SCC of the oesophagus and the head and neck based on the genetic polymorphisms of alcohol dehydrogenase-1B (ADH1B) and aldehyde dehydrogenase-2 (ALDH2) which are closely associated with developing oesophageal SCC. No studies have evaluated the risk of developing a third (or more) SCC after ER for SCC of the oesophagus.

Aims & Methods: The study group included patients who underwent ER for SCC of the oesophagus at Hokkaido University Hospital. All patients were followed up by endoscopic examination for ≥2 years. Overall, 126 patients were included in the study. The drinking and smoking histories before and after ER were carefully documented. To examine two single nucleotide polymorphisms (SNPs) on ADH1B and ALDH2 genotyping, we obtained approximately 1 ml of saliva with a pipette or cotton swab before the endoscopic review board at each hospital, and we obtained written informed consent from all patients. Using Lugol chromoendoscopy, we evaluated the dysplastic squamous epithelium in the esophagus. Lugol voiding lesion (LVL) was graded into 3 categories (A = no lesion; B = 1 to 9 lesions; C = ≥10 lesions per endoscopic view). Endoscopic images obtained from eligible patients at study entry were registered. The proportions of the different grades of LVL were A = 50% (15.2%), B = 52.7%, and C = 47.3% (32.1%). After adjusting for sex and age, the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), liking high-temperature food (4.6%, 19.6%, 20.8%, and 20.7%, respectively, p < 0.0001), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in moderate and heavy drinkers before ER (OR = 3.7; p < 0.0001) than non-temperate drinkers (OR = 2.3; p < 0.0001) and moderate and heavy drinkers after ER. Six of the seven patients had an inactive heterozygous ALDH2. We analyzed the 63 patients with inactive heterozygous ALDH2 and moderate and heavy drinkers before ER based on their temperance history and found 38 patients in the temperance group (light drinkers after ER) and 25 patients in the non-temperance group. The 3-year cumulative incidence of SCC was 3.4% in the temperance group and 16.2% in none. The 5-year cumulative incidence of SCC was 6.2% in 49.8%, respectively (p < 0.05). The 5-year cumulative incidence rate of a third SCC revealed an incidence of 0% vs 23.8%, respectively (p < 0.01). The 7-year cumulative incidence rate of a fourth SCC revealed an incidence of 0% vs 16.9%, respectively (p < 0.01).

Conclusion: Among the patients who underwent ER for oesophageal SCC, an inactive heterozygous ALDH2 with a continue drinking habit were the significant risk factors of developing metachronous multiple SCC. These are the greater risk factors for developing a third or more SCC. Patients with an inactive heterozygous ALDH2 and a drinking habit should receive strict instruction for temperance.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: All patients with endoscopic diagnosis of early gastric cancer (EGC) and biopsy confirmed to be high grade dysplasia or adenocarcinoma were recruited. They underwent staging investigations including image enhanced endoscopy, EUS and CT and those predicted to be T1a (intramucosal) neoplasia were randomly assigned to receive ESD or LAG. ESD were performed according to the EGJ (D2) lymph node dissection in the group with INFa, INFb, or lymphovascular invasion were 100% and 87%, respectively. The recurrence-free survival rate was significantly higher in the group with INFa and no lymphovascular invasion than in the group with INFb, INFb or lymphovascular invasion.

Conclusion: Our outcome data support the clinical validity of the curative precautions after ER for MM/S1 ESCC of the JES guidelines. However, MM/S1 ESCC with INFa and no lymphovascular invasion may have more possible curative precautions after ER without additional treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
or those in which the biopsies were still taken from the different anatomical areas were excluded.

**Results:** Only 148 patients were admitted to the study. The mean age was 49.7±2.8 years, and 60% were female (CI: 52–67, 95%). 264 vials were sent with biopsies of normal gastritis or mucosa and 32 (21.6%) had endoscopic diagnosis of PCLS. From 148 patients with endoscopic diagnosis of gastritis or normal mucosa, LCPM was identified in 46 patients (39.6%) (p < 0.001) and 1 of them were low-grade dysplasia. From 32 of patients with suspected endoscopic PCLS, the diagnosis was confirmed with histology in 26 patients (81.2%). A total of 72 patients had PCLS vs. 32 who were initially suspected (p < 0.01), with a total patients of CI: 40.7–56.6, 95%).

**Conclusion:** Pre-malignant conditions and lesions of the stomach (PCLS) can show as normal mucosa or gastritis during endoscopic procedure. 39.9% of patients who underwent endoscopic procedure with presumptive gastritis had PCLS. PCLS may be under-diagnosed if random biopsies are not taken. Therefore, taking biopsies from areas without suspected PCLS causes a change in the clinical management of patients, both for the initial diagnosis and for the staging according to OLGA and OLGUSM systems.

**Introduction:** Prognosis of GC has a noticeable relation with its clinical stage. Atrophic gastritis (AG), intestinal metaplasia (IM) and dysplasia are well-recognized risk factors for intestinal type GC (GC). A large cohort study confirmed that the annual incidence of GC were approximately 0.1% for patients with AG, controlled and their occurrence could be reduced with clipping prophylactic hemos.

**Aims & Methods:** We aimed to discuss the correlation between the combination of Helicobacter pylori antibody and pepsinogen and OLGA/OLGIM staging system in gastric precancerous lesions risk assessment. A total of 331 patients were enrolled after the examination of endoscopy at Endoscopy Center, the First Affiliated Hospital of Zhejiang Chinese Medical University from October 2014 to December 2015. According to the result of gastroscopy, gastric secretion and serum Helicobacter pylori antibody test, the patients were divided into four groups: Group A: Hp (+)P (−), Group B: Hp (+)P (+), Group C: Hp (−)P (+) and Group D: Hp (-)P (−). PG positive was defined as PG1<70µg/L and PGR<15%. According to the range and degree of atrophy/intestinal metaplasia, patients were assigned into five groups on the basis of OLGA/OLGIM staging system. The levels of Hp infection rate, PG I, PG II and PGR were compared between different groups, and the correlation between ABM method and OLGA/OLGIM staging system were evaluated. Statistical analysis was accomplished by chi-square test and logistic regression modeling analysis.

**Results:** A total of 331 patients were enrolled. 214 patients were classified into group A, 106 patients into group B, 8 patients into group C and 7 patients into group D, respectively. According to the pathological results, 177 cases were non-associated and 54 cases associated atrophic gastritis. The Hp infection rate was significantly higher in patients with AG than those in AG and PGR level correlated inversely with the rising OLGA stages (F = 5.127, P =0.0013). Logistic regression modeling showed significant correlations between Hp infection rate, OLGA stages and OLGIM staging system (P<0.001).

**Conclusion:** Serological ABC method and histological OLGA/OLGIM staging system are closely linked in gastric precancerous lesions risk assessment. Serum pepsinogen test could be applied for high risk population identifying and provide a recommendation for further endoscopy examination.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic treatment of sporadic duodenal adenoma is mainly performed in tertiary centers because it is technically challenging and associated in major complications (perforation 1–5% and delayed bleeding 10–15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non ampullary sporadic duodenal adenomas (SADA) in two tertiary centers in a large series and to try to determine the predictive factors of outcomes with a long follow-up.

**Aims & Methods:** This retrospective study was conducted in two tertiary centers between 12/2003 to 03/2016. All the patients who underwent at least one endoscopic treatment by EMR for SDA histologically proven were included. Patients with PAF and ampullary adenoma were excluded. All the following outcomes were systematically recorded in both centers: complete endoscopic resection, resection with negative lateral and vertical margins, recurrence, success of the en-bloc resection and adverse events (Perforation, intra-procedural bleeding, delayed bleeding, others). There were analysed with multivariate analysis.

**Results:** 134 procedures were performed. The mean patient age was 65 years (33–83), 50.7% were women. The mean SDA size was 20.7mm (5–50mm), mostly located in the second duodenum (47.8%), 64.9% of the adenomas had a villous component, 33.4% with high grade dysplasia and 7.5% with in situ intramusco. Discrepancy between biopsies and the final histology was demonstrated, 19.7% of the lesions being upgraded at the first biopsy and 7.5% being downgraded. An EMR was performed in 98.5% of the cases with a complete endoscopic resection rate of 96.2% which was associated in multivariate analysis with the lesion size and pronounced depression. The en-bloc resection’s rate was 44%. Vertical margins were negative in 91.8% of the cases. Negative lateral and vertical margins was associated in multivariate analysis with the lesion size and its en-bloc resection.

**Conclusion:** Endoscopic treatment of SDA appears to be effective and relatively safe in tertiary centers. The major complications were mostly associated with major complications (perforation 1–5% and delayed bleeding 10–15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non ampullary sporadic duodenal adenomas (SADA) in two tertiary centers in a large series and to try to determine the predictive factors of outcomes with a long follow-up.

Introduction: Additional surgery should be recommended in patients with non-curative endoscopic resection for early gastric cancer (EGC). However, this decision has often been hesitated according to patient condition such as advanced age or comorbidities. After the recognition of recurrence, the salvage surgery has been considered difficult. However, little has been reported on it.

Aim of the study: The aim of this study was to clarify the results of salvage surgery for recurrence after non-curative ESD for EGC using data from multicenter retrospective study (EAST study). Of 15,785 patients who underwent ESD for EGC at 19 participating institutions from January 2000 to August 2010, we aimed to meet the current curative criteria for ESD were retrospectively reviewed. Among 1,585 patients who underwent ESD for EGC and were included in the study, 1,064 patients underwent additional surgery, and 905 patients were observed without any additional treatment. We evaluated first site of recurrence, clinical course after salvage surgery, and long-term survival on non-survival group. Recurrence was classified regional LNM, and distant metastasis.

Results: Over a median follow-up period of 64 months, recurrence was detected in 27 patients. Among them, 2 patients were excluded from this study due to missing data. Therefore, 25 patients with recurrence were only local site (intra-gastric relapse 3, regional LNM 7), and distant metastasis 15 (60%). The first treatments for recurrence were endoscopic treatment 1, salvage surgery 7 (28%), chemotherapy 6, and best supportive care 1. Only one patient was alive without any recurrence for 31 months after salvage surgery. And one patient died of acute myocardial infarction just one month after salvage surgery. In the remaining 5 patients, recurrence was detected at 0, 2, 3, 5, 30 months after salvage surgery, and all of them died of gastric cancer. Median survival time of all 25 patients with recurrence was 16 months after salvage surgery. All survival of patients who underwent salvage surgery was only 7 months from salvage surgery.

Conclusion: More than half of recurrence after non-curative ESD without additional surgery was distant metastasis, and the survival rate after salvage surgery was quite low.

Introduction: Since population-based screening for gastric cancer in Korea was implemented in 2002, endoscopic treatment of early gastric cancer (EGC) has been popularized. Most patients with early neoplasm have no alarming symptoms/signs. In addition, the strategy for detecting factors predicting curative endoscopic resection of EGC is being popularized, because the general population is aging and considering the quality of life after treatment.

Aims & Methods: This study investigates factors affecting curative endoscopic resection of EGC in the era of population-based screening for gastric cancer. The subjects consisted of patients newly diagnosed with stomach cancer at Seoul ST. Mary’s Hospital between May 2011 and May 2016. All patients completed questionnaires about symptoms, social history, family history, knowledge of national cancer screening program, the reason for screening, and the interval between endoscopy screening examinations for gastric cancer.

Results: Of a total of 469 patients, 147 (31.3%) had a curative endoscopic resection, 260 (55.4%) had a curative surgical resection and 62 (13.3%) were in non-curative surgical resection or an inoperable state. The patients with curative endoscopic resection had minimal abdominal symptoms and few alarm symptoms/signs (a family history of gastric cancer, anemia, and clinically important weight loss), whereas alarm symptoms were more common in patients with advanced cancer. In multivariate analysis, regular surveillance endoscopy was only the factor predicting the curative endoscopic resection [Odd ratio (95% CI) 6.099 (2.532 ~ 14.933), p = 0.000]. In addition, the proportion of curative endoscopic resection was significantly higher in the 1-year [Odd ratio (95% CI) 10.381 (4.081 ~ 26.405), p = 0.0000], 2-year endoscopy interval groups [Odd ratio (95% CI) 3.161 (1.106 ~ 9.035), p = 0.032] than patients who had no endoscopy within 2 years.

Conclusion: Most patients with the curative endoscopic resection have minimal abdominal symptoms and no alarming symptoms/signs. Regular surveillance endoscopy was the only factor predicting the curative endoscopic resection of gastric cancer. In addition, more frequent endoscopic surveillance could help to early detect gastric cancers with curative endoscopic resection.

P0576 USEFULNESS OF OPERATIVE LINK ON GASTRITIS ASSESSMENT (OLGA) AND OPERATIVE LINK ON GASTRIC INTESTINAL METAPLASIA (OLGIM) FOR DIAGNOSIS OF HELICOBACTER PYLORI-ASSOCIATED GASTRIC CANCER REGARDLESS OF TISSUE TYPE IN KOREA

Introduction: Atrophic gastritis and intestinal metaplasia are the cancerization field in which gastric cancer (GC) develops in case of intestinal type. The OLGA and OLGIM staging systems have been suggested to provide risk estimation for GC.

Aims & Methods: The aim of this study is to evaluate the usefulness of OLGA and OLGIM staging according to Lauren’s histological classification of GC in considering with other risk factors of gastric cancer. From January 2006 to December 2015, 607 GC patients and 677 control subjects were enrolled who underwent esophagogastroduodenoscopy. Biopsies were taken from the greater and lesser curvatures of the antrum and mid-body, respectively. The OLGA and OLGIM stage (0-IV) was recorded by combining antral with body atrophy scores using the Updated Sydney System. Stage III and IV OLGA or OLGIM was classified as high-risk stage group and Stage 0-II as low-risk group. Helicobacter pylori infection was assessed by modified Giemsa stain, rapid urease test and culture and was defined by a positive result on any of these tests. Multivariate logistic analysis was performed for the age, sex, smoking, alcohol and family history of GC.

Results: GC patients had more high-risk OLGA stages (25.9%) than controls (6.8%, P < 0.001) and high-risk OLGIM stages (18.3%) than controls (4.9%, P < 0.001). In the multivariate logistic analysis, Old age [odds ratios (ORs), 1.932; P = 0.004 and 2.584, P < 0.001 for ages in the 40 ~ 59 and > 60, respectively], family history of GC (OR, 2.119; P < 0.001), and H. pylori infection (OR, 1.963; P < 0.001) were independent risk factors for GC in the diffuse type as well as intestinal type (Table). High-risk OLGA stages were significantly associated with increased risk of GC in comparison to low-risk (OR, 3.778; P < 0.001): intestinal-type (OR, 4.318; P < 0.001) and diffuse-type (OR, 2.920; P < 0.001) (Table). High-risk OLGIM stages were also significantly associated with increased risk of GC in comparison to low-risk (OR, 3.306; P < 0.001): intestinal-type (OR, 3.051; P < 0.001) and diffuse-type GC (OR, 3.981; P < 0.001).

Conclusion: High-risk OLGA and OLGIM stages were useful for intestinal type as well as diffuse type. This usefulness will be increased when combined with H. pylori status and family history of GC in regions with high prevalence of GC. Analysis regarding specific interaction among these three factors is undergoing.

Introduction: The association between body mass index (BMI) and digestive cancer mortality is not conclusive in East Asians.

Aims & Methods: We evaluated the relationship between BMI and digestive cancer mortality, using prospective cohort data by the National Health Insurance Service in Korea, which consisted of more than one million subjects. A total of 510, 148 Korean adults were followed-up until 2010. The adjusted hazard ratios (HRs) of cancer mortality were calculated using a Cox model.

Results: During follow-up, 7774 total deaths occurred from digestive cancer, HR for digestive cancer mortality across seven BMI categories. Below 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were 0.43 (95% confidence interval [CI] = 0.32-0.58) for esophageus cancer, 0.70 (0.62-0.79) for stomach cancer, and 0.70(0.65-0.90) for colorectal cancer. Over 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were 1.30 (95% CI = 1.04-1.64) for colorectal cancer, 1.28 (1.07-1.53) for liver cancer, and 1.28 (0.96-1.71) for gall-bladder cancer and biliary tract cancer. BMI were not associated mortality from small intestine cancer and pancreatic cancer.

Conclusion: Low BMI were predictors of mortality from esophageal cancer and stomach cancer. High BMI were predictors of mortality from liver cancer and gallbladder cancer and biliary tract cancer. Both low and high BMI were predictors of mortality from colorectal cancer. Further research is needed to evaluate whether interventions involving weight change (loss or gain) reduce the risk of cancer or improve the survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
BMI, body mass index; CI, confidence interval; GB, gallbladder; HR, hazard ratio. *Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency, five or more times/week, one to four times/week, less than one time/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], 1 United States dollar = 1170 KRW as of August 1, 2004; < 500, 000, 500, 000–990, 000, 1, 000, 000–1, 490, 000, ≥ 1, 500, 000, missing information), and physical activity (yes, no). HRs were not presented for causes with less than 10 deaths.

Aims & Methods: A novel robotic suture manipulator is composed of control panel and a working arm, which grasp and move objects at the end of scope. A total of 10 porcine stomachs were used for the test. Pigs were sacrificed randomly to 2 groups and ESD was performed on mucosa of stomach using conventional technique and new endoscopic technique with robotic manipulator. Endoscopic experts and novice endoscopists performed ESD in 2 parts (antrum & body) of stomach. During procedure, robotic manipulator lifts up dissected tissue of stomach to make better visibility. Procedure time, complete resection rate, and complications such as perforation were recorded.

Results: The average procedure time for the robotic manipulator and conventional ESD was 42 minutes and 45.9 minutes. In novice endoscopists, the average procedure time using robotic manipulator is faster than conventional ESD group (42 minutes vs 53.5 min, p < 0.005). Both robotic expert and novice endoscopists completed the ESD procedure for en bloc resection of target lesions using KUMC robotic manipulator. There was no difference in complete resection rates between two groups. No complication such as perforation occurred in both groups during the procedures. There was no difference depending on resected location in stomach.

Conclusion: The robotic manipulator, which can perform ESD more easily showed feasible result comparing with conventional ESD. ESD using robotic manipulator could be helpful, especially in novice endoscopists. This research proposes a novel approach for safe and feasible method during ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Newly developed endoscopic IRE ablative catheter works with single channel of endoscope. A pair of dipolar electrodes consist of pre-shaped f 0.63 mm nitinol wire and the distance between each electrode is 10 mm. The electrodes are loaded within braided tube for sient delivery system then deployed when IRE catheter put in stomach through the endoscope. We performed animal study. Results: We developed new endoscopic IRE device, and studied about its effectiveness and feasibility in animal model.

Conclusion: Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumors. An advantage of IRE is its mechanism to remove undesired cells by affecting the cell membrane without thermally destructing blood vessels, nerves and the surrounding tissues. Several clinical trials for applying IRE to human organs such as liver, pancreas and kidney are being conducted. Furthermore, there are several clinical trials for applying IRE ablation for gastrointestinal tumors also have been conducted recently. Here, we developed endoscopic IRE device, and studied about its effectiveness and feasibility in animal model.

Disclosure of Interest: All authors have declared no conflicts of interest.

The electrodes are loaded within braided tube for sient delivery system then deployed when IRE catheter put in stomach through the endoscope. We performed animal study and IRE ablation was done on pigs' stomach mucosa by using endoscopy with newly developed IRE catheter. We divided pig's stomach into 2 parts (antrum & body), and IRE ablation was applied on each part of the stomach. Pigs were sacrificed after 24 hours, and we collected their stomachs with surgical technique. Following fixation, tissues were stained with H&E.

Results: Ten male Yorkshire pigs and in vitro stomachs were used in this study. The tissue with H&E stain showed diffuse cell death 24 hr after IRE ablation.

Aim: To investigate the risk factors for lymph node metastasis in ulcerative type EGC. Methods: Our study consisted of 1450 EGC cases; 749 cases were patients with GB cancer and 701 cases were patients with no GB cancer. A Cox proportional hazards model was used to evaluate the risk factors for lymph node metastasis in ulcerative type EGC. Results: Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency, five or more times/week, one to four times/week, less than one time/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], 1 United States dollar = 1170 KRW as of August 1, 2004; < 500, 000, 500, 000–990, 000, 1, 000, 000–1, 490, 000, ≥ 1, 500, 000, missing information), and physical activity (yes, no). P0581 DIAGNOSIS OF MICROVASCULAR PATTERN IS MORE IMPORTANT THAN MICROSCOPIC SURFACE PATTERN TO DELINATE GASTRIC CANCERS DETECTED AFTER H. PYLORI ERADICATION BY MAGNIFYING ENDOSCOPY

T. Iwasaki, K. Uchita, K. Kojima, S. Iwamura
Kochi Red Cross Hospital, kochi/Japan

Contact E-mail Address: space-rendez-vous@sings.jp

Introduction: It is difficult to delineate gastric cancer that is detected after successful eradication of Helicobacter pylori. One reason is reportedly the difficulty in identifying the demarcation line between the cancerous lesion and non-cancerous gastric mucosa due to a mixture of non-neoplastic epithelial-lined structure inside the neoplasm. However, almost all previous studies have only used magnifying endoscopy (ME) at low magnification which could evaluate microendoscopy pattern (MSP) but could not evaluate microvascular pattern (MVP).

The highest power magnification was necessary to evaluate MVP accurately. ME findings of the demarcation line, irregular MSP and irregular MVP were not shown in any of the gastric cancers that were not accurately assessed in these studies.

Aims & Methods: The aim of this study was investigating diagnostic efficacy of ME with narrow band imaging (NBI) in delineating the gastric cancers after eradication HP, using ME at highest power magnification, and classifying ME features of the marginal area according to the vessel plus surface classification system (VSCS) to realize which was more important ME findings MSP or MVP to detect demarcation line. Endoscopic examination was performed using a magnifying endoscopy (GIF-H260Z, Olympus Medical Systems Co, Tokyo, Japan) and NBI system (EVIS LUCERA Spectrum system; Olympus Medical Systems Co, Tokyo, Japan). Endoscopic imaging procedures were performed at low-power magnification followed by highest power magnification. On the day of ESD, the resection line was marked 3–5 mm outside of the margin of the lesion. A lesion meeting all of the following criteria was defined as a lesion with successful delineation: (1) the demarcation line of the lesion is endoscopically identified with a high level of confidence; (2) According to histopathological findings, the lesion is identified as a demarcation line. The diagnostic accuracy of ME-NBI in delineating the lesions was evaluated. On the other hand the ME findings of the marginal area in each lesion were classified in terms of microsurface pattern (MSP) and microvascular pattern (MVP) according to the VSCS to identify the findings that were useful in delineating the lesions in patients with differentiated-type early gastric cancers. The classification according to the VSCS was made in the marginal area with the least irregular findings.

Results: Of 178 consecutive lesions of differentiated-type early gastric cancer treated by endoscopic submucosal dissection (EM-SD) between August 2013 and March 2017, the study included 59 lesions that were detected after successful H. pylori eradication. The result of ME-NBI findings are summarized in the table. Gastric cancer was successfully delineated in 98.3% (57/59) of the lesions with regular MVP or irregular MVP with a demarcation line. Among the ME findings of the demarcation line, irregular MSP and irregular MVP were present in 67.7% (40/59) and 93.2% (55/59), respectively, according to the VSCS, with a higher percentage of lesions with irregular MVP than those with irregular MSP. In addition, there was no finding which was irregular MVP and regular MSP, but 27.1% (16/59) was regular MSP and irregular MVP, which indicated that the ME findings of MVP was more important than MSP. One lesion showed regular MSP or regular MVP without a demarcation line in a portion of the marginal area, resulting in unsuccessful delineation.

Conclusion: The accuracy of ME with NBI in delineating gastric cancer detected after H. pylori eradication was 98.3%, which was higher than the values reported previously. In addition, the MVP as visualized by ME appeared to be a more reliable biomarker which we know that some play an important role in the cancer. However, the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrates, which are widely presented in daily food, are actively discussed as carcinogenic to humans. There is no clinical and epimediological evidences that the nitrosamines itself can induce the stomach cancer.

Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrates in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out with male adult rats (n = 200). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (over-population during 9 months); 2) the daily using of toluidine (2 g/kg) in food and water with nitrates (2 g/l); 3) the combined effects of stress + nitrosamines. The

Introduction: Endoscopic forceps biopsy (EFB) is the gold standard for gastric epithelial tumor diagnosis. However, definitive diagnosis is often difficult, and some cases are diagnosed as gastric indefinite neoplasia (GIN), which corresponds to category 2 in the revised Vienna classification. GIN lesions require short periods of follow-up. The most appropriate forceps size for gastric biopsy has yet to be determined. In the Japanese Classification of Gastric Cancer, diagnoses of GIN are attributed, at least partly, to the full size of biopsy specimens. Since specimens yielded by small biopsy forceps are small, the use of small biopsy forceps is expected to increase the rate of GIN diagnoses.

Aims & Methods: The relationship between forceps size and the frequency of GIN was investigated. The patients in this cohort were divided into two historical groups. The first group comprised patients evaluated during the period when standard biopsy forceps (SF) were used (April 2010–March 2011), and the second comprised patients evaluated during the period when small biopsy forceps (SmF) were used (April 2011–March 2013). Standard caliber endoscopy was used for all esophagogastroduodenoscopy(EGD). We count the number of GIN and gastric carcinoma lesions. Patient characteristics, lesion characteristics (e.g., size, macroscopic appearance, and color tone), endoscopist experience level, biopsy sample groups diagnoses as GIN, the clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Results: Among the 5420 patients who underwent EGD in the first period, 2, 584 (30.7%) underwent gastric biopsy with SF. Among the 15,986 patients who underwent EGD in the second period, 4204 (26.3%) underwent gastric biopsy with SmF. Gastric carcinoma was diagnosed in 7.93% (205/2584) and 7.54% (317/4204) of the SF and SmF groups, respectively (P = 0.556). GIN was diagnosed in 10.01% (258/2584) and 12.5% (529/4204) of the SF and SmF groups, respectively (P = 0.048). The two groups diagnosed as GIN did not differ significantly in terms of the patient characteristics, the lesion characteristics, endoscopist experience level and biopsy related hemorrhage. The mean minor-axis lengths of the biopsy samples were 1.50 ±0.50 mm and 1.38 ± 0.40 mm in the SF and SmF groups, respectively. The SmF group samples tended to be shorter (P = 0.088). In both groups, 40% of the final diagnoses were epithelial neoplasia; no significant differences were observed.

Conclusion: SmF use may increase the rate of GIN. Thus, SmF use should be avoided with a standard caliber endoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Stomach cancer is a leading cause of cancer-related deaths in the eastern Europe. It well knows that stress play an important role in the cancer. However, for the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrates, which are widely presented in daily food, are actively discussed as carcinogenic to humans. There is no clinical and epimediological evidences that the nitrosamines itself can induce the stomach cancer.

Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrates in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out with male adult rats (n = 200). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (over-population during 9 months); 2) the daily using of toluidine (2 g/kg) in food and water with nitrates (2 g/l); 3) the combined effects of stress + nitrosamines. The
upper endoscopy was performed using our in-house custom-made multichannel endoscopy system. Histological assay performed to analyze the changes in the gastric tissues.

Results: Using upper gastroscopy, we studies the stomach tissues during 9 months of lining of rats in chronic stress. There were no changes in the gastric mucosa during the first 2 months. In the third month 35% (7 of 20) animals demonstrated multiple small peptic ulcer (n = 11). These changes progressed during other time of observation. 9 months of experiment. So, this time all rats showed peptic ulcers both types with significant increase in the number of ulcers (n = 21) at the end of the experiment. Thus, this series of experiments clearly showed that chronic stress plays provoking role in the peptic ulcer formation in the stomach of rats. The deleterious effects of nitrosamines on the gastric mucosa observed 4 months after the beginning of daily using of toluidine and nitrides in 75% of the rats showed symptoms of atrophic gastritis. Other 25% (5 of 20) animals did not demonstrate any changes in gastric mucosa.

Thus, this series of experiments markedly showed that effect of long-term eating low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. Using similar protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (131 of 160) with tumor lesions was accompanied by the migration of metastatic tumor cells through the bloodstream in the liver. The number of metastatic nodes varied from 1 to 5.

Conclusion: Thus, in our research we clearly show that only combination of two parameters: stress and nitrosamine, cause development of gastric cancer with metastasis in the liver while the presence of these factors alone contribute mucosal injuries without oncolgical changes in the stomach.

Introduction: Gastric cancer (GC) contributes a heavy burden to the global health, especially in Asian countries. Early diagnosis is crucial to improve patients’ outcome, but reliable biomarkers are desperately needed. In our previous studies, we established several endogenous fluorescence spectra of gastric juice for GC diagnosis and screening [1, 2], isolated and identified three fluorescence signatures (aromatic amino acids, AA), which can be used to distinguish GC from non-neoplastic gastric diseases (NGD) regardless of the stage [3, 4]. However, the characteristic biosignature for the whole metabolic spectra of gastric juice free amino acids (GJFAs) in GC patients remain unclear. Although many investigators had reported on the changes of amino acids’ concentrations in the peripheral blood, urine and tissues of GC patients [5, 6].

Aims & Methods: In order to determine the metabolic patterns of GJFAs in GC and NGD patients, gastric juice samples were collected from GC patients (n = 47) and age-matched NGD patients (n = 83) from December 2015 to May 2016, and then measured by an automatic amino acid analyzer. Orthogonal partial least squares discriminant analysis (OPLS-DA) and Mann-Whitney U test are used for data analysis. The diagnostic value of GJFAs was evaluated by ROC curve. Furthermore, significantly altered metabolic pathways were identified by pathway analysis using public databases such as KEGG and MetaAnalysis 3.0.

Results: GJFAs profiles significantly differed between the GC and NGD patients. A total of 14 kinds of GJFAs, whose first principal component of variable importance in the projection (VIP) value exceeding 1 and P-value than 0.05, were screened as differential GJFAs. Compared with the NGD patients, GC patients had higher levels of threonine, serine, alanine, valine, methionine, isoleucine, leucine, tyrosine, phenylalanine, lysine and arginine,
together with lower levels of phosphoserine, ethanolamine phosphate and urea (Table 4). The 14 GFAAs revealed diagnostic values with AUC from 0.666 to 0.868, and the combined AUC of them reached to 0.902 (95% CI, 0.846–0.959) for the diagnosis of GC. Importantly, their AUCs were from 0.649 to 0.857, and the combined AUC reached to 0.880 (95% CI, 0.792–0.969) for the diagnosis of early GC, particularly, leucine, threonine and serine are the most altered three GFAAs between the two groups, whose fold change more than 2 and AUC value greater than 0.8. Moreover, the combined AUC of the 3 non-AAAs was 0.869 (95% CI, 0.805–0.934) for the diagnosis of GC. It was slightly higher than that in comparison with 3 AAPs 0.841 (95% CI, 0.773–0.908). Additionally, the pathway of aminoacyl-tRNA biosynthesis metabolism was excessively activated, which significantly responsible for the above alteration in amino acids metabolism.

P-value, Statistically significant difference using Mann-Whitney U test; VIP, variable importance; AUC, area under the ROC curve; 95% CI, 95% confidence interval.

Conclusion: GJFAA profiles may be helpful for improving GC diagnosing even in the early stage and for providing more information about its metabolism. Leucine, threonine and serine, three non-AAAs, warrant further validation as alternative metabolic biomarkers for GC.

PO0587 THE ASSOCIATION BETWEEN MMP-2/9 AND TYPE IV COLLAGEN LEVELS OF AMINO ACIDS IN GASTRIC JUICE OF GASTRIC CANCER PATIENTS

J. Liu, Y. L. Zhou, R. S. Lin, Z. Jin, J. Y. Han, Y. Xue, E. X. Yan, M. L. Meng
Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: liujian-825@163.com

Introduction: It is reported that aromatic amino acids (AAAs) in gastric juice could be used as potential diagnostic biomarkers to screen gastric cancer (GC) [1–3]. However, the underlying mechanism remain elusive [4]. Our group had previously reported that 29 GC patients with MMP-2/9 mRNA levels in gastric juice were measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Furthermore, the association between them was evaluated by Spearman correlation analysis.

Results: On the one hand, the expression intensity of MMP-2/9 in GC group were significantly higher than those in NGD group, while MMP-9 was markedly lower than that in NGD group (P < 0.001 for all). Moreover, there was a positive correlation between the expression level of MMP-2 and MMP-9 (rho = 0.439, P < 0.01), but they were both negatively correlated with Col IV (rho = −0.454, P < 0.01; rho = −0.392, P < 0.01). On the other hand, significantly higher level of AAAs in gastric juice were observed in GC patients than those in NGD individuals (P < 0.001 for all). Ultimately, the expression levels of MMP-2/9 in gastric mucosal tissues were both positively correlated with the concentrations of AAAs in gastric juice (MMP-2: rho = 0.282, 0.329, and 0.293, respectively, P < 0.01 for all; MMP-9: rho = 0.457, 0.455, and 0.417, respectively, P < 0.001 for all), but Col IV was negatively correlated with them (rho = −0.283, −0.280, and −0.273, respectively, P < 0.01 for all) (Table 1).

Table 1: Relationship between the expression levels of MMP-2/9 and Col IV in gastric tissues and the levels of AAAs in gastric juice

</table>

**represents significant correlation using Spearman correlation analysis when the confidence level was 0.01; ***represents significant correlation using Spearman correlation analysis when the confidence level was 0.001.

Conclusion: The overexpression of MMP-2/9 resulting in the degradation of Col IV in basement membrane and extracellular matrix may lead to the variation of AAAs’ levels in gastric juice of GC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO0588 MISSING RATE OF GaSTRIC CANCER DURING UPPER GaSTRONTESTINAL ENDOCOpY AND INFLUENCE ON THE NATURAL HISTORY OF THE DISEASE

1Gastroenterology, Hospital General Universitario de Ciudad Real, Ciudad Real/Spain
2Hospital General Universitario de Ciudad Real, Ciudad Real/Spain
3Endoscopy Unit, Hospital General Universitario de Ciudad Real, Ciudad Real/Spain

Contact E-mail Address: salmoral72@gmail.com

Introduction: Gastric cancer (GC) is the fourth most common type of cancer and the second leading cause of cancer related death. The gold standard for diagnosis is the esophagogastroduodenoscopy (EGD) with targeted biopsies. The aim of this observational and descriptive study in patients diagnosed of gastric cancer from January 2013 to December 2016 in the area of Ciudad Real (Spain). Missing rate of gastric cancer was defined as the percentage patients who had a negative EGD three years before the diagnosis of CG. A survival analysis was performed with Kaplan Meier curves, mainly focussing on the influence of missing rate for gastric cancer. We studied the features related to EGD that could lead this issue.

Results: 162 patients were included, 65% male with a mean age at diagnosis of 72 years. Intestinal type was the most common histology (76%). A rate of 6.8% missing of gastric cancer was detected with an average of 20 months in delay of diagnosis. However, the survival rate was similar between patients with and without a previous EGD (7.08 vs. 5.05 months p = 0.60). Among the patients who passed away, a longer delay period was observed comparing to patients who were still alive (6 months vs. 25 months; p = 0.006). In the aforementioned subgroup, biopsias were taken in 72% with gastric atrophy in all these cases. Helicobacter pylori infection was detected in 30% of them. 55.6% of the EGDs were conducted without sedation. At no point chromoendoscopy was performed, pictures were taken and withdrawal times were not reflected.

Conclusion: Despite the fact that EGD is by far the most effective method to diagnose gastric cancer, 1 out of 10 cancers or premalignant lesions are not found during EGD. Therefore, it is of utmost importance to put in place quality protocols in EGD that may help to increase the diagnosis of early gastric cancer, and by this way, improve the survival rate of these patients.

Introduction: Several studies have demonstrated serum PGII level as a marker of the functional gastric mucosa, and a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood. The aim of this study was to analyse the polymorphisms in the TATA BOX region, which provides a binding site for the transcription factor and then the expression of the corresponding gene, are under investigation. This study will be important to deeper understand the physiopathological PG2 role in GC.

Aims & Methods: Genetic function of 180 patients (67 GC, 71 first-degree relatives of GC patients (FDR-GC) and 42 autoimmune chronic AG (ACAG)) was assessed by gastropanel test. We investigated the PG2 TATA BOX polymorphism frequencies in relation to serum PG2 (sPG2) expression level, HP positivity and risk for GC. TATA BOX DNA fragments were amplified by PCR and analyzed by the capillary-electrophoresis (GeneMapper software). Association among clinical data and PG2 polymorphisms were estimated by Receiver operating characteristic (ROC) curve and linear regression analyses.

Results: After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL PG2 cut-off was 70.15% and 79, 65% sensitivity and specificity, respectively (AUC: 75, p < 0.0001). We obtained 26 different PG2 TATA box fragments (280 bp to 479 bp). These fragments were grouped into 4 sized categories (1 = 308–400 bp; 2 = 401–436 bp; 3 = 437–483 bp; 4 = 439–479 bp). A positive correlation among the increase of PG2 sized fragments and the sPG2 level was found in the GC group (linear regression y = 16, 4381 + 2, 6846 x, p = 0.02).

Conclusion: In the literature, we confirm sPG2 level as a marker discriminating between GC and individuals at risk for GC (i.e ACAG and FDR) in our series. In addition we reported a correlation between the shortest PG2 TATA BOX fragments and the lower PG2 level. Since highest PG2 level was related to the GC condition, our data suggest that carriers having longer TATA BOX region may produce higher sPG2 level than patients with shorter region. The clinical significance of the differences in PG2 level associated with the TATA BOX fragments, by interfering with the transcriptional factor and then with the expression of the corresponding gene, are under investigation. This study will be important to deeper understand the physiopathological PG2 role in GC.

P0950 HELICOBACTER PYLORI INFECTION ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE: A LARGE-SCALE COHORT STUDY

T. Kim, T.J. Kim, H. Lee, J.J. Kim
Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack836@samer.com

Introduction: Previous studies suggested a link between Helicobacter pylori (H. pylori) infection and nonalcoholic fatty liver disease (NAFLD), yet large-scale longitudinal studies are lacking to elucidate this association.

Aims & Methods: A cohort study of 17,028 adults without NAFLD at baseline, who participated in a repeated health screening examination including an H. pylori-specific immunoglobulin G antibody test, was conducted to evaluate the association between H. pylori and NAFLD development. Fatty liver was diagnosed by ultrasonography.

Results: During the 83,130 person-years follow-up, participants with H. pylori infection had a higher rate of incident NAFLD than those who were uninfected. In a multivariable model adjusted for age, sex, body mass index, smoking status, alcohol intake, regular exercise, year of screening exam, and education level, the hazard ratio (HR) for NAFLD development in participants with H. pylori-infection compared to those without infection was 1.21 (95% confidence interval [CI], 1.10–1.34). The association persisted after further adjustment for metabolic variables, inflammatory marker, and liver enzymes. The association between H. pylori and NAFLD was still evident in an analysis using fatty liver index as a surrogate marker of NAFLD. In addition, the association between H. pylori infection and incident NAFLD did not differ across clinically relevant subgroups evaluated.

Conclusion: H. pylori infection was significantly associated with the development of NAFLD, independent of metabolic and inflammatory risk factors. H. pylori infection may play a pathophysiological role in NAFLD development, indicating that H. pylori eradication might play a role in reducing risk of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

H. pylori infection reduces the risk of Barrett's adenocarcinoma and is independent from the geographical location, a meta-analysis

B. Eross1, N. Farkas2, K. Márta1, P. Hegyi1
1Centre For Translational Medicine, University of Pecs, Pecs/Hungary
2Institute Of Bioanalysis, University of Pecs, Pecs/Hungary
3Institute For Translational Medicine, University of Pecs, Pecs/Hungary

Contact E-mail Address: xerovalai@yahoo.fo

Introduction: The European and Northern American populations a decreasing prevalence of H. pylori infection has been observed, along with an increasing prevalence of Barrett’s oesophagus and an increasing incidence and prevalence of the adenocarcinoma of the oesophagus and gastro-oesophageal junctional cancers. HP has been proven a constructive factor against Barrett’s oesophagus, but some individual studies suggested the opposite.

Aims & Methods: Our aim was to scrutinize all data available on the relationship between H. pylori infection and Barrett’s oesophagus prevalence, to see, if H. pylori has a protective role for Barrett’s oesophagus and if it is dependent from the geographical location. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). We conducted a systematic search in PUBMED, EMBASE and COCHRANE databases from inception to December 2016, for the keywords of Barrett’s, Barrett’s metaplasia, Barrett’s oesophagus, Barrett’s oesophagus, Barrett oesophagus, Helicobacter pylori, H pylori and Helicobacter. We also used information from the references of relevant publications to find further eligible studies. We have conducted a meta-analysis of the data from all studies included. We used the random effects DerSimonian and Laird.

Results: We have found 568 articles in PUBMED, 741 in EMBASE and 15 in COCHRANE databases. After exclusion of the articles without sufficient data on the prevalence of H pylori and Barrett’s oesophagus, we have identified 83 articles suitable for statistical analysis. This meta-analysis involved 98 665 patients with Barrett’s oesophagus and 720 800 patients without Barrett’s oesophagus. The statistical analysis from all 83 studies from five continents and 27 countries showed a protective effect of H pylori for Barrett’s oesophagus, not in Africa, overall Odds Ratio = 0.63 (95% CI:0.55, 0.71). The OR and 95% CI values were 0.34 (0.17, 0.67) for Asia, 0.71 (0.55, 0.91) for Europe, 3.05 (0.59, 15.73) for Africa, 0.60 (0.51, 0.71) for North America, 0.95 (0.56, 1.64) for South America and 0.56 (0.39, 0.83) for Australia. The OR and 95% CI values were 0.84 (0.43, 1.64) for Eastern Europe; 0.68 (0.52, 0.90) for Western Europe and 0.71 (0.55, 0.91) for all of Europe, suggesting that the protective role of H pylori infection is not different across Europe.

Conclusion: This large meta-analysis has given further evidence, that Helicobacter pylori infection has a protective role for Barrett’s oesophagus and this protective role is independent from the geographical location, apart from Africa. In view of the decreasing prevalence of H pylori in developed countries and the epidemiological rise of Barrett’s oesophagus and adenocarcinoma, it would be important to conduct further large, prospective, multinational studies on the effect of H. pylori infection on Barrett’s oesophagus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter Pylori (H. Pylori) has been implicated in worsening outcomes in patients with hepatic encephalopathy. This is believed to be the result of its urease enzyme that increases the production of ammonia. Small studies so far have yielded contradictory results on whether the presence of H. pylori worsens treatment outcomes in hepatic encephalopathy. Therefore, the aim of this study was to assess the impact of H. pylori on mortality, morbidity and resource utilization among patients with hepatic encephalopathy using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publicly available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of hepatic encephalopathy were included. There were no exclusion criteria. Patients positive for H. pylori were identified using the appropriate ICD-9CM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization as measure by use of abdominal imaging (CT scan and ultrasound of the abdo-

Multivariate regression analyses were used to adjust for the following confounders: Age; sex; race; income in patients’ zip code; Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 55,360 patients with hepatic encephalopathy were included in the study, of which 20 had H. pylori infection. The mean patient age was 60 years and 42% were female. After adjusting for confounders using multivariate analysis, patients with and without H. pylori had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.71, 95% CI: 0.62-4.74, p = 0.30). As far as resource utilization, patients with and without H. pylori had similar adjusted odds of hospitalization (aOR: 0.92, 95% CI: 0.88–1.00, p = 0.08), LOS (adjusted mean difference: 1.7 days, 95% CI: –0.02-3.42, p = 0.52), and total hospitalization charges (adjusted mean difference: $16888, 95% CI: $4499 - $37675, p=0.12). However, patients with H. pylori had higher adjusted total hospitalization charges ($6128, 95% CI: $1141 - $11115, p=0.01)

Conclusion: Presence of Helicobacter Pylori has no impact on inpatient mortality among patients with liver cirrhosis and hepatic encephalopathy. In addition, the presence of Helicobacter Pylori is not associated with any increase in resource utilization among this patient population, with the exception of total hospitalization costs. It is surprising to note that, although total hospitalization costs differed between the two groups, they received the same total hospitalization charges from admitting hospitals.

Introduction: Due to increasing prevalences of clarithromycin resistance in H. pylori infection, current guidelines recommend quadruple therapies as first-line therapy1-3. Bismuth quadruple therapy (BQT) has been proven superior to standard triple therapy in clinical trials, however little is known about the efficacy of BQT in clinical routine practice.

Aims & Methods: In a prospective single center cohort study we analyzed consecutive patients in whom three-in-one capsule BQT (Pylér® + omeprazole) has been prescribed between 1/2013 and 12/2016. All patients were instructed in a standardized fashion and a prospective follow-up was planned. In a subgroup of patients, genotypic susceptibility testing for clarithromycin and levofloxacin by PCR was carried out on gastric biopsies before treatment. Treatment outcome was assessed by 13C urea breath test or by histology not earlier than 4 weeks after end of treatment.

Results: Three-in-one capsule BQT has been prescribed in 322 patients (mean age 41 years (18-80), 65% female, 26% active smoker). 71% of patients had a migrational background including Southern/Eastern Europe, Eurasia/Central Asia, Southeast-Asia, Africa, and Central/South America. PCR results were available in 163 patients (50.6%) and identified resistance to clarithromycin and levofloxacin in 29 (17, 8%) and 20 (12, 3%) of cases, respectively. BQT was administered as firstline, secondline and rescue treatment in 74%, 17% and 9% of cases, respectively. 5 patients discontinued treatment prematurely due to side effects (1, 8%) and 43 patients were lost to follow-up (13, 4%). By modified intention-to-treat and per-protocol analysis the H. pylori eradication rates were 94, 9% (95% CI: 92.1-97.5%) and 96.7% (95% CI: 94.4-98.8%), respectively. The low number of treatment failures (n=9) did not allow to identify risk factors for failure.

Conclusion: Three-in-one capsule bismuth quadruple therapy is highly effective and safe for treatment of H. pylori infection in clinical routine practice, irrespective of the patient’s migrational background or the number of previous treatment failures.

Introduction: Background: Eradication of Helicobacter pylori (H. pylori) infection represents a clinical challenge. The current requirements demand eradication rates above the 90%, which has made that the use of triple treatment including clarithromycin or metronidazole alone has been given up on those countries, such as Spain, with high resistance rates. Quadruple therapy with a proton pump inhibitor (PPI) plus a single three-in-one capsule containing bismuth subcitrate potassium 140 mg, metronidazole 125 mg, and tetracycline 200 mg has shown high eradication rates in clinical trials.

Aims & Methods: We aimed to evaluate the efficacy and safety of a PPI-bismuth based quadruple therapy in patients diagnosed of H pylori infection in a clinical setting of a Private Hospital, located at the North of Madrid (Spain). A prospective and real-life study was conducted, between March 2016 to February 2017, on consecutive patients with confirmed H pylori infection eradication indication. Patients were treated for ten days with a daily regimen containing bismuth subcitrate potassium 140 mg, metronidazole 125 mg, and tetracycline 125 mg, three capsules four times daily, and esomeprazole 40 mg twice daily and proton pump inhibitors (PPIs) for a first-line Helicobacter Pylori eradication.

Results: A total of 100 patients, 60 (60.0%) women and 40 (40.0%) men, who fulfilled the respective demands of the inclusion and exclusion criteria, were enrolled consecutively. Five of these were lost to follow-up. Mean (standard deviation) [95% confidence interval] age was 47.1 (15.4) [44.0 to 50.2] years. Twenty-five (25.0%) patients had a prior history of using medications to treat H. pylori. The urea breath test performed, at least 28 days, after the end of treatment. Intent-to-treat (ITT) efficacy analyses included all patients who received study medication and took at least one dose of study medication; patients without an observed outcome were considered as treatment failures. Patients included in the ITT population, which excluded patients who did not complete the study or who had major protocol violations, were also conducted to confirm the ITT results.

Conclusion: In patients with confirmed H pylori infection, 10 days of treatment with vonoprazan, bismuth, metronidazole and tetracycline plus esomeprazole provides high eradication rates not only as first-line but also as rescue therapy, with an acceptable safety profile.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: This study was evaluated the effectiveness and safety of Vonoprazan, a potassium-competitive acid blocker (P-CAB) compared with proton pump inhibitors (PPIs) for a first-line Helicobacter Pylori eradication.

Aims & Methods: We retrospectively analyzed data from first-line H. pylori eradication treatment (vonoprazan or PPIs with 400 mg clarithromycin and 400 mg pantoprazole) in Japan during a single hospital setting, which included patients who did not complete the study or who had major protocol violations, were also conducted to confirm the ITT results.

Results: ITT and PP analysis of the first-line H. pylori eradication for vonoprazan, lansoprazole, rabeprazole, and esomeprazole were 75.5%/86.8%, 63.9%/76.2%, 59.1%/76.0%, 68.0%/79.5%, and 63.2%/70.8%, respectively. The vonoprazan eradication rates were significantly higher than those of these PPIs (P < 0.05), respectively. There was no significant difference in the adverse events between the two therapies.

Conclusion: Aims & Methods: The aim of the current study was to evaluate the efficacy and safety of VPZ (400 mg/day), and amoxicillin (ABPC: 1500 mg/day) triple therapy in post-marketing use in Japan. A randomized, open-label, single-center study was conducted to verify the superiority of VPZ to esomeprazole (EPZ) as part of first-line triple therapy in patients with HP infection. Three hundred and forty-nine Japanese patients with HP infection diagnosed using a rapid urease test were enrolled between June 2015 and October 2016. The patients were randomly allocated to VPZ group (VPZ 40 mg/day, ABPC 1500 mg/day, and CAM 400 mg/day) or EPZ group (EPZ 40 mg/day, ABPC 1500 mg/day, and esomeprazole 400 mg/day) with stratification according to acid-related gastrointestinal sequelae. A phase III study revealed that VPZ is superior to esomeprazole as part of first-line therapy for Helicobacter pylori (HP) infection when combined with 400 or 800 mg/day clarithromycin (CAM).

Aims & Methods: The aim of the current study was to evaluate the efficacy and safety of VPZ, CAM (400 mg/day), and amoxicillin (ABPC: 1500 mg/day) triple therapy for vonoprazan-resistant H. pylori infection. Patients were randomly allocated to VPZ group (VPZ 40 mg/day, ABPC 1500 mg/day, and CAM 400 mg/day) or EPZ group (EPZ 40 mg/day, ABPC 1500 mg/day, and esomeprazole 400 mg/day) with stratification according to acid-related gastrointestinal sequelae. A phase III study revealed that VPZ is superior to esomeprazole as part of first-line therapy for Helicobacter pylori (HP) infection when combined with 400 or 800 mg/day clarithromycin (CAM).

Results: In patients with confirmed H pylori infection eradication rate in patients with CAM-sensitive HP (87.2% [82/94] versus 84.6% [81/96]) was significantly lower than that in the patients with CAM-resistant HP (91.5% [108/119] versus 84.6% [81/96]) using a random urease test were enrolled between June 2015 and October 2016. The patients were randomly allocated to VPZ group (VPZ 40 mg/day, ABPC 1500 mg/day, and CAM 400 mg/day) or EPZ group (EPZ 40 mg/day, ABPC 1500 mg/day, and esomeprazole 400 mg/day) with stratification according to acid-related gastrointestinal sequelae. A phase III study revealed that VPZ is superior to esomeprazole as part of first-line therapy for Helicobacter pylori (HP) infection when combined with 400 or 800 mg/day clarithromycin (CAM).

Disclosure of Interest: All authors have declared no conflicts of interest.
the patients with low eGFR, 65.3% [34/53] in the patients with high eGFR [P = 0.0342], which was significantly higher in the VPZ group than that in the EPZ group (79.3% [23/29] versus 50% [11/13], respectively, [P = 0.025]). The first-line eradication rate in continuous smokers was significantly lower than that in non-smokers (81.0% [187/231] in non-smokers vs. 64.3% [27/42] in continuous smokers [P = 0.016]). However, there were no significant differences between the VPZ and EPZ groups in non-smokers (84.2% [96/114] versus 77.8% [91/117], respectively, [P = 0.21]) and in continuous smokers (84.2% [12/16] versus 57.7% [15/26], respectively, [P = 0.33]). Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric duodenal ulcers/scars. There were no significant differences with regard to adverse effects between the two groups.

Conclusion: In contrast to the previous reports, the first-line eradication rate of VPZ-based triple therapy with 400 mg/day CAM and 1500 mg/day ABPC was similar to that of EPZ-based triple therapy in all groups except in patients with CAM-resistant HP and high eGFR. It is necessary to determine the most appropriate conditions that will maximize the therapeutic effect of VPZ-based triple therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The impact of amoxicillin resistance on the efficacy of regimens containing amoxicillin for Helicobacter pylori (H. pylori) eradication remains inconclusive. Therefore, we aimed to investigate whether the efficacy of amoxicillin containing regimens is affected by amoxicillin resistance and to identify the optimal breakpoint of amoxicillin resistance.

Aims & Methods: This was a post-hoc analysis of five randomized trials conducted in Taiwan from 2007 to 2016. Patients who received amoxicillin-containing regimens were recruited. The minimum inhibitory concentrations (MICs) were determined by agar dilution test. Meta-analysis was performed to assess the frequencies of all polymorphisms between AG patients and controls were 33/80/50%. There was no difference between the 3 groups in these parameters. However, a significant difference in the rate of submucosal invasion is presented that the pigmentation in GAFG may relate with PPI (p=0.025). The first-line eradication rate in continuous smokers was significantly lower than that in non-smokers (81.0% [187/231] in non-smokers vs. 64.3% [27/42] in continuous smokers [P = 0.016]). However, there were no significant differences between the VPZ and EPZ groups in non-smokers (84.2% [96/114] versus 77.8% [91/117], respectively, [P = 0.21]) and in continuous smokers (84.2% [12/16] versus 57.7% [15/26], respectively, [P = 0.33]). Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric duodenal ulcers/scars. There were no significant differences with regard to adverse effects between the two groups.

P0604 ASSOCIATION BETWEEN GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE AND H. PYLORI INFECTION

M. Matsuura, H. Kinugasa, K. Miyahara, M. Nakagawa

Internal Medicine, Hiroshima City Hiroshima Citizens Hospital, Hiroshima/Japan

Contact E-mail Address: maaaaay0917@ymail.com

Introduction: Gastric adenocarcinoma with low-grade atypia occurring in the mucosa of the fundic gland without atrophy, and is recognized that it is not related to H. pylori (Hp) infection. However, HpAGFAG is also found in Hp-infected and past Hp-infected patients. It may not deny the relationship between the progress of GAFG and Hp infection.

Aims & Methods: Ten lesions of GAFG resected endoscopically or surgically in our hospital from December 2010 to October 2016 were classified as Hp-uninfected, Hp-infected and past Hp-infected (n=3) past Hp-infected (n=2), and each endoscopic and clinicopathological features were examined.

Results: Median age of Hp-infected/past Hp-infected/Hp-uninfected were 65/71/54.5 years old, respectively, male ratio were 100/80/0, occupied site U area were 33/80/50%. There was no difference between the 3 groups in these parameters. However, a significant difference in the rate of submucosal invasion is recognized between the Hp-uninfected and past Hp-infected group and the Hp-uninfected group (submucosal invasion was found at 80/100/0%, p=0.035). According to endoscopic features, background mucosa of gastric fundus gland mucosa without atrophic change was found in 100/100/100%, whitish color in 67/60/50%, submucosal tumor shape in 67/60/0%, dilated vessels with branching architecture in 100/100/50%. The association with Hp infection was not clear. In immunohistochemical staining, MUC6 positive and MUC5AC positive, MUC2 negative, CD 10 negative in all cases, whereas the rate of MUC5AC positive was significantly higher in the Hp-infected group as 0.2/100/0% (P=0.045). We reported that black pigmentation is recognized in GAFG (stomach and intestine 50:1521-1531, 2015), but no association between Hp infection and black pigmentation was observed. On the other hand, the rate of PPI administration divided pigmentation (n=6) no pigmentation (n=4) are 50/0%, and it is suggested that the pigmentation in GAFG may relate with PPI (p=0.091).
The prevalence of hepatic disorders in celiac patients is estimated at...

Results: 28). A cryptogenetic hypertransaminase is found in 12.3% of cases (1.062–109.634), p = 0.0001, df (Q) = 2) of the cases and ascitic decompensation in slightly more than half of cases 55.6% (n = 5).

Conclusion: Hp infection is suggested to be related to the invasion depth of CD. The infection may also be an important profile in GAFG cases. Pigmentation in GAFG is found frequently, but it may be related to taking PPI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0605 MUCIN EXPRESSION IN THE SMALL BOWEL OF CELIAC DISEASE – A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Nis1, R. Shamir2
1Dept. Of Gastroenterology, Rabin Medical Center, Tel Aviv University Gastroenterology, Petach Tikva/Israel
2Gastroenterology, Schneider Children Hospital, Petach Tikva/Israel

Contact E-mail Address: yni@clalit.org.il

Introduction: Mucins, heavily glycosylated glycoproteins, synthesized by mucosal surfaces and have an important role in healthy and malignant states. Changes in mucin synthesis, expression and secretion may be a primary event or may be secondary to inflammation and carcinogenesis.

Aims & Methods: Since untreated celiac disease (CD) is associated with intestinal mucosa abnormalities, we aimed to assess the current knowledge about mucin expression in the small bowel of CD patients, and to look for a possible association between mucin profile and gluten-free diet. English Medical literature searches were conducted for “mucin” and “celiac”. Observational studies were included. Meta-analysis was performed by using Comprehensive meta-analysis software. Pooled odds ratios and 95% confidence intervals were calculated.

Results: Out of 18 titles initially generated by the literature searches, 3 observational studies that fulfilled the inclusion criteria remained eligible for meta-analysis. They included 58 patients and 68 controls from 3 countries (Finland, Japan, USA). Mucin expression was significantly increased in small bowel mucosa of CD patients than in normal small bowel mucosa [OR 10.789, 95%CI (1.062–109.634), p = 0.044] (random-effect model). Heterogeneity was significant: Q = 4.470, df (Q) = 3, P = 0.024, I² = 62.832%, ORs for MUC2 and MUC5AC expression in the small bowel mucosa of untreated CD patients were 1.143, 95%CI 0.060–21.870, P = 0.929 and 21.429, 95%CI 3.883–118.255, P < 0.0001, respectively.

Conclusion: We found that expression of certain mucin genes in the small bowel mucosa of CD patients may serve as a diagnostic tool, and assist in surveillance programs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0606 HEPATIC ABNORMALITIES ASSOCIATED WITH CELIAC DISEASE

D. Tagrou1, A. Tebaibia2, N. Oumnia3, N. Benfenatki3
1Medicine, Hospital University Center, Tizi Ouzou/Algeria
2Medicine, University Hospital Center, Algiers/Algeria
3Medicine, University Hospital Center, Algiers/Algeria

Introduction: Celiac disease (CD) is a gluten-sensitive enteropathy that resolves with a gluten free diet (GFD). It’s now considered as a multisystem disorder. A number of studies have shown the occurrence of liver diseases at a higher frequency in patients with CD compared with that in the general population. Cytokine- and growth factor-mediated events in the small intestinal mucosa of untreated CD patients are involved in the pathogenesis of liver disease.

Aims & Methods: The aim of this work is to determine the prevalence and clinical characteristics of the chronic liver disease observed during CD. Prospective multicenter work involving 154 adult celiac patients (42H, 112F), with an average age of 36.1 years ±13.6, recruited between 01-01-2013 and 30-06-2014 with a minimum follow-up of 12 months. The diagnosis of CD was made in all cases by clinical, serological and histological arguments. Thrombotic complications were noted as well as their modalities of occurrence.

Results: Vascular thrombosis was involved in 13 patients (8.4%), and occurred almost exclusively in women (84.6%) (11 F - 2 H). There are 6 cases of portal cavernoma, one associated with lower limb thrombosis, 4 cases of stroke and 3 cases of thrombosis of the lower limbs. The diagnosis of thrombosis revealed the diagnosis of MC in 8 patients (61.5%) with an average delay of 11.6 months and extreme delays of 1 to 43 months. These include 4 cases of a portal cavernoma, one associated with deep limb thrombosis, 3 cases of stroke, and one case of deep thrombosis of the lower limbs. The diagnosis of CD was made on average 72 months after that of thrombosis in 4 patients (30.8%). In one case, thrombosis was complicated 39 years after diagnosis of CD diagnosed in childhood at the age of 5 years without gluten-free diet. The thrombophilia assessment was carried out in all patients and. The thrombophilia assessment was was negative in 11 cases (84.6%). A S protein deficiency associated with the CD in one case and an antithrombin III deficiency in another case were detected. The use of oral contraceptives and in all cases a micro-dosed oestro-progestin was found in 7 women (63.6%). 7 cases women involved intrahepatic thrombosis.

Conclusion: The diagnosis of CD must be evoked when there is a thrombosis disease without obvious cause, factors of thrombophilia may be present during the CD. Early CD diagnosis with respect to the gluten-free diet may prevent the development of this complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0607 CELIAC DISEASE ASSOCIATED WITH VASCULAR THROMBOSIS

D. Tagrou1, A. Tebaibia2, N. Oumnia3, N. Benfenatki3

Introduction: Celiac disease (CD) is a life-long autoimmune disease affecting multiple organs of genetically susceptible individuals. One of the extra intestinal manifestations of the disease is thromboembolic events like strokes and veins’ thrombosis.

Aims & Methods: The aim of this work is to determine the prevalence and clinical characteristics of the thrombosis observed during CD. Prospective multicenter work involving 154 adult celiac patients (42H, 112F), with an average age of 36.1 years ±13.6, recruited between 01-01-2013 and 30-06-2014 with a minimum follow-up of 12 months. The diagnosis of CD was made in all cases by clinical, serological and histological arguments. Thrombotic complications were noted as well as their modalities of occurrence.

Results: Vascular thrombosis was involved in 13 patients (8.4%), and occurred almost exclusively in women (84.6%) (11 F - 2 H). There are 6 cases of portal cavernoma, one associated with lower limb thrombosis, 4 cases of stroke and 3 cases of thrombosis of the lower limbs. The diagnosis of thrombosis revealed the diagnosis of MC in 8 patients (61.5%) with an average delay of 11.6 months and extreme delays of 1 to 43 months. These include 4 cases of a portal cavernoma, one associated with deep limb thrombosis, 3 cases of stroke, and one case of deep thrombosis of the lower limbs. The diagnosis of CD was made on average 72 months after that of thrombosis in 4 patients (30.8%). In one case, thrombosis was complicated 39 years after diagnosis of CD diagnosed in childhood at the age of 5 years without gluten-free diet. The thrombophilia assessment was carried out in all patients and. The thrombophilia assessment was was negative in 11 cases (84.6%). A S protein deficiency associated with the CD in one case and an antithrombin III deficiency in another case were detected. The use of oral contraceptives and in all cases a micro-dosed oestro-progestin was found in 7 women (63.6%). 7 cases women involved intrahepatic thrombosis.

Conclusion: The diagnosis of CD must be evoked when there is a thrombosis disease without obvious cause, factors of thrombophilia may be present during the CD. Early CD diagnosis with respect to the gluten-free diet may prevent the development of this complication.

2Celiac Disease, Gastroenterology and Liver Disease Research Institute, Tehran/Iran
3Immunology Department, School of Medicine, Shahid Beheshti University of Medical Sciences, Tehran/Iran
4Milton University Hospital, birmingham/United Kingdom

Contact E-mail Address: m.rostami@gmail.com

Introduction: Celiac disease (CD) is an organ-specific autoimmune disease, and both adaptive and innate immunity are involved in its development. Recent studies suggest the dysregulation Toll-like receptors (TLRs) in innate immunity can confer risk to autoimmune diseases such as CD.
Introduction: The mucus layer, covering the gastrointestinal mucosa, is considered the first line of defence against mechanical, chemical, or microbiological aggressions arising from the luminal contents1. Among all different cell types of the intestinal epithelium, the goblet cell functions are specialised in the secretion of mucus constituent2. As an example of failing barrier function, patients with coeliac disease (CD) have been reported to have altered intestinal barrier3. Human colonic mucus-secreting cells HT-29-16E are valuable tools to explore the effect of a specific treatment on permeability and mucus production by the human intestinal epithelium.

Aims & Methods: We investigated the new and innovative gluten detoxified bread (GFB; patent PCT/IB2013/000797) effects on mucus production by means of Alcian blue staining in comparison to the control bread (CB). In addition, MUC2 and MUC3 were quantified by ELISA and the permeability of the intestinal epithelium monolayer was evaluated by transepithelial resistance (TEER) measurement. The statistical analysis was conducted by one-way ANOVA followed by a Bonferroni post-hoc t-test.

Results: Mucin production by Alcian blue staining was expressed as % background subtracted from Image J measurement. GFB increased MUC2 expression by 24.2% after 24 hours by Alcian blue staining (10.28 ± 1.82; P = 0.01), whereas CB did not (9.94 ± 0.67; P = 0.05). Higher MUC2 concentrations expressed as ng/ml were found on cells treated with GFB (10.82 ± 1.35; P = 0.01) compared to controls (9.24 ± 0.18; P = 0.03). Alcian blue TEER values, expressed as a percentage of initial TEER, were observed after 24 hours of incubation with GFB in comparison to the control (163.2 ± 33.8, P = 0.01) which was not observed or CB (139.4 ± 28.8, P = 0.05).

Conclusion: It could be concluded that GFB has a potential of inducing MUC2 secretion by intestinal epithelial cells and improving intestinal epithelium permeability in vitro. Such observed potential may effectively contribute to consequent benefits such as higher gut barrier defence, decreased susceptibility to infections and better absorption regulation, thus ameliorating such alterations in colonic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0609 IMMUNOHISTOCHEMICAL LYMPHOCYTE PATTERN OF NON CELIAC GLUTEN SENSITIVITY MAY SUPPORT THE INVOLVEMENT OF INNATE IMMUNE

G. Losordo, F. Pezzuto, C. Covelli, F. Fortezza, A. Marra, A. Iannone, A. Amoruso, M. Barone, M. Principi, E. Ierardi, A. Di Leo
Emergency And Organ Transplantation, University of Bari, Bari/Italy

Contact E-mail Address: giuseppelos@yahoo.it

Introduction: Non-celiac gluten sensitivity (NCGS) is a gluten-related enteropathy with distinct features compared to celiac disease. Patients with NCGS experience symptoms, such as diarrhea or abdominal pain, shortly after gluten exposure. Differently from celiac disease, serology is negative, and histological picture is characterized by no lesion or a mild enteropathy (Marsh 1 stage). Few studies have investigated possible histopathological characteristics of NCGS. An immune response against gluten elicited exclusively by innate immunity has been hypothesized. On these bases, we attempted to depict an immunohistochromatograph pattern of NCGS by exploring markers of lymphocyte and innate immunity activation.

Aims & Methods: Duodenal biopsy samples of patients diagnosed of NCGS according to Salerno criteria were retrieved. Duodenal biopsy samples of positive controls ( overt seropositive celiac disease at Marsh 1 stage) and negative controls (functional dyspepsia and normal microscopic picture) were selected. Immunohistochemistry for CD3 (intraphelial lymphocytes), CD4 (T-helper lymphocytes), CD7 (T-cytotoxic lymphocytes) and CD1a (Langerhans cells) was performed. Cell count was carried out both in the epithelial layer (expressed as positive cells/100 enterocytes) and in the lamina propria (positive cells/mm2).

Comparison of means was performed by ANOVA test with Bonferroni’s post-hoc analysis.

Results: Twenty NCGS, 12 celiac patients (positive controls) and 16 negative controls were selected. CD3+ intraphelial lymphocytes in NCGS were expressed at intermediate levels (18.5 ± 6.4) between negative controls (11.9 ± 2.8) and celiac disease (40.8 ± 8.1, p < 0.0001). CD4+ T-helper lymphocytes were present only in lamina propria and NCGS had a lower level (3.1 ± 0.6) than controls (7.2 ± 2.9) and celiac disease (10.3 ± 15.7, p < 0.0001). Intraphelial CD7+ cells were similar between NCGS and negative controls (14.0 ± 7.4 versus 17.8 ± 4.2), but lower than celiac disease (34.0 ± 7.1, p < 0.0001). CD1a+ Langerhans cells were over-expressed in the lamina propria of NCGS (1.9 ± 1.1) in comparison to celiac disease and negative controls (respectively 0.3 ± 0.8 and 0.4 ± 0.5, p < 0.0001).

Conclusion: NCGS is characterized by a mild immunologic reaction, as shown by the slight increase in CD3 intraphelial lymphocytes. The over-expression in the
lamina propria of Langerhans cells, which are antigen presenting cells mainly involved in innate immunity, seems to support previous hypotheses of the predisposition of NGCS. Additionally, this finding could represent an useful pathological feature of NGCS.

P0612 FUNCTIONAL DYSPESIA SYMPTOMS ARE STRONGLY ASSOCIATED WITH COELIAC DISEASE: RESULTS FROM A POPULATION-BASED STUDY

1Faculty Of Health And Medicine And Priority Research Center For Digestive Health And Neurogastroenterology, The University of Newcastle Australia, Callaghan/Australia/NSW
2Anatomical Pathology, University of Newcastle, Newcastle/Australia/NSW
3Psychology, Macquarie University Psychology, North Ryde/Australia

Contact E-mail Address: Michael. Poterr@hnheath.nsw.gov.au

Introduction: Coeliac disease (CD) is estimated to affect up to 1 in 100 Australians (1). Although CD has a wide range of clinical manifestations, patients frequently present with gastrointestinal (GI) symptoms which overlap with functional GI disorders, particularly irritable bowel syndrome (IBS) and functional dyspepsia (FD); the prevalence of biopsy proven CD is higher in IBS (2) and in dyspepsia (3). Patients with CD have been shown to experience persistent GI symptoms despite long term treatment with a gluten-free diet (4).

Aims & Methods: The aim of this study was to define GI symptoms reported in an Australian cohort with a doctor diagnosis of CD and compare with those not reporting CD. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate =45%) which contained questions on whether the participant had ever been told by a physician that they had CD, and questions regarding GI symptoms to establish whether they had co-existent functional GI disorders. Adherence to a gluten-free diet was not assessed. Prevalence of CD, FD and IBS are reported with 95% exact confidence intervals. The difference between symptoms in those with CD compared with the unaffected population was tested for significance by the Pearson chi-square test.

Results: The prevalence of doctor-diagnosed CD was 1.2% (95% CI 0.84–1.59) in this cohort. Subjects with CD reported significantly higher levels of GI symptoms than unaffected individuals, including abdominal pain associated with abnormal bowel habit, diarrhoea, bloating, distension, epigastric burning and early satiety (see Table). There was no significant difference observed in symptoms of post-prandial fullness, nausea, constipation, abnormal stool consistency, or straining with defecation. The prevalence of FD as defined by Rome III criteria in the CD cohort was 37.5% (95% CI 22.7–54.2) compared to 13.9% (95% CI 12.8–15.1) in the non-affected population (OR 2.7, 95% CI 1.9–7.1, p<0.001). There was no significant difference in the prevalence of IBS in the affected compared with the non-affected cohort (30.8% versus 22.2%, p=0.2).

Table: Gastrointestinal symptoms reported by patients with and without self-reported coeliac disease (CD). Items reported as greater than one day per week (*) or greater than or equal to “often” (**) Symptoms

</tbody>
</table>

Conclusion: The prevalence of gastrointestinal symptoms and in particular functional dyspepsia symptoms are significantly higher in patients with a doctor diagnosis of CD than in unaffected individuals. Studies on whether biopsy proven coeliac disease in IBS is higher in IBS cohorts than healthy controls (2) and the value of screening with duodenal biopsy testing for CD in FD is concluded to be useful (3), this study supports these views.

P0613 MALE GENDER AND UNDERWEIGHT ARE ASSOCIATED WITH OSTEOPOROSIS IN PATIENTS WITH NEW DIAGNOSIS OF COELIAC DISEASE

G. Galli, E. Lahner, L. Conti, G. Esposito, M.C. Sacchi, E. Di Giulio, B. Annibule Department Of Medical-surgical Sciences And Translational Medicine, Sant’Andrea Hospital, University Sapienza, Rome,Italy

Contact E-mail Address: gloria.galli5@gmail.com

Introduction: Osteoporosis is a systemic skeletal disorder characterized by low bone density and micro-architectural deterioration with increase of bone fragility and consequent fracture risk. About 50–75% of patients (pts) with untreated coeliac disease (CD) suffer from bone mass loss (osteopenia or osteoporosis). Despite this strong correlation, guidelines do not express with certainty on the need to undergo a dual-energy X-ray absorptiometry (DEXA) scan in every patient with new diagnosis of CD. Recently, the DEXA screening was suggested for CD peri-post menopausal females, males over 55 years, pts with overt malabsorption or with a history of fragility fractures. Studies on bone mineral density (BMD) in CD pts led to discrepant results, probably due to heterogeneous designs.

Aims & Methods: The aim of this study was to evaluate, in a cohort of consecutively newly diagnosed CD adults, the prevalence of BMD alterations at diagnosis time and to evaluate associated clinical features. From January 2004 to December 2016, 258 consecutive pts (F = 72.4%) were diagnosed with CD. All pts were adults (median age 38, range 18–72 years), had atrophic disease and were invited to undergo a DEXA within 3 months from diagnosis to screen for osteoporosis (T-score < −2.5) or osteopenia (T-score < −1 and ≥ −2.5). A total of 214 (82.9%) pts underwent the DEXA scan and were included in the study (F = 71.5%, median age 38, range 18–72 years). On the basis of DEXA results (classified according to WHO classification) pts were divided into 3 groups: pts with normal BMD, with osteopenia, and with osteoporosis. For each patient, reported risk factors for low BMD (underweight, alcohol intake, drugs, menopause, smoke) and serological PTH values were assessed. The signs/symptoms leading to CD and their duration before diagnosis, autoimmune/nutritional comorbidities, familiarity for CD, previous fractures and serological assays (specific antibodies for CD, ferritin, cholesterol, triglycerides, and albumin) were also assessed. All the variables described were analyzed and compared between the 3 groups. Logistic regression was performed including into the model those independent variables which showed a significant difference at univariate analysis.

Results: At the DEXA scan, 85 (39.7%) and 129 (60.3%) pts had normal or low BMD, respectively. Among pts with low BMD, 91 (42.5%) had osteopenia and 38 (17.8%) osteoporosis. At logistic regression, clinical features significantly associated with osteoporosis were male gender (OR 4.7; 95%CI 1.3 to 17.4), underweight (OR 8.1; 95%CI 1.8 to 35.3) and increased PTH values (OR 5.1; 95%CI 1.4 to 18.8), while age, gender and gastrointestinal symptoms at diagnosis time, menopause, alcohol intake and previous fractures were not associated. Clinical features significantly associated with osteopenia were underweight (OR 4.0, 95% CI 1.4 to 10.2) and increased PTH values (OR 2.6, 95%CI 1.1 to 6.4).

Conclusion: In newly diagnosed coeliac pts, the overall prevalence of BMD alterations was more than 60%, with osteoporosis in nearly 1/5. Osteoporosis was more frequently associated with male gender, underweight and increased PTH. This study suggests that at CD diagnosis, DEXA scan might be of benefit, in particular in male underweight pts.

Introduction: Coeliac disease (CD) affects 0.6–1% of the population worldwide (1). Wheat avoidance in the absence of CD is common, and studies report a population prevalence of self-reported wheat or gluten sensitivity (SRWS) of
up to 13% (2, 3). SRWS is defined as gastrointestinal (GI) or extra intestinal symptoms on ingestion of wheat or gluten-containing food (2, 3).

Aims & Methods: The aim of this study was to determine the prevalence of SRWS in an Australian population, define associated GI symptoms, and relate the diagnosis to demographic, lifestyle and medical factors. A total of 3825 people (mean age 58.4 years, age range 18–80 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on wheat avoidance, GI symptoms, demographic, medical and lifestyle factors. We defined SRWS as people who reported gastrointestinal symptoms on ingestion of wheat based foods, but did not suffer from doctor diagnosed coeliac disease, inflammatory bowel disease or bowel cancer. Prevalence of SRWS is reported with 95% exact confidence intervals. The association between SRWS prevalence and potential risk factors was reported using unconditional logistic regression. The degree of differentiation of SRWS from health was evaluated through the area under the receiver-operator-characteristic curve.

Results: The prevalence of SRWS in this cohort was 13.5% (455/3331, 95% CI 12.5–14.9%). Only 11% (50/455) of these 113 doctor diagnosed had received a diagnosis of celiac disease. The most commonly reported GI symptoms (reported as more than weekly or often) associated with SRWS included abdominal pain relieved by bowel movements (54.5%), bloating (37.6%) and abdominal distention (30.8%). In a multivariate analysis, a diagnosis or SRWS was significantly associated with irritable bowel syndrome (IBS) and functional dyspepsia (FD) (Rome III criteria), female gender, and food allergy (see Table). Older age was negatively associated with SRWS. In this multivariate model, factors with no observed association included body mass index, depression, anxiety, sleep problems, proton pump inhibitor use, gastrointestinal infection, rheumatoid arthritis, scleroderma, migraine, Parkinson’s disease, asthma, pollen allergy, animal allergy, and recent antibiotic use. The model provided useful although imperfect differentiation of SRWS from health (AUC = 0.76).

Conclusion: SRWS has a prevalence of 13.5% in this Australian cohort. Those with SRWS are likely to report abdominal symptoms, including abdominal pain associated with bowel habits, bloating or abdominal distention. SRWS is significantly associated with IBS and FD, younger age, female gender, and food allergy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Epidemiological studies estimate a worldwide prevalence of CD of approximately 1:100 individuals, with a considerable proportion of patients remaining undiagnosed and untreated. According to a study performed by the National Health and Nutrition Examination Survey in the United States, the prevalence of self-prescribed GFD in an unselected population of subjects aged 6 years or older was 0.5%. Epidemiological studies report a prevalence of WA in American population of around 0.4% until 0.6%.

The diagnosis of WA is classically based on skin prick tests (SPT), in vitro specific Immunoglobulin E (sIgE) assays and functional assays. SPTs and sIgE in vitro assays are the first-level diagnostics for WA. However, they are affected by a low predictive value. In particular, their low sensitivity can be explained by the fact that the commercial test reagents are mixtures of water/salt-soluble wheat proteins that lack allergens from the insoluble gluten fraction. The association between food allergy and celiac disease (CD) is still to be clarified. Gluten-related disorders are an epidemiologically relevant phenomenon with a global prevalence that is estimated around 5%, drawing the attention of the scientific community.

Aims & Methods: We visited in our unit of celiac disease and gluten-related conditions during 2016 423 (F/M:312/111) new patients with clinical suspicion of CD. Of these 113 they were not celiac but were investigated for suspected non-celiac gluten sensitivity. After in vitro tests for the exclusion of celiac disease, to verify the real prevalence of food allergy particularly to wheat protein, in non celiac patient referred our unit for symptoms after gluten ingestion, all these patients underwent allergologic workup consists on: skin prick tests for food including wheat (Alk-abello), LTP (lipid transfer protein) (peach Alk abello), alpha amylase, wheat flour, barley, corn, rice, grass pollen and histamine. Also all they performed patch tests for suspected allergy to nickel, if they reported contact dermatitis. After in vitro tests for the exclusion of gluten. Molecular-based allergy (MA) diagnostics could overcome some limitations of sIgE in vitro assay using wheat flour extracts. We have used omega-5 gliadin (TR1 a 19) and mLTP (TR1a 14), gh, ghin, wheat, gluten that are available in the immunoCap assay, whereas the Alfa Aesar: α-amylase/trypsin inhibitor (Alfa A/Ti) is available only in the Pharmacia ISAC assay. The sIgE to omega-5 gliadin assay is highly reliable and now widely used to identify the patient with WDEIA.

Results: In our overall population, 113 (26.7%) non celiac patients had a history of immediate or not immediate reaction after ingesting gluten: the Allergologic tests found wheat protein sensitization in 14 patients of these 12 (4.9%). In addition we also found 5 (4.3%, 4F) patients with real allergy to wheat or wheat protein.

Conclusion: In our population 19/113 (16.8%) non celiac patient had real reaction after ingesting gluten: 14 (12.3%) had wheat protein sensitization and 5 (4.5%) had WA. These Percentages are different and very high than that reported in the literature.

P0617 A QUESTIONNAIRE-BASED SYMPTOM EVALUATION STUDY IN 381 PATIENTS DIAGNOSED WITH BILE ACID MALABSORPTION BY SEHCAT FROM 2003 TO 2016
H.R. Clausen, B. Damsgaard, J.F. Dahlerup, J. Aghnholz, S.P. Jorgensen, K. Krogh
1Department Of Hepatology And Gastroenterology, Aarhus University Hospital, Aarhus/Denmark

Contact E-mail Address: helmerandsklausen@studmed.au.dk

Introduction: Excessive amounts of bile acids entering the colon cause chronic diarrhoea (bile acid diarrhoea (BAD)). Diagnosis of BAD is possible by measuring the retention level of orally ingested 3H-Selenium homoaooarcic acid (SeHCAT). Standard treatment of BAD is bile acid sequestrants (BAS), such...
as colestyramine. Short-term outcome of having BAD is well-described, but long-term effects remain unclear. The aim of the present study was to describe long-term symptoms, adherence to treatment and quality of life in a well-defined group of patients with BAD.

Aims & Methods: Between 2003 and 2016, 559 patients referred to our hospital for differently low self-CAT retention levels (<15% at day 7). Questionnaires about medical history, bowel function, use of medication, and quality of life were sent to all patients.

Results: Among 559 patients, 381 (68.2%) responded (242 women (63.5%), median age: 53 years (range 22 to 89), median age at diagnosis 47 years (range 16 to 85). In 123 respondents (32.3%) BAD was due to ileal dysfunction (type 1), 199 (52.2%) had idiopathic BAD (type 2), and 59 (15.5%) had BAD due to cholecystectomy (type 3). At follow-up, 272 patients (73.9%) still reported both enterocoele diarrhea and 248 (65.5%) regularly used anti-diarrheal medication. Treatment included BAS in 45.1% while 32.3% of patients used other treatment. 184 patients (49.9%) reported that treatment had improved their symptoms, while 116 (31.4%) reported that they were the same, and 69 (18.7%) felt worse. In 242 patients (65.5%) symptoms were either alleviated or free from cycle 1 to cycle 2 in 242 patients (65.5%).

Conclusion: BAD must be considered as a chronic disease and despite correct diagnosis and treatment, most patients continue to have significant diarrhoea and reduced quality of life. This supports the need for further research in pathophysiology and new therapy principles.

P0618 EFFICACY OF PERCUTANEOUS ENDOSCOPIC GASTRO-JEJUNOSTOMY (PEG-J) DECOMPRESSION THERAPY FOR PATIENTS WITH CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CITO)

H. Ohkubo1, T. Higurashi2, J. Arimoto3, A. Nakajima3

Introduction: Chronic intestinal pseudo-obstruction (CITO) is an intractable rare digestive disease manifesting persistent small bowel distension without any mechanical cause. Intestinal decompression is a key treatment, but conventional methods including a transnasal small intestinal tube is invasive and painful. Therefore, a less invasive and tolerable new decompression method is urgently desired. We conducted a pilot study and assessed the efficacy and safety of percutaneous endoscopic gastro-jejunostomy (PEG-J) decompression therapy in CITO patients.

Aims & Methods: Eight definitive CITO patients (2 males and 6 females) were enrolled. All patients received PEG-J decompression therapy. The number of days with any abdominal symptoms in a month (NODASIM), body mass index (BMI), serum albumin level (Alb), and small intestinal volume before and after PEG-J were compared in all patients.

Results: PEG-J was well tolerated and oral intake improved in all patients. NODASIM has significantly decreased (24.3 vs 9.3 days/months) and BMI/Alb have significantly increased (4.9 vs 17.2 kg/m² and 2.6 vs 3.8 g/dl, respectively), whereas total volume of the small intestine has not significantly reduced (4.05 vs 2.59 L, p = 0.18). Reflex esophagitis and chemical dermatitis were observed in one case but was successfully treated conservatively.

Conclusion: PEG-J decompression therapy was found to be a safe and invasive novel decompression therapy for CITO patients available at home. However, accumulation of more CITO patients and long-term observation is needed.

3Department Of Pediatrics, IRCCS Policlinico San Matteo, Pavia/Italy

Contact E-mail Address: irene.benedetti89@gmail.com

Introduction: Gluten-susceptible subjects, gluten exposure determines celiac disease, but it has also been shown that gluten ingestion could alter intestinal absorption even in patients with non-intestinal diseases (Doherty, Lancet 1981) and in healthy subjects (Levine, NEJM 1966). However, whether gluten causes intestinal or extra-intestinal inflammation is still a matter of debate: in Doherty we recently demonstrated that gallbladder motility and gastric emptying were not affected by the ingestion of gluten, while a slight increase of intestinal fermentation was evident (Di Stefano, LDL 2015). A cytotoxic effect of gluten on intestinal cell lines was also previously shown (Rivabene, BBJ 1999). We recently demonstrated that in dyspeptic patients the ingestion of a standard meal induces both an inflammatory and an antioxidant response, correlated with symptom occurrence (De Stefano, UEGW 2016). It is therefore possible that food-related alterations of the intestine could be responsible for post-prandial activation of inflammation and anti-oxidant systems.

Aims & Methods: We therefore studied whether gluten intake induces alterations of post-prandial activation of inflammation and anti-oxidant systems. Twenty consecutive, non-smoking, normal-weight HV (8 females, mean age 27.9 ± 6 years) were enrolled. The presence of another monostotic disorders was excluded in all of them. After an overnight fast and at the same time in the morning, all the subjects underwent evaluation of post-prandial modifications of serum levels of pro-inflammatory cytokines (IL-1β, IL-6, TNFα), endogenous antioxidant system (uric acid), glucose, insulin and serum lipopolysaccharide (LPS), measured as putative factors responsible for inflammatory response. Serum samples were collected at fasting and every 30 minutes for 4-hour period after an oral gluten load of 2 gr (in 10 HV) or 20gr (in the other 10 HV). The presence and severity of a post-prandial symptom, epigastric burning, fullness, early satiety, abdominal pain, abdominal distension, bloating, flatulence, nausea, vomiting, belching, heartburn, regurgitation, diarrhea, and headache, were evaluated by visuo-analog score at fasting and every 30 minutes in the post-prandial period.

Results: In comparison with mean fasting values, none of the measured parameters showed a significant increase in the post-prandial period after the ingestion of 2 gr of gluten. On the contrary, after the ingestion of 20 gr of gluten mean post-prandial values of TNFα and IL-8 showed a significant increase (2.45 ± 1.75 pg/mL and 0.65 ± 0.31 pg/mL) as compared to mean fasting values (1.17 ± 1.49 pg/mL and 0.29 ± 0.15 pg/mL, p < 0.05). Mean post-prandial values of glucose were also significantly higher (74.98 ± 5.02 mmol/L) as compared to fasting values (45.34 ± 10.08 mmol/L, p < 0.05). No significant differences were detected in IL-6, glucose, insulin and LPS a after the ingestion of the 20 gr gluten oral load. Symptoms were absent after both oral loads.

Conclusion: The ingestion of gluten does not alter oral load of gluten induces a significant post-prandial inflammatory response causing the manifestation of the main endogenous anti-oxidant system. In HV, these activities are not accompanied by a symptomatic response. Further studies are needed to investigate the inflammatory and anti-oxidant post-prandial response in patients with gluten-related disorders.

P0620 THERAPEUTIC ACTION OF KETOCENIC ENTERAL NUTRITION IN OBSESE AND OVERWEIGHT PATIENTS: A RETROSPECTIVE PROSPECTIVE, CONTROLLED, STUDY

C. Papadia1, P. Basset2, G. Capannolo2, R. Shidrawi3
1Gastroenterology, Homerton University Hospital, London/United Kingdom
2Statsconsultancy, London/United Kingdom
3Clinical Nutrition, Rome/Italy

Contact E-mail Address: cinzia.papadia@nhs.net

Introduction: Ketogenic Enteral Nutrition (KETON3) is a modification of Blackburn’s protein-sparing modified fast, using a hypocloric, ketogenic liquid diet. The study is about Ketogenic enteral nutrition (KETON) in overweight and obese patients during treatment of the obese of weight loss with a 24 h hour infusion. It is a retrospective analysis that examines safety, weight loss and body composition changes after three sequential 10-days cycles of KETON therapy.

Aims & Methods: Anthropometric and bio-impedance data from 629 patients were collected before and after 1, 2 and 3 complete cycles. The study focuses on the change in outcomes from the first cycle to the second cycle and from the first cycle to the third cycle. The following outcomes were explored: weight, waist circumference, BMI, fat mass, lean mass, phase angle, waist marker, water mass as a percentage of total body weight. The cycle 1, 2 and 3 outcomes were analyzed using descriptive statistics (mean, standard deviation, n) summarizing the outcome at each cycle. Statistical tests were used to test for significance between paired cycle 1 and cycle 2 outcomes and also between paired cycle 1 and cycle 3 outcomes. For normally distributed outcomes, the paired t-test was used. Whereas for skewed outcomes, the Wilcoxon signed-ranks test was used. Scatter plots were used to plot percent change in weight loss against phase angle. The Pearson’s correlation coefficient was calculated. Regression analysis for the outcome percent change in weight from cycle 1 to cycle 2 for phase angle and basal metabolic rate (BMR)/Weight ratio as predictors was carried out.

Results: The results suggested significant changes for all analyzed parameters. There were significant decreases in weight, waist circumference, BMI, fat mass, lean mass, dry lean mass and phase angle. Quantitative changes in lean mass and dry lean mass were negligible with respect to changes in fat mass. There was also a statistically significant increase in the weight of total body weight and water mass marker from cycle 1 to cycle 3. The Pearson’s correlation coefficients r = 0.18, p = 0.004 and r = 22, p = 0.04 indicated changes in cycle 1 and cycle 3 in percentage of weight excess to be significantly, positively correlated to phase angle. The Pearson’s correlation coefficient was calculated. Regression analysis for the outcome percent change in weight from cycle 1 to cycle 2 for phase angle and basal metabolic rate (BMR)/Weight ratio as predictors was carried out.

Conclusion: KEN treatment is safe, well tolerated and results in rapid fat loss without detriment to dry lean mass.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0621 ANALYSIS OF LONG-TERM WEIGHT REGAIN IN OBSESE PATIENTS WITH INTRAGASTRIC BALLOON

1Dept. Of Bariatric Endoscopy, Sander Medical Center, Belo Horizonte/Brazil
2Bariatric Endoscopy, Dr. Alberti, São Paulo/Brazil
3Bariatric Endoscopy, Scarparo Scopia, São Paulo/Brazil
4Bariatric Endoscopy, Faculdade de Medicina do ABC - Hospital Mário Covas, São Paulo/Brazil
5Cirurgia, Faculdade de Medicina da UFMG, Belo Horizonte/Brazil

Contact E-mail Address: brunosander@hotmail.com

Introduction: Obesity is a global disease and its management includes pharmaco-
ologic and surgical approaches. The intragastric balloon (IGB) is an option.

Objective: To analyze the obesity regained after balloon removal. The previ-
ous studies of the IGB had shown only follow-up of weight loss and not weight regain.

Method: All obese patients (BMI > 35) treated with IGB in a specialized obesity
center, and that underwent balloon removal from June 2009 to June 2013 were
invited to participate in the study. Exclusion criteria: pregnancy or bariatric
surgery after balloon removal, impossibility to contact, and refusal to participate.

Results: Out of the study of patients, 81.3% (182) were women. The average weight
at the moment of IGB implantation was 110.4 ± 28.2 kg. The average weight loss was
4.6 ± 4.9 kg; 3 years (n = 83): 8.66 ± 6.96 kg; 4 years (n = 54): 9.99 ± 8.44 kg and 5 years (n = 3): 19.96 ± 12.24 (p = 0.51). The lower the BMI at the beginning of the treatment, the greater the weight regain after the IGB withdrawal. This correlation was inverse (r = -0.20) and significant (p < 0.01).

Conclusion: The correlation between patient BMI and weight regain after the IGB withdrawal is a significant factor for weight regain after the removal of the device.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0622 LONG TERM EFFECT OF DUODENAL-JEJUNAL BYPASS LINEAR IMPLANTATION ON WEIGHT REDUCTION AND GLYCEMIC CONTROL

S. Fishman1, L. Mlynarsky1, L. Ben-Haim2, J. Rutenberg3, M. Shinell4, E. Sando1
1Obesity Service, Dept. Of Gastroenterology, TASMC Dept. of Gastroenterology, Tel Aviv/Israel
2Dept. Of Endocrinology, TASMC Dept. of Gastroenterology, Tel Aviv/Israel

Introduction: The Duodenal Jejunostomy Bypass Linear (DJBL) is an endoscopic device which prevents ingested nutrients absorption in the duodenum and first part of jejunum. The resultant effects are weight reduction and improvement in glycemic control in patients with type 2 diabetes mellitus (T2DM).

Aims & Methods: The study aim was to assess weight regain in insulin and glycemic
control changes resulted from the device implantation and a year after the device removal. Between February 2013 and September 2016, 51 diabetic patients were treated with DJBL in our center. This prospective observational study included a total of 306 follow-up periods for 9 months of active treatment. However, adverse events and early removals were analyzed for the whole cohort. Blood tests, body weight and medications data were collected during scheduled visits and phone interviews. The primary end points were body weight and glycemic control changes a year after the end points were the same
parameters after device removal. The protocol was approved by the local ethic committee.

Results: Thirty six patients (52.8% male) were treated for at least 9 months with the device. 10 of which completed a whole year follow-up after device removal. At the end of 12 months post implantation, the average body weight and BMI dropped from 109.5 ± 19.1 kg and 37.4 ± 5.0 kg/m² to 93.7 ± 20.4 kg and 29.6 ± 4.1 kg/m² (P = 0.001). Although the HbA1c dropped from 7.3 ± 1.1% to 6.9 ± 0.9% (P = 0.001) followed by those in which

Introduction: NASH is the most important cause of chronic liver disease and is
considered the hepatic manifestation of the metabolic syndrome associated with
type 2 diabetes. The prevalence of NASH in the general population reaches 15–
20% and it goes up to 70 to 90% in the obese population. The search of new non-
toxic drugs for prevention of the development of obesity is the most important
challenge of modern science. The question about impact of probiotics and
biotics on fat metabolism and obesity is being actively debated in the scientific
literature. So the aim of the study was to investigate the effect of synthetic (S) on
development of experimental obesity in rats with NAFID.

Aims & Methods: The study was carried out on 60 white rats, that were divided
into 6 groups (I-III – males, IV-VI – females). I and IV groups were intact control
(4-month old). Newborn rats of groups II and III s.c. in volume 8
mL saline or monosodium glutamate (MSG) (4 mg/g) at 2–10 days of age
were administered a saline or monosodium glutamate (MSG) (4 mg/g) at 2–10 days
of life. Since the age of 1 month, rats of III and V group had been injected with
water, rats III and VI groups - S (Inulin, Lactobacillus, Bifidobacterium and
Saccharomyces boulardii) (“Opferla” World Medicine) in a dose of 1, 94 ± 109
mg/kg/day and insulin. Interventions were performed by 13 months (3 months
courses alternated with two-week breaks) for 3 months. In 4-month rats anthropometric parameters and visceral adipose (VAT) tissue mass were esti-
minated, and adiponectin in serum and leptin in VAT were measured by ELISA.

Results: In our study we observed increased levels of the anthropometric para-
eters and significant increase of VAT mass that confirmed development of
visceral obesity. In male rats, there were more pronounced changes. It was estab-
lished that under condition of obesity caused by the introduction of MSG, the
level of adiponectin in serum decreased but leptin in VAT was increased. S
significantly improvement lipid profiles and histological state of liver: decrease
of dystrophy, inflammation and necrosis and reduction of the NASH incidence.
Also consumption of S led to reduction of pro-inflammatory cytokines and leptin and increased anti-inflammatory cytokines and adiponectin.

Conclusion: The introduction of S reduced the obesity, that shows the effectiveness of therapy for the prevention of obesity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic bariatric approaches are gaining traction as possible treatment modalities for obesity. Especially, intragastric balloon was demonstrated to be associated with a significant weight loss in obese patients. Despite many advances in the design and material of intragastric balloon devices, there still remains a need for improved devices which is safer, faster, and less expensive than before. In the present study, we evaluated feasibility of newly developed intragastric balloon.

Aims & Methods: We used a newly developed intragastric balloon with improved employment for this study. The intragastric balloon was supplied as delicately rolled up inside a thin silicon sheath and mounted by surrounding the endoscope. Endoscopic intragastric balloon placement and positioning was simply performed by two endoscopists. 10 pigs were subjected to the novel intragastric balloon placement. We evaluated feasibility of the intragastric balloon and compared procedure time between the novel intragastric balloon and End-ball (Endalis, Brignais, France) intragastric balloon.

Results: In all cases, the novel intragastric balloons were successfully placed under usual sedation of diagnostic endoscopy. The procedures were simple and fast; the mean insertion time was 41.34±13.43 sec and 158±134.8 sec in novel intragastric balloon group and end ball group, respectively. The mean inflation time was 421.64±152.83 sec in novel intragastric balloon group and end ball group, respectively.

Conclusion: This preliminary data suggest that the procedure with the new intragastric balloon attain technical improvements in the placement without severe adverse events. The new intragastric balloon could offer constantly effective procedure regardless of the ability of the endoscopy practitioner.

Conclusion: The results of this observational study show that re-implantation of the DJBL is viable and safe even after 4 months after explantation. After re-implantation, weight and HbA1c levels decreased one more time.

Disclosure of Interest: J. Stein has received speakers’ honoraria from GI Dynamics. All other authors have declared no conflicts of interest.

Conclusion: Obesity in the young population is becoming increasingly prevalent. It is associated with short- and long-term consequences. Early and effective interventions are paramount. Current treatment options include: lifestyle modifications, pharmacological therapies, endoscopic treatments and bariatric surgery. However, the relative effectiveness of these treatments in this cohort remains unclear.

Aims & Methods: To systematically identify and meta-analyse studies evaluating treatments that reduce body mass index (BMI) in overweight and obese young people. A systematic literature review of EMBASE and MEDLINE databases was conducted. Studies were included/excluded based on pre-specified eligibility criteria. Included patients were 21 years or younger. Lifestyle modification and pharmacological therapy searches were restricted to randomised control trials.

Results: 16,372 studies were identified with 80 studies complete with sufficient data for meta-analysis. Bariatric surgery caused the most weight loss in the short- and medium-term [pooled estimate of mean BMI loss: 13.77 kg/m²]. Lifestyle modifications and pharmacological therapy had a more modest impact on weight [pooled estimate of mean BMI loss: 0.99 kg/m² and 0.94 kg/m² respectively]. Individual studies demonstrated that endoscopic treatment results in short-term BMI reduction, however insufficient data prevented meta-analysis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: All analyzed microRNAs were present in all studied foods with highest expression found in poultry and meat. Especially, hash, beef and salmon showed the highest miRNA expression, while lowest expression was found in cheese and milk. Food processing led to only marginal changes (max. 1.5-fold) in miRNA expression and thus demonstrating its stability against degradation. Short-term changes in diet (from usual to vegetarian and to meat-rich diet) in healthy subjects was not associated with variation in miR-21, miR-155 and miR-16 expression. Interestingly, in comparison to several previous reports, we repeatedly failed to detect any plant miR-168 in sera. However, we did observe a slight increase in miR-155 expression in sera (up to 8-fold), while meat-rich diet was associated with slight decrease if compared to the starting time point (mean ± SD 0.031 ± 0.002 for no diet vs 0.025 ± 0.042 for vegetarian vs. 0.0016 ± 0.00096 for meat-rich; p = 0.03 Kruskal-Wallis test, with p = 0.05 for Dunts multiple comparison test for vegetarian vs. meat-rich).

Conclusion: The results of this study show that various foods provide a great source of miRNAs, which remains stable despite processing. We further demonstrate that short term changes in diet have only minor impact on the miRNA expression pattern in sera and blood supporting its value as biomarkers. Functional role of diet-induced increase in plant-derived miRNA expression needs further evaluation.

Introduction: The gut and brain peptide neuromedin U (NMU) is reported to contribute to its anorexigenic effect. During OGTT, blood was sampled to measure insulin secretion. [14]C-glucose tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice. The gut and brain peptide neuromedin U (NMU) is reported to contribute to its anorexigenic effect. During OGTT, blood was sampled to measure insulin secretion. [14]C-glucose tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice. Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice. The gut and brain peptide neuromedin U (NMU) is thus considered as a promising candidate for the treatment of obesity and diabetes. However, in contradiction with previous observations, NMU was recently presented as a “decretin” hormone able to decrease insulin secretion. The pathways through which NMU controls glucose are thus uncertain and we sought to clarify some of NMU mechanisms of action on glucose homeostasis.

Aims & Methods: Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice. Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice. The gut and brain peptide neuromedin U (NMU) is thus considered as a promising candidate for the treatment of obesity and diabetes. However, in contradiction with previous observations, NMU was recently presented as a “decretin” hormone able to decrease insulin secretion. FODMAP intake was successfully reduced, and main additional changes were used to evaluate HRQOL. A 3-day food record was used to estimate base-line intake of FODMAPs, to reveal dietary changes and to assess adherence to LFD throughout a 4-week intervention period. IBS Severity Scoring System (IBS-SSS) and IBS Symptom Questionnaire (IBS-SQ) were used to assess symptoms. An Ad hoc questionnaire measured grade of tissue damage and typical RISBD complaints (fecal incontinence, rectal mucus and rectal bleeding). Short Form Nepean Dyspepsia Index (SF-NDI) and 12-item Short Form Health Survey (SF-12) were used to evaluate HRQOL. A 3-day food record was used to estimate baseline intake of FODMAPs, to reveal dietary changes and to assess adherence to the diet. All schemes were completed at baseline and at 4 weeks. The study included no control group.

Results: FODMAP intake was successfully reduced, and main additional changes in the diet were reduced intake of energy, carbohydrates and fiber. The adherence to the diet was high (mean 94.8%). IBS symptoms improved significantly based on mean total score of IBS-SSS and IBS-SQ, which changed from 310.2 ± 9.4 to 18.3 ± 8.2 (p = 0.001) and based on mental (p = 0.047) and physical (p = 0.134) component summary score of SF-12.

Conclusion: The low FODMAP diet seems effective in alleviating IBS symptoms, and improving HRQOL in patients with RISBD. High compliance to LFD is possible with adequate diet counseling and continuous guidance. Further controlled studies with larger sample size should be conducted to verify our results and hopefully enable the implementation of LFD as a future management strategy for chronic RISBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
is similar to the oral glucose-stimulated secretion of glucagon-like peptide 1 (GLP-1) and nitric oxide from enterointerine L cells (EEC) from the distal gut. GLP-1 and glucagon, both originate from the same proglucagon precursor, differentially processed by prohormone convertase 2 (PC2) into glucagon in pancreatic α cells and by prohormone convertase 1/3 (PC1/3) into GLP-1.

Aims & Methods: We hypothesized that, after pancreatectomy, proglucagon can also be processed into glucagon in EEC. We developed a 75% subtotal pancreatectomy model in C57Bl/6 mice. Control (Ct) mice underwent a laparatomy. Post-surgery, blood samples were measured for blood glucose and oral glucose tolerance tests (OGTT) were performed after 1 week. Insulinemia and glucagonemia were also measured in fed and fasted mice and during OGTT. After 2 weeks, animals were sacrificed and the remnant pancreas was sampled for glucagon and insulin immunohistochemistry in whole-organ alpha- versus beta-cell mass quantification. Proximal and distal intestinal segments were sampled for morphometric analyses as well as measurement of proconvertase and proglucagon mRNA levels. Colonic segments were incubated in a glucose-enriched medium for one hour and glucose-induced secretion of glucagon and insulin were measured in the supernatant and in the supernatant.

Results: As soon as one day post-surgery, pancreatomezzized (Px) mice developed a hyperglycemia that maintained for over a week (351 mg/dl in Px mice vs 140 mg/dl in Ct mice, P < 0.05, 5 days post-surgery). This hyperglycemic state was accompanied by an oral glucose intolerance (area under the curve +278% in Px mice, P < 0.01 vs Ct mice, 1 week post-surgery). During OGTT, intestinal glucose absorption increased (slope between 0 and 15 min +69.9% in Px mice vs 0% in Ct mice, 1 week post-surgery). Glucagonemia increased in fasted pancreatomezzized mice (+146.6% in Px mice P < 0.01 vs Ct mice 1 week post-surgery). After sacrifice, alpha cell mass was decreased in the remaining pancreas (~79.25% in Px mice P < 0.05 vs Ct mice, 2 weeks post-surgery). However, the proximal colon to secret glucagon and vaso was observed (+290.6% in Px mice P < 0.05 vs Ct mice, 2 weeks post-surgery). In pancreatomezzzed mice, an hypertrophy of the duodenum was associated with an increase in crypt depth (+77.7%, in Px mice P < 0.05 vs control mice, 2 weeks post-surgery) and villus height (+53.8% in Px mice P < 0.05 vs control mice, 2 weeks post-surgery).

Conclusion: These data establish an ability of the whole gut to adapt in response to pancreatectomy. The upper intestine (duodenum) become hyperplasic and more glucose-induced intestinal response to absorb glucose. The distal intestine (colon) is able to produce glucagon and may participate to the development of the reported hyperglycagonemia.

Introduction: Percutaneous endoscopic gastrostomy (PEG) is currently one of the most common endoscopic procedures performed worldwide. To date, the mortality of patients after PEG insertion or PEG replacement. This is a relative (without legal guardianship) in 49.6%, patient in 28.2%, legal guardian in 10.5%, legal guardian in 16.25%, medical director in 7% of patients. Thirty-days mortality was 2.4%

Conclusion: Our data confirm that PEG placement is a safe procedure with a mortality rate of 30 days of 8%. To our knowledge this is the largest prospective study on the use of PEG. Surprisingly in more than 50% of patients the consent form was not properly signed, leading to possible medico-legal consequences. Moreover, in 9% of the cases PEG was placed for an early discharge (more than for clinical indication).

PO037 MEDICAL REGISTRAR REPORTING OF CHEST X-RAYS FOR NASOGASTRIC TUBE POSITION: HOW CAN IT BE MADE SAFER?

Contact E-mail Address: mavee.tierney@nhs.net

Introduction: Nasogastric tube (NG) feeding is an essential part of in-patient care. Tubes can be placed at the bedside with no need for specific equipment or sedation. However placement of NG tubes is not without risk and avoiding the introduction of substances into the respiratory tract through a misplaced NG tube was highlighted as a UK National Patient Safety Agency alert in 2005. In 2011 the NPSA made this a ‘never event’. The only acceptable methods of checking the position of an NG tube are: pH < 5.3 on aspiration or confirmation of flow of NG (CRM) by competent medical staff. Reporting a CXR for NG tube position is a frequent request particularly for junior doctors out of hours. Practise varies across the UK - some trusts require NG checking to be done only by senior clinicians (medical registrars or consultants) and some only allow reporting by a consultant radiologist. We assessed documentation of NG position on CXR by medical registrars from the region to find out if documentation was adequate, as would be expected of senior clinicians. NPSA guidance suggests four points should be documented in the medical notes to confirm NG position: 1. Does the tube follow the contours of the oesophagus and avoid those of the bronchi? 2. Does the tube clearly bisect the carina or the bronchi? 3. Does it cross the diaphragm in the midline? 4. Is the tip clearly visible below the left hemi-diaphragm? All four criteria were met in only 17.6% of responses and answers were considered incorrect in 20.5%. An aide-memoir sticker with an abbreviated version of the above four points, time, date, doctor signature and whether tube is safe to use or not with Yes/No answers, is used on some wards in Southampton and we assessed whether its use would improve quality of reporting both a correctly placed and misplaced NG tube.

Aims & Methods: Medical registrars from first to final year of specialist training and from various specialties were presented with a CXR showing a correctly sited NG tube and were asked to complete a sticker answering yes or no, to check position and whether it was safe to use. Following this they were presented with a CXR showing an incorrectly sited NG tube and asked to use the sticker to assess position. The CXR was projected and anonymous responses collected after sufficient time for the group to complete both stickers. Results: 31 complete responses were obtained for the correctly sited tube with 58% stating that it should be used and 42% that they would not use the tube without further review. 10 incomplete responses were obtained and therefore 86% of responses met NPSA guidance for reporting CXR for NG position. 28 complete responses were obtained for the incorrectly sited tube and 100% stated that the tube should not be used.

Conclusion: Use of the sticker increased compliance with NPSA guidance for CXR reporting for NG tube position from 17.6% to 86%. The misplaced tube was correctly reported and not used in 100% of responses. The correctly sited tube was reported as safe to use in 58%. The CXR used was of an anonymous real patient and was slightly rotated to reflect a real-life scenario which meant the tube was slightly off the midline. In this real-life scenario some trainees would be happy to make a judgement considering these factors and others may be cautious and follow the sticker statements exactly prompting further review by radiology or removal of the tube. Overall this increases patient safety and avoids use of a misplaced tube in accordance with UK guidelines. We recommend the use of a CXR sticker on all wards which use NG tubes to rapidly improve documentation and patient safety. The other option we may consider is developing a pathway for radiology consultants to report all these CXRs before the NG tube is used; however this is likely to take considerable time and is unlikely to be available out of hours.

P0638 MICRONUTRIENT MONITORING IN HOME PARENTERAL NUTRITION PATIENTS: AN AUDIT OF PRACTICE IN A REGIONAL REFERRAL CENTRE

M. Tierney, L. Bakewell, E. Buse, C. Rutter, C. Pither, T. Smith Nutrition, University Hospitals Southampton, Southampton/United Kingdom

Contact E-mail Address: maeve.tierney@mhs.net

Introduction: Intestinal failure patients by definition have reduced ability to absorb fluid and macronutrients through the gastrointestinal tract. Type two intestinal failure patients require months of intravenous nutrition (parenteral nutrition) for weeks or months either in hospital or at home. Type three intestinal failure patients generally require long-term parenteral nutrition (PN), which is given at home (HPN) and may be life-long. In addition to a reduction in the ability to absorb macronutrients, patients on long-term PN have a reduction in absorption of micronutrients (copper, zinc, selenium and manganese) and vita-
mins (A, B12, D and E) which are required for metabolism and enzymatic reac-
tions at a cellular level. PN is routinely supplemented with micronutrients and show that therapy can occur at high levels and deficiency can cause a variety of symptoms. ESPEN guidelines recommend that serum vitamin and trace element levels be checked at baseline and at least once per year. NICE guidelines specify more frequent monitoring for in-patients and that selenium; manganese and vitamin D should be checked three to six monthly in HPN patients. Some trace elements (copper and zinc in particular) are affected by acute illness. Current local practise is to avoid checking levels until there is evidence that inflammation or infection has resolved.

Aims & Methods: Our aim was to audit the frequency of micronutrient screening in our cohort of HPN patients. All type two and three intestinal failure out-
patients were included. Current in-patients were excluded due to the effect of acute illness on micronutrient levels. Patients on parenteral fluid rather than nutrition were excluded as current guidelines give recommendations for HPN patients and do not specify recommendations if fluid alone is required. A search of the blood results system was performed for all micronutrient results from one full year to the date of the search. Results were recorded in spreadsheet format and analysed. Many patients live out of the region; however, many local trusts do not have the laboratory facilities to check micronutrient levels so they tend to be done in Southampton. If no results were available on the Southampton system then the local hospital was contacted for local results if available.

Results: 57 home parental nutrition patients were identified. 51 (89.5%) of these patients had micronutrients checked at some point during their care. 44 of 49 (88.7%) had micronutrients checked within one year (two of the 51 had other recently so did not have results within a year). 32 (61.5%) of those who had micronutrients checked had them done within the last six months. 6 patients had never had micronutrients checked. One had them requested just prior to the time of audit but results were not yet available. Two were out of area and had not been in hospital that year. One of these commenced PN in 2015 and found it difficult to attend clinic. The other had not been seen in clinic due to an administrative error and has now been seen with micronutrients requested. Two further patients had never had micronutrients checked due to a persistently raised CRP.

Conclusion: Despite a lack of clarity between guidelines about the frequency of monitoring of micronutrients, it is recommended that HPN patients receiving long-term intravenous nutrition should have regular monitoring to reduce risk of deficiency or toxicity. The majority of our cohort of HPN patients had micro-
nutrients checked annually and over half were checked six monthly. This is compliant with ESPEN guidelines; however, we need to aim for 100%. We have introduced a template to use in clinic to trigger review of results and request micronutrient levels when required. Alongside this we have introduced a virtual ward round to remotely review all out-patients regularly and plan ahead to request blood tests when required. Following the introduction of these measures we will repeat the audit to find out if the situation has improved.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0639 CLINICAL NUTRITION - ARE WE IGNORANT OR NEGLIGENT?

T.M.A. Gan, R. Asokkumar, E. Salazar Gastroenterology And Hepatology, Singapore General Hospital, Singapore/Singapore

Contact E-mail Address: aaron.gan2@mohh.com.sg

Introduction: Early recognition and delivery of nutritional care by physicians has been shown to improve outcomes in malnourished hospitalized patients. However, physicians encounter multiple barriers in providing appropriate nutrition intervention. These are interspecial and nutritional train-
ing in medical education have been introduced to overcome these barriers, there appears to be a discrepancy in practice amongst physicians despite the availabil-
ity of these resources.

Aims & Methods: We aim to assess the knowledge and attitudes of physicians towards clinical nutrition in a large tertiary teaching hospital in Singapore. An anonymous questionnaire comprising 15 multiple-choice questions from stand-
ard nutrition textbooks was administered. The questionnaire was designed to assess (a) recognition of nutritional needs of hospitalized patients, (b) knowledge on the role of clinical nutrition, and (c) application of nutritional intervention in common clinical practice. We included consultants, fellows and residents working in units where nutritional problems were common. Finally, we conducted a separate 5-question opinion survey to assess each participant’s nutri-
tional training and exposure, based on a 5-point Likert scale ranging from “strongly agree” to “strongly disagree”.

Results: A total of 305 physicians volunteered to participate in this study. Forty (15%) did not reveal their specialty or staff grade and were excluded from ana-
lysis. Of the remaining 265 responders comprised 77 (29%) consultants, 88 (22%) fellows, and 130 (49%) residents. Amongst them, 232 (87%) were from medical disciplines and 33 (13%) from surgical disciplines. The median aggregate score (out of a maximum score of 15) obtained by consultants, fellows and residents was 6.0 ± 2.2 (range 2–12), 7.0 ± 1.8 (range 3–11), 7.0 ± 1.8 (range 1–10) respectively. All 3 grades of physicians achieved less than 50% of the maximum possible score. No significant difference in median aggregate score was observed between physicians from medical disciplines (6.5 ± 1.9) and those from surgical disciplines (6.5 ± 1.9). However, gastroenterologists performed significantly better than non-gastroenterologists (median aggregate score 9.0 ± 2.2 vs 6.0 ± 1.8, p < 0.001). In the opinion survey, a majority of physicians (63%) believed that nutrition-related teaching was inadequate during residency training and 44% felt that clinical nutrition was accorded insufficient attention during ward rounds. Only 33% of responders reported that they performed nutritional screening on admission, and a mere 10% were confident in providing nutrition counselling to malnourished patients. Interestingly, their overall performance was not different from that of other participants (see Table 1).

</table>

Conclusion: Our study highlights that knowledge on nutrition and its clinical application to hospitalized patients remains inadequate across all physician grades, especially amongst non-gastroenterologists. The current state of clinical nutrition-related teaching during residency training falls short of achieving its goals, and may need re-examination.

Introduction: Per-oréal endoscopic myotomy (POEM) is a novel treatment mod-
ality for achalasia cardia (AC). The studies are limited in paediatric population. Aims & Methods: In this study our aim was to analyse the feasibility, safety and efficacy of per-oréal endoscopic myotomy in children We retrospectively evalu-
ate the data of all children (<18 years) who underwent POEM at our institution from September 2013 to February 2017. All POEM procedures were performed under general anaesthesia in an endoscopy suit. Technical feasibility, safety and efficacy were analysed. Clinical success was defined as Eckardt score ≤ 3. Objective postoperative indwelling-timed barium swallow and high resolution mano-
metry were assessed and compared before and after POEM.

Results: Thirty children (15-boys, 15-girls) with mean age of 14.1 ± 3.2 (4–18) years, underwent POEM during the specified period. The sub-types of AC were-
type I (6), type II (19) and type III (1). Eight children had prior treatment with pneumatic balloon dilatation. POEM was successfully performed in all children. Anterior myotomy was performed in majority of children 23 (76.7%). Mean total length of myotomy was 10.9 ± 2.2 cm, with 7.9 ± 2.0 cm on esophageal and...
Aims & Methods: We aimed to study the composition of the microbiota in the biopsy material of the antral part of the stomach, according to the 16S-rRNA sequencing, of children with chronic gastritis, in the presence or absence of HP, and also to compare it with the histological data. Biopsy materials of mucous coat from antral part of the stomach were taken from 16 children aged 10–17 with chronic gastritis and after the preliminary extraction the biopsy materials were examined using the method of sequencing with a pair of oligonucleotide primers, which are specific for the conservative regions of the 16S-rRNA gene, on the Life Technologies Ion Torrent sequencer using the 318v2 chip. Bioinformatic processing was conducted using the QIIME package. The results were compared with the data from the histological examination of the biopsy materials from the same part of the stomach as well as with the results of diagnosis using rapid urease test AMA RUT Expert with digital Reader.

Results: 8 out of 16 patients were identified as HP(+) positive, 2 of them had HP in small amounts, 6 of them – in significant amounts. The dominant types of bacteria in the stomach of all children were Proteobacteria, Bacteroidetes, Firmicutes; in a lesser extent - Actinobacteria, Cyanobacteria, Fusobacteria. 64.1% of HP(+) patients’ microbiome was constituted of HP, among Proteobacteria it reached 75–99%, the amount of other bacteria herewith shor- tened, and the microbiota diversity decreased. Non-helicobacter microbiota of children with small amount of HP was almost identical in composition as HP(-) patients’, the amount of other microbes was more numerous and diverse, also within Proteobacteria. The signs of inflammation in mucous coat of the stomach in case of HP presence were more pronounced than in HP absence, they corre- lated with the amount of HP.

Conclusion: Microbiome of the children’s stomach is diverse, it is similar to adults’. The infection from HP inhibits another microbiota and it is accompanied with the signs of mucous coat inflammation, which correlates with the amount of HP.

Introduction: Because of high prevalence of gastric malignancies in the adult population, high Helicobacter pylori (Hp) prevalence in Armenia is suspected. Rising antibiotic resistance of Hp both in children and adults lead to decrease of effectiveness of standard eradication therapy [1, 2]. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children.

Aims & Methods: 47 children with suspected gastroduodenal disease (GDD), hospitalized in Arabkir MC, were selected from April to December 2016 (23 boys and 24 girls, average age 8.98±4.40). Hp-associated GDD were diagnosed according to clinical, endoscopic and histological criteria. Antral biopsy was cultured on 3% sheep blood Columbia agar and selective Hp media. Antibiotic susceptibility test by disk diffusion method was conducted.

Results: Hp-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). Seven out of 47 children were excluded from the study due to both histology and culture negative for Hp. Thirty-four (85%) were treatment-naive patients and 6 (15%) had received eradication therapy previously. Main clinical symptoms were recurrent epigastric pain 34 (85%), nausea 28 (70%) and vomiting 13 (32.5%). By Hp eradication therapy, Hp(+) and/or duodenitis was seen in 18 (45%), non-erosive gastritis in 16 (40%), PUD in 3 (7.5%), normal mucosa in 3 (7.5%). Rapid urease test was positive in all antral biopsies (100%). Histology showed chronic gastritis and/or duodenitis in 28 (70%), atrophic gastritis in 5 (12.5%), gastric glandular dysplasia in 2 (5%), gastric metaplasia of duodenal mucosa in 3 (7.5%), normal mucosa in 2 (5%). Hp was positive in 38 (95%) and negative in 2 (5%). Cultures were positive for Hp in 14 of 40 patients (35%). Susceptibility test was possible in 12 Hp strains from available 14: all but 2 were resistant to metronidazole (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to amoxicillin and levofloxacin (100%), 6 strains were tested and found susceptible to rifuratol.

Conclusion: The data indicate a high rate of resistance to conventional triple therapy antibiotics: metronidazole (83.3%) and clarithromycin (33%). High resistance to doxycycline also was seen, despite limited use of this antibiotic in Armenian paediatric practice. High susceptibility to rifuratol might be useful for further development of specific eradication schemes for Armenia. High frequency of both erosive and non-erosive gastritis as well as high rate of gastric atrophy and dysplasia in these patients were noticed.

**P0645 CURRENT STATUS OF THE FIRST AND SECOND LINE THERAPY FOR HELICOBACTER PYLORI INFECTION IN SYMPTOMATIC CHILDREN: A SINGLE CENTER STUDY**

V. Hurduc, B. Luiza, P. Doina
Pediatric Gastroenterology, Victor Gomoiu Clinical Children Hospital, “Carol Davila” University of Medicine and Pharmacy, Bucharest/Romania

Contact E-mail Address: v.hurduc@yahoo.com

Introduction: Current evidence suggests the decline of the eradication rates of *H. pylori* infection in children treated with standard first line therapy, partly determined by its antibiotic resistance.

Aims & Methods: To evaluate the effectiveness of current first and second-line therapies for *H. pylori* eradication in children. We conducted a prospective open-label study of 158 symptomatic children (age 6 months−18 years; 106 girls) who required a first upper digestive endoscopy over the past year. Active *H. pylori* infection was documented in 122 of the 158 investigated children (77.2%). Infected children were randomly assigned to receive either a 7−14 days standard empiric triple therapy consisting of esomeprazole (Eso) plus amoxicillin (AMO) and clarithromycin (CLA) or metronidazole (MET), either a sequential therapy for 10−14 days. Bismuth salts are not easily available in our country.

Results: Thirty CD patients completed the study. After 12-weeks intervention, the biochemical blood parameters remained normative in all CD patients, and the gut microbiota counts within each experimental group did not differ from their counts at baseline. However, in comparison with placebo group, bifidobacterium counts was significantly (*p* < 0.01) higher in CD children consuming OEF−supplemented GFD. Moreover, the counts of Clostridium leptum group in children of prebiotic group did not show the decreasing tendency among the time of GFD intervention was observed in placebo group. These changes were reflected into bacteria after the intervention that was constant in prebiotic group but tended to fall in placebo group. Microbiota corresponded well with microbial metabolic activity. In comparison with placebo group, concentration of short chain fatty acids (SCFA) was higher in prebiotic group (50.27 ± 69.55 μmol/g, *p* < 0.05) mainly due to a significantly higher acetate formation (28.82 ± 44.06 μmol/g, *p* < 0.05).

Conclusion: Imbalanced gut microbiota is suggested to be involved in the pathogenesis of celiac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microbial composition, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients.

Aims & Methods: The aim of the present study was to assess the effect of prebiotic oligofructose-enriched inulin (OEI) administration on the quantitative gut microbiota characteristics of CD children following a strict GFD for ≥1 year. A randomized, placebo-controlled 12-weeks dietary intervention was conducted on 34 CD children (62 % female, mean age 10 years) on GFD who were randomly assigned to prebiotic (OEI: 10 g/day) or placebo group (multidextrin; 7 g/day). Before (baseline) and after the intervention, the anthropometric (weight, height) and biochemical blood parameters (C-reactive protein, creatinine, aspartate aminotransferase, alanine aminotransferase), quantitative gut microbiota characteristics (by real-time PCR) and concentration of short-chain fatty acids (by gas chromatography with a flame ionization detector) were assessed.

Results: Treatments were analysed by x2 test and the Odds Ratio (p < 0.05) was considered statistically significant. There were no association between *H. pylori* infection and Ig E mediated food allergy. Undernutrition and overnutrition were not associated with the *H. pylori* infection and food allergy in our patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: *H. pylori* is one of the most widespread bacterial infections worldwide, therefore nowadays its prevalence is decreasing, mostly in developed countries. There are some studies which support that *H. pylori* could favor the development of food allergy.

Aims & Methods: To assess the relationship between *H. pylori* infection and specific immunoglobulin E (Ig E) antibodies to food allergens in symptomatic children. We conducted a prospective study of 394 symptomatic children (249 girls, age range 6 months−18 years), mostly with uninvestigated dyspepsia requiring an endoscopic evaluation in our unit, from January 2015 to December 2016. All patients were evaluated for *H. pylori* infection by at least two standard invasive tests and for specific immunoglobulin E antibodies to major food allergens (R-Biopharm, Germany). The nutritional status of patients was assessed in all cases by the new World Health Organization (WHO, 2007) growth charts. EPI−INFO version 7 was used for statistical analysis. A two sided p-value less then 0.05 was considered statistically significant.

Results: Active *H. pylori* infection was documented in 246 (62.3%) cases. The allergic sensisation to at least one of the food allergens was identified in 134 of 394 patients (34%). The majority of Ig E positive children (109 of 134 cases; 80.55%) were positive for cow’s milk followed by egg (17.9%), wheat (7.46%), potato (5.95%), soybean (3.73%). The allergic sensitization to food allergens was associated with abnormal levels of specific Ig E antibodies to common inhalatory allergens in 55 of 134 cases (41.04%). Regarding the association of *H. pylori* infection with an elevated serum Ig E level to at least one of the food allergens tested, there was a weak but present correlation (p = 0.14, 77 of 134 (51.30%) patients positive for food specific Ig E antibodies were *H. pylori* infected and 57 of them (38.55%) were *H. pylori* negative (Fisher exact test = 0.08). The assessment of the patients nutritional profile in relationship with *H. pylori* infection and food allergy not revealed any statistical significance between the two the poor nutritional status (undernutrition and overnutrition).

Conclusion: The recent decline of *H. pylori* infection is not evident in our study. There was no association between *H. pylori* infection and Ig E mediated food allergy. Undernutrition and overnutrition were not associated with the *H. pylori* infection and food allergy in our patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0648 EVALUATING GLUTEN IMMUNOGENIC PEPTIDES AS NON-INVASIVE MARKER OF GLUTEN-FREE DIET ADHERENCE IN PAEDIATRIC CELIAC DISEASE**

Introduction: Treatment for celiac disease (CD) is a lifelong strict gluten-free diet (GFD). Patients should be followed-up with dietary interviews and serology as CD markers to ensure adherence to the diet. However, none of these methods is sufficiently sensitive. The current study aims to use a non-invasive method to evaluate adherence to dietary restriction in children and adolescents with CD.

Methods: A total of 62 children and adolescents (32 males, 30 females; mean age 7.3 ± 3.1 years) with CD followed up for at least 1 year were included in this study. The patients were questioned using a validated questionnaire to identify adherence to dietary restrictions. A protein antigen mixture enriched in gluten immunogenic peptides was used to evaluate the adherence to dietary restriction. A second-line therapy was recommended in 26 of cases with an overall eradication rate of 80.76% (21/26 cases) for ITT analysis and respectively 87.5% (21/24 cases) for PP analysis.

Conclusion: This endoscopic series reveals a high rate of *H. pylori* infection (77.2%). The sequential therapy achieved a significantly higher eradication rate than the standard empiric triple regimens regardless of using ITT (78.57% versus 61.35%) or PP (85.93% versus 65.30%) analysis. The eradication rates for the second-line therapy was significantly higher (87.5% for PP analysis) compared with standard first line triple therapy (76.99% for PP analysis).

**A390 United European Gastroenterology Journal 5 (S5)**
offer an accurate measure of dietary compliance. Presence of gluten related sub-
stances in faeces may falsely suggest that transit through gastrointestinal tract happened and 
confirms gluten ingestion.

**Aims & Methods:** Detection of gluten immunogenic peptides (GIP) in stools as a marker of GFD adherence in CD paediatric patients was evaluated and compared against traditional methods of GFD monitoring. A prospective, non-randomized, multi-centre follow-up study, 2 years long, including 64 CD patients started on GFD when diagnosed (age range 9–18 years). Fecal GIP was quantified by enzyme-linked immunosorbent assay (ELISA). Anti-tissue transglutaminase (anti-TTG) IgA and anti-deamidated gliadin peptide (anti-DGP) IgA antibodies were measured simultaneously, during basal and follow-up visits at 6, 12, 6 and 24 months. Correlations between fecal GIP and serum antibodies were established by Cochran’s and Friedman tests.

**Results:** 62 patients (97%) had detectable GIP levels in stools, during basal visit, before initiation of the GFD, whereas 20.3% of the patients were found to have positive GIP after treated with a GFD. Dietary transgressions were more frequent in the first 6 months of starting GFD. 11% of them showed more than one detected transgression. Anti-TTG IgA remained in high concentrations in 48, 34 and 20% of the patients at 6, 12 and 24 months of follow-up. Anti-DGP was positive in 13, 4.5 and 0% of cases when tested at 6, 12 and 24 months follow-up. Both serological methods did not correlate with GIP in stools (P < 0.05).

**Conclusion:** The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of trau-

Introduction: Nowadays food allergy continues to increase, especially in western countries and is now recognized as a worldwide problem. Transforming growth factor-β1 (TGF-β1) is a profibrotic cytokine, which plays an important role in promoting the structural changes in food allergy. Also for patients with food protein - induced enterocolitis syndrome TNF-α appears to have an important role.

Aims & Methods: The aim was to determine the significance of the Transforming Growth Factor - β1[TGF – β1] and Tumor Necrosis Factor – α (TNF – α) in children with food protein induced enterocolitis syndrome. It was examined 38 patients with FPIES at the age from 4 months to 3 years, the average age was 19 ± 4 months. The control group consisted of 11 healthy children of the same age. The determination of TGF-β1 and TNF-α in serum was performed by an enzyme immunoassay kits from Bender MedSystem (Austria).

Results: The level of TGF-β1 in patients with FPIES exceeded the norm and was respectively 33.5 ± 1.6 ng/ml, at norm 20.2 ± 2.1 ng/ml, p < 0.001. The indices of TNF-α were also increased and amounted to 8.8 ± 1.3 ng/ml in comparison with the control group, p < 0.001. For comparison, it was characterized by an increase in specific antibodies IgE to cow’s milk in 18 (47.3%) children. In these cases disease was more severely with vivid clinical manifestations (indomitable increase in specific antibodies IgE to cow’s milk in 18 (47.3%) children. It is likely that an increase in TNF-α level was significantly higher than in the control group, amounting to 42, 01 ± 7.5 ng/ml. TNF-α indicators were also increased: 11 ± 2.1 ng/ml.

Conclusion: It is believed that TGF – β1 promotes allergic inflammation, but in our observations its increase in its values was established, especially the case of children with high specific IgE levels to cow’s milk. It is likely that an increase in TGF – β1 stimulates the release of TNF – α, which supports chronic inflammation in allergic diseases.

Introduction: Newborns’ birth weight is influenced by maternal factors (mother’s weight at the onset of pregnancy, gestational weight gain - GWG), genetic, obstetrical and environmental factors, but also socio-economic ones. Excessive GWG, mother’s increased BMI and the adipose tissue mass determine a bigger birth weight and increase the risk of newborns’ obesity. Glutathione S-transferases (GSTs) is an oxidative stress-related gene which is associated with androst interactions.

Aims & Methods: The aim of the study was to investigate the role of mother-child GST1 and GSTM1 polymorphisms as independent risk factors for newborns’ weight, but also to establish correlations between these polymorphisms and anthropometrical parameters, and bioimpedance (BIA) ones, respectively. We assessed the anthropometrical parameters in both mothers and their newborns (BMI- body mass index, MUAC – medium upper arm circumference, TST – tricipital skin thickness, weight - W), BIA parameters in mothers, but we also determined the clinical, paraclinical and genetic parameters in both mothers and newborns.

Methods: We performed a cross-sectional study on 202 mothers and their newborns in a Clinic of Neonatology & Gynecology and Obstetrics from Romania. Results: We noticed that in newborns with W > 3000 gr there was a significant statistically correlation between weight and mother’s GST1 polymorphism (p = 0.046), birth at term (p < 0.001), with mother’s percentage of fat mass assessed by BIA (p < 0.001), and multi parity, respectively (p < 0.001). We obtained a tendency towards correlations between W > 3000 gr and basal metabolism rate (p = 0.086), and GWG seemed to be a protective factor for this W (p = 0.072). We also found that GSTM1 in newborns was a risk factor with tendency towards statistical significance in newborns with increased birth weight. We did not find any interaction effect between newborns’ and mothers’ GST1 polymorphisms and anthropometrical parameters (p = 0.545 for newborns’ clinical parameters).

Conclusion: Mother’s GSTM1 is an independent risk factor for newborns’ W > 3000 gr, while mother’s GWG seems to be a protective factor for W > 3000 gr. Further studies are needed in order to determine the clear role of the polymorphisms in newborns’ obesity risk. This research was supported by the Research Grants of the University of Medicine and Pharmacy Tirgu Mures, Romania - “The role of genetic determinism of the mother in child’s obesity correlated with measurements of bioimpedance and anthropometry” no.275/4/11.01.2017.

**Introduction:** Primary lactose intolerance (PLI) is a frequent condition caused by a genetically programmed and progressive loss of lactase expression. It is considered that PLI is the ancestral variant, while lactase persistence is caused by 2 polymorphisms: the dominant C/T13910 and G/A22018. Homozygotes (CC or GG) have undetectable lactase levels. In clinical practice only half of people with PLI have symptoms. However, some studies showed that PLI subjects have lower dairy intake.

**Aims & Methods:** To investigate whether genetical predisposition to PLI influences the quality of life and dairy intake in a group of Romanian children. We conducted a prospective study, recruiting consecutive children evaluated in our unit in May-August 2016. Our study population included 87 children aged 6–17 years (mean age 10.64 ± 3.51 years), 45 (51.72%) girls. We used strip genotyping to identify key genetic determinant to PLI. Subjects were asked to complete a validated quality of life questionnaire and a dairy intake questionnaire. We used Spearman's test to evaluate the correlation between IPL and quality of life and dairy intake.

**Results:** (51.7%) subjects had a CC genotype. 30 (34.5%) subjects had a GG genotype. Our results were consistent with Hardy-Weinberg equilibrium. We found no correlation between homozygosity for PLI and dairy intake (CC: r = 0.11, p = 0.34). There was evident tendency to be lower in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) (p = 0.049). However, ROC analysis showed poor discriminant power for FGF21 serum level in differentiation between more and less extensive steatosis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGF21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGF21 and omentin-1 mRNA levels (r = 0.73, p < 0.001). Fibrosis stage was associated with serum glucose and HOMA-IR (p = 0.03 and p = 0.02, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

**Conclusion:** In conclusion our study, which focused on hepatic FGF21 and omentin-1 mRNA expression, confirmed a marked expression of both molecules in the liver of morbidly obese patients with NAFLD. mRNA levels were affected by clinical and pathological abnormalities. More extent steatosis was associated with evident change in serum FGF21 concentration in morbidly obese women with NAFLD. The vast amount of fat, both visceral and subcutaneous in severely obese patients may affect FGF21 and omentin-1 serum levels. **Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0658 LOUREIRIN B INHIBITS THE PROLIFERATION OF HEPATOCYTE STELLATE CELLS VIA DOWN-REGULATING FRIZZLED-7**

Z. Dept. Of Gastroenterology, First Peoples Hospital, Kunming/China

Contact E-mail Address: song175@163.com

**Introduction:** Liver fibrosis is the result of repeated healing repair and interstitial reconstruction after chronic liver injury. Activation of hepatic stellate cells represents a critical event in fibrosis because these cells become the primary source of extracellular matrix in liver upon injury. Inhibiting HSCs' activation, proliferation, extracellular matrix production and promoting HSCs' apoptosis are the important therapeutic approaches of liver fibrosis.

**Aims & Methods:** We aimed to investigate the anti-liver fibrosis ability of lourierin B and the molecular mechanisms involved it. After hepatic stellate cells controlling liver fibrogenesis. Its role in a liver fibrosis scenario needs to be further investigated.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
(HSCs), which were separated from Sprague-Dawley rat, were treated with dif- fering concentrations of Loureirin B, MTX such of steatohapatitis.

HSCs proliferation, western blot were used to test the expressions of Frizzled-4 receptor protein and α-SMA. In addition, enzyme-linked immunosorbent assay (ELISA) was performed to measure the content of α-SMA, TGF-β1 and VEGF in the treated HSCs’ supernatant, and reverse-transcription PCR (RT-PCR) were utilized to detect the expressions of Frizzled-4 and α-SMA genes.

Results: MTX test showed that the proliferation of HSCs was inhibited significantly with a time and dose dependent relationship by the treatment of Loureirin B at 1.0 μM, and the inhibitory concentrations of 11.80±0.53 % (IC50 = 0.180±0.08 μg/mL). Western blot analysis showed that the expressions of Wnt receptor Frizzled-4 protein and α-SMA were obviously lower in the group of Loureirin B treatment than that in the control group. Moreover, the Loureirin B allele (GC/TG) 0.01, TGFβ1 (p = 0.05) secretion in the cultured HSCs’ supernatant in different degree by the ELISA assay, and RT-PCR results revealed that Loureirin B down-regulated the expressions of Frizzled-4 and α-SMA genes in the level of mRNA.

Conclusion: CONCLUSIONS: The Loureirin B mediated anti-hepatic fibrosis by inhibiting the proliferation of HSCs through restraining the Wnt signaling pathway.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Macrophages play a pivotal role in the pathogenesis of non-alco-
holic steatohepatitis (NASH) and are a major component of inflammatory cells
infiltrated in NASH. However, the precise mechanism by which macrophages contribute to the pathogenesis of NASH remains unexplored.

Aims & Methods: We aimed to characterize the role and molecular regulators of macrophages in NASH and the therapeutic effects of macrophage depletion on NASH. C57BL/6 wildtype (WT) mice and transgenic LysM-Cre:DTI mice were fed a high-fat diet and a high lipid diet for 5 weeks. The liver tissue was collected for RNASeq analysis. Hepatocytes were isolated from the liver by collagenase digestion and cultured with selected derivatives efficiently prevented FFA-induced cell death and lipid accumulation. Pre-incubation of HepG2 cells with BA derivatives co-incubated with oleic and palmitic acids (2:1) for assessment of cellular cytotoxicity and intracellular lipid accumulation.

Results: From the compound library, five BA derivatives showed stronger activation of FXR, similar with their natural precursors. Incubation of HepG2 cells with FAs led to a ~25% reduction in cell viability and ~55% increase in cell death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of cells with selected derivatives efficiently prevented FFA-induced cell death and lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse hepatocytes with BA derivatives strongly increased FXR, RXR, SHP, BSEP, FGFl9 and VLDLR mRNA levels, and repressed PARP1, LXR, SREBP1-c and CYP7a1 mRNA expression. Molecular docking studies and FXR reporter assays confirmed ligand affinity to FXR. Furthermore, chenodeoxycholic acid (CDCA) co-incubation and CYP-based derivatives were identified as activators of FXR at lower concentra-
tions comparing with the parent molecule.

Conclusion: In conclusion, we identified novel BA derivatives that directly mod-
ulate liver nuclear receptors, such as Fxr and Lxr, thus protecting liver cells from steatosis. Our results showed that CDCA co-incubation and CYP-based derivatives were identified as activators of Fxr at lower concentra-
tions comparing with the parent molecule.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is considered the hepa-
tic manifestation of metabolic syndrome, with simple liver steatosis being capable of gradually progressing to inflammation, fibrosis, cirrhosis and even hepatocellu-
lar carcinoma. Still, disease pathogenesis is complex and no targeted therapies have yet been approved for NAFLD. Bile acids (BAs) constitute a wide class of steroid molecules with pleiotropic functions, contributing to the homeostasis of lipids and glucose. In the liver, they specifically modulate nuclear receptors from the NRI subfamily, such as Farnesoid X Receptor (FXR) and Liver X Receptor (LXR), thus tightly regulating bile acid synthesis and oxidation and storage of triglycerides.

Aims & Methods: Our aim was to screen BA derivatives for their potential to selectively activate Fxr, thus protecting liver cells against free fatty acid (FFA)-
induced lipid accumulation and lipotoxicity. Nineteen novel BA derivatives were analyzed in silico molecular docking studies for Fxr and Lxr, and further evaluated in human cells using a FXR reporter assay. Assessment of Fxr-depend-
tent gene and protein expression was analyzed upon incubation of primary mouse hepatocytes and HepG2 cells with selected BA derivatives. In parallel, BA derivatives were co-incubated with oleic and palmitic acids (2:1) for assess-
ment of cellular cytotoxicity and intracellular lipid accumulation.

Results: From the compound library, five BA derivatives showed stronger activa-
tion of Fxr, with similar efficacy as their natural precursors. Incubation of HepG2 cells with FAs led to a ~25% reduction in cell viability and ~55% increase in cell death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of cells with selected derivatives efficiently prevented FFA-induced cell death and lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse hepatocytes with BA derivatives strongly increased FXR, RXR, SHP, BSEP, FGFl9 and VLDLR mRNA levels, and repressed PARP1, LXR, SREBP1-c and CYP7a1 mRNA expression. Molecular docking studies and FXR reporter assays confirmed ligand affinity to Fxr. Furthermore, chenodeoxycholic acid (CDCA) co-incubation and CYP-based derivatives were identified as activators of Fxr at lower concentra-
tions comparing with the parent molecule.

Conclusion: In conclusion, we identified novel BA derivatives that directly mod-
ulate liver nuclear receptors, such as Fxr and Lxr, thus protecting liver cells from steatosis. Our results showed that CDCA co-incubation and CYP-based derivatives were identified as activators of Fxr at lower concentra-
tions comparing with the parent molecule.

alone and in combination with 100 mM Bafilomycin and 2 mM Caffeine. RT-qPCR was performed and also real time fluorescence monitoring of HepG2 cells stably expressing ectopic MAP1LC3B-GFP-RFP-tag was performed with Incucyte.

**Results:** FLS-ob/ob mice, representing a NASH mouse model, showed an over-expression of the autophagy markers Becn1, Map1lc3b, Uvrag and Tfeb, Prkaa1_1 and Prkaa2_1 in comparison with FLS mice that represent the NAFL model. Furthermore, the protein level of Becn1 and Map1lc3b was down-regulated in FLS-ob/ob mice, whereas SQSTM and UVRAG were up-regulated. Interestingly, the phosphorylation of AMPK and AKT was found up-regulated in FLS-ob/ob mice, while FLS mice did not show a significant phosphorylation of P-AMPK. AMPK was found stably expressed in both FLS-ob/ob and FLS mice. HepG2 cells treated with oleic acid showed a down-regulation of Becn1, Map1lc3b, UVRAG and SQSTM2 proteins. AMPK and its phosphorylated form remained unvaried. Interestingly, Caffeine treatment caused a stronger reduction of autophagy markers, including the reduction of P-AMPK. The combination of Caffeine and oleic acid caused a stronger suppression of autophagy markers protein level. Bafilomycin caused a reduction of MAP1LC3B and UVRAG only. Its combination with OA caused a stronger reduction of protein level. HepG2 MAP1LC3B-GFP-RFP showed an increase of red fluorescence after 48 h of treatment with 2 mM OA.

**Conclusion:** Autophagy mechanism is significantly activated in FLS-ob/ob mice, leading to an increase of red fluorescence after 48 h of treatment with 2 mM OA.

**P0662 MODULATION OF MITOCHONDRIAL DYNAMICS BY MIRNAS IN NAFLD**

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) pathogenesis associates with intracellular lipid accumulation in the liver. In addition, recent evidence supports a functional role for both mitochondrial dysfunction and microRNAs (miRNA/miRs) in NAFLD pathogenesis. In particular, deregulation of mitochondrial dynamics proteins, like mitofusin-2 (Mfn2) is frequently observed in obese and diabetic patients.

**Aims & Methods:** Our aims were to profile global liver mRNA expression changes during NAFLD progression and correlate them with the development of liver steatohepatitis. Expression of mitochondrial and human NAFLD, C57BL6 mice were fed either a standard or a fast food (FF) diet for 25 weeks; or a methionine- and choline-deficient (MCD) diet for 2 and 8 weeks. miRNA profiling was performed using liver RNA from 8 weeks MCD-fed mice, in TqMan MicroRNA arrays. qPCR array data was analyzed using the HTqPCR package in Bioconductor. Liver biopsies were obtained from patients with simple steatosis or NAFLD. mRNA and protein expressions were analyzed by qRT-PCR and immunoblotting, respectively. miRNA targeting was evaluated by dual-luciferase reporter assays.

**Results:** Both FF- and MCD-fed mice developed NAFLD-like features, including liver steatosis, inflammation and insulin resistance; as well as progressive steatohepatitis, severe liver damage and fibrosis. Strikingly, liver Mfn2 protein levels significantly decreased in both models (p < 0.05). Inversely, expression of Drp1, a mitochondrial fission protein, was found increased (p < 0.05). Other mitochondrial proteins, such as the voltage-dependent anion channel (VDAC), presented no expression changes. In human patients, Mfn2 protein levels decreased from steatosis to NASH (p < 0.05). Microarray profiling indicated that liver miRNAs are significantly modulated during NAFLD progression. Specifically, 25 miRNAs were found significantly increased in the liver of MCD-fed mice, while, inversely, 27 miRNAs were decreased. Curiously, in silico analysis revealed that several of the up-regulated miRNAs could target Mfn2 in at least, one Mfn2 3’UTR binding site. Binding of miRNAs to Mfn-2, including mir-34a, was validated in HepG2 cells using a dual-luciferase reporter vector containing the Mfn2 3’UTR. Finally, overexpression of mir-34a in C212 muscle cells lead to Mfn2 inhibition and insulin resistance (p < 0.05).

**Conclusion:** In conclusion, mitochondrial dysfunction, particularly downregulation of Mfn2, plays a key role in human and experimental NAFLD and is targeted by miRNA/miRs such as mir-34a. A better understanding of the potential role of miRNAs targeting mitochondrial proteins during NAFLD may help in the development of novel targeted therapies for metabolic diseases associated with mitochondrial dysfunctions. (Supported by PTDC/BIM-MEC/0989/2014, STREP-651404/2010, FCT, PT and Gilead Sciences International Research Scholars Program 2015).

mononuclear layer containing stem cells is a novel approach for regeneration of liver cells. However, this therapeutic option is not currently approved and requires repeated PBMC transplantation.

Aims & Methods: To determine the outcome after intrasplenic or intrahepatic injection of autologous bone marrow stem cells (ABMSC) transplantation in patients with liver cell failure secondary to chronic hepatitis C infection. Sixty chronic hepatitis C patients with liver cell failure were prospectively enrolled. They were classified into 3 groups; group I: 20 patients underwent (ABMSC) injected intrasplenic. Group II: consisted of 20 patients underwent (ABMSC) injected intra hepatic (right portal branch). Group III: Control Group, consisted of 20 patients treated with their conventional medical therapy. The aim of this study was to determine how much impact the risk factors of metabolic syndrome has on ultrasoundographic fatty liver, especially NAFLD.

Results: Our study included 60 patients (78.33% males) with mean age ±SD (49.9 ± 6 years). Patients who had ABMSC injection showed improvement in clinical parameters as bleeding tendency, ascites, lower limb edema and hepatic encephalopathy. There was statistically significant improvement in serum albumin, ascites, lower limb edema and hepatic encephalopathy. There was improvement in serum albumin, ascites, lower limb edema, bleeding tendency and physical activity. Also there was improvement in MELD score and performance status. Additionally, there was recovery of platelets count. The improvement in biochemical parameters as bleeding tendency, ascites, lower limb edema and hepatic encephalopathy were expressed as percentage ratios. Statistical analysis was done by Wilcoxon signed-rank test using Statistica v.12 software. p value ≤ 0.05 was considered significant. Females gender (OR-1.78, p < 0.001) and unhealthy eating (p < 0.001) were associated with prevalent CO. Inadequate physical activity was not associated with either. 2137(72%) attended follow-up in 2014. Of those who were initially non-obese who attended follow-up, 189(64.9%) had developed GO (annual-incidence 2.27%, p < 0.001) and 206/947(21.9%) [56.3% women] had developed CO (annual incidence 3.12%) after 7 years. TBF and VFP significantly correlated with incident GO and CO (p < 0.001). Females gender (OR-1.8, p < 0.001; 2.81, p < 0.001) and NAFLD (OR-2.93, p < 0.001) independently predicted incident GO and CO respectively.

Conclusion: The prevalence and incidence of GO and CO were high in this cohort. Both incident GO and CO were associated with female gender and

Blood biochemical data in patients with alcoholic liver cirrhosis. However, effect of this therapeutic option is not currently approved and requires repeated PBMC transplantation.

Disclosure of Interest: All authors have declared no conflicts of interest.

In vitro, the proliferation of BPA-exposed HepG2 cells at two different concentrations (0.025 and 0.05 μM) was evaluated, both at high (H-HepG2), in order to simulate human hyperglycemia, and at low (L-HepG2) glucose concentrations, for better-replicating periporatorium conditions experienced by T2DM patients.

Results: BPA levels were significantly higher in 60 NAFLD subjects, both in urine and in plasma (p < 0.0001) if compared to controls and, among this group, it appeared to be higher in 30 non-alcoholic steatohepatitis (NASH) patients compared to 30 simple steatosis (NAFL) ones (p < 0.05), independently from the presence of T2DM. After following a BPA-free diet for one month, NAFLD patients showed a significant reduction of BPA circulating levels (p < 0.05) without a significant reduction of urine levels, which represents the only way to eliminate BPA amount released into circulation by the adipose BPA reservoir. In fact subjects with a higher fat percentage in body composition showed higher BPA levels in plasma and urine. In our population study, NASH patients showed a higher fat percentage in body composition in comparison to NAFL ones. Only H-HepG2 cells treated with the BPA amount released in urine showed higher proliferation compared to controls at 48 h (p < 0.0001). Moreover, BPA increased TBARS levels at 48 h in H-HepG2 cells versus controls.

Conclusion: Our study reveals a possible role of BPA as an environmental factor influencing the progression of NAFLD, particularly in obese and/or T2DM patients.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing disease worldwide. The pathogenesis of NAFLD is not well recognized. Thyroid is totally involved in regulation of lipid and carbohydrate metabolism, body weight, and energy homeostasis. Therefore, the role of thyroid hormones in pathogenesis of hepatic steatosis is anticipated.

Aims & Methods: This study aimed to investigate thyroid hormone abnormalities in euthyroid subjects with hepatic steatosis. A cross-sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy. In liver histology, liver histology was categorized into steatosis 2500C > T and a nontumor pretransplant checkup before living related liver transplantation. Liver function tests, age, gender, weight, height, fasting plasma glucose, thyroid hormones, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist for steatohepatitis and steatosis. Individuals with a history of chronic liver disease, hepatitis B or C infection, hepatitis-biliary cancers, those with >20 grams/day alcohol consumption, and individuals receiving medications causing hepatic steatosis were excluded from the study.

Results: A total of 210 individuals (130 women and 80 men) were included. Seventy six individuals (36.19 %) had hepatic steatosis and 19 individuals had hepatic steatosis were excluded from the study.

Introduction: In patients with morbid obesity, dietary treatment and physical activity are the first line of treatment, but if not responding, bariatric surgery is a properly validated alternative. The main surgical procedures are sleeve gastrectomy (SG) and gastric bypass (GBP), and they are chosen in function of BMI, age and comorbidity. Both techniques have proven effective in weight loss. It is known that liver fibrosis evaluation with Point Shear Wave Elastography (pSWE) is difficult in these patients.

Aims & Methods: To study the difference between SG and GB and their impact on main clinical and laboratory hepatic metabolic indicators and scores 6 and 12 months after the intervention and pSWE at 12 months. We studied 68 obese subject candidate to bariatric surgery (45 female, 23 male). 28 underwent GBP and 40 GB. Blood tests, physical examination were assessed before surgery, after 6 months (68 patients) and after 12 months (51 patients) and pSWE after 12 months.

Results: In the comparison between GBP vs SG there was a statistically significant difference in the reduction in Fatty Liver Index (61% vs 37%, p = 0.015), waist circumference (26% vs 18%, p = 0.045), BMI (34% vs 28%, p = 0.016), total cholesterol (23% vs 0.05%, p = 0.001), ALT (increased by 15% in GBP, decreased by 27% in SG, p = 0.023) while no differences were observed in the other indicators considered. Ferritin level increased (52%) in SG and decreased (25%) in GBP (p = 0.02). No difference was observed for pSWE.

Conclusion: This study showed some significant differences in clinical and laboratory terms between the two types of intervention, in fact GBP seems to have a more powerful effect on weight loss and all related markers: all steatosis scores (FLI, HSI, LAPI), BMI, waist circumference. This can be explained by better malabsorptive effect of this intervention and by a lower BMI starting point for reasons related to the intervention technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Glucosidase II is part of the functional pathway of co-translational protein translocation and maturation in the endoplasmic reticulum. It is implicated in autosomal dominant polycystic liver disease (ADPLD) and autosomal dominant polycystic kidney disease (ADPKD). The Φ-subunit of glucosidase II, encoded by PRKCSH, has been identified as one of the causative genes of ADPLD. Recent data suggest that the Φ-subunit of glucosidase II (ΦΓ), encoded by GANAB, is associated with ADPKD and ADPLD. We aimed to identify GANAB mutations in an independent cohort of patients with the primary phenotype of polycystic liver disease (PLD) and to predict the influence of these mutations on glucosidase II function.

Aims & Methods: We identified genetic mutations in GANAB using molecular inversion probe (MIP) analysis in a cohort of PLD patients. Both patients with ADPKD and ADPLD were included for analysis. Mutations identified with MIP analysis were validated using Sanger sequencing. Bioinformatics prediction tools (PolyPhen-2, Align GVGD, SIFT, MutationTaster) were used to predict the functional significance of the mutations. YASARA&WHAT IF were used for analysis of the structural effects of the mutations. Primary cholangiocytes obtained from a patient with GANAB mutation (c.2515C > T) were used to study loss of heterozygosity.

Results: We identified and validated 6 new bona fide GANAB mutations in 7 unrelated families. These are 2 frameshift (c.687delT and c.11_16delTAGGG), 1 splicing (c.2691-28C > G), 2 nonsense (c.2509C > T and c.11_16delTAGGG, and 1 missense (c.1835G > C) mutation. In silico analysis showed c.687delT and c.11_16delTAGGG are located in N-terminal domain of the protein. These mutations probably lead to a total defective protein, c.1835G > C is located in the active site of the protein. It is predicted to disrupt the composition of the active site and reduce enzymatic activity. The remaining mutations (c.2691-28C > G, c.2509C > T) are located in catalytic C-terminal domain, which interacts with PRKCSH. The mutations could result in early termination of this domain. It is speculated this disrupts the ability of the two subunits to interact. Western Blot showed no differences in Glhase expression in an ADPKD patient with GANAB mutation c.2515C > T compared to primary cholangiocytes obtained from a patient without PLD. This indicates in this patient no loss of heterozygosity occurs in cholangiocytes lining the hepatic cysts.

Conclusion: We describe six novel GANAB mutations that can cause PLD in a mixed population of ADPKD and ADPLD patients. These mutations are found in functionally important domains of Φ-subunit of glucosidase II, which may lead to impaired enzymatic activity of the complex. In contrast to other PLD related genes no loss of heterozygosity was found for GANAB in cyst epithelium.

References
J Clin Endocrinol Metab 2016;101(8):3204–11

Aims & Methods: We included 95 patients with NAFLD, from which 53 were with MS and 42 without MS.

Results: Out of a total 1674 patients in the PLD registry, 1222 patients (1110 ADPKD, 112 ADPLD) could be selected. In the ADPKD group, height adjusted total liver volume was measured prior to liver reducing therapy. Liver reducing therapy was typically reported using semi-quantitative scores. Inter- and intra-observer variability in the current scoring systems may impact upon histological staging, and consequently upon the interpretation of responses to interventions in clinical trials.

Conclusion: We developed an automated method for steatosis and fibrosis quantification using biopsies of NAFLD patients. We further validated Liver Stiffness Measurements (LSM) and controlled attenuation parameter (CAP) in this group, using quantitative assessment as reference. 246 consecutive patients with biopsy-confirmed NAFLD and transient elastography within 3 months of the biopsy were evaluated. Biopsies were independently scored by two histopathologists and digitalised at 2x magnification. Areas of steatosis and fibrosis were annotated manually using the NDP.view2 to facilitate machine learning. Each image was then analysed by the automated software: fat percentage (fat%) and collagen Proportionate Area (CPA) computed by the software were compared with the manual annotation. They were also correlated with LSM and CAP.

Introduction: Today, non-alcoholic fatty liver disease (NAFLD) is the most prevalent form of liver disease and it is an increasingly frequent cause of cirrhosis. Although several factors have been associated with the disease, the biological basis of the histological diversity of severity of NAFLD remains unknown. Several relatively noninvasive parameters have been identified as predictive for advanced fibrosis stage in patients with NAFLD, but none of them has sufficient sensitivity or specificity to replace liver biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Today, non-alcoholic fatty liver disease (NAFLD) is the most prevalent form of liver disease and it is an increasingly frequent cause of cirrhosis. Although several factors have been associated with the disease, the biological basis of the histological diversity of severity of NAFLD remains unknown. Several relatively noninvasive parameters have been identified as predictive for advanced fibrosis stage in patients with NAFLD, but none of them has sufficient sensitivity or specificity to replace liver biopsy.
Aims & Methods: Aim of our study was to compare two non-invasive methods: fibrosis score on serum markers and transient elastography (TE). We included 152 patients with NAFLD, 40 males (26.31%) and 112 females with age from 23 to 79 years.35 patients (23.02%) were overweight, 9 patients had normal weight and 24 (15.79%) had severe obesity. In all patients we calculated BMI and fibrosis scores: BARD, FIB-4 and NAFLD FIBrosis score (NAFLD-FS). Blood samples were collected to determinate aminotransferases, glucose, albumin level, platelet count. The abdominal ultrasonography was performed by the same physician and steatosis was graded using a semi-quantitative scale from 0 to 3. TE was also performed by a single physician using conventional M probe or XL probe, with 10 valid acquisitions. We considered significant fibrosis (F2) when estimated cutoff of F2 was 7.1 kPa, severe fibrosis (F3) when cutoff value was 9.5 kPa, and cirrhosis (F4) with cutoff value conventional M probe or XL probe, with 10 valid acquisitions. We considered significant fibrosis (F2) when cutoff value was 9.5 kPa, and cirrhosis (F4) with cutoff value 10.09 kPa.

Results: 86.84% patients had metabolic syndrome and 51.31% had diabetes mellitus.40 patients had mild steatosis, 59 had moderate and 53 had severe steatosis. After we performed TE 69.07% of patients had no significant fibrosis, 14.47% had F2, 9.86% had F3 and 7.23% had F4. The area under the receiver-operating characteristic curve (AUROC) of TE was 0.823 (95%, 0.252–0.394) (p < 0.0001). Sensibility and specificity for cutoff 7.1 kPa was 0.74 respectively 0.79 to exclude significant fibrosis. NAFLD-FS correlated statistically significant with TE (p < 0.0001); BARD score did not correlate with TE and NAFLD-FS for significant fibrosis FIB-4 correlated with TE for high degree fibrosis (p = 0.004).

Conclusion: NAFLD-FS, FIB-4 and TE can be used together to evaluate the progression of fibrosis in NAFLD and to select the patients for liver biopsy. In our study BARD score was not useful in detection of high degree fibrosis.

P0678 EFFECTS OF UDCA AND STATIN COMBINATIONS ON LIPID PROFILE IN NAFLD PATIENTS
S. S. Vyalov
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svialov@mail.ru

Introduction: Dyslipidemia has an important role in NAFLD and inflammation progress and insulin resistance development. The studies suggested the role of UDCA in lipid profile correction. UDCA replaced bile acid balance and improved triglyceride and cholesterol levels in NAFLD patients, has immunomodulatory action.

Aims & Methods: The aim of study was estimation of the efficacy of different dosage of ursoodeoxycholic acid (UDCA) with statin combination treatment in patients with NASH and NAFLD. There are 180 patients with NAFLD. It was divided into two subgroups: fatty liver (90 subjects) – patients with normal level of ALT, and nonalcoholic steatohepatitis (NASH, 90 subjects) – patients with elevated level of ALT (the median is 78.5 U/l). All patients were divided in 3 groups. The blood test, liver enzymes, lipid profile, HOMA-IR, Fibroscan and stool test was checked every 2 weeks of treatment. First group was taken UDCA 10 mg/kg/day + Statin. Second group was taken UDCA 15 mg/kg/day + Statin. Third group was fed the low-liquid and low-glucose diet index only (900 kcal/day). After 1 months of treatment patients of third group (diet only) add UDCA 15 mg/kg/day to treatment for 3 months.

Results: The subgroups did not show any difference in terms of initial total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and triglycerides (TG). Analysis of the lipid spectrum showed a more intense dynamics in the group of patients taken UDCA combined with statin. After 3 months of follow-up there was a significant reduction in TC to 4.2 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the fatty liver subgroup, and TC to 4.1 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the NASH subgroup. Changes were similar in the subgroups. The level of total cholesterol, triglyceride and liver enzymes were decreased faster in group taken UDCA and statin independent from UDCA dosage. There are no side effects or liver enzyme elevation in group treated with UDCA and statins. In the NASH subgroup there was a significant decrease in ALT to 35 U/l. At the end of the first month of statin therapy combined with UDCA in the NASH subgroup a significant positive dynamics of ALT was found in patients with NASH (initially 78.5 U/l; after treatment decrease to 38.5 U/l). Stage of liver fibrosis was significant in patients taken UDCA and statin, as evidenced by the decrease in the index of fibrosis.

Conclusion: 3-month statin therapy in combination with UDCA showed significant lipid-lowering effects in patients with NAFLD, as well as normalization of ALT. In the first 2 weeks, the NASH subgroup had shown a decrease in both ALT and TS. The NASH subgroup had a significant decrease in ALT and in the index of fibrosis.

P0679 EFFECT OF GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF) ON MORTALITY AND COMPLICATIONS VIZ. SEPSIS, ENCEPHALOPATHY, HEPATORENAL SYNDROME AND GASTROINTESTINAL BLEED IN SEVERE ALCOHOLIC HEPATITIS: A RANDOMIZED CONTROLLED STUDY
A. Sharma
Gastroenterology And Hepatology, Fortis Escorts Hospital Jaipur, Jaipur/India

Contact E-mail Address: abhinav_11005@yahoo.com

Introduction: Severe alcoholic hepatitis has very high short-term mortality. Compared to standard medical therapy (SMT), GCSF improves clinical and biochemical profiles, morbidity and mortality in these patients. We evaluated efficacy of G-CSF in modulating the disease course of severe alcoholic hepatitis over period of 3 months in terms of mortality, morbidity by Discriminant function (mDF), Child–Turcotte–Pugh (CTP) and Model for End-Stage Liver Disease (MELD) scores and various complications viz. sepsis, GI bleed, encephalopathy, hepatorenal syndrome (HRS) in comparison to SMT. We also studied the mobilising effect of GCSF on bone marrow stem cells measured by CD34+ cells from peripheral blood.

Aims & Methods: The present study was performed to evaluate the safety and efficacy of GCSF on mortality and complications viz. sepsis, encephalopathy, hepatorenal syndrome (HRS) and gastrointestinal bleed (GI Bleed) and also to investigate whether G-CSF therapy could improve the indices of severity of liver disease, such as Discriminant function (mDF), Child–Turcotte–Pugh (CTP), Model for End-Stage Liver Disease (MELD) score in patients with severe alcoholic hepatitis. 50 patients with severe alcoholic hepatitis were randomly assigned to groups A and B (25 in each). Both groups were given SMT, while in addition, patients in group A were given 5µg/kg GCSF subcutaneous (10 doses for 5 days).

Results: The baseline parameters in both groups were comparable. On day 6 group A had higher mean leucocyte and CD34 counts than group B (p < 0.0001). In 90 days follow up 17 patients in group A (68%) and 9 in group B (36%) survived (p = 0.04). Mean changes for different scores were greater in group A then group B i.e. CTP (−41.97% vs −8.84%), MELD (−50.89% vs 10.09%) and mDF (−74% vs 18%) (p < 0.001). The percentages of patients who developed HRS, HLN, or sepsis were lower in group A (28% vs 64%, 32% vs 64%, and 28% vs 68%, respectively) (p < 0.001). There was no significant difference in GI bleed in both groups.

Conclusion: In severe alcoholic hepatitis, GCSF therapy significantly improves the survival. It also significantly reduces CTP, MELD and mDF scores and prevents the development of complications.

Contact E-mail Address: ruiolpessagasp@gmail.com

Introduction: Steatosis/steatohepatitis is one of the most common liver diseases with increasing prevalence and results from excessive alcohol consumption (alcoholic liver disease) or nonalcoholic fatty liver disease (NAFLD). The differential diagnosis is of paramount importance as they have different management and therapeutic approaches, being liver biopsy the gold standard for establishing the diagnosis. The distinction between these two entities without biopsy is...
difficult due to the unreliable history of alcohol consumption and lack of sensi-
tivity of a single marker. In order to overcome these difficulties, a ANI (alcoholic liver disease/nonalcoholic fatty liver disease index) was created for a non-invasive determination of fatty liver diagnosis.

Aims & Methods: The aim of this study was to evaluate the reliability of ANI as a non-invasive diagnostic tool. A retrospective study between 2010 and 2015 in patients with definite diagnosis of NAFLD and ALD based on clinical, biochemical and histological criteria was performed. ANI scoring system in the differentiation of ALD and NAFLD was evaluated through the area under receiver operating curve (AUROC). ANI score was calculated through Mayo Clinic formula.

Results: This study was carried out in 22 patients with ALD and 120 with NAFLD, 87 men (61.3%) with a median age of 51 ± 13 years. NAFLD patients presented a body mass index (BMI) of 29.0 ± 5.9 vs 23.9 ± 6 in ALD. ANI showed a sensitivity of 81% and specificity of 79% for the diagnosis of ALD with a cut-off value of −1.96 [AUROC 0.806 (0.715–0.898), p < 0.001]. ANI greater than −1.96 indicates a diagnosis of ALD whereas ANI less than −1.96 indicates a diagnosis of NAFLD.

Conclusion: ANI scoring system is a non-invasive diagnostic and reliable tool that may be used to distinguish NAFLD from ALD, decreasing the need for liver biopsy. ANI greater than −1.96 suggests the diagnosis of ALD and ANI lesser than −1.96 suggest NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:

the CTCAE scale was used. Overweight was detected in 40 patients: BMI = 25–29.9 – in 29 (34.5%), BMI ≥ 30 – in 11 (13.1%) patients. Depending on overweight presence the patients were divided into 2 groups: I (n = 44) – patients with AL with normal body weight, II (n = 40) – patients with AL and overweight.

**Results:** In AL patients of group I before the start of chemotherapy functional liver dysfunction was not significantly different from healthy people. In group II there was an increase of ALT activity in 1.5 times, AST – in 1.2 times, ALP and GGT in 1.4 times compared to the norm (p < 0.05) and reached grade I level, and no change in bilirubin and total protein levels. On the 28th day of treatment in 3 (6.8%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 1.5 times, AST – in 1.2 times, ALP – in 1.3 times, GGT – in 1.5 times compared to normal levels, that consistent with grade I level, the bilirubin and total protein levels remained in the normal range. In group II the hepatocytotoxicity was detected in 19 (47.5%), which was characterized by the increased activity of ALT and AST in 2.3 and in 2.2 times respectively, GGT and ALP in 1.9 and 2.4 times respectively, the level of total bilirubin increased in 2.1 times (p < 0.05), of which in 17 (42.5%) patients hepatopathy of grade I and in 2 (5%) – of grade II level, with no statistically significant changes in protein synthesis liver function. On the 56th day of treatment in 7 (15.9%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 1.8 times, AST – in 1.3 times, ALP – in 1.6 times, GGT – in 1.9 times compared to normal levels, the bilirubin and total protein levels remained in the normal range, that consistent with grade I level. In group II hepatotoxicity was detected in 26 (65%), which was characterized by the increased activity of ALT and AST in 2.6 and in 2.3 times respectively, GGT and ALP in 2.6 and 3.7 times respectively, the level of total bilirubin increased in 3.6 times (p < 0.05), of which in 10 (25%) patients hepatotoxic reactions were of grade I and in 16 (40%) – of grade II level.

**Conclusion:** The presence of the overweight results in a significant increase in the frequency and degree of hepatotoxic reactions in patients with AL during chemotherapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Severe alcoholic hepatitis (SAH) remains a condition which bears high mortality and morbidity rates, as well as high healthcare costs. This is why adequate selection of patients who would benefit the most from corticotherapy is of utmost importance. Although serum biomarkers are available (Maddrey Discriminant Function - MDF), the diagnostic of SAH relies on liver biopsy. Previous metabolic studies have shown a core metabolic phenotype represented by decreased serum lysophosphatidylcholines (LPC) and increased serum bile acids that occurs relatively early in liver diseases regardless of etiology, and remains stable in their evolution, including liver cirrhosis and hepatocellular carcinoma (1). Our previous work also showed that decreased LPC levels are associated with alcoholic liver disease (ALD).

Aims & Methods: The aim of the study was to assess the metabolic profile of patients with ALD and to identify potential new biomarkers associated with severity. Between December 2015 and September 2016, 64 patients with biopsy proven AH were included (38 with SAH - MDF ≥ 32 and 24 with non-severe AH - MDF < 32). Fasting serum was stored at −80 degrees after centrifugation at 5000 rpm for 10 minutes. Specific purification protocol metabolic analysis was performed using Thermo Scientific UHPLC UltiMate 3000 system, equipped with a Dionex quaternary pump delivery system and a Bruker Daltonics MaXis Impact MS detection equipment (version 2012). Biostatistical analysis The chromatograms obtained were processed using CompassDataAnalysis_4.2 software (Bruker, Germany) and about 3000–4000 molecular masses were identified. Those data were further processed using ProfileAnalysis (Bruker, Daltonics): time alignment, normalization by sum of bucket values in analysis, 80% bucket filter, internal recalibration, etc. The matrix obtained was further processed by MetaboAnalysis, to analyze samples through univariate and multivariate statistical analysis. Results: Univariate and multivariate statistical analysis by MetaboAnalysis identified 10 potential biomarkers. Among them, LPC (18:0) showed good discrimination for SAH (AUROC = 0.804) with significantly lower values as compared with non-severe AH (0.38 fold change, p = 6 × 10−11).

Conclusion: SAH appears to have a different metabolic profile, mainly due to changes in lysophosphatidylcholine metabolism. Targeted metabolic studies are required in order to confirm the results and to evaluate the possible applications in current clinical practice.

P0688 APPLICATION OF THE ICA-AKI CRITERIA IN THE DIAGNOSIS OF ACUTE KIDNEY INJURY IN PATIENTS WITH ACUTE DECOMPENSATION OF CIRRHOSIS

R. Azevedo, J. Pinto, H. Ribeiro, F. Pereira, C. Leitão, A. Caldeira, E. Pereira, R. Sousa, A. Banhudo
Gastroenterology, Amato Lisboa Hospital, Castelo Branco/Portugal
Contact E-Mail Address: richardazevedo13@gmail.com

Introduction: Acute kidney injury (AKI) is a common complication in patients with decompensated liver cirrhosis. Recently, the International Club of Ascites (ICA) defined new diagnostic criteria: the ICA-AKI criteria.

Aims & Methods: This study aims to identify patients hospitalized for acute decompensation of cirrhosis with AKI, according to the ICA-AKI criteria, and to determine if its application leads to a greater prognostic accuracy and a better identification of outcomes.

Methods: Retrospective analysis of hospitalized patients in a gastroenterology department for acute decompensation of cirrhosis, without acute-on-chronic liver failure, between January 2014 and December 2015. Identification of AKI patients was based on ICA-AKI criteria. Data collected: severity of liver disease and in-hospital and short-term mortality among patients with and without AKI. Compared the accuracy of the conventional criteria vs. ICA-AKI criteria in the prediction of mortality.

Results: 161 patients included, 85.7% male, mean age of 65 ± 10.8 years. Average length of stay of 11.6 ± 9.5 days. 39.8% of patients had AKI on admission or during hospitalization according to the ICA-AKI criteria (60.9% in stage 1, 20.3% in stage 2 and 18.8% in stage 3). Patients with AKI according to ICA-AKI had longer hospitalizations (14.55 ± 9.7 days, p < 0.05), higher severity of hepatic disease quantified by the MELD and MELD-Na scores (17.62 ± 12.83 vs. 10.05 ± 0.05) and higher in-hospital, 28 and 90-day mortality compared to patients without AKI (33.4 vs. 6.2% vs. 9.3%, p < 0.05, 42.9 vs. 23.7%, p < 0.05). There was a statistically significant association between the presence of infection and the development of AKI (p < 0.05). The ICA-AKI area under the curve (AUC) to predict in-hospital, 28 and 90-day mortality was significantly higher than the AUC of conventional criteria (0.682 vs 0.533; 0.678 vs. 0.588; 0.618 vs. 0.509, p < 0.05).

Conclusion: The ICA-AKI criteria allow the identification of decompensated cirrhotic patients in whom a worse prognosis is predicted. Thus, they constitute a useful tool in daily clinical practice.

P0689 NESTED CASE-CONTROL STUDY FOR RISK FACTORS OF HEPATIC ENCEPHALOPATHY IN PATIENTS WITH LIVER CIRRHOSIS

L.T.E. Yuan1, S. Chua2, S. Yang3, C. Liang2, C. Wu2, W. Tai1, T. Hung1, S. Nguang4, J. Wang5, K. Tseng6, M. Ku7, P. Hsu8, D. Wu5, C. Hsu9

Introduction: The pathophysiology of hepatic encephalopathy is not fully understood. A nationwide nested case-control study was conducted to investigate risk factors in the development of hepatic encephalopathy (HE) among patients with liver cirrhosis (LC) in Taiwan.

Aims & Methods: A total of 913 patients with incident HE and 3499 patients without HE (control) were identified from a cohort of liver cirrhosis (n = 14,428) using the population-based, Longitudinal Health Insurance Database 2000 in 1997–2012. Controls were matched to case patients on age at LC diagnosis (< ± 2 years), sex, Charlson Comorbidity index score, year of LC and follow-up time at 1:1 ratio. A multivariate logistic regression model for HE was developed to explore the relative contribution of various risk factors, including patient demographics, infections, cirrhosis-related complications (hepato cellular carcinoma, spontaneous bacterial peritonitis, H. pylori therapy, bleeding ulcer and bleeding).

Contact E-Mail Address: emyuany@hotmail.com

Results: 714 cases of HE and matched to 714 controls were enrolled in the analysis. Infections (adj. OR, 3.41; 95% CI, 2.7–4.31; p < 0.001) and frequency of infection yearly (≥3 days/adj. OR 11.26, 95% CI, 5.7–22.2); 1–3: adj. OR 2.82, 95% CI, 2.26–3.53) were significantly associated with increased risk of HE. H. pylori infection (13.31% vs. 8.68%, p = 0.0052) and sites of infections such as pneumonia (14.99% vs. 10.50%, p = 0.0011), peritonitis (14.29% vs 2.52%, p < 0.0001), sepsis (25.63% vs. 9.52%, p < 0.0001), biliary tract infection (7.14% vs. 3.22%, p = 0.0008) and cellulitis (11.62% vs. 3.98%, p = 0.0207) increased risk for HE. HE (adj. HR, 0.90, 95% CI, 0.76–1.06, p = 0.02) and infections (adj. HR, 1.13, 95% CI 0.93–1.38, p = 0.23) increased hazards of death but did not reach statistical significance.

Conclusion: This is the first reported case-control study of HE in Taiwan. The study provides further evidence that infections are strongly associated with HE development in cirrhotic patients, and that the hospital site and severity of infection can provide useful data to identify relative frequencies and sites of infections. These data provide important information relevant to the prevention and management of cirrhotic patients at risk for HE.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
predictors of in-hospital mortality. Patients with Sepsis-3 had higher incidence of acute kidney injury (36 vs. 11%) and hypothermia (17% vs. 2%), septic shock (15 vs. 0%), p < 0.001) and transfer to the ICU (16 vs 2%; p = 0.001) than those without Sepsis-3. Similar findings were found for qSOFA.

Conclusion: Sepsis-3 criteria are more accurate than SIRS criteria in predicting the severity of infections in patients with cirrhosis. qSOFA is a useful bedside tool to assess risk for worse outcomes in these patients. Patients with Sepsis-3 and positive qSOFA deserve more intensive management and strict surveillance.

P0691 A SUBCLINICAL HIGH TRICUSPID REGURGITATION PRESSURE GRADIENT IS A RISK FACTOR FOR SURVIVAL AFTER LIVING DONOR LIVER TRANSPLANTATION
Gastroenterology And Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan/Japan
Contact E-mail Address: at841205@gmail.com

Introduction: Portopulmonary hypertension (PHOP) is characterized by pulmonary vasconstriction, while hepatopulmonary syndrome (HPS) is characterized by vasodilation. Given that HPS could be resolved after orthotopic liver transplantation (OLT) even when hypoxemia were severe (PaO2 < 80 mmHg), implications for OLT is accepted not only for deceased donor LT (DDLT), but also to living donor related LT (LDLT). However, the post-OLT course of POFH complicated patients are often unsatisfactory and severe (mPAP > 45 to 50 mmHg) patients are considered as an absolute contraindication for OLT. The International Liver Transplantation Society Practice Guidelines indicate that, unlike HPS, there are no data to support the concept that POFH (treated or untreated) should be an indication for OLT. Furthermore, the Practice Guidelines recommend that patients with mPAP < 35 mmHg be indicated for OLT, and PA-targeted therapy should be initiated in patients with mPAP>35 mmHg. However, almost all of the patients in these articles had received DDLT, and no such analyses have been for LDLT patients. Given that left or right lobe LDLT grafts are smaller than DDLT grafts, PH-induced hepatic venous pressure may result in a strong congestive impact on the LDLT grafted liver. Although patients with confirmed PHOP and HPS are rare, relatively pulmonary hypertensive patients and mild HPS patients may be more common.

Aims & Methods: The present objective is to investigate the clinical impact of subclinical PH on the inevitably small survival in grafted living donor OLT (LDLT). We recruited 84 OLT candidates for liver cirrhosis in a retrospective cohort study. Patients exhibiting a tricuspid regurgitation pressure gradient (TRPG) >25 mmHg (median) on echocardiography were categorized as poten- tially having PH (subclinical PH; n = 34), and the mean pulmonary artery pressure (mPAP) measured after general anesthesi with FIO2 0.6 (mPAP-FIO20.6) was also also included as advisory data. Patients exhibiting O2 < 80 mmHg and an alveolar-arterial oxygen gradient (AaDO2) >25 mmHg were categorized as potentially having subclinical HPS. The clinical course after LDLT was investigated according to subclinical PH or HPS.

Results: Subclinical PH was correlated with a worse 1-year survival (p = 0.003). Severe PH (New York Heart Association: IV) and older donor age (p = 0.008) were correlated with a poor 40-month survival. Although a higher mPAP-FIO20.6 was expected to correlate with a worse survival, a high mPAP-FIO20.6 was not a significant risk factor for the post-LDLT survival. When the post-LDLT survival was inves- tigated according to the TRPG and mPAP-FIO20.6 status, it was worst in patients who had a high TRPG and low mPAP-FIO20.6. The patients with a high mPAP-FIO20.6 and low TRPG showed a good survival, probably because co-existing HPS released the regurgitation pressure.

Conclusion: In cirrhosis patients, mPAP-FIO20.6 may not accurately reflect the congestive pressure to the liver, as the pressure might escape via a pulmonary shunt. Subclinical high TRPG is an important marker for predicting congestive pressure to a grafted small liver, resulting in a worse survival after LDLT.

Contact E-mail Address: gilda_iri25@yahoo.com

Introduction: Portal vein thrombosis (PVT) is recognized as an independent factor of variceal bleeding. Beta blockers are the mainstay treatment to prevent variceal bleeding in cirrhotic patients. Carvedilol has been shown to be equal to propranolol in preventing first bleeding in cirrhotic patients, however, the efficacy of this policy in patients with PVT is unknown.

Aims & Methods: The aim of this study was to evaluate the efficacy of carvedilol versus propranolol as primary prophylaxis of variceal bleeding in cirrhotic patients with occlusive portal vein thrombosis. Between January 2014 and December 2015, cirrhotic patients with occlusive non-malignant PVT were enrolled in a tertiary center. PVT was suspected by Doppler ultrasound and confirmed by computed tomography. Cirrhotic patients with esophageal varices and no previous variceal bleeding were randomized to carvedilol 6.125 mg daily or Propranolol 40 mg daily. End points were esophageal variceal bleeding or death.

Results: During the study period forty eight patients were evaluated. Twenty one and twenty seven patients were randomized in carvedilol and propranolol arms respectively. Mean age was 49 ± 12.2 years; 33 (68.7%) were males; 60.4% had viral cirrhosis; mean Child-Pugh score was 7.2 ± 2.6 and mean follow up was 12.3 ± 9.1 months (range 1-25 months). All the patients had exclusive non-malignant PVT, most of them involving only the trunk, and grade 2 or 3 esophageal varices. Both carvedilol and propranolol groups had comparable variceal bleeding rates (14.2% vs. 14.8%, P = 0.062), bled related mortality (9.5% vs. 11.1%, P = 0.027) and overall mortality (23.8% vs. 22.5%, P = 0.044) respectively. Adverse events in carvedilol group were hypotension (n = 2), requiring cessation of therapy, while and dyspnea (n = 3) resolved spontaneously. In the propranolol group there was 1 adverse event that required discontinuation of treatment (grade 2 intraventricular block).

Conclusion: Our study suggests that carvedilol is probably not superior to pro- pranolol in preventing first variceal bleeding in cirrhotic patients with occlusive PVT, and they both can be used as primary prophylaxis.

3School Of Medicine, University Of Minho, Life and Health Sciences Research Institute, Braga/Guimarães/Portugal
Contact E-mail Address: smaxavier@gmail.com

Introduction: The ALBI score was recently developed to assess the severity of liver dysfunction, taking into account albumin and bilirubin levels. We aimed to assess its prognostic performance in patients with liver cirrhosis complicated with upper gastrointestinal bleeding (UGIB) while comparing it with Child-Pugh (CP) and MELD scores.

Aims & Methods: Retrospective uncenter study, including consecutive adult patients with cirrhosis admitted for UGIB between January 2011 and November 2015. Clinical, analytical and endoscopic variables were assessed and ALBI, CP and MELD scores at admission were calculated. Statistical analysis was performed using SPSS v21.0 and MedCalc v16.4.3, and a two-tailed p value < 0.05 was defined as indicating statistical significance.

Results: Included 111 patients with a mean age of 57 ± 12 years, 76.6% were males. Liver cirrhosis was most frequently alcoholic (89.2%) and the most common cause was hepatitis C virus infection in 75.5% of patients. During the first 30 days of follow-up 12 patients (10.8%) died, and during the 1st year of follow-up another 10 patients died (1st year mortality of 19.8%). When comparing the three scores, regarding in-stay and 30 days mortality, only ALBI score showed statistical significant results, with an area under the curve (AUC) of 0.82 (p < 0.001) for both outcomes. Regarding 1st year mortality, AUC for ALBI, CP and MELD scores, were 0.71 (p < 0.01), 0.72 (p < 0.05) and 0.66 (p = 0.02), respectively. While for global mortality AUC were 0.75 (p < 0.01), 0.72 (p < 0.01) and 0.72 (p < 0.01), respectively. When comparing the AUC of the three scores, no significant differences were found regarding 1st year mortality and global mortality.

Conclusion: In our series, ALBI score accurately predicted both in-stay and 30 days mortality (AUC 0.82 (p < 0.01)), while CP and MELD scores weren’t able to predict these outcomes. All scores showed a fair prognostic prediction performance regarding 1st year and global mortality. These results suggest that ALBI score is particularly helpful in the assessment of short term outcomes, with a better performance than the most commonly used scores, and may assist the clinician in the stratification of care at admission and maybe even in the referral to liver transplant.

Introduction: Despite the progress in the treatment of cirrhosis, infections remain a common problem, being responsible for the great majority of morbidity and mortality in these patients.

Aims & Methods: The aim of this study was to identify predictive factors for infection in the first hospitalization for decompensated cirrhosis (DC).

Retrospective analysis of patients with the first hospitalization for DC between January of 2009 and March of 2016. Demographic, clinical and biochemical data was compared between patients with and without infection in the first hospitalization for DC.

Results: From the 175 patients with a first hospitalization for DC, 6% had ascites on admission, 45.8% had upper gastrointestinal bleeding, 38.5% had jaundice, and 28.5% had hepatic encephalopathy. Regarding medication, 29.6% of the patients were taking proton pump inhibitors (PPI), 22.3% had beta-blockers prescribed, and 1.7% were on prophylactic antibiotic. In those 53 patients with proven infection, spontaneous bacterial peritonitis was the most common infection (34%), followed by urinary tract infection (30.2%) and pneumonia (13.2%).

Among those with urinary tract infection, the indication for the use of these drugs should be strictly reviewed and their interruption considered in cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

CRITICAL FLICKER FREQUENCY TEST PREDICTS THE FIRST EPISODE OF OVERT HEPATIC ENCEPHALOPATHY IN PATIENTS WITH COMPENSATED LIVER CIRRHOSIS

Introduction: Critical flicker frequency (CFF) values ≤3 Hz identify cirrhotic patients with minimal hepatic encephalopathy (mHE) and predict their risk of developing overt hepatic encephalopathy (oHE). However, these results have been obtained in cirrhotics with advanced liver disease suffering a previous episode of liver decompensation (74% of patients) or oHE (14% of patients).

Aims & Methods: Herein, we evaluated the effectiveness of CFF in predicting the first episode of oHE in compensated outpatients undergoing a long-term follow-up. A total of 134 selected patients and 150 healthy subjects were evaluated using CFF.

Results: At baseline, we evaluated demographic characteristics, laboratory tests, model for end-stage liver disease (MELD) score, and Child-Pugh class in all patients. Then, they were followed up for 31.5 ± 18.9 months and received clinical examinations and laboratory tests every six months.

Results: At baseline, all controls had a CFF > 39 Hz with a mean value significantly higher than that observed in 93 patients with CFF > 39 Hz (p < 0.001), while the remaining 41 patients showed a CFF ≤39 Hz. Our analysis demonstrated a significant correlation between CFF and MELD score (r = -0.0003, p = 0.0003), while the prevalence of CFF values ≤39 Hz significantly increased with the progression of the Child-Pugh class (p = 0.003). Interestingly, the CFF value at baseline was predictive of the first episode of oHE both by log-rank test (p = 0.001) and Cox regression analysis (HR = 5.623; 95% CI = 2.433–12.991; p < 0.001).

Conclusion: We demonstrated, for the first time, that CFF predicts the first episode of oHE in a population of compensated cirrhotics that never experienced an HE attack. Cirrhotic patients should be routinely screened by CFF to identify patients at risk of oHE.

Introduction: The Fontan circulation causes some degree of hepatic congestion by its nature of anatomical reconstruction. This may lead to liver fibrosis or even cirrhosis, but to what extent is unknown. A profound hepatic evaluation, incorporating several non-invasive and invasive modalities, in an asymptomatic Fontan patient cohort may further elucidate this.

Aims & Methods: Consecutive patients with a Fontan circulation are prospectively included for screening of liver fibrosis. This screening consists of a blood panel including biomarkers, liver ultrasound, transient elastography (Fibroscan), contrast-enhanced liver MRI or CT-scan and liver biopsy. Liver biopsies were systematically scored with the Fontan specific fibrosis score. Mild fibrosis was defined as a maximum score of 2 of sinusoidal and portal fibrosis component, severe fibrosis as score 3 or 4 on at least one component. Non-invasive markers for portal hypertension (PHT) such as presence of collaterals and splenomegaly on imaging, platelet count (N/L mm³) spleen diameter (mm) ratio (PSR) and von Willebrand factor (VWF) were measured.

Results: From November 2015 until March 2017, 52 Fontan patients were included (mean age 27.5 ± 7.5 years, 60% male). The majority of patients had one or more elevated liver enzymes (elevated GGT in 68%, median 67 μmol/l IQR 51–107). Median platelets were 174 × 10^9/l (IQR 147–213) and mean VWF 104 ± 23%. Mean liver stiffness was 1.8 ± 0.45 kPa. The majority (77%) of ultra-sonographies showed no sign of cirrhosis or splenomegaly (mean spleen size 11.9 ± 1.8 cm). However, 54% of advanced imaging (MRI or CT-scan) showed cirrhosis, 23% congestion and in 21% signs of PHT were observed. Of 33 patients with histology, none were without fibrosis or sinusoidal dilatation and cirrhosis was present in 21%. Of these only 57% also showed signs of cirrhosis on imaging. Of all patients with signs of PHT on imaging only one (13%) patient had histologically confirmed cirrhosis whereas five (63%) had mild fibrosis. Liver stiffness was equal in patients with mild (22.3 ± 9.3 KPa). The majority (77%) of ultra-sonographies showed no sign of cirrhosis or splenomegaly on imaging. Of all patients with signs of PHT on imaging only one (13%) patient had histologically confirmed cirrhosis whereas five (63%) had mild fibrosis.

Conclusion: All Fontan patients are at risk of developing severe liver fibrosis, irrespective of age, duration of Fontan circulation and even when asymptomatic. Portal hypertension may occur in the absence of severe fibrosis. Assessment by solely non-invasive modalities may both under- and overestimate the incidence of fibrosis. For generalizability of the current findings, Fontan patients should be prospectively assessed with multimodality assessment in larger cohorts.

Introduction: Probiotics has been recently used to treat cirrhotic patients with any grade of acute or chronic hepatic encephalopathy (HE). Herein, we evaluated the efficacy of Lactobacillus Rhamnosus GG (LRG001) on the treatment of minimal HE (mHE) in compensated cirrhotics.

Aims & Methods: 134 patients were screened by critical flicker frequency (CFF) to diagnose mHE. Among them, 41 patients were CFF+ (≤39 Hz) and were
randomized to placebo or LRGG treatment, for 2 months. In all intention to treat analysis, 124 patients were evaluable for outcome analysis, 61 patients in the placebo group and 63 patients in the LRGG group. The primary end point was measured by the change in the mean CFF value from baseline to week 6. Results: The frequency of the C allele of TLR 7 rs3853839 polymorphism was significantly higher in both HCV spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.42 (95% CI 0.21 to 0.82, Pc < 0.0372) and OR 0.40 (95% CI 0.23 to 0.71, Pc < 0.0054)] respectively. The same results was also reported in the male subpopulation as the same allele was found to be significantly higher in both HCV spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.289 (95% CI 0.14 to 0.59, Pc < 0.0021) and OR 0.17 (95% CI 0.1009 to 0.28, Pc < 0.0001)] respectively.

Table(1): Association of the allele T of TLR3 rs3775291 polymorphism among the studied groups.

<table>
<thead>
<tr>
<th>Allele</th>
<th>SVC vs Control</th>
<th>SVC vs CHC</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>0.0234</td>
<td>0.0003</td>
</tr>
<tr>
<td>T</td>
<td>0.0078</td>
<td>0.0001</td>
</tr>
<tr>
<td>P</td>
<td>0.9306</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

Conclusion: The risk of development of chronic HCV infection was associated with T allele carriage of TLR3rs3775291 SNP. While the carriage of C allele of TLR3 rs3853839C allele was associated with spontaneous HCV clearance in both male and female subpopulations in Egyptian families.

Introduction: TH17 cells are involved in liver fibrosis by activating hepatic stellate cells (HSCs). We aimed to investigate whether HSCs could regulate the function of TH17 cells and the relevant mechanism.

Aims & Methods: Sixty-five patients diagnosed with chronic hepatitis B (CHB) were enrolled in this study. To unravel the effect of HSCs on T cells, naïve CD4+ T cells and TH17 cells were sorted from CHB patients and cultured with or without activated-HSCs, and cytokines expression and genes transcription were analyzed. In addition, the regulatory mechanism of HSCs was also investigated.

Results: ELISA and qRT-PCR showed that TH17 cells from CHB patients were more pathogenic via the expression of IL-17A, IL-23R, RORC, CCL20 and CCR6, and meanwhile, they could activate the primary HSCs. The co-culture experiment indicated that activated HSCs dramatically promoted the proliferation of CD4+ T cells in a time- and dose-dependent manner. In addition, they could also induce the naïve CD4+ T cells into TH17 cells which had a more pathogenic phenotype. Moreover, activated-HSCs-mediated induction of TH17 cells might depend on IL-1β and IL-6 release as well as COX-2/PGE2 pathway. Conclusion: TH17 cells cooperated with HSCs in a proinflammatory feedback loop provide us a more understanding of the pathogenic role of TH17 cells in the chronicity of HBV infection.

Introduction: Direct antiviral agents (DAAs) have led to high sustained virological responses (SVR) in HCV patients. However, genotype 3 patients respond to treatment in a suboptimal way.

Aims & Methods: This study aims to identify which of the several treatment schedules for genotype 3 would constitute the best option.

Results: Twenty-four Italian centers were involved in this real-life study where HCV genotype 3 patients treated with DAAs. To evaluate the number of cases, we conducted a systematic review of literature on the outcome of genotype 3 patients treated with DAAs.

Results: A total of 233 patients with HCV genotype 3 were enrolled. Cirrhotic patients accounted for 83.7%. Overall, the SVR12 rate was achieved by 205 subjects (88.0%); the SVR rates were 78.8% after sofosbuvir/ribavirin, 92.5% after sofosbuvir/daclatasvir and 100% after sofosbuvir/ledipasvir.

Conclusion: Our results reinforce the concept that HCV genotype 3 should not have more considerable difficulty to treat individuals. The optimal therapeutic regimens for these patients appears to be the combination sofosbuvir/daclatasvir, administered for 12 weeks without the use of RBV in non-cirrhotic patients.

virological response (SVR) [1]. However, the impact of DAAs on the occurrence of hepatocellular carcinoma (HCC) and HCC recurrence after curative hepatic resection of HCC has been recently discussed [2, 3], but remain unclear.

**Aims & Methods:** The clinical data of 97 patients who underwent curative hepatic resection for primary HCC with HCV at our department between January 2012 and March 2017 were reviewed to clarify the impact of DAAs on HCC occurrence and recurrence. SVR was defined as no detection of HCV RNA in the serum at 24 weeks after the cessation of antiviral therapy.

**Results:** SVR was achieved in 21 patients treated with interferon (IFN)-based regimens and in 21 with DAAs at hepatectomy. Between the two groups, there were no significant differences in the clinical characteristics, including the age, prevalence of diabetes mellitus, drinking history, preoperative liver function, operative procedures, tumor size and presence of liver cirrhosis, but the median duration from the date of SVR to the date of HCC incidence was significantly shorter in patients treated with DAAs (14 days, range: 123 to 235 days) than in those treated with IFN-based regimens (324 days, range: 33 to 4190 days). In particular, HCC was detected within 24 weeks after the cessation of antiviral therapy in 3 patients treated with DAAs. After hepatectomy, SVR was achieved in 21 (DAAs: 16 patients, IFN-based regimens: 5 patients) of the 67 patients without SVR when hepatectomy was performed, and the 1- and 3-year disease-free survival (DFS) rates were 93.3% and 83.0% in patients after SVR treated with DAAs and 90.9% and 71.8% in patients with IFN-based regimens (n = 26) and 57.8% and 19.7% in patients without SVR (n = 40), respectively, regardless of the timing of hepatectomy, respectively. The DFS rate was significantly higher in patients with SVR than in those without SVR (p < 0.001), but was not markedly different according to the antiviral treatments (p = 0.594).

**Conclusion:** While DAAs were able to reduce the DFS rate, the early occurrence of HCC in patients after SVR treated with DAAs is more frequent than that among patients treated with IFN-based regimens. Therefore, careful follow-up with imaging series is needed even for patients with SVR treated with DAAs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic hepatitis C infection is a systemic disease, one of the leading causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HRQoL) burden.

**Aims & Methods:** The aim of this study was to assess HRQoL, impairment of hepatitis C virus (HCV) infection among a broad sample of compensated HCV cirrhotic patients. We conducted a prospective study between January 1st 2016 to January 31, 2017, in a tertiary center, in which we included 110 patients with compensated HCV cirrhosis, aged between 50 and 75, with no history of neuropsychiatric illness but associated comorbidities (diabetes type 2, hypertension, dyslipidemia). The patients were completely evaluated according to the national protocol. Health status and fatigue of our patients were evaluated using the FACIT- F (version 4) and SF-36 survey. Respondents with HCV compensated cirrhosis were compared with a control group matched for age and sex with no prior history of HCV infection on the Mental (MCS) and Physical (PCS) Component Summary scores.

**Results:** Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACIT- F utility scores (43.2 ± 35.5 ± 0.05 vs 49.5 ± 5.5 vs 0.05). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.5% (7 patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs 49.72, p < 0.05). Control group registered higher PCS score (53.30 vs 45.2, P < 0.05) compared to the study group.

**Conclusion:** Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HRQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0708 EFFICACY AND SAFETY OF SOFOSBUVIR AND RIBAVIRIN IN HCV POSITIVE PATIENTS WITH RENAL IMPAIRMENT**

**M.O. T. Butt**

Gastroenterology And Liver Transplant, Shifa International Hospital, Islamabad, Islamabad/Pakistan

**Contact E-mail Address:** mosamabutt2016@gmail.com

**Introduction:** Hepatitis C virus infection is a leading cause of chronic liver disease affecting more than 170 million people worldwide. HCV infection in the setting of renal impairment is not uncommon. Despite the major developments in the treatment of HCV, treatment of this subgroup of patient with impaired renal function is still a challenge.

**Aims & Methods:** The aim of this study is determine the efficacy and safety of sofosbuvir and ribavirin in HCV positive patients with renal impairment. All consecutive patients of HCV related liver disease with creatinine clearance less than 50 ml/min were included in the study. Data was collected for tolerability, efficacy and on treatment adverse events. All the patients received Sofosbuvir and dose adjusted Ribavirin according of CrCl. Virological response was checked at 1 month (RVR), 3 months (EVR) and at the end of treatment.

**Results:** A total of 31 patients were included in the study were 31 out of which 17 (54.8%) were male. Mean age was 52.3 ± 17.6 years while the mean BMI was 25.0 ± 4.30 kg/m². 10 (32.3%) patient were on regular hemodialysis. 26 (83.9%) patients had CTP-A while 5 (16.1%) had CTP-B disease. Majority of the patients 22 (71%) were genotype 3 while 7 (22.6%) were genotype 1. 24 (77.4%) patients were treatment naïve, while those who were treatment experienced. 3 patients received each Interferon and Peg interferon therapy. Treatment was stopped in 2 (6.5%) patients because of disease decomposition while 3 (9.7%) were lost to follow up. ETR was achieved in 25 (86.1%) out of 26 patients who completed treatment. Similarly 12 (80 %) out of 15 patients have achieved SVR-12 so far. During the therapy 10 (32.3%) patients had adverse events, 6 (19.4%) suffered from depression while 4 (12.9 %) developed grade H anemia.

**Conclusion:** In resource constraint population where newer DAAs are not available combination of sofosbuvir and low-dose ribavirin in patients with renal impairment seems to be better tolerated and efficacious in terms of achieving the virological response.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0709 SOFOSBUVIR IN COMBINATION WITH RIBAVIRIN IN GENOTYPE 3 HEPATITIS C PATIENTS WITH CIRRHOSIS. AN EXPERIENCE FROM TERTIARY CARE HOSPITAL**

Gastroenterology Section, Medical Unit IV, Jinnah Postgraduate Medical Centre, Karachi Pakistan

**Contact E-mail Address:** draliaibbar12@gmail.com

**Introduction:** Hepatitis C virus (HCV) is the most common cause of cirrhosis in this part of the world. Advent of Directly acting antivirals (DAAs) like Sofosbuvir (SOF) has dramatized the treatment and is the corner stone in treatment of (HCV). Most trials have been conducted in HCV genotype 1 and data for Interferon free regimen in genotype 3 (GT-3) is limited especially in cirrhotics.

**Aims & Methods:** We aimed to evaluate the safety and efficacy of SOF plus Ribavirin (RIB) in patients with compensated and decompensated cirrhosis. This is a prospective real-world cohort study of HCV with compensated or decompensated cirrhosis. Efficacy was assessed by Sustained Viral Response after 6 months of completion of treatment. Adverse events were recorded on designed proforma on serial follow-up visits.

**Results:** The cohort consisted of 9 1consecutive patients out of which 41 were compensated cirrhotics and 50 had decompensated cirrhosis. The mean age was 53.4 ± 11years. Males were 9 (51.6%) and females were 44 (48.4%). Mean CTP and MELD score were 7.71 and 9.21 respectively. In compensated cirrhosis, SVR was achieved in 25 (84.%) treatment naïve patients compared to treatment experienced patients where 5 (80%) achieved SVR. In decompensated cirrhosis SVR was achieved in 22 (77.3%) treatment naïve patients, whereas 13 (76.9%) patients achieved SVR in treatment experienced group. In 72% patients with cirrhosis, there were no side effects whereas most common adverse event was fatigue and drop of Hemoglobin by 1.0 gm/dl. Furthermore, CTP and MELD scores decreased to 6.9 and 8.7 respectively after treatment.

**Conclusion:** Sofosbuvir in combination with Ribavirin in GT-3 HCV patients achieved good SVR in compensated cirrhosis than decompensated cirrhosis whereas fatigue and drop of Hb were the most common adverse effects.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: New direct-acting antivirals (DAA) have changed the management
of HCV infection by being effective in more than 90% of cases [1, 2].
Unfortunately, it has been reported an unexpected high rate of HCC early recurrence following DAA treatment, but more data are needed [3–5].
Aims & Methods: From a national prospective cohort, enrolling 3717 Romanian
patients with hepatitis C virus compensated liver cirrhosis who received reimbursed DAA with Paritaprevir/Ombitasvir/ritonavir, Dasabuvir and Ribavirin
(OBV/PTV/r þ DSV þ RBV) for 12 weeks, from December 2015 to August 2016,
we analyzed 21 patients with previous HCC. Most of them were treated through
surgical resection (9/21), followed by radiofrequency ablation (RFA) 6/21, transarterial chemoembolisation (TACE) 5/21 and only one percutaneous ethanol
injection (PEIT). The patients received DAA treatment only if they had no
cancer relapse 6 months after their last therapy session for HCC. All these
patients were evaluated through CT scan or MRI 3 to 6 months after having
finished their DAA therapy. The median follow-up is 6 months (3 12). Data
were obtained from the Romanian National Health Agency.
Results: Two female patients decompensated and died because of acute liver
failure (9.5%), the first one after having finished the 12 weeks therapy, and the
other one in week 7 of DAA therapy. This cohort was 52% females, median age
64 years (51 - 77), 76% IFN pre-treated, 50% associated NASH, 67% with severe
necroinflammatory activity (severity score 3 - Fibromax), 30% with co-morbidities, 24% with Child Pugh A6. The median MELD score was 9 (6 11). SVR
was reported in 19/21 as per protocol analysis (90.5%). Recurrence rate of HCC
was 29%, higher in males (40%) than females (18%), higher in patients treated
with TACE (40%) than in those with hepatic resection (33%), and the lowest risk
of recurrence was encountered in RFA (17%). These differences were not statistically significant because of the small sample size. The pattern of recurrence was:
intrahepatic growth (1 patient), new intrahepatic lesion (1 nodule in 2 patients,
up to 3 nodules less or equal to 3 cm in 1 case) and infiltrative ill-defined
hepatocellular carcinoma in 2 patients. We found no correlation between the
HCC-free interval of time and recurrence rate (p ¼ 0.62).
Conclusion: Early recurrence rate of HCC in treated patients with compensated
liver cirrhosis that received DAA with OBV/PTV/r þ DSV þ RBV was 29%,
significantly increased compared to the natural recurrence rate. This rate is
higher in males (40%) and in patients treated with TACE (40%).
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Shear wave elastography (SWE) has been used in clinical practice as
a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness.
Aims & Methods: The usefulness of SWE in the diagnosis of esophagogastric
varices (EGVs) associated with portal hypertension was evaluated. 550 patients
who underwent measurements of liver stiffness (LS), spleen stiffness (SS) and
EGV evaluation between January 2011 and July 2016 were included (no varices,
n ¼ 340; esophagus only, n ¼ 107; stomach only, n ¼ 14; esophagus and stomach,

n ¼ 89). Virtual Touch Quantification (VTQ) was used for measurements of LS
and SS, and the spleen index (SI) was calculated. EGVs were evaluated according
to forms and red colour sign (RC sign) based on the General Rules for Study of
Hypertension in Japan.
Results: LS, SS and SI showed significant increase in accordance with the severity
of forms (p 5 0.01). The area under the receiver operating characteristic curve
(AUROC) of LS, SS and SI for detecting EGVs were 0.8526, 0.9048, 0.8199, with
the cut off values 1.67 m/s, 2.81 m/s, 18.5cm2, respectively, and SS showed usefulness in detecting EGVs. When LS, SS and SI were compared for their ability to
detect EGVs which were 5F2 or with RC sign positive, LS, SS and SI were
significantly higher for EGVs which require treatment (p 5 0.001). The AUROC
of LS, SS and SI for detecting EGVs which require treatment were 0.8131,
0.8693, 0.8270, respectively. All modality showed good detecting ability, and
SS particularly showed better performance. When each modality was compared
in detection of gastric varices, LS and SS were significantly higher with the
presence of gastric varices, but SI did not show a significant difference. The
AUROC of LS, SS and SI for detecting gastric varices were 0.7359, 0.8611,
0.6470, respectively, and SS showed a superior detecting ability while LS and
SI showed decreased abilities.
Conclusion: LS, SS and SI were all useful in detecting EGVs and predicting the
presence of EGVs which require treatments. SS particularly showed the highest
diagnostic ability.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0713 STAGING HEPATIC STEATOSIS IN NONALCOHOLIC
FATTY LIVER DISEASE BY QUANTITATIVE CONVENTIONAL
ULTRASOUND IMAGING, VALIDATED WITH HISTOPATHOLOGY

Introduction: Nonalcoholic fatty liver disease (NAFLD) is the most common liver
disorder in developed countries with a global prevalence of approximately 25%.
NAFLD represents a spectrum of disorders and starts with benign steatosis
(NAFL, 5% hepatic steatosis but may lead to nonalcoholic steatohepatitis
(NASH), inflammation with hepatocyte injury with or without fibrosis, which
may lead to cirrhosis. Liver biopsy still is the gold standard for staging steatosis.
The BRUNT score stages steatosis in 4 categories (5%, 5–33%, 34–66%,
66%), which provides a limited sensitivity to detect changes in steatosis content.
For evaluation of treatment and disease activity a quantitative and preferably
non-invasive tool is needed urgently. Therefore we developed and tested a computer aided ultrasound (CAUS) protocol for the non-invasive assessment of
hepatic steatosis using ultrasound (US) B-mode images, which showed high predictive values (area under the curve (AUC) up to 0.95) in cows and similar
correlations in a human pilot study. The current study was conducted in order
to assess the predictive values of CAUS in staging hepatic steatosis in-vivo.
Aims & Methods: Consecutive patients indicated for a liver biopsy received a
simultaneous transabdominal US examination (Siemens Acuson X150; Siemens
Healthcare GmbH, Erlangen, Germany, with CH5-2 transducer). Currently 205
patients with liver biopsies and QUS images are included. Biopsies were qualitatively scored using the Brunt-score for steatosis grading. Metavir, Ishak and/or
Roenigk scores were used for disease specific fibrosis staging. All US images were
further post-processed using the CAUS method. In CAUS corrections are
applied for the: look up table (linearization); beam-profile; attenuation caused
by the superficial tissue layers. Furthermore segmentation of large blood vessels
and bile ducts is performed automatically. Finally echo-level and texture parameters are estimated on average and as a function of depth by estimation of slope
and intercept of a linear fit.
Results: Best correlating CAUS parameter with BRUNT steatosis stage was
found to be the residual attenuation coefficient (RAC, R ¼ 0.79, p 5 0.01).
Parameters used in the multiple linear regression analysis using the leave one
out method were: Residual attenuation coefficient (RAC ¼ slope of the mean
echo level (MU)); MU; slope of the Signal to noise ratio; and the lateral speckle
size. AUC for HS was found to be 0.95 (n ¼ 71) with a sensitivity and specificity
of 86% and 85% respectively, which are in line with previously performed studies. 87% of the included patients were found to have NASH with fibrosis.
However, no significant correlations of the CAUS parameters to a pure fibrosis-group (N ¼ 106) was found.
Conclusion: CAUS is able to classify steatosis accurately and does not suffer from
the presence of fibrosis, making CAUS a feasible tool for screening and evaluation of hepatic steatosis.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0714 UTILITY OF A NEW FUNCTION IN 3D SIM-NAVIGATOR:
ELECTRIC FIELD, WHICH INDICATES THE PREDICTED
ABLATIVE AREA

Introduction imaging technique has been reported as useful for radiofrequency ablation (RFA) and various models of ultrasound equipment have been developed to include fusion imaging systems. The 3D Sim- Navigator (HITACHI) is a navigation system that can be used in real-time with volumetric tomography and navigating the 3D positions of electrodes. As an addition, the 3D Sim-Navigator is now equipped with a new system that shows the predicted ablative area. This function indicates the electric field that occurs around the electrodes as the predicted ablative area on MP images. The E-field Simulator (E-field) can manage various electrodes, such as monopolar and bipolar RF systems. E-field can be used to predict the ablative areas from not only a single electrode but also multiple electrodes, which was difficult to do in the past. We therefore examined the accuracy of E-field on 3D Sim-Navigator.

Aims & Methods: We evaluated 10 nodules treated using a bipolar RF system (CelonPOWER: Olympus Medical Systems) with multiple electrodes and 72 nodules treated using a monopolar RF system (VIVARF system: STARmed) between April 2016 and March 2017 prospectively. We compared the major and minor axes of maximum axial ablative area for 72 nodules ablated by the monopolar RF system on both E-field and on post-RFA contrast-enhanced CT. Finally, we compared treatment efficacy using a grading system (J Gastroenterol 2013 Aug;48(8):951-65.) on E-field and on post-RFA contrast-enhanced CT.

Results: On the evaluation of maximum axial ablative area by monopolar electrodes, major and minor axes were smaller on E-field than on CT, but these differences were not significant. On the evaluation of ablative volume by bipolar electrodes, the activity coefficient for an ablative area of CEUS for the predicted area was greater than 0.96. On comparing treatment efficacy based on the grading system, the degree of agreement between E-field and CT was 0.691 and the weighted kappa coefficient was 0.929.

Conclusion: Ablative volume on E-field correlated well with that on post-RFA contrast-enhanced CT. Furthermore, good agreement was observed between the treatment efficacy based on E-field and post-RFA contrast-enhanced CT. E-field can be used to predict the ablative area from not only a single electrode, but also multiple electrodes, which was difficult to do in the past. The present results suggest that contrast-enhanced CT may become unnecessary for confirming therapeutic effects in the future.

Introduction: The presence of fat droplets in the hepatocytes (micro- or macrovesicular hepatic steatosis) under condition of chronic diffuse liver disease (CDDL) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for real-time US attenuation measurement (attenuation coefficient measurement – ACM – patent UA №2014 111234). Aims & Methods: From total of 327 patients we underwent to comprehensive analysis of ACM in our clinic: 979 were diagnosed with HDD on ultrasonography according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement on SonoP 7 device (Ultrason, Ukraine), with a 1-6 MHz convex transducer in the right and left lobes. For diagnostic accuracy assessment (used ACM values standard and comparison with CAP measured by Fibroscan (Echosens, France) we included 142 patients for subanalysis. Evaluation of diagnostic accuracy of ACM performed by ROC-analysis.

Results: Depending on the stage of steatosis according to B-mode median, 25 and 75 IQ are as follows: control group: 1.57 (1,32; 1,53); 1.16 (1,78-2,11); S2-2, 26 (2,0-2,49) and respectively for 52-2,7 (40-2,82) dB/cm. ACM value increase parallel the hepatic steatosis progression (p < 0.001), which was also accompanied with presence of very strong correlation between these parameters (r = 0.814, p < 0.001). In patient with NAFLD the association between maximum value of ACM and duration of T2DM and triglycerides (model 1, multiple correlation coefficient = 0.55; R² = 0.26; p = 0.004) and ALT (model 2, multiple correlation coefficient = 0.55; R² = 0.25; p = 0.005) were observed. After adjustment by the duration of T2DM the level of triglycerides (r = 0.44, p = 0.012) and activity of ALT (r = 0.44, p = 0.012) significantly correlated with ACM. The AUROC of ACM for steatosis diagnosis was 0.925 (95% CI 0.877-0.973). The optimal cutoff point was > 2.272 dB/cm, with sensitivity, specificity, PPV and NPV respectively 91.5, 77.3, 84.6 and 83.8%. ACM value significantly correlated with CAP (r = 0.630, p = 0.001).

Conclusion: The ACM as novel real-time ultrasound approach can be used for noninvasive hepatic steatosis diagnosis, allows clinicians to monitor disease progression and response to treatment.

overexpressed. Knock-down of CUX1 determined a significant down-regulation of HIF-1α, FH1-1 and VEGF. Interestingly, the expression of CDKNA1 was only attenuated after CUX1 knock down and hypoxic stress. HIF1α and transcriptional activity is dependent by CUX1 expression.

Conclusion: CUX1 exerts an oncogenic role in liver cancer by sustaining the survival mechanism and hypoxia. CUX1 silencing results in suppression of the hypoxia inducible factor and its target VEGFA causing a block of cell cycle in liver cancer cells modulated by the stable expression of CDKNA1.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Our results support the hypothesis that overexpression of BRG1 increases cell growth and cell invasion in HCC. Furthermore, the data highlight genes promoting proliferation and invasion that are regulated by BRG1 during hepatocarcinogenesis. In particular, CyclinB, D, E and MMP7 appear to play a major role in this context and might be an important link between BRG1 expression and HCC development.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0720 PROGNOSTIC ROLE OF NEUTROPHIL-TO-LYMPHOCYTE RATIO IN HEPATOCELULAR CARCINOMA (HCC)
Sahloul, Sousse/Tunisia

Contact E-mail Address: Elleuchghorb.elnour@yahoo.fr

Introduction: Inflammation may play an important role in progression, and a high neutrophil-to-lymphocyte ratio (NLR) has been reported as a poor prognostic indicator in several malignancies.

Aims & Methods: This study was aimed to investigate the prognostic value of NLR in patients with HCC. We performed a retrospective study including patients with hepatocellular carcinoma admitted in the hepatogastroenterology department of Sousse between January 2010 and December 2015.

Results: A total of 76 patients were included in this study. Mean age was 59.8 (33–87 years). The sex ratio was 3.22 (M/F = 58:18). Hepatocellular carcinoma occurred on a liver of cirrhosis in the majority of cases (90.7%). The main causes of cirrhosis were hepatitis B virus infection (43 patients-62.3%), hepatitis C virus infection (11 patients-16%), non alcoholic steatohepatitis (6 patients-8.6%) and alcohol consumption (5 patients-7.2%). Our results showed that high NLR was associated with poor overall survival (OS) in HCC regardless of therapeutic choice (P < 0.05). Otherwise, high NLR was significantly correlated with the presence of vascular invasion (P = 0.002), lymph node metastasis (P = 0.04), tumor multifocality (P = 0.01) and higher incidence of AFP > 200 ng/mL (P = 0.04).

Conclusion: Elevated NLR indicates a poor prognosis for patients with HCC. The NLR is a readily available and inexpensive biomarker, and its addition to established prognostic scores for clinical decision making warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0721 REIC/DKK-3 PROTEIN CONCENTRATION INDUCE THE POSITIVE EFFECT TO THE MORTALITY OF HEPATOCELULAR CARCINOMA
A. Ohyama, D. Uchida, H. Shiraha, H. Sawahara, H. Kato, H. Okada
Gastroenterology And Gastrology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City/Japan

Contact E-mail Address: at841205@gmail.com

Introduction: The Wnt/b-catenin plays essential roles in the growth of hepatocellular carcinoma (HCC). The Dickkopf (Dkk) protein family (Dkk1–4) is known as Wnt signal antagonists, and reduced expression in immortalized cells (REIC)/Dkk-3 over-methylcytidylation is associated with poor prognosis of HCC patients. But the roles of REIC/Dkk-3 in inhibiting Wnt signaling remains still unclear.

Aims & Methods: In our previous study, REIC/Dkk-3 protein induced significant proliferation of inter foam liverocytes incubated with pancreatic cancer cells, indicating that REIC/Dkk-3 protein might activate cancer immunity in the tumor-bearing patients.1 We hypothesized that REIC/Dkk-3 expression was correlated with cancer immunity in HCC patients. Thus, we investigated the correlation between serum REIC/Dkk-3 protein level and the prognosis in HCC patient. We retrospectively studied 58 HCC patients who underwent primary liver resection for HCC admitted to out unit from 2008 to 2017. Patient serum was gathered before resection. Serum REIC/Dkk-3 protein level was measured by an enzyme-linked immunosorbent assay.

Results: 58 HCC patients were divided into two groups, 41 REIC/Dkk-3 high concentration group (protein level > 800) and 17 Dkk-3 low concentration group (protein level < 800), according to the presence of REIC/Dkk-3 proteins in the blood, as detected by ELISA spectrometry. There was no significant difference in age, sex, Child-Pugh score and HCC stage in the patient groups. REIC/Dkk-3 Protein tended to be declining in liver cancer patients with poor prognosis. (p=0.186)

Conclusion: Our results demonstrated that the serum Dkk-3 protein levels might be a prognosis marker in HCC patients. Further study is necessary with more number of HCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0722 SURGICAL OUTCOME OF PATIENTS WITH FIBROLAMELLAR HEPATOCELULAR CARCINOMA: DOES IT DIFFERS FROM COMMON HEPATOCELULAR CARCINOMA?
E. El-Hanafy
Faculta Of Medicine, Mansoura University, Gastroenterology Surgical Center, Cairo/Egypt

Contact E-mail Address: dr_elah_elhanafy@yahoo.com

Introduction: Fibrolamelluar hepatocellular carcinoma (FL-HCC) has conventionally been considered to be a histologic variant of hepatocellular carcinoma (HCC), with distinct clinicopathologic features. It is a rare primary hepatic malignancy that was first described as a pathological variant of HCC by Edmondson in 1956 [1]. The etiology of FL-HCC remains unclear. It typically occurs in normal livers without underlying liver fibrosis or cirrhosis [2]. In contrast to HCC which usually found in the presence of cirrhosis or chronic hepatitis [3], FL-HCC has been reported to occur in association with focal nodular hyperplasia (FNH) a type of benign liver lesion. Many series have mentioned that FL-HCC is less aggressive than conventional HCC [4]. However, other studies have failed to confirm the observation of a better outcome in FL-HCC [6]. Other studies reported that the survival was similar between common HCC and FL-HCC, and that may be related to the higher resectability rate which improve the survival of patients with FL-HCC [1].

Aims & Methods: The aim of this study was to evaluate the clinicopathological features and the surgical outcomes of patients with FL-HCC who were referred to our tertiary referral center over a 15-year period. This is a retrospective study including 22 patients with a pathologic diagnosis of FL-HCC who underwent hepatectomy over a 15-year period. Tumor characteristics, survival and recurrence were evaluated.

Results: There were 11 male and 11 female with a median age of 29 years (range from 21 to 58 years). Two (9%) patients had hepatitis C viral infection and only 2 (9%) patients had alpha-fetoprotein level > 200 ng/mL. The median size of the tumors was 12 cm (range from 5–20 cm). Vascular invasion was detected in 5 (23%) patients. Four (18%) patients had lymph node metastases. The median follow up period was 42 mo and the 5-year survival was 65%. Five (23%) patients had a recurrent disease, 4 of them had a second surgery with 36 mo median time interval. Vascular invasion is the only significant negative prognostic factor.

(continued)
Conclusion: Percutaneous ablation of HCA using Microwave or Radiofrequency thermal Ablation is safe, feasible and able to eradicate the targeted hepatic focal lesion and prevent known complications of HCA. Of note Microwave ablation is much more efficient in treating larger lesions through single puncture in contrast to Radiofrequency which needs more than one puncture.

Disclose of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolic disorders, such as obesity and diabetes, are well known risk factors for hepatocellular carcinoma (HCC). Conversely, their impact on the natural history of HCC patients has not been established.

Aims & Methods: This study aimed at evaluating the impact of metabolic disorders on clinical features, treatment and survival of HCC patients regardless of its etiology. We analyzed the Italian Liver Cancer (ITA.LI.CA) database regarding 839 HCC patients prospectively collected from 2009 to 2014. The following metabolic features were analyzed: BMI, diabetes, arterial hypertension, hypercholesterolemia and hyperglycemia. According to these features, patients were divided into 3 groups: 0–1 metabolic features, 2 metabolic features, 3–5 metabolic features.

Results: As compared with patients with 0–1 metabolic features, patients with 3–5 features showed lower percentage of HCC diagnosis on surveillance (p = 0.021), larger tumors (p = 0.038), better liver function (higher percentage of patients with Child-Pugh A [p = 0.007] and MELD < 10 [p = 0.003]), higher percentage of metastases (p = 0.024), and lower percentage of portal vein thrombosis (p = 0.010). The BCLC stage and treatment options were similar among the 3 groups, with the exception of a less frequent access to locoregional therapies for BCLC stage B patients with 3–5 features (p = 0.012). Overall survival and survival according to BCLC stage and/or treatment did not significantly differ among the 3 groups. Diabetic patients showed a lower survival (p = 0.046). MELD score, HCC
Grade 1 or higher HFS was observed in 22 patients (53%), and it was significant predictive factors. The following were not significant predictive factors. The presence of HFS (hazard ratio, 0.41; 95% CI, 0.19 to 0.88; p = 0.045) was also associated with higher risk for HCC. (P < 0.001), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show that LVI > 1 and presence of LC were independent predictors of HCC (HR: 63.53, CI. 1.24-1244.28, P < 0.001: HR: 3.10, CI. 1.28-7.51, P = 0.12, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

P0727 HAND AND FOOT SYNDROME AS A PREDICTOR OF OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH SORAFENIB

M. Ochi, A. Okawara, N. Kakinoki, T. Kamoshida, S. Hirai
Department Of Gastroenterology, Hitachi General Hospital, Hitachi City/Japan

Contact E-mail Address: masaochii@hotmail.co.jp

Introduction: Sorafenib is a multi-thyrosine kinase inhibitor classified as a neo-vascularization inhibitor. A previous study indicated that the administration of a thyrosine kinase inhibitor, cetuximab, significantly prolonged the survival of patients with dermal disorder1. However, few studies have reported the efficacy of sorafenib administration in patients with hand and foot syndrome (HFS).

Aims & Methods: In this study, we investigated the prognosis of sorafenib-treated patients with HFS. HFS grading was conducted according to the Common Terminology Criteria for Adverse Events (CTCAE) v.4.0. Patients with grade 1 or higher dermal disorder were regarded as having HFS, and grade 0 patients as not having HFS. For HFS evaluation, a double-check system was adopted: primary evaluation based on a specific evaluation sheet at the Pharmacists' Outpatient Clinic and final evaluation by physicians at the outpatient clinic.

We examined the influence of HFS on the effects of treatment after the introduction of sorafenib in 42 patients with a history of multidisciplinary treatment, such as transcatheter arterial chemoembolization (TACE), between May 2009 and March 2017.

Results: Grade 1 or higher HFS was observed in 22 patients (53%), and it was absent in 20 (47%). Overall, the median sorafenib administration period was 2.1 months. In the HFS-free and HFS groups, it was 0.9 and 2.7 months, respectively (p < 0.001). Survival analysis was performed using the Kaplan-Meier method. Overall, the median survival was 5.2 months. In the HFS-free and HFS groups, it was 3.0 and 7.8 months, respectively (p = 0.001). Multivariate analysis showed that the presence of HFS (hazard ratio, 4.01; 95% CI, 0.19 to 0.88; p = 0.023) and administration period (hazard ratio, 0.45; 95% CI, 0.20 to 0.98; p = 0.045) were significant predictive factors. The following were not significant predictive factors: age, BCLC staging, dosage, and tumor markers.

Conclusion: The prognosis of hepatocellular carcinoma patients receiving sorafenib treatment was closely related to the presence of HFS and administration period. HFS was a predictor of outcome in patients with hepatocellular carcinoma treated with sorafenib. This study indicated that a multi-thyrosine kinase inhibitor, sorafenib, prolonged survival in patients with HFS, as demonstrated for cetuximab. HFS reduces the quality of life (QOL), and it is a sorafenib administration-inhibiting factor. In our hospital, a system for patients to initially consult the Pharmacists' Outpatient Clinic, followed by the feedback of grade-based HFS control strategies to physicians at the outpatient clinic, was established. Skin control for sorafenib-treated patients with HFS may have prolonged the administration period, improving the prognosis.

Introduction: Hepatocellular carcinoma is the most common primary tumor of the liver and is estimated to cause more than a quarter of a million deaths each year throughout the world. Extrahepatic metastasis of HCC occurs in about 30-50% of patients, and it depends on HCC stages. I The most frequent site is lung, followed by lymph node, bone, and adrenal gland.2 Extrahepatic metastases to unusually sites from HCC have been reported in a few case reports. We report cases of patients with unusual extrahepatic metastatic sites from HCC.

Aims & Methods: We carried out a retrospective study of 16 patients with unusual extrahepatic metastases of hepatocellular carcinoma out of 1047 cases of HCC treated at the hepatagastroenterology department "Medicine C" of the Ibn SINA University Hospital during the past 22 years. The diagnosis was suspected based on clinical signs and imaging data, and confirmed by histology when the biopsy of the metastasis was possible, were excluded from this study, patients with lung metastasis, lymph node and portal thrombosis.

Results: Our study included 16 patients, 10 men and 6 women with a mean age of 58.5 years ranging from 37 years to 75 years. 13 patients had cirrhosis due to hepatitis C virus, 1 patient had a cirrhosis due to viral B infection and 2 patients had HCC with anacirrhotic liver. All patients had one or more HCC, ranging in size from 2 to 10 cm. The AFP was normal in 11 cases and elevated in 4 cases (> 200ng/ml). We collected 4 cases of adrenal metastases, 5 costovertebral metastases, 2 brain metastases, 1 cranial metastasis, 1 caval metastasis, 1 ovarian metastasis, 1 nasopharyngeal metastasis, and a case of metastasis in the path of percutaneous biopsy of HCC. In 4 cases the diagnosis of HCC and metastasis was synchronous while in 12 cases median time from diagnosis of hepatocellular carcinoma and extrahepatic HCC was 15.5 months.

Therapeutic abstention was decided in 14 patients for the advanced stage of the disease. cutaneous metastasis was resected surgically and HCC occurring in healthy liver was treated by lumbectomy and upper pole gastrectomy in gastric metastasis. The average survival was estimated at 14 months with a decline of 17.3 months, 6 cases were lost to follow and 6 deaths occurred in our series.

Conclusion: The incidence of unusual and extrahepatic metastasis of HCC diagnosed during clinical course was not frequent. The prognostic diagnostic procedures for extrahepatic metastasis has not been standardized, however considering the significantly high survival of patients with dermal disorder1, we performed a retrospective study of 16 patients with unusual extrahepatic metastatic sites from HCC. The detection of extrahepatic HCC is crucial for patients to receive appropriate therapy, which ultimately determines patient survival.

Introduction: Hepatocellulargliocarcinoma is a rare primary hepatic tumor comprising features of both, cholangiocarcinoma and hepatocellular carcinoma (CHC-ICC). Few data concerning the epidemiology of chHCC-ICC have been reported, mainly from surgical series in Asian and American populations.

Aims & Methods: The main objective of this retrospective multicenter study was to evaluate epidemiological features and overall survival of histologically proven advanced CHC patients in a French population. Data from patients treated for histologically proven chHCC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, therapeutic features and OS were reported. Statistical analysis was performed using Graph Pad Prism 6.

Results: Thirty patients had HCC. 367 patients were included (76.6% of men, median age 64 years [extreme 37-88]. Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively,
5 (16.6%) and 2 (6.6%) patients; and 1 co-infection was observed. Chronic alcoholism in 33.3%, diabetes and obesity (body mass index ≥30 kg/m²) were both present in 26.6% of cases. Alpha-fetoprotein, Carbohydrate Antigen 19-9 and carcinoembryonic antigen serum levels were above normal in respectively 35% (median = 5.3 μg/L [2.2–47.9]), 50% (median = 21.8 IU/mL [4.5–20 000]) and 14% (median = 2.4 μg/L [2–88]) of cases. Six patients (20%) were initially treated by surgical resection. At the diagnosis of advanced non resectable disease, 66.6% of patients presented a multifocal hepatic lesions, 50% presented distant metastases (bones metastases (21.3%), lungs metastases (20%) and peritoneal metastases (13.3%). Twenty-seven patients (90%) received first line of systemic treatment. Twenty-four patients were treated by chemotherapy: Gemcitabine (Gem) alone (n = 1), Gem + oxaliplatine (n = 12), Gem + oxaliplatine + bevacizumab (n = 9), Gem + cisplatine (n = 2). Two patients were treated by chemobezolization and 1 patient received sorafenib. Twenty-nine (70%) and 4 (13.3%) patients received a second and third line of treatment, respectively. Median overall survival was 14.5 months.

Conclusion: Advanced eHCC-ICC appear to be aggressive tumors with a poor prognosis. Cirrhosis was associated in one third of patients. Systemic treatments are not standardized and must be evaluated in a dedicated study.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this study was to evaluate the clinical manifesta-
tions, risk factors and prognosis in lymphomas with hepatic involvement. We conducted a retrospective study of patients diagnosed with hepatic lymphoma at our center between 2005 and 2016.

Results: During the 12 years, 36 hepatic lymphomas were identified, 27 primary hepatic lymphomas and 9 with secondary hepatic involvement. The mean age at diagnosis was 53.5 ± 14.6 years and 50% were males. Only one patient had hepatitis B and none had hepatitis C. The majority (94.4%) had symptoms at the time of diagnosis, with fatigue (83.3%), night sweats (61.1%) and loss of weight (61.1%) being the most common. The imaging presentation was of a single mass in 47.2% of cases, multiple masses in 30.6% and infiltrative mass in 22.2%. The most common lymphoma subtypes were diffuse large B-cell lymphoma (52.8%), MALT lymphoma (11.1%) and Hodgkin’s lymphoma (11.1%). Survival at the end of one year was 63.8% and 27.8% at 3 years. Age > 60 years (p = 0.004) was the only factor that was significantly associated with higher mortality.

Conclusion: Hepatic lymphomas are rare entities that may occur in different ways, with diffuse large B-cell lymphoma being the most common subtype. They presented a 3-year survival of only 27.8% and the age over 60 years was the only factor significantly associated with mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary tumors of the liver, beyond hepatocellular carcinoma, are difficult to characterize and are associated with poor prognosis. Hepatic involve-
m ent in the lymphomatous process is uncommon and primary hepatic lympho-
mas are rare. The etiology is not yet known but it is thought that hepatitis B and C may be risk factors. The therapeutic approach is not yet fully defined.

Aims & Methods: We aimed to evaluate the effects of various kinds of bile acids on microbiotas are very diverse. Each individual have a characteristic microbiotal distribution and composition within the intestinal tract, presumably related to the composition of their respective char-
geracteristic bile acids. The bile acids, released into the intestinal tract, are mostly reabsorbed (about 95%) through the enterohepatic circulation and recycled. If a certain bile acid is continuously orally supplied, the ratio of supplied bile acid to the total bile acid is gradually increased due to the continuous enterohepatic circulation. It has been reported that changes in the composition of intestinal bile acids cause dysbiosis, and it is presumed that an artificial change in the composition of bile acid can be an effective method of controlling the proliferation of target microbiota.

Aims & Methods: First, we wanted to identify the effects of certain bile acids on each microbiotas. We observed the effect of bile acids in human body (cholic acid, deoxycholic acid, lithocholic acid, and UDCA). We cultured several organims by the disk diffusion method, used for antibiotic susceptibility test. Second, we intended to observe actual intestinal microbial changes through the supply of specific bile acids in animal models. Specific bile acid (UDCA), which is not reabsorbed, was fed to rats for 1 month after bile duct ligation rat model. Next generation sequencing (NGS) method was used to analy-

Introduction: Inhibition of microRNA-21 (miR-21) prevents necroptosis in the mouse pancreas. In turn, we recently showed that necroptosis contribute to hepatic necro-inflammation in the common bile duct ligation (BDL) murine model.

Aims & Methods: We aimed to evaluate the role of miR-21 in mediating deleterious processes associated with cholestasis. The functional crosstalk between miR-21 and necroptosis was investigated in vitro. miR-21 expression was evaluated in the liver of primary biliary cholangitis (PBC) patients. C57BL/6 wild-type (WT) or miR-21-deficient (miR-21−/−) mice were subjected to BDL or sham surgeries, with biochemical, molecular and histological analysis of hepatic damage, fibrosis, necroptosis and bile acid metabolism, after either acute (3 days) or chronic (14 days) injury.

Results: Studies in miR-21−/− primary mouse hepatocytes established a functional link between miR-21 and necroptosis through cyclin dependent kinase 2 associated protein 1 (CDKAP1). miR-21 expression increased in the liver of PBC patients (P=0.02). miR-21−/− mice displayed decreased serum levels of liver injury markers compared with WT mice, accompanied by reduced hepatocellular degeneration, oxidative stress and pro-fibrotic gene expression. Hallmarks of necroptosis were decreased in the liver of BDL miR-21−/− mice, via relieved repression of CDKAP1. Further, miR-21−/− mice displayed improved adaptive response in the expression of bile acid homeostasis-associated genes.

Conclusion: miR-21 ablation ameliorates liver damage and necroptosis in BDL murine model. miR-21 should be a promising approach to treat cholestatic liver diseases. Supported by FCT, Portugal through grants PTDC/ HMI-MEC/08953/2014 and UID/DTP/04138/2013, and fellowships SFHR/BD/ 9119/2012 (MBA), SFHR/BD/82212/2012 (FMR), and SFHR/BD/191460/201 (ALS).

Introduction: Bile Duct Injury (BDI) following laparoscopic cholecystectomy is a persisting problem. The rendezvous procedure (RV) provides a combined endoscopic and percutaneous approach in order to re-establish bile duct continuity in complex BDI.

Aims & Methods: The aim of this study is to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary center were analyzed retrospectively. RV procedure was performed when endoscopic stenting or PTC failed and when deemed feasible by a dedicated multidisciplinary team including a hepato-pancreato-biliary surgeon, gastroenterologist and interventional radiologist. Classification of BDI, technical success of RV, procedure-related complications and outcomes were assessed.

Results: Among a total of 812 patients, RV was performed in 47 (5.8%) patients, of which 31 (66%) were diagnosed with complete transaction of the bile duct (type D3/Narseth type E injury). Primary success rate of RV was 94% (44/47 patients). Reasons for failure (N = 3) were inability to pass a stricture and inability to make contact between the two wires. In 26/47 patients (55%) RV was the final successful treatment. In 17/47 patients (36%) RV acted as a bridge to during the endoscopic procedure, and total number of endoscopic procedures did not significantly differ between the two groups. The median number of stent change was one (range 0–5) and two (range 1–5) (P = 0.013), while the median diameter of the largest stones was 9 mm (range 0–27) and 14 mm (range 5–32) (P = 0.001) in the complete and incomplete stone removal groups, respectively. During the follow-up period, OS was 33.5% and 41.9% and DSS was 5.66% and 3.23% in the complete and incomplete stone removal groups, respectively. Kaplan-Meier analysis found no significant difference in OS and DSS between the two groups (P = 0.187 and P = 0.581, respectively). Conclusion: Patients in the incomplete stone removal group tended to have more numerous and larger stones. This single-centre retrospective study revealed no significant difference in OS and DSS between the two groups. Complete stone removal might not be always necessary in extremely elderly patients aged 90 years and older.

P0736 THE EVALUATION OF TRANSPAPILLARY ENDOSCOPIC GALLBLADDER DRAINAGE WITH THE USE OF INTRADUCTAL ULTRASONOGRAPHY

Gastroenterology, New Tokyo Hospital, Chiba/Japan

Contact E-mail Address: dr2007@ck2.so-net.ne.jp

Introduction: The number of indications for endoscopic transpapillary gallbladder drainage (ETGBD) to treat biliary colic in elderly patients aged 90 years was increased due to the aging of the population and prescribing antithrombotic agents. ETGBD is one of the challenging procedure because it is difficult to identify the cystic duct (CD) orifice. From November 2015, we performed with ETGBD using intraductal ultrasonography (IDUS) complementarily. The CD orifice can be identified using IDUS, resulting in cannulation to the CD. We investigated the success rate and clinical outcomes of ETGBD in combination with using IDUS.

Aims & Methods: ERCP was performed in 1000 patients (1400 times) at New Tokyo Hospital between January 2012 and December 2016. Among them, a total of 97 patients underwent ETGBD, 58 patients with IDUS and 39 without IDUS. In this study, we investigated the success rate of ETGBD retrospectively. The success of ETGBD was defined as cannulation into the gallbladder within two trials. Results: The mean age and male proportion of patients in the group with IDUS was similar to that in the group without IDUS (74.5±11.4 vs 73.3±11.3; P = 0.600 and 18/40 and 13/26; P = 0.828). The procedure success rate was 78.4% (76/97) in total; 86.2% (50/58) in the group with IDUS and 66.7% (26/39) in the group without IDUS (P = 0.026). Using IDUS under fluoroscopic image allowed all patients in the group with IDUS to identify the CD orifice. ETGBD procedures in eight patients were unsuccessful because of a highly flexion of the CD in seven patients and an obstruction of the CD orifice caused by tumor invasion in one patient. Although both groups developed mild pancreatitis (one patient in the group with IDUS, and two patients in the group without IDUS), no significant difference was observed in the two groups (P = 0.563). All patients were successfully managed with conservative treatment. There were no any other complications in the two groups.

Conclusion: The success rate of ETGBD in the group with IDUS was significantly higher than that in the group without IDUS. IDUS is may be useful as a complementary option of endoscopic gallbladder drainage.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.
surgery; although the RV was initially successful, late complications (stenosis, stent dysfunction) required elective hepaticojjunostomy (HJ). Procedure-related adverse events occurred in 10 patients (18%) with cholangitis being the most frequent complication (N = 4.7%). No life-threatening adverse events and no 30-day mortality occurred.

Conclusion: In experienced hands, RV is safe with a final non-surgical success rate of 55%. When endoscopic stenting fails in patients with complex BDI, RV can be considered as a viable treatment option before surgical repair.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0739
TRANSCRECTAL GALLBLADDER PRESERVING ChoLecystolithotomy and PolyPectomy by pure NOTES
B. Liu
Gastroenterology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou/China
Contact E-mail Address: 3217265358@qq.com

Introduction: Transcolonic and transrectal NOTES in human cases was greatly restricted by the fact of fecal contamination. We developed a detachable intracolonic balloon to help keep the colon sterile by blocking the colonic lumen. Although cholecystectomy is widely used for treating gallbladder polyps and gallstones, there is still a controversy about whether or not the gallbladder should be preserved. However, postcholecystectomy syndromes, such as biliary duct injury and the correlation with colon cancer, remind us of the importance of gallbladder preservation.

Aims & Methods: Approved by the Independent Ethics Committee, we’ve completed 8 transrectal gallbladder preserving cholecystolithotomy (TRGCP) and 3 transrectal gallbladder preserving polypectomy (TRGPP) and 2 combined cases by pure NOTES. Moreover, 1 case of TRGCP was done by hybrid NOTES. As the figures show, the balloon was placed in the transverse colon to block the colonic lumen, and the distal colon cavity was disinfected with povidone-iodine solution. An incision was made on the anterior rectal wall 12–17 cm from the anus. The endoscope was advanced into the peritoneal cavity with liver and gallbladder identified. The bile was aspirated before an incision on the gallbladder wall was made. Stones and/or polyps were found inside of the gallbladder. Stone extractor and biopsy forceps were used to take out the stones. The polyps were coagulated and removed by electric biopsy forceps. The muscular layer and the adventitial layer were successively closed with endolips. Peritoneal cavity lavage was performed with sterile saline. The rectal incision was closed with endoclips and endoloops tightly. At the end of the procedure, the balloon was pulled out after being deflated.

Results: The mean operation time (from incision making till the last clipping) was 180.5 min. (89–467 min.). 6 hours after anesthesia, the patients could drink water, and liquid diet was resumed 24 hours later. Postoperatively, 4 of the 14 patients felt mild abdominal distention which disappeared within 12 hours when they were able to get off the bed. For 1 patient with acute cholecystitis, a hybrid NOTES with laparoscopy was performed. Moreover, gallbladder drainage and peritoneal lavage were used, and the abdominal pain relieved soon. All the patients were discharged without any adverse events and all felt good during the follow-ups.

Conclusion: The usage of the detachable balloon can prevent the operative field from fecal contamination effectively. TRGCP and TRGPP by pure NOTES are suitable for both males and females. Transrectal route provides a novel alternative approach for the treatment of gallbladder polyps and gallstones. To our knowledge, this is the first human case series of transrectal gallbladder preserving cholecystolithotomy and polypectomy by pure NOTES. However, multi-centered, prospective, controlled researches with more cases are needed in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sodium metarsenite (NaAs2O3: code name KML001) is an orally bioavailable arsenic compound with potential anti-cancer activity. However, the effect of KML001 has not been evaluated in patient with biliary tract cancers. We investigated the potential of KML001 as palliative chemotherapy in patients with advanced biliary tract cancers who non-respond to gemcitabine-based chemotherapy.

Aims & Methods: The study was designed to evaluate safety, tolerability and effectiveness of KML001 as palliative chemotherapy in advanced biliary tract cancer. Inclusion criteria were 1) inoperable or metastatic cholangiocarcinoma and gallbladder cancer, and 2) previous history of failure to gemcitabine-based chemotherapy. Exclusion criteria were 1) naïve patient to chemotherapy, 2) ECOG PS > 3, and 3) history of decompensated congestive heart failure, uncontrolled arrhythmia, and QT prolongation (QTc > 480 ms). KML001 (Kominos, Komipharm International Co., Ltd.) was administered as 7.5 mg daily to eligible subjects. Every two months, patient took response evaluation by biliary CT scan.

Results: A total of 44 patients (21 females and 23 males) were enrolled prospectively between November 2011 and October 2014. Mean age of the patients was
Conclusion: KML001 was safe and well tolerated in respects of adverse events. The percentage of drained segments. This percentage was calculated by dividing intubated patient. The quality of the drainage was evaluated by calculation of ques could be associated. A Ct-scan or MRI was performed before and after operators performing ERCP, EUS-drainage, and per-cutaneous drainage. The drainage of malignant stenosis of the hilum. Drainage were performed by 5 unilateral or bilateral palliative drainage has to be perform for this kind of drained in case of unresectable hilary liver stenosis, however it remains unclear if ESGE stated in 2012 that more than 50% of the liver had to be Morphin requirement, n (%) increased 8 (18.6%) ECOG, n (%) Increased 19 (43.2%) Progression, n (%) Decreased 11 (24.7%) Table 1: Treatment outcomes Study period, mean, mo (range) 1.5 (0.5–10.0) Progression free survival, mo (IQR) 1.7 (0.8–2.3) Survival from study-enroll, mo (IQR) 2.5 (1.4–4.9) Best response, n (%) SD 3 (6.8%) PD 23 (53.2%) Not evaluated 18 (40.9%) ECOG, n (%) Increased 19 (43.2%) Main 24 (54.5%) Morphin requirement, n (%) increased 8 (18.6%) maintain 31 (72.1%) decreased 4 (9.3%) Adverse event, n (%) Grade 1 16 (36.4%) Grade 2 29 (65.9%) Grade 3 12 (27.3%) Grade 4 0 (0%) Drop out cause, n (%) - drug reaction 1 (2.3%) - Adverse event 4 (9.1%) - Patient’s death 7 (15.9%) - Disease progression 22 (50.0%) - Withdrawal consent 5 (11.4%) - Loss of follow-up 2 (4.5%) - Poor general condition 3 (6.8%) Conclusion: KML001 was shown promising result in disease control and pain control. The other factors with impact on the survival was an invasion of the liver > 50% by tumor. There was no impact on the survival according to the different techniques used to drain the bile ducts. To confirm the efficiency of the quality of the drainage, a ROC curve was performed establishing a correlation between patients receiving chemotherapy and percentage of liver drained (area curve = 0.77 (0.65–0.88)). Disclosure of Interest: All authors have declared no conflicts of interest.

Aim & Methods: The study is a retrospective analysis of a prospective registry of patients with malignant stenosis of the biliary confluence. The aim of our study was to evaluate the efficiency of hilar drainage in function of the number of segments drained. The number of liver segment drained with the number of liver segment measured by removing the segments with the segments resected in case of surgery, and/or the segments with invasion of more than 50% by tumor. The aim of the study was to evaluate the effect of the quality of the drainage on the patients survival. Quality of the drainage was defined by the percentage of liver segments drained.

Results: 60 (38 men) patients were included from from 01/2015 to 07/2016. Mean age = 69.84 years old. The classification of the stenosis was type II for 17 (29%) patients, type III for 20 patients (34%), type IV for 22 (37%). Histology corre- sponded to hepatic cell carcinoma (53%), metastasis from colorectal cancer for 15 patients (25%) and others cancers for 19 (32%). Median follow-up was 8.5 months (5.5–16.5). The median of survival was 5 months (2.3–12.3). In univaried and multivaried analysis there was a significant correlation between the percentage of segments drained > 50% (p < 0.05) and the survival. The other factors with impact on the survival was an invasion of the liver > 50% by tumor.

Disclosure of Interest: The patient with a malignant stenosis of the biliary confluence is highly correlate with the rate of the liver segment drained.

Aims & Methods: The aim was to determine and compare the accuracy of TAUS and EUS for diagnosis of gallbladder polyps. The decision to perform cholecystectomy is based on presence of gallbladder polyp on transabdominal ultrasound (TAUS) or endoscopic ultrasound (EUS), or both. This decision also influences whether the polyp is to be removed or to be left alone (true or pseudo polyp. Pseudo polyps are non-neoplastic and do not need surgery. True polyps are neoplastic, either benign (adenoma) or (pre)malignant (dysplastic polyp/carcinoma). True polyps usually need surgery, as they are thought to have malignant potential through the adenoma-carcinoma sequence. (Pre)malignant lesions should be operated sooner than benign lesions. There has been no systematic review and meta-analysis on the accuracy of TAUS and EUS in the diagnosis of gallbladder polyps, true gallbladder polyps and (pre)malignant polyps.

Results: A total of 17 studies were included in this review. For diagnosis of gallbladder polyps six studies on TAUS were included. The sensitivities and specificities of the studies ranged from 0.45 to 1.00, and 0.91 to 0.98 respectively. There were no studies on EUS for this topic. For differentiating between true and pseudo polyps, seven studies were included. All seven studies reported on TAUS, four studies also reported on EUS. The sensitivities and specificities of the studies ranged from 0.47 to 1.00 and 0.51 to 0.98 for TAUS, and from 0.63 to 1.00 and 0.84 to 0.96 for EUS. For differentiating between (pre)malignant and benign polyps, five studies were included. Four studies reported on TAUS and three studies on EUS. The sensitivities and specificities of the studies ranged from 0.22 to 0.99 and 0.46 to 1.00 for TAUS and from 0.69 and 0.92, and 0.87 to 0.95 respectively.

No studies were of high methodological quality. The results of the pooled sensitivities, specificities and test–post–test probabilities are shown in Table 1. HSROC analysis showed no significant difference between the diagnostic accuracy of TAUS and EUS for differentiating between true and pseudo polyps and for
determining diagnostic accuracy of TAUS for diagnosis gallbladder polyps is moderate and decreases further when differentiating between polyp types. TAUS would regularly provide false positive results, leading to unnecessary surgery. There was no evidence that diagnostic test accuracy of EUS was better than TAUS. Further studies of high methodological quality are needed to determine diagnostic accuracy of EUS and TAUS for differentiating between polyp types.

This abstract is based on a pre-peer review draft of a Cochrane Review.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In its early stages, gallbladder cancer is an asymptomatic disease, and is associated with a poor prognosis if found in an inoperable condition. Several investigators have reported the utility of contrast-enhanced ultrasonography (CEUS) in low mechanical index (MI) contrast mode using a microbubble contrast agent for gallbladder lesions. However, CEUS images with low MI setting are influenced by the echogenicity of background B-mode and cannot depict precise vessel images, in contrast with high MI contrast mode.

Aims & Methods: The aim of this study was to assess the diagnostic value of CEUS in high MI contrast mode for characterizing polypoid lesions of the gallbladder (PLG). Thirty-six patients with PLG, including 17 with gallbladder cancer and 19 with benign polyps, who underwent CEUS were enrolled. The institutional review board approved this study and informed consent was obtained. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement, were calculated. Subsequently, patients were stratified according to lesion size at the largest diameter, and the diagnostic accuracy for gallbladder cancer in B-mode and CEUS were assessed.

Results: Two patients with malignant PLG could not be evaluated in B-mode due to sludge. Kappa values for CEUS were graded as good or excellent, and were better than in B-mode. Age and size of malignant PLGs were significantly larger than benign lesions. In B-mode, 80% (12/15) of malignant PLGs exhibited heterogeneity (p < 0.01). On CEUS, malignant PLGs exhibited sessile-shape (76% [13/17]), dilated vessels (71% [12/17]), irregular vessels (82% [14/17]), and heterogeneous enhancement (59% [10/17]) (p < 0.01). Except for heterogeneous enhancement, all features remained significantly different after stratification according to size of PLG between 11 mm and 20 mm on CEUS. The sensitivity, specificity, and accuracy for diagnosis of gallbladder cancer was 80% (12/15), 79% (13/19), and 73% (25/34) in B-mode, 94% (16/17), 89% (17/19), and 92% (33/36) on CEUS, and 88% (7/8), 91% (10/11), and 89% (17/19) on CEUS after stratification according to size, respectively.

Conclusion: CEUS in high mechanical index contrast mode was a useful modality for differentiating gallbladder cancer and benign PLGs.

Introduction: Multiple recent studies have indicated that some of adipose tissue-derived hormones may significantly influence the growth and proliferation of GI tumors including liver cancer (1, 2). However, the role of adipokines such as adiponectin and leptin in biliary tract cancer have not been well studied before. The aim of the study was to analyze plasma concentrations of adiponectin and leptin in cholangiocarcinoma (CC) patients and to compare these concentrations to clinopathological parameters.

Aims & Methods: Baseline levels of adiponectin and leptin were determined in 38 consecutive patients with newly diagnosed cholangiocarcinoma and 38 healthy control subjects. The association between adiponectin and leptin and tumor stage was evaluated using nonparametric Spearman’s correlation test. Control subjects were matched to case patients by age, sex and BMI. Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.

Results: Overall median adiponectin concentrations were lower in CC patients versus control subjects (5.1 vs 9.3 mg/mL, P = 0.001). In CC patients with T stage 2–4 (n = 22) median adiponectin concentrations were significantly lower than in CC patients with T stage 1 (n = 16) (3.8 vs 6.6 mg/mL, P = 0.001). The mean leptin levels were not significantly decreased in CC patients (P = 0.45). Adiponectin concentrations were inversely correlated with tumor T stage (r = -0.811, P = 0.01) of CC patients. Higher adiponectin levels at baseline were associated with increased overall survival in T stage 2-4 patients (Cox F test = 2.139, P < 0.05).

Conclusion: This study identified an association between adiponectin levels and tumor stage suggesting a potential role for adiponectin in progression of cholangiocarcinoma. Furthermore these results suggest, for the first time, that serum adiponectin levels might represent a prognostic indicator in patients with CC. Our results support the hypothesis linking adipose-tissue derived hormones levels to growth of obesity-associated cancers (3). Adipokines appear to play an important role in risk prediction and management of cholangiocarcinoma patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

weigh, 23–24.9 kg/m²; obese, retrospectively reviewed. The relationship between BMI (kg/m²) and overall incidence. Vary in different cancers. Biliary tract cancer was less frequently analyzed and most of the studies were on the relationship between obesity and cancer incidence. Aims & Methods: We performed this study to investigate the association between BMI and survival in advanced biliary tract cancer patients with chemotherapy. Between January 2005 and December 2015, two hundred and eighty-four patients who underwent chemotherapy for biliary tract cancer were retrospectively reviewed. The relationship between BMI (kg/m²) and overall survival (OS) was assessed. Based on World Health Organization BMI category and 2014 Clinical Practice Guidelines for Overweight and Obesity in Korea, BMI was classified as follows: underweight, <18.5 kg/m²; normal, 18.5–22.9 kg/m²; overweight, 23–24.9 kg/m²; obese, ≥25 kg/m². Results: Median OS was 12.1 months for underweight patients, 10.5 months for normal-weight patients (BMI 23–24.9 kg/m²) had a reduced risk of mortality in significantly associated with better survival. Compared with normal patients, overweight patients (BMI 23–24.9 kg/m²) had a reduced risk of mortality in multivariate analysis (HR 0.491, CI 0.334–0.721; 95% p = 0.036). In the additional analysis for the effect of change in body weight and BMI to the overall survival, larger amount of change in body weight was associated with further decrease in overall survival. Conclusion: Slightly overweight status and the maintenance of body weight during the initial period of chemotherapy is independent predictor of better overall survival in advanced biliary tract cancer patients with good performance status. P0746 THROUGH THE CATHETER BIOPSY METHOD FOR BILIARY CARCINOMA

T. Okuzono
Department Of Gastroenterology, Sendai Kousei hospital, Sendai Japan

Contact E-mail Address: okuzonotoru@gmail.com

Introduction: To perform curative operation of biliary carcinoma, the pre-operative identification of exact proximal and distal margins is important. A biopsy forceps is conventionally inserted to common bile duct via duodenal ampulla, guided with an antecedent guide wire. Cannulation of the bile duct with the biopsy forceps may sometimes be difficult in cases where no sphincterotomy is performed, placing the patient at risk of post-ERCP pancreatitis after multiple attempts to advance the forceps into the duct. Pancreatobiliary endoscopists have reported the biopsy methods. Aims & Methods: The aim of this study was to assess the feasibility and safety of the technique. This was a retrospective review of bile duct biopsies with this new method conducted in Sendai Kousei hospital from February 2015 to October 2016. All patients who had biliary stenosis were included. Patients’ demographic data, technical success, adverse events and the diagnostic accuracy were evaluated. Results: A total of 95 biopsy procedures were performed in 40 patients. The technical success rate was 95% (90/95). Post-ERCP pancreatitis occurred in 1 of 40 patients (2.5%, 1 grade 1 patient). There were no other adverse events like perforation or bleeding. The diagnostic yield of biopsy procedures was 100% (7 of 7 patients). Conclusion: The new biopsy methods to biliary stricture were feasible and safe. It opens up exciting possibilities for endoscopic preoperative diagnosis of the biliary carcinoma. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Malignant biliary obstruction has a poor prognosis unless secondarily to a resectable primary cancer. Recent data on PTC for the relief of malignant obstruction in a palliative setting demonstrated a high early mortality. We have therefore examined outcomes of ERCP in inoperable malignant obstruction.

Aims & Methods: The Hospital Episode Statistics (HES) database contains diagnostic and procedural data for all hospital attendances in England. HES is linked to the Office for National Statistics (ONS) to provide mortality data. All subjects from April 2001 to April 2015 in England with an ICD10 code for cancer 2 years prior to ERCP or in the following 6 months were examined. Subjects undergoing a curative surgical procedure were excluded. Associations between demographics, co-morbidities, unit ERCP volume and mortality were examined by logistic regression.

Results: 49055 subjects were included in the study of whom 48.7% were male, median age 74.5 years (range 19–104). Pancreatic cancer was the most common aetiology (63.5%), followed by liver and intrahepatic bile duct malignancy (19.4%). Mortality was 4.16%, 10.9% and 19.6% for 7 day, in hospital and 30 day mortality respectively. Multivariate analysis male gender (OR 1.14, (95% CI 1.08–1.20) p < 0.001); increasing by age quintile 64–71 (1.34, (1.23–1.47) p < 0.001), 72+ (1.12, (1.04–1.20) p < 0.001), 1.68–2.00) p < 0.001); increasing co-morbidity score 1 to 5 (1.09, (1.02–1.16) p < 0.001), 6–8 (1.32–1.35, p < 0.001); 11 to 15 (1.19, (1.33–1.66) p < 0.001); 16 to 20 (1.21, (1.14–1.30) p < 0.001); male gender, increasing co-morbidity score 1 to 5 (1.09, (1.02–1.16) p < 0.001), 6–8 (1.32–1.35, p < 0.001); 11 to 15 (1.19, (1.33–1.66) p < 0.001); 16 to 20 (1.21, (1.14–1.30) p < 0.001); and upper tertile of unit ERCP activity (p = 0.024) were associated with increasing 30 day mortality. Asian ethnicity (0.82, (0.67–0.99), p = 0.036), Cancer of extrahepatic and unspecified parts of biliary tree (0.60, (0.47–0.74), p < 0.001); advancing year of ERCP 2013/14 (0.78, (0.68–0.89), p < 0.001), 2014/15 (0.85, (0.74–0.98), p = 0.028); and previous renal failure (1.92, (1.77–2.09), p < 0.001) were associated with increasing 30 day mortality.

Conclusion: Short-term mortality in subjects with malignant biliary obstruction following ERCP was high. A better prognosis was observed in; high-volume ERCP units, Asian ethnicity and extrahepatic primary cancers. Male gender, advancing age, increasing co-morbidity score, greater deprivation and previous renal failure predicted death at 30 days.

P0750 EARLY DEVELOPMENT OF NONALCOHOLIC FATTY LIVER DISEASE IN GENETICALLY PREDISPOSED CHILDREN WITH OVERWEIGHT AND OBESITY DOES NOT COINCIDE WITH METABOLIC DERANGEMENTS

K. Karnebeck1, J. Plat2, A. Vreugdenhil3
1Department Of Pediatrics, Maastricht University Medical Centre, Maastricht/Netherlands
2Department Of Human Biology, School Of Nutrition And Translational Research In Metabolism (nutrim), Maastricht University, Maastricht/Netherlands

Contact E-mail Address: kylie.karnebeck@umcu.nl

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease and in particular a health threat in obese children. Single nucleotide polymorphisms in genes encoding PNPLA3 (rs738409) and TM6SF2 (rs58542926) contribute to the development of NAFLD. It is however unknown whether liver parameters and cardiometabolic disturbances coincide in non-carriers and non-carriers of these risk alleles in an at-risk obese pediatric population. Therefore, we assessed cardiometabolic derangements, genetic predisposition for NAFLD and liver transaminase levels in children with overweight and obesity.

Aims & Methods: One hundred and seventy-four children (49% boys) from the Centre for Overweight Adolescent and Children’s Healthcare (COACH) at the Maastricht University Medical Centre were genotyped for PNPLA3 I148M and TM6SF2 E167K. Anthropometric, cardiometabolic risk and liver-related parameters were determined.

Results: Anthropometric parameters did not differ significantly between carriers and non-carriers of the risk alleles. ALT and AST were significantly higher in PNPLA3 G allele carriers as compared to the C allele carriers (ALT; CC 21 (0, 101), GG 26 (0, 101); p = 0.034, 0.000; GG 27, 50 (21, 00, 40, 00); p = 0.015) for the PNPLA3 G genotype, compared to the CC genotype. Carriers of the PNPLA3 risk allele did not show a deteriorated metabolic profile compared to non-carriers.

Conclusion: Despite significantly higher liver transaminase levels and a positive correlation between ALT levels and triglyceride and fasting insulin concentrations in PNPLA3 G allele carriers, these children did not have a more deteriorated cardiometabolic profile compared to non-carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0751 TWO-DIMENSIONAL SHEAR WAVE ELASTOGRAPHY IN CHILDREN: WHAT IS THE MEANING OF MEASUREMENTS NEEDED FOR A HIGH QUALITY EVALUATION?

C. Pienar1, P. Velea1, D. Gherhardt2, I. Ciucci3, C. Paul4, O. Béli5, S.A. Popescu1, E. Sporea2

Introduction: Pediatric chronic liver diseases are becoming a public health issue. Ultrasound based elastographic techniques have emerged as non-invasive methods of pediatric liver fibrosis assessment. The most recent are two dimensional (2D) SWE techniques. While elastography appears to be highly reproducible in children, there is still no consensus regarding the number of measurements to be performed for a high-quality evaluation.

Aims & Methods: We aimed to investigate the number of liver stiffness measurements (LSM) needed for a high-quality evaluation using a 2D SWE technique. We conducted a prospective study which included 73 children (age range: 3–17 years, mean age 11.73 ± 3.35 years, 37% girls, mean body mass index (BMI) 25.12 ± 7.38 kg/m²). We used the 2D-SWE.GE (Logiq E9, GE Healthcare, Chalfont St. Giles- UK), with a C1-Transducer. One examiner performed 10 LSM for each child. We randomly extracted 1 LSM, 2 LSM, 3 LSM and 5 LSM from all 10 and calculated their respective medians. We employed the Friedman test to compare the medians of 1, 2, 3, 5 and 10 LSMs. We used the interclass correlation coefficient (ICC) to assess the agreement between the medians of 1, 2, 3, 5 and 10 LSMs.

Results: Medians calculated from 1, 2, 3, 5 and 10 LSMs were similar (ICC = 0.893 (0.72–0.95) vs 4.22 ± 0.91 kPa, 4.25 ± 1.03 vs 4.2 ± 0.99 kPa vs 4.19 ± 0.99 kPa, p = 0.94). Furthermore, the agreement between medians calculated from 1, 2, 3, 5 and 10 LSMs was excellent (ICC = 0.960, 95% confidence interval: 0.944–0.974).

Conclusion: We suggest obtaining 5 LSM for a high-quality evaluation using this 2D SWE technique.

P0752 PERCUTANEOUS EMBOLIZATION OF VISCERAL ARTERY PSEUDO-ANEURYSMS – A TERTIARY CENTER EXPERIENCE

R. Chavan1, J. Singh1, Z. Nabi, R. Kalapala2, D.N. Reddy3
1Gastroenterology, India Institute of Gastroenterology, Hyderabad, Hyderabad/India

Contact E-mail Address: drradhikachavan@gmail.com

Introduction: Visceral artery pseudo-aneurysms are rare, but potentially fatal if rupture. Pseudoaneurysm usually occurs most frequently after pancreatitis. Angiembolization with conventional trans-catheter approach is the standard treatment. Direct percutaneous embolization has been commonly used for treatment of peripheral artery pseudoaneurysm when trans-catheter approach is not feasible. However, very limited data is available regarding its safety and efficacy in visceral artery pseudoaneurysm.
Aims & Methods: We aimed to assess the technical feasibility, safety and effic- iency of percutaneous embolization as an alternative treatment option for visceral pseudo aneurysms. We retrospectively evaluated the data of patients who underwent percutaneous embolization at our institution from Feb 2007 to March 2017. All procedures were performed under ultrasound (US) guidance and both embolization techniques (transarterial and transvenous) were used. Technical feasibility, safety and efficacy of percutaneous embolization were analysed. At 30 days follow up US with color Doppler/dual phase computed tomography was done to see for recurrence of pseudoaneurysm.

Results: 23 patients (18 male) with mean age of 34.47 ± 21.28 (7–72) years, under- went direct percutaneous embolization for visceral pseudo aneurysm. Most common aetiology for pseudo aneurysm was pancreatitis (16) followed by trauma (3), paracentesis (3) and surgery (1). The site of pseudo aneurysm was splenic artery (3), left gastric artery (3), hepatic artery (3), inferior epigastric artery (3) and gastroduodenal artery (1). Mean size of pseudo aneurysm was 1.8 ± 0.6 (1–3.5) cm. Reasons for choosing percutaneous approach over transcatheter embolization included: technical difficulties in 11 patients, excess collat- erals that would obstruct the feeding artery in 5 patients, and recurrence after pre- vious embolization in 6 patients. Agents used for embolization-glue with lipiodol (21), coil (1) and coil with glue (1). Mean procedural time was 11.3 ± 2.11 (8–16) minutes and fluoroscopy exposure time was 2.4 ± 1.14 (1–6) minutes. Percutaneous embolization was successfully performed in all patients (technical success 100%). Mild adverse events included: local site pain in 19 (80%) patients. Moderate adverse event included: splenic infarct in 5 patients, all of which responded to conservative management. There were no major adverse events and no occurrence of distant embolization. At median follow up of 910 days (30–3186) there was no recurrence of pseudoaneurysm (clinical success 100%).

Conclusion: Percutaneous embolization is safe and effective for treatment of visceral artery pseudoaneurysm. Percutaneous technique may be considered as an alternative to trans-catheter embolization in cases of challenging anatomy, multiple collaterals and recurrence after previous embolization precluding transcatheter approach.

Introduction: Chronic (CP) and autoimmune pancreatitis (AIP) are characterized by different pathophysiologic mechanisms. Whether CP is a preseucibility for autoimmunity is still unclear. AIP is considered mostly a T-cell mediated disease; however, in induction of chronic pancreatitis macrophages play a pivotal role. Cytokine dependent kinase (cdk) inhibitors are critical regulators in inflammatory disease and pancreatic fibrosis, activating autophagy, differentiation of macrophages, and apoptosis. In particular, p21 has been described as a mediator of inflammation and various autoimmune diseases by regulating T-cell activation and promoting macrophage development. We therefore examined the role of p21-mediated inflammation in AIP.

Aims & Methods: Human pancreas samples from CP and AIP patients were evaluated for p21 expression. To investigate the effects of p21 in pancreatitis, we intercrossed lymphotixin overexpressing mice (Tg(Elf-1/L-a,b)−/−) a model to study CP and AIP – with p21 deficient (p21−/−) mice. Infiltrating cells were visualized by immunohistochemistry, supported by gene expression analysis in an early and a progressive phase. Circulating autoantibodies and the presence of circulating autoantibodies and the presence of circulating autoantibodies and neutrophil infiltration to the pancreas. Interestingly, neutrophils do not recruit into the interstitium, suggesting that they are present as a result of local processes.

Results: p21 was upregulated in human CP patients but remained unchanged in AIP patients. p21 deficiency in LT mice (LtP21−/−) prevented early pancreatic injury. LtP21−/− mice had normal serum amylase, reduced inflammatory gene expression and histopathology. In acinar cells diminished proliferation and aberrant activation of non-canonical NF-kB pathway was observed. In contrast, 12 months old LT mice with and without p21 had similar inflammatory gene expression and T & B cell infiltration. Interestingly, Lt and LtP21−/− mice had comparable tertiary lymphoid organs (TLOs), autoreactive and elevated IgG levels. However, acinar cell proliferation, acinar-to-duodenal metaplasia and acinar non-canonical NF-kB pathway activation remained impaired in LtP21−/− pancreata.

Conclusion: Our findings indicate that p21 is crucial for pancreatitis in LT-driven pancreatic injury. p21 is involved in early acinar secretion of inflammatory mediators that attract innate immune cells. However, p21 is not essential for humoral immune response, accountable for autoimmunity and lack of p21 does not rescue AIP. Notably, p21 interventional NF-kB activation and renders acinar cells less susceptible to proliferation and transdifferentiation. We therefore suggest that chronic and autoimmune pancreatitis follow different inflammatory processes.

Introduction: Various forms of pancreatitis (e.g. severe acute pancreatitis, auto- immune pancreatitis type 2) are characterized by an infiltration of neutrophil granulocytes. Yet, despite sharing the feature of granulocytic infiltration, these diseases take opposing natural courses of disease. A novel function of granulo- cytes, the formation of aggregated neutrophil extracellular traps (aggNETs), has been described and called for a reevaluation of the specific role of neutrophils in pancreatitis. We were interested in the specific function of granulocytes in various models of pancreatic inflammation.

Aims & Methods: Experimental models of pancreatic inflammation were employed including caerulein-induced pancreatitis and a novel model of IL-17A-induced pancreatitis. The outcome of disease was characterized by immu- nohistochemistry, DNA expression and flow cytometric analyses.

Results: Transgenic systemic delivery of IL-17A alone can induce granulocytosis and neutrophil infiltration to the pancreas. Interestingly, neutrophils do not recruit into the interstitium, suggesting that they are present as a result of local processes.

Conclusion: Granulocytes aim to contain an inflammatory focus and enter pan- creatic ducts with potentially detrimental consequences to dependent areas of the organ.

Introduction: Mitochondrial dysfunction is a hallmark of several disease patho- genesis including acute pancreatitis (AP). Our results suggest that mitochondrial damage is crucial in bile acid induced inhibition of pancreatic ductal HCO3− secretion, however the details of mitochondrial function and dysfunction in pan- creatic ductal epithelial cells (PDEC) is not known yet.

Aims & Methods: The aim of our study was to characterize the mitochondrial function and distribution in pancreatic ductal epithelial cells under physiological and pathophysiological conditions. Guinea pig and Cyclophilin D WT and knock out (KO) mouse pancreatic ducts were used. Mitochondrial distribution was studied by electron microscopy (EM). Mitochondrial membrane potential (ΔΨm) was measured by confocal microscopy and pancreatic ductal HCO3− secretion by microfluorometry.

Results: EM measurements revealed that the mitochondrial density is signifi- cantly higher on the apical side of the guinea pig PDEC compared to the middle or the basal segment in HEPES solution. The apical mitochondrial den- sity increased further in CO2/HCO3− buffered solution, or during the adminis- tration of 5 µM forskolin. It was also confirmed by the ΔΨm measurements as we detected increased TMRM fluorescence on the apical side of the PDEC during stimulation. The genetic KO of cyclophilin D WT markedly reduced the loss of ΔΨm and protected pancreatic ductal HCO3− secretion during the adminis- tration of 500 µM chenodeoxycholic acid.

Conclusion: Our results revealed that mitochondrial function has a central role in the function of PDEC presumably by providing ATP for fluid and ion secretion. On the other hand the opening of MPTP seems to be crucial in the bile acid induced toxicity offering a potential therapeutic target in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

United European Gastroenterology Journal 5(5S)

Introduction: Inflammatory complications are major causes of mortality in severe acute pancreatitis. Most infections in AP are intestinal origin (2). The Nucleotide oligomerization domain 2 (NOD2) is a NOD-like receptor family member that senses and responds to bacterial wall peptides (3). Guenther et al. reported that p.R702W mutation was found to be associated with multiple organ failure and mortality in patients with AP (4). We aimed to investigate whether there is a correlation between NOD2 variants and AP severity in this study.

Aims & Methods: Group 1 (n = 27) was healthy. Group 2 (n = 36) and Group 3 (n = 32) were composed of mild and severe pancreatitis patients according to the Atlanta 2012 classification (5). Four NOD2 variants and serum interleukin-6 (IL-6), Tumor Necrosis Factor-α (TNF-α) and lipopolysaccharide-binding protein (LBP) levels were studied.

Results: We detected p.R702W variant in 3 patients (3/32, 9.4%) in severe pancreatitis group, but this variant was not seen in the other two groups. 1007fs variant was found in 3, 3 and 1 patient in mild (3/36, 8.3%) and severe pancreatitis (3/32, 9.4%) groups, and in healthy group (1/27, 3.7%), respectively. There was no significant difference in the frequencies of NOD2 variants between groups. Serum IL-6, TNF-α and LBP levels were significantly higher in the severe pancreatitis group than in the healthy group and mild pancreatitis group (all p < 0.001). However, there was no significant difference between these cytokine levels and NOD2 variants.

Conclusion: Our results suggest that there may be a relationship between the presence of p.R702W variant and severe pancreatitis.

P0757 DETERMINANTS OF SEVERITY IN ACUTE PANCREATITIS - A NATION-WIDE PROSPECTIVE MULTICENTER STUDY

Introduction: Pancreatic pseudocyst (PC) and walled-off necrosis (WON) are frequent complications of acute pancreatitis. Drainage procedure is required for complications such as pain, biliary obstruction, infection, or reflux of bowel contents while improving the stent patency. The aim of this study is to investigate the efficacy and the rate of complications of EUS-guided drainage using novel LAMS with anti-reflux valve for PC and WON.

Aims & Methods: We compared the technical success, outcomes of the LAMS group compared to the plastic stent group. Ten patients underwent EUS-guided drainage using the novel LAMS (LAMS group) and eighteen patients using conventional plastic stents (plastic stent group) from December 2013 to October 2016. A novel LAMS used in this study was designed to have bilateral flare ends, 4 anti-migration flaps (at each side) and a pair of 2 anti-reflux valves (inside the lumen). Technical success was defined as a successful placement of the stent. Clinical success and clinical success is defined as a resolution of the PC/WON and disappearance of the symptoms.

Results: Among 10 patients treated with LAMS, 4 patients had complicated PC and 6 patients had WON. In plastic stent group, 15 patients had complicated PC and 3 patients had WON. The median size of fluid collection before treatment was 69.5 mm (range, 48-214 mm) in LAMS group and 92.0 mm (56-253 mm) in plastic stent group. Median duration of stent placement was 47 days (1-355 days) in LAMS group and 55 days (1-216 days) in plastic stent group. Treatment outcomes of the LAMS group were not inferior despite the significantly higher proportion of WON patients in the LAMS group compared to the plastic stent group. There were no statistically significant differences in the technical success rate (100% vs. 94.4%; p = 0.959), clinical success rate (70% vs. 77.8%; p = 0.491), resolution rate (76.8% vs. 80.7%; p = 0.705), complication rate (40% vs. 50%; p = 0.456). In LAMS group, 3 patients experienced mild fever and 1 patient showed peritonitis due to immediate stent migration. In plastic stent group, mild fever was developed in 4 patients, all amount of pneumatic peritonitis was in 1 patients, self-migration of stent (after resolution of fluid collection) was in 2 patients. 3 patients showed serious adverse events - 1 patient in each group experienced peritonitis due to immediate stent migration and 1 patient with plastic stent group developed active bleeding. Procedure time (30.7 minute) vs. 41.2 minutes; p = 0.106) and fasting period after treatment (3.1 days vs. 2.1 days; p = 0.344 were also not different between two groups.

Conclusion: For EUS-guided drainage, LAMS showed acceptable treatment outcome compared to the rate in conventional drainage even in relatively small amount of pancreatic fluid collection. And no additional fasting period was required in the LAMS group compared to the plastic stent group. Further well-designed prospective studies are needed to validate these findings.

An attack is lower than patients without cholecystectomy, and the difference was
5.35–16.30); 30.6% (26/85), 6.18 (IQR 2.60–9.07). To biliary AP, the recurrence

Aims & Methods: This study aimed to retrospectively correlate the clinical char-
acteristics of the necrotic cavity with the extent of endoscopic transmural drainage: 49
patients (38 males; mean age 60.79 ± 13.44) with symptomatic WON treated by
an attempted EUS-TD initially were enrolled in this study. The relationship
between the outcome of treatment and the clinical characteristics including morpho-
logical and endoscopic characteristics of WON was assessed.

Results: The mean size of WON was 126.63 ± 46.79 mm. EUS-TD was techni-
cally successful in 48/49 (97.9%) patients and 26 (54.2%) improved with EUS-
TD alone while step up approach was needed in 19 patients. DEN, percutaneous
necrosectomy may be required. The factors

Introduction: Endoscopic ultrasound-guided transmural drainage (EUS-TD) has
been shown to be a safe and effective minimally invasive treatment for walled-off
necrosis (WON). However, in some cases, simple drainage is not sufficient to manage
the symptoms of WON and step up approaches such as direct endoscopic
necrosectomy (DEN) and surgical necrosectomy may be required. The factors
associated with the outcome of endoscopic treatment for WON remain unclear.

admission to European hospital. A receiver operating characteristic (ROC) analysis was built up to classify patients of severe AP. Later, a multiple discriminant analy-sis was performed, using the Wilks lambda test, to identify the variables that differ most between patients with mild AP and moderate/severe AP. A ratio calculated using the most discriminant cytokines was studied in relation to sever-ity and mortality.

**Results:** ROC curves showed that TH1 cytokines IL6, IFN-γ and TNF-α can be measured for the prediction of severe AP, while TH2 cytokines IL4, IL13, GM-CSF, for the prediction of a mild or moderate condition. A stepwise analysis showed that IL13 and IFN-γ were the biomarkers which contributed most to the discrimination between mild and moderate/severe AP (Wilks’ lambda = 0.855, p < 0.0001; Wilks’ lambda = 0.747, p < 0.0001, respectively). We calculated the IL13/IFN-γ index. This ratio was significantly higher in patients with mild AP with respect to patients compared between groups (p = 0.025). This difference was also observed between severe AP and the rest of the patients (p = 0.007). The ROC curve was also modified, increasing the area under the curve (AUC), the sensitivity and the specificity, in relation to AP severity.

Comparing an IL13/IFN-γ ratio that could be of great interest in the assessment of prognosis in AP. A high value of the IL13/IFN-γ ratio at hospital admission is associated with a good prognosis of AP.

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is a common and serious adverse event following ERCP, with a reported incidence of 9.7% in unselected patients [1]. Given huge economic and clinical burden, effective approaches for post-ERCP pancreatitis prophylaxis remains a major priority for research. Nonsteroidal anti-inflammatory drugs (NSAIDs) have also been shown the potential efficacy in prophylaxis PEP across high-risk patients, especially for diclofenac or indomethacin [3–5]. Recently, a prospective, double-blind, controlled trial conducted by Levenick [6] and colleagues in the USA showed that the reduction in PEP using indomethacin was not as significant as previously reported. In fact, even more cases of pancreatitis occurred in indomethacin group compared with placebo group. Subsequently, a high-quality meta-analysis also concluded that there is no prophylaxis for the prevention of PEP among average-risk patients[7]. These findings raised the question that whether administration of rectal indomethacin should be recommended in average-risk patients.

Aims & Methods: We aimed to determine the beneficial effect of rectal indomethacin in the prevention of post-ERCP pancreatitis in average-risk of patients. We systematically searched for Medline and EMBASE, Web of science, and Cochrane library before October 2016. Studies that evaluated rectal administration of indomethacin in the prevention of post-ERCP pancreatitis were included in the analysis. We adopted a random-effects model to calculate overall relative risk (RR) and 95% confidence interval (CI).

Results: We identified ten randomized clinical trials from initial search and finally included in the meta-analysis. Administration of rectal indomethacin significantly reduced the incidence of PEP in combined population (RR, 0.63; 95% CI, 0.50–0.77). There was no significant heterogeneity across included studies (I² = 14.2%, P = 0.31). In subgroup analysis, rectal indomethacin was effective in both high-risk (RR, 0.49; 95% CI, 0.35–0.71) and average-risk (RR, 0.69; 95% CI, 0.55–0.86) patients and reduced the risk of mild and moderate to severe pancreatitis. The overall results remained unchanged and robust in sensitivity analysis. There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Rectal administration of indomethacin is an effective approach to prevent the incidence of post-ERCP pancreatitis both in high-risk and average-risk population undergoing ERCP. However, more high-quality randomized controlled trials are needed to further investigate the optimal timing for administration of indomethacin.

Disclosure of Interest: All authors have declared no conflicts of interests.

Introduction: Acute pancreatitis (AP) is one of the most common gastrointestinal diseases requiring hospitalization with an annual incidence of 13–50 cases per 100,000 persons. It is a potentially fatal disease with an overall mortality ranging from 2 to 8%. Both epidemiology and outcomes are variables according to the different hospitals. Furthermore, few studies have evaluated the impact of the hospital units on AP outcomes.

Aims & Methods: To evaluate both the trend and outcomes of acute pancreatitis according to the admitting hospital units: Surgery, Internal/General Medicine, Gastrointestinal (GI) Unit, Intensive Care Unit (ICU). This is a retrospective
cohort study based on the anonymous computerized database of hospital discharge (Veneto Region, North-East of Italy). The principal diagnosis of AP according to the International Classification of Diseases 9th revision, Clinical Modification (ICD 9-CM, code 577.0) of the hospital discharges was selected. The period from January 2001 to December 2015 was analysed. Veneto population was considered as the reference population (in the period, it varied from 4,529,823 to 4,927,527 inhabitants, with 51% females). Hospitalization, Length of stay (LOS), in-hospital mortality, need for surgery (according to the DRG 191–194, 199–201 which identified bila-pancreatic surgery) were reported according to hospital Units. Statistics: Chi squared for trend and Odds Ratio (OR) were applied.

Results: During the analysed period, 23,389 overall hospitalizations for AP, annual hospitalizations of 32 patients/100,000 inhabitants and in-hospital mortality of 3.2% were observed. Characteristics of the patients were: mean age: 62.2 ±/−19.3y, 54% Males (M); Female (F) mean age: 65y/+/−19.3ys, male mean age: 59.4y/+/−19.3ys (p < 0.05). Hospitalizations was higher in males (M: 35.4: F: 28.4, OR 1.24 (95% CI: 1.20–1.27, p < 0.001). On comparison to General Medicine Units, GI units were associated with a low in-hospital mortality (OR: 0.37, CI 95%: 0.28–0.49, p < 0.05) and an high NFS (OR: 2.88, CI 95%: 2.18–3.81, p < 0.05).

Admitting Hospital Unit: Number of In-Hosp. Lengths of stay (%) Mortality (%)
(2001–2015) cases (%) (days) General Medicine (Non GI) 6, 980 (30%) 13.5 ± 10.7 4.3% 88 (1.3%)
Gastrointestinal (GI) Units 3, 797 (16%) 12 ± 11.2 1.7% 135 (3.6%)
Surgical Units 12, 112(52%) 13 ±/−13.6 2.7% 443 (3.7%)
Intensive Care Unit 52 (2%) 17.2 ± 21.8 12.9% 42 (8.1%)

**Conclusion:** During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality rate and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a best outcome: lower in-hospital mortality and probably, more eligible patients for surgical treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0768 ACUTE PANCREATITIS IN PATIENTS WITH IPMNS: RETROSPECTIVE STUDY OF 346 PATIENTS OBSERVED FROM 2009 TO 2016
L. Brozzi1, A. Amadio1, F. De Marchi1, R. Teresa Marzia1, I. Bromi1, P. Campagnola1, S.F. Cirino1, A. Gabbrielli1, L. Frulloni1
1 Medicine, AOUI Verona-Pancreas Center, verona/Italy
2Gastroenterology, University of Verona, Verona/Italy
Contact E-mail Address: Lorenzo.brozzi89@gmail.com

Introduction: In literature the frequency of acute pancreatitis (AP) in patients with IPMNs varies between 12 and 65%, but most of studies are from surgical series and often pancreatitis occurred after surgery was included. Furthermore, most of the studies includes in the dictum of "symptomatic IPMNs" the presence of less severe disorders, such dyspeptic symptoms, making series unclear.

Aims & Methods: The aim of this study was to investigate the correlation between the severity of IPMN and acute pancreatitis and his disease severity. A retrospective analysis was performed on all observed patients with IPMN-MD, IPMN-BD and mixed type at Gastroenterology Unit in the period between January 2009 and March 2016. In the study patients with an instrumental or histological diagnosis of IPMNs were included.

Results: A total of 346 patients (164 males and 182 females, mean age at the first report 61.6 ± 12.2 years). At the time of radiological diagnosis, 45% were asymptomatic, 51% had had symptoms, while 4% of the data were missing: the frequency of AP (excluding biliary etiology) of all 346 patients with IPMN was 26%. AP was edematous in 85% of patients and necrotic in 15%. We found increased frequency in patients with PA with IPMN of the main pancreatic duct (MD and mixed), and unfocal type. The localization to the body seems to more be correlated with the presence of AP. The number of cysts (for IPMN-BD and mixed type) was significantly lower in patients who have had AP.

Conclusion: Our medical extraction series confirms that the PA is an event that occurs in 26% of patients with IPMN, with a prevalence of the male sex, it is associated with a IPMN central and mixed type, predominantly located in the head to the body. The pancreatitis is not associated with malignancy in resected patients.

P0769 APOLIPOPROTEIN B AND A-I RATIO PREDICTS SEVERE ACUTE PANCREATITIS
J. Kim, K.J. Lee
Internal Medicine, Yonsei University Wonju College of Medicine Dept. of Internal Medicine, Wonju/Korea, Republic of Korea

Contact E-mail Address: jawkim96@yonsei.ac.kr

Introduction: Severe acute pancreatitis (SAP) has a considerable mortality and morbidity rate. Although many indices have been developed to classify the severity of acute pancreatitis (AP), there is no ideal method for predicting SAP. The ratio of apolipoprotein B to A-I (apoB/A-I) is associated with metabolic syndrome and inflammatory status.

Aims & Methods: This study aims to investigate the association between severity of AP and serum apoB/A-I ratio. Patients with AP were prospectively enrolled at Yonsei University Wonju College of Medicine from March 2015 to August 2016. The severity of acute pancreatitis was assessed according to the revised Atlanta classification criteria (Atlanta 2012).

Results: Of 191 patients with AP, 134 (70.2%) were classified as mild AP, 42 (22.2%) as moderately severe AP, and 15 (7.9%) as SAP. The apoB/A-I ratio was highest in patients with SAP compared with those with mild and moderately severe AP (p<0.001). The apoB/A-I ratio positively correlated with Atlanta classification, computed tomography severity index, and Bedside index for severity of AP. The apoB/A-I ratio showed the highest ability to predict SAP in patients with AP compared with apolipoprotein B or apolipoprotein A-I alone.

Conclusion: Serum apoB/A-I ratio appears to have value in predicting SAP in patients with AP.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0770 IMAGING IN CHRONIC PANCREATITIS – DATA FROM THE SCANDINAVIAN-BALTIC PANCREAS CLUB DATABASE

1Department Of Clinical Medicine, University of Bergen, Bergen/Norway
2Pediatric Department, Hankelund University Hospital, Bergen/Norway

Contact Email Address: trond.engjom@helse.bergen.no

Introduction: The Scandinavian-Baltic Pancreas-Club database collects data from patients with chronic pancreatitis (CP) in Nordic countries. Grading of structural changes is important in the description of a CP cohort.

Aims & Methods: We aimed to characterise structural changes of the pancreas in patients with CP. Subjects with definitive or probable CP according to the M-ANNEHIM diagnostic-criteria were included. Structural changes were graded according to the M-ANNEHIM-classification. A subgroup was also scored by the modified Cambridge score. Clinical data on disease-duration, nutrition, exocrine function, pain, alcohol/smoking habits and frequencies of malnutrition and diabetes were collected. A grouping of the M-ANNEHIM score (A: Normal = 0, B: Minimal change = 1 to 2 and C: Moderate/marked = 3–4) was performed for correlation to the clinical data.

Results: The database contains 932 patients (623 men). The M-ANNEHIM-score was present from 446 subjects and both imaging scores from 93 subjects. According to M-ANNEHIM subjects were graded as 0: Normal (8,1%), 1: Equivocal (22,9%), 2: Mild (12,1%), 3: Moderate (17,9%) and 4: Marked (39,0%). Correlation of the imaging scores: The imaging-scores demonstrated acceptable correlation (ρ = 0.75, p < 0.001) and good agreement (ICC = 0.71 (0.59, 0.8), p < 0.001). Agreement was best for groups with marked changes. The clinical parameters divided by M-ANNEHIM groups are presented in the table.

<table>
<thead>
<tr>
<th>Clinical parameter</th>
<th>A: Normal</th>
<th>B: Minimal change</th>
<th>C: Marked</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disease duration (Years)</td>
<td>3.6(5.2)</td>
<td>4.6(5.8)</td>
<td>5.0(6.4)</td>

<td>0(0–18)</td>
<td>0(0–18)</td>
<td></td>
</tr>
</tbody>
</table>

*p < 0.05 (Kruskal-Wallis). No other differences reached significance. Values: mean (SD) or median [IQR-range]. Malnutrition: BMI < 18.5.

Conclusion: Subjects with marked structural changes had the highest lifetime smoke-doses. There was poor correlation of structural changes to the clinical features. The two imaging scores demonstrated acceptable correlation and agreement. Poor agreement in normal/minimal-change groups may reduce the value of the scores where they are most needed. The results are presented on behalf of the SBPC study group.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In patients with chronic pancreatitis (CP) malabsorption of vitamins D and K, alcoholism, smoking and inflammatory status contribute to low bone mineral density (BMD). A recent meta-analysis estimated the prevalence of osteoporosis (25%) and osteopenia (40%) in CP and highlighted limitations of the reviewed studies.

Aims & Methods: To evaluate the prevalence of osteoporosis and osteopenia in patients with CP and to investigate the correlation between BMD and CP features, and vitamin D and PEI. This is a multicentre cross-sectional study (P-BONE, A Pancreas 2000 project) on prevalent CP patients. The Diagnosis and severity of the disease was defined according to the M-ANNEHIM classification. Clinical information and biochemical variables were recorded: PEI was assessed by fecal elastase. Standardized dual-energy X-ray absorptiometry was performed by dual energy x-ray absorptiometry (DEXA). Categorical variables were analysed by means of Fisher’s exact test, and continuous variables by t-test. A logistic regression analysis was performed to identify risk factors for osteoporosis or osteopenia. The relationship between continuous variables was assessed with Pearson correlation coefficient.

Results: 211 consecutive CP patients were enrolled at 6 Centres (67% M; mean age 60 ± 13 years). Osteopenia was diagnosed in 42% and osteoporosis in 22% of cases. Aetiology was alcoholic in 43%, and 18% had severe CP. 56% of patients had PEI. The mean value of vitamin D was 20ng/ml and 56% of cases had vitamin D insufficiency. There was no correlation between vitamin D levels, or elastase levels and t-score at either spine or femur. Alcoholic aetiology was associated with higher risk of osteoporosis at low levels of fecal elastase (p 0.02) and with lower level of vitamin D (p 0.001) but not with osteoporosis or osteopenia. Female sex and older age seems to be associated with a higher risk of developing osteoporosis (OR 4.595%CI 2.98–9.001; OR 1.09 95% CI 1.30–1.50) while a higher BMI is associated with a reduced risk of its occurrence (OR 0.89 95%CI 0.77–0.94 p 0.001).

Conclusion: The present data confirm a high rate of osteopathy in CP patients. However, there was apparently no correlation between BMD, pancreatic exocrine function, severity of the disease or vitamin D levels. Other factors, such as vitamin K might deserve investigation for their possible relationship with bone mineral density in CP patients.

Introduction: The Scandinavian-Baltic-Pancreatic-club database collects patients with chronic pancreatitis (CP) from Nordic countries. Description of exocrine pancreatic insufficiency (EPI) and consequences is important in characterization of CP cohorts.

Aims & Methods: Characterise EPI from CP in a Northern European cohort. Patients with definitive or probable CP (M-ANNHEIM diagnostic criteria) were included from nine centres. Demographic data, body-mass index (BMI), faecal elastase (FE), enzyme-doses and lab-parameters were collected. Values: Mean (SD) unless otherwise stated. EPI-classification grouped patients as follows: A: Normal, B-Mild: EPI not requiring enzymes, C-Proven: EPI requiring enzymes.

Clinical parameter (A) Normal (B) Mild insufficiency (C) Proven insufficiency

Exocrine pancreatic function (%)

33 16 51

Faecal Elastase (µg/g) (mean (SD)) p < 0.001

368 (161) 128 (144) 51 (69)

Nutrition: (kg/m²) (mean (SD)) p < 0.005

24.6(4.9) 23.7(4.3) 22.6(4.3)

Frequency BMI > 25 (%)

5 16

Vitamin D: Frequency BMI < 18.5 (%)

5 23.7 17.6

Enzyme Treatment (lipase-units/day) (median [IQ range])

0[0–7500] 120000

Hemoglobin: (median [IQ range]) p < 0.05

11.8(2.7–3.0) 10.7(2.8)

Faecal Elastase and disease duration (years)**

<10: 143(175) >10: 91(18)

*p < 0.001. 9% received <5000 lipase-units/day. 14 subjects having FE > 200 received enzymes, 48 subjects with FE < 100 received no enzymes. **no age/sex differences in EPF

Conclusion: In our material frequency of EPI is higher than reported in the NAPS2 study (31%). Consequences of EPI were lower BMI, underweight, higher enzyme-doses and lower haemoglobin. Need for vitamin D supplements was highest in the group with mild EPI not receiving enzymes.

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ductal alkaline fluid (which is regulated mostly by the anion exchanger and CFTR) is diminished in CP.

Aims & Methods: In this study we would like to understand whether smoking has any effects on pancreatic ductal fluid and HCO3− secretion. Guinea pigs were exposed to cigarette smoke four times a day for 30 min for 6 weeks. The CFTR expression was analysed by immunohistochemistry. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking of 15 cigarettes into 10 ml distilled water by a smoking machine. Intracellular Ca2+ concentration and pH were evaluated by microfluorometry. Fluid secretion was measured by video microscopy. CFTR currents were detected by whole cell configuration of patch clamp technique.

Results: Cigarette smoking significantly diminished the expression of CFTR and the fluid and HCO3− secretion in guinea pig pancreas. CSE dose dependently decreased fluid and HCO3− secretion in guinea pig pancreatic ducts via inhibition of anion exchanger, Na+/H+ exchanger and Na+/HCO3− cotransporter and also forskolin-stimulated Cl− current of CFTR Cl− channel. CSE incubation altered the pattern of carbazochrome-induced Ca2+ signal in pancreatic ducts suggesting that some of the inhibitory effects may be regulated by calcium signalling.

Conclusion: Tobacco smoking and CSE inhibits pancreatic ductal fluid and HCO3− secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA, SZTA and UNKP.

Introduction: Rapid on-site cytologic evaluation (ROSE) for determining the suitability of a specimen often provides high efficacy of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA). In our center, we propose an additional role of ROSE in histological diagnosis aimed at improving diagnostic accuracy.

Aims & Methods: From January 2009 and December 2015, 215 patients were evaluated who underwent both endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) for pancreatic solid lesions and surgery. We retrospectively compared the diagnostic performance of ROSE during EUS-FNA with the final diagnosis confirmed by surgically resected specimens. Diagnosis by ROSE using Diff-Quik was carried out by both a cytopathologist and an endoscopist.

Results: The median of needle passes required for ROSE was 1 (range, 1–5). Final diagnoses for the 215 lesions were pancreatic ductal adenocarcinoma (PDAC; n = 102), pancreatic ductal adenocarcinoma (PDAC; n = 9), pancreatic neuroendocrine tumor (pNET; n = 30), solid pseudopapillary neoplasm (SPN; n = 9), metastatic tumors (n = 4), and acinar cell carcinoma (ACC; n = 1). Primary lesions for metastatic tumors in the pancreas were renal cell cancer (RCC; n = 2), small cell lung cancer (SCLC; n = 1), and colon cancer (n = 1). When adenocarcinoma (including suspicious cases) was suspected by ROSE, ROSE diagnosed 94.6% (159/168) of adenocarcinomas. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, ROSE diagnosed 96.4% (27/28) of special type tumor.

Conclusion: All adenocarcinomas suspected by ROSE were malignant tumors. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, Diagnostic accuracy of ROSE was 96.4%. Diagnostic accuracy using ROSE is high agreement in final histological diagnosis. It is suggested that ROSE may also be useful for diagnosis of special type tumor.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has one of the most dismal prognoses of all cancer types. Diagnostic techniques for early malignant lesions are limited, which shows an evident need to understand the pathomechanism leading to PDAC and find a suitable marker for early detection. Initial processes in PDAC development involve acinar to ductal metaplasia (ADM) with further neoplastic progression into four pancreatic intraepithelial neoplastic (PanINs) stages. After accumulation of mutations, these lesions will further evolve into PDAC. Gastrokin 1 & 2 (GKN1 & GKN2) are secreted proteins found in the stomach where they are involved in gastric epithelial homeostasis. While current research focuses on the exploration of tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of KRAS, Tp53, Cdkn2a, Cdkn2b and macroautophagy (hereafter referred to as autophagy) has been implicated in some of human diseases, lesions in vitro was tested.

Results: GKNs were upregulated during early stages of pancreatic carcinogenesis in mouse and human tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of KRAS, Tp53, Cdkn2a, Cdkn2b and macroautophagy (hereafter referred to as autophagy) has been implicated in some of human diseases, lesions in vitro was tested.

Conclusion: We identified for the first time specific gastrokine expression in pancreatic ductal adenocarcinoma (PDAC) in human and mouse pancreatic tissue. The secretion into pancreatic juice. Preliminary results from the first timepoint of analysis showed accelerated tumor development in GKN1+ve KC mice. Wild type acinar cells transdifferentiated in vitro only in the presence of TGFa. On the contrary, GKN1+ve acinar cells transdifferentiated spontaneously, and resulted in higher number of ADMs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0778 AUTOPHAGY IS ESSENTIAL FOR PANCREATIC CANCER DEVELOPMENT IN A NEW HUMANIZED GENETICALLY-MODIFIED ADULT MOUSE MODEL

Introduction: Pancreatic ductal adenocarcinoma is one of the deadliest malignancies and there are no effective therapies for it. According to a search of The Cancer Genome Atlas (T-CGA) project (release 8.0), pancreatic cancer has one of the highest numbers of deleterious mutations in human cancers. TCGA, alterations in Kirsten rat sarcoma (KRAS), Tumour protein (TP)53, Cdkn2a and Cdkn2b genes. Besides, increased autophagy was observed in the lenti- and shRNA-KTCC infected primary cells. This finding provides considerable insight into the role of autophagy in pancreatic cancer and autophagy inhibition might be a potential target in treating pancreatic cancer.

Aims & Methods: Our aim was to analyse gastrointestinal cancer cell response to various hyperthermia levels, accompanied by chemotheraphy, in a manner of cell cytotoxity, apoptosis and intracellular cisplatin concentration. Cancer cell lines of gastric (AGS), pancreatic (T4M4) and colorectal (Caco-2) origin were exposed to cisplatin and different temperature regimens (37°C to 45°C) either in isolated manner, or in combination. Cells were treated for one hour, mimicking HIPEC timing in clinical setting. The intracellular concentration of cisplatin was measured immediately after experiment by mass spectrometry. 48 hours later changes of cell viability and apoptosis rates depending on temperature in addition to cisplatin treatment were evaluated by MTT and Annexin-V/AAD flow cytometry respectively.

Results: Response of AGS to hyperthermia was as implied. Viability of the cells was gradually decreasing by raising the temperature. CACO-2 cells had no significant response to temperature rise up to 42°C, but at 43°C viability dropped by 14% constantly remaining at higher temperatures. T4M4 cells acted in an unexpected manner, whereas decreasing viability by 30% in the interval between 37°C to 42°C and 20% increase at 43°C was observed. Following simultaneous exposure to hyperthermia and cisplatin we observed no additive temperature alteration in the cell survival. However, at particular temperature regimens, we observed temporary proliferation increase: AGS – at 42°C (33%); T4M4 – at 43°C (32%). Higher temperatures dramatically inhibited AGS – by 70%; T4M4 - by 76%. There was the linear pattern of slight decrease (up to 26% at 45°C) of viability in CACO-2 cells. Isobologram analysis of combined hyperthermia and cisplatin treatment revealed strong antagonism of hyperthermia and chemotherapy in all analyzed cell lines. Nevertheless, hyperthermia of 43°C in addition to cisplatin promoted apoptosis of AGS cells by 33%, CACO-2 by 26%, T4M4 by 19%. Moreover, application of hyperthermia (43°C) could contribute to increase of intracellular cisplatin concentration by 30%, 20% and 18% AGS, CACO-2 and T4M4 cells respectively.

Conclusion: Our results indicate that there is no linear contribution of hyperthermia to chemotherapy in all analyzed cell lines. Therefore, in clinical setting it should be applied individually, regarding cancer type. Moreover, particular temperatures can worsen the treatment and increase cancer cell growth.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0779 HIPEC IN GI CANCERS. IS HYPERTHERMIA FRIEND OR FOE?

Introduction: Hyperthermia as a positive additive to chemotherapy is described in multiple studies. Despite controversial results hyperthermic intraperitoneal chemo-therapy (HIPEC) is a standard treatment option for some types of gastrointestinal cancer that invades peritoneum. However, the results of clinical data and basic research are uneven. Moreover, there is a lack of fundamental knowledge on additive cytotoxic effect of hyperthermia on cancer cells of different origin.

Aims & Methods: We aimed to analyse gastrointestinal cancer cell response to various hyperthermia levels, accompanied by chemotherapy, in a manner of cell cytotoxity, apoptosis and intracellular cisplatin concentration. Cancer cell lines of gastric (AGS), pancreatic (T4M4) and colorectal (Caco-2) origin were exposed to cisplatin and different temperature regimens (37°C to 45°C) either in isolated manner, or in combination. Cells were treated for one hour, mimicking HIPEC timing in clinical setting. The intracellular concentration of cisplatin was measured immediately after experiment by mass spectrometry. 48 hours later changes of cell viability and apoptosis rates depending on temperature in addition to cisplatin treatment were evaluated by MTT and Annexin-V/AAD flow cytometry respectively.

Results: Response of AGS to hyperthermia was as implied. Viability of the cells was gradually decreasing by raising the temperature. CACO-2 cells had no significant response to temperature rise up to 42°C, but at 43°C viability dropped by 14% constantly remaining at higher temperatures. T4M4 cells acted in an unexpected manner, whereas decreasing viability by 30% in the interval between 37°C to 42°C and 20% increase at 43°C was observed. Following simultaneous exposure to hyperthermia and cisplatin we observed no additive temperature alteration in the cell survival. However, at particular temperature regimens, we observed temporary proliferation increase: AGS – at 42°C (33%); T4M4 – at 43°C (32%). Higher temperatures dramatically inhibited AGS – by 70%; T4M4 - by 76%. There was the linear pattern of slight decrease (up to 26% at 45°C) of viability in CACO-2 cells. Isobologram analysis of combined hyperthermia and cisplatin treatment revealed strong antagonism of hyperthermia and chemotherapy in all analyzed cell lines. Nevertheless, hyperthermia of 43°C in addition to cisplatin promoted apoptosis of AGS cells by 33%, CACO-2 by 26%, T4M4 by 19%. THE INTRACELLULAR CYTOSKELETON MARKER IS OVEREXPRESSED IN PANCREATIC DUCTAL ADENOCARCINOMA

Aims & Methods: Our goal was to assess the significance of activin protein expression in PDAC related to the clinical stage and survival. There were included patients with histological proven of adenocarcinoma (n=115) and a median follow-up of 24 months (SD 124). The plasma levels of activin were analyzed using western blot. The t test was used to determine the difference between the two groups, Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Results: Activin was overexpressed more frequently in PDAC compared to controls (p=0.001), and has been closely related to advanced clinical stage (stage III-IV), tumor size, location and with the presence of metastasis (p<0.05). Activin expression was higher in patients with type 2 diabetes (p=0.04). No relationship between activin level and the patients age, sex or tumor size, was noted. Patients with activin high expression had a shorter survival time than PDAC patients with activin low expression (Log-rank = 4.35; p=0.03).

Conclusion: Activin pathway is related to cachexia and the local spread of PDAC, the presence of diabetes and survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0782 QUALITY OF LIFE DURING CHEMOTHERAPY IN JAPANESE PATIENTS WITH UNRESECTABLE ADVANCED PANCREATIC CANCER

K. Shibayama1, F. Koga2, S. Nakashita3, N. Oza4, T. Otsuka4, N. Ureshimo5, Y. Kawaguchi6

1Department Of Nursing, Saga-Ken Medical Centre Koseikan, Saga/Japan
2Department Of Hepatobiliary And Pancreatology, Saga-Ken Medical Centre Koseikan, Saga/Japan
3Department Of Oncology, Saga-Ken Medical Centre Koseikan, Saga/Japan

Introduction: This study is to assess QoL during chemotherapy in patients with advanced pancreatic cancer. Twenty-one Japanese patients with unresectable advanced pancreatic cancer and performance status 0–1 were included in this study. All patients were treated with FFX or Gn as first-line chemotherapy. QoL was assessed using the Japanese Organization for Research and Treatment for Cancer Quality of Life Core Questionnaire (EORTC QLQ-C30), and anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS) at baseline and 2 weeks and every month after initiation of chemotherapy. Changes between score at baseline and median score after chemotherapy were compared using Wilcoxon signed-rank test. Continuous variables are presented as median (range).

Results: Thirteen male and 8 female patients were included, with a median age of 65 (59–75) years and BMI of 21.3 (16.0–26.2) kg/m2. The chemotherapy regimens were FFX in 5 men and 2 women, modified-FFX in 4 men and 4 women, and Gn in 4 men and 2 women. Eight patients took opioids for pain, and 4 received celiac plexus neurolysis. Regarding global health status (GHS) and functional scales in QLQ-C30, baseline scores were: GHS, 50 (17–92)%; physical, 87 (53–100)%; role, 83 (33–100)%; emotional, 67 (33–100)%; cognitive, 83 (33–100)%; and social, 67 (11–100)%.

Conclusion: Pain as well as QoL factors should always be considered to manage chemotherapy properly in patients with advanced pancreatic cancer. Disclosure of Interest: All authors have declared no conflicts of interest.

treated by EUS-CPN. Clinical information was obtained retrospectively from the medical report. The follow-up was associated with the patient died or was lost to follow-up. Between November 2014 and March 2017, 70 patients with PC pain were enrolled. We performed EUS-CPN by injection of 5 ml of bupivacaine mixed with 15 ml of pure ethanol on the celiac axis and normally occluded pancreatic duct by an endoscopic ultrasound-guided fine needle aspiration needle. Treatment response was assessed by self-reported pain relief and change in the daily dose requirement of morphine. Treatment response was defined as or decrease or stay of the same amount of morphine consumption after EUS-CPN, or achieve morphine dosage level within 4 weeks after EUS-CPN if morphine consumption temporarily elevated because of the delayed response of EUS-CPN. Pain evaluation was conducted at 1 week, 4 weeks after EUS-CPN and tumor disease progression.

Results: The pain relief rate was 81.4% (57/70). The median duration of pain relief was 4 months. 10 patients required a second EUS-CPN due to pain relapse, and 90% (9/10) showed response to the repeat procedure. Of the 44 patients who showed response to the initial EUS-CPN during chemotherapy, the response is related to the diagnosis of metastasizing in 18% of cases compared to 45% of other presentations (P = 0.017). Between the response group and no-response group, there were significant differences in the prevalences of liver metastasis (47 vs. 92%, P < 0.001), lower metastasis (12 vs. 38%, P = 0.02) and lymph node metastasis (56 vs. 92%, P < 0.015), and in the serum levels of CEA (median: 6.7 vs. 17.1 mg/ml, P = 0.017), CA19-9 (median: 617.2 vs. 3519 U/ml, P = 0.009), CRP (median: 0.61 vs. 1.91 mg/dl, P = 0.029) and albumin (median: 3.4 vs. 3.8 g/dl, P = 0.029). Univariate analysis revealed a significantly smaller percentage of patients with CRP level elevation over 3.0 mg/dl from baseline within 4 weeks after EUS-CPN (11 vs. 38%, P = 0.01). The overall survival after EUS-CPN was also significantly longer in the response group as compared to the no-response group (median: 5.8 vs. 1 month, P = 0.03).

Conclusion: Our study demonstrated that EUS-CPN had therapeutic effect on intractable pain in unresectable PC in the long follow-up. Repeat EUS-CPN was also effective in patients who showed a treatment response to the first EUS-CPN. Positive benefit from EUS-CPN had strong cancer inflammation and aggressiveness, indicative of higher CRP, CA19-9 and lower albumin levels, and the higher frequencies of liver metastasis.

Introduction: Pancreatic ducal adenocarcinoma (PDAC) 5-year survival rate is only 6% as only 20% of patients are eligible for surgery at diagnosis, due to distant metastases, and chemotherapy is often only palliative. Given the highly accurate assay, risk assessment of the IPMN cases was tested. At present, 92 PDA and 145 IPMN patients with either benign or malign disease stage at diagnosis. However, symptoms and delay do not seem to affect disease stage at diagnosis. However, symptoms and delay do not seem to affect prognosis. These results suggest that diagnosis at the preclinical stage is necessary to change disease prognosis.

P0786  TREATMENT EFFICACY AND ADVERSE EVENTS OF GEMCITABINE PLUS NAB-PACLITAXEL USED FOR METASTATIC PANCREATIC CANCER: A RETROSPECTIVE COHORT STUDY
Department Of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: irae0428@yuhs.ac

Introduction: Pancreatic cancer is a lethal disease and the fifth most common cause of cancer-related death in Korea. Pancreatic cancer patients show dismal prognosis with a 5-year survival rate less than 10%, because the majority of patients are diagnosed in advanced stage. Since the late 1990s, gemcitabine-based chemotherapy has been used as a mainstay of metastatic pancreatic cancer (mPC) treatment and various combination therapies (such as combination with capetibafone or erlotinib) had been attempted to improve the patients’ survival, so far. Recently, MPACT trial, a randomized phase III trial showed that combination of gemcitabine and nab-paclitaxel had statistically significant survival benefit compared with gemcitabine monotherapy. Based on the results of this trial, gemcitabine with nab-paclitaxel combination therapy is currently being used as a standard therapy for pancreatic cancer patients. However, only 2% of the MPACT trial study population was Asian, and other researches on Asian population group are also lacking. Therefore, we investigated treatment efficacy and safety of gemcitabine plus nab-paclitaxel combination therapy for mPC treatment in Korean population.

Aims & Methods: Total 66 metastatic pancreatic cancer patients treated with gemcitabine (1000mg/m²) and nab-paclitaxel (125mg/m²) regimen (on day 1, 8, 15 of a 28-day cycle) as the first line chemotherapy from February 2016 were identified using the Severance Hospital Pancreatic Cancer Cohort Registry. Treatment efficacy (overall survival (OS), progression-free survival (PFS), objective response rate) and treatment-related adverse events (AE) of patients (occurrence rate, severity grade and dose-intensity) were analyzed.

Results: The median follow-up period was 7.4 months (range 1.5–14.9 months); during this period, 21 (31.8%) patients died. Median cumulative dose of gemcitabine was 685.5mg/m² (range 251.9–1070.8mg/m²) and nab-paclitaxel was 3021.4mg/m² (range 1095.8–6031.3mg/m²). Grade 3/4 neutropenia was the most common AE (59.1%) followed by general weakness (48.5%), alopecia (48.5%), nausea (45.5%), and nausea and vomiting (42.4%). The incidence of neutropenia was 54.5% and 12 (18.2%) patients experienced grade 3 neutropenia. 30 (45.5%) patients showed grade 3 neuropathy and 10 (12.2%) patients had febrile neutropenia. Grade 3 gastrointestinal AE was observed in 11 (16.7%) patients and 26 (42.4%) patients experienced dermatologic AE such as alopecia and skin eruption. About 59% of patients experienced treatment delays due to adverse events. Dose reduction was performed in 39 (59.1%) patients and 14 patients experienced treatment cessation due to severe AE.

Conclusion: These results suggest that gemcitabine and nab-paclitaxel combination therapy is effective for metastatic pancreatic cancer treatment in East-Asian population group. Similar to previous studies, this combination therapy showed remarkable neurotoxicity and myelosuppression. Careful monitoring and proper management during chemotherapy is required.

P0787  IMPACT OF PREOPERATIVE EUS-FNA ON PERITONEAL RECURRENT AND SURVIVAL IN PATIENTS WITH PANCREATIC CANCER
Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: ilonaelona@hanmail.net

Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is a useful and safe method for tissue confirmation of malignancy. This method has the risk of tumor cell dissemination along the needle track or within the peritoneum by preoperative EUS-FNA.

Aims & Methods: The aim of our study was to estimate the risk of peritoneal recurrence and the impact on long-term outcomes by preoperative EUS-FNA in resected pancreatic cancer. The records of patients diagnosed with pancreatic cancer who underwent curative resection between 2009 and 2013 were reviewed retrospectively. A total of 394 patients were included: 78 patients with preoperative EUS-FNA (EUS-FNA group) and 316 without preoperative EUS-FNA (Non-EUS-FNA group). Peritoneal recurrence was diagnosed based on image findings.

Results: Median length of follow-up was 23 months (range 1~94 months). A total of 82 patients had peritoneal recurrence: 34.6% (27/78) in EUS-FNA group vs. 28.2% (89/316) in Non-EUS-FNA group (P=0.20). Cancer-free survival and overall survival were not different between the groups: median cancer-free survival in EUS-FNA group was 10.8 months compared with 10.6 months in Non-EUS-FNA group (P=0.83), and median overall survival in EUS-FNA group was 56.4 months compared with 56.7 months in Non-EUS-FNA group (P=0.93).

Conclusion: Preoperative EUS-FNA for pancreatic cancer was not associated with an increased rate of peritoneal recurrence and mortality. Our study suggests that EUS-FNA is a safe method for obtaining tissues of pancreatic masses.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gemcitabine (Gem) therapy had been the standard treatment for advanced pancreatic ductal adenocarcinoma (PDAC) for long time. Even though FOLFIRINOX, a combination of fluorouracil, oxaliplatin and irinotecan, and gemcitabine-nab-paclitaxel (GnP) therapy are currently recommended as first-line drugs, Gem is still one of the important options. Efficient permeation of Gem into cells requires specialized integral membrane transporter proteins to cross plasma membranes. Among these transporters, the major mediators of Gem uptake into human cells are the human equilibrative nucleoside transporter 1 (hENT1). In the previous study started since 2005, we found hENT1 expression in endoscopic ultrasonography-guided fine-needle aspiration biopsy (EUS-FNAB) samples to be a useful prognostic marker of Gem-based chemoradiotherapy (Gem-CRT) for pancreatic ductal adenocarcinoma (PDAC) (Pancreas 2016). Since November 2011, our institution has replaced Gem + tegafur/gimeracil/oteracil (S-1) (GS-CRT) with Gem-CRT in an attempt to improve clinical response and prognosis. Aggregate median survival time (MST; months) of GS-CRT was compared with previous Gem-CRT result, and the superior efficacy of GS-CRT was observed (MST: 16 versus 20, respectively), particularly in hENT1-negative patients (MST: 9 versus 14, respectively). However, there were no differences in
Six were excluded (4 with IPMN without worrisome features nor surgical indication were considered. A further assessment of DPD expression was carried out in those samples determined to have sufficient material remaining (n = 58). This is the first meta-analysis showing that statins exert a protective effect on the incidence of PDAC. Future studies taking into account statin dose, duration and subgroup of patients are needed in order to clarify the association.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this study, we aimed to overcome the subsampling issue and to establish a more reliable framework for quantification of rare tumor cell-derived mutant alleles for non-invasive diagnosis of gastrointestinal cancer. To establish more reliable ddPCR protocol for quantification of low-frequency alleles within a limited cfDNA pool, two-step multiplex ddPCR targeting eight KRAS-gene-relevant mutant KRAS variants was examined using a Bio-Rad QX200 droplet digital PCR platform. Plasma samples from patients with colorectal cancer (n = 10) and pancreatic cancer (n = 9) were evaluated, and cfDNA from healthy volunteers (n = 30) was utilized to calculate reference intervals.

Results: Limited cfDNA yields in patients with resectable colorectal and pancreatic cancers did not meet the requirement for efficient capture and quantification of rate mutant alleles by ddPCR. To overcome the subsampling issues and achieve better assay specificity, we attempted pre-amplification of plasma cfDNA using primers flanking KRAS exon 2 as the first-step PCR. Eight pre-amplification cycles followed by a second-run ddPCR were sufficient to approximate 5000–10,000 target alleles/ng cfDNA, resolving the subsampling issue; furthermore, the signal-to-noise ratio for rare mutant alleles against the massive background was present by the wild-type allele was significantly enhanced. The cut-off limit of reference intervals for mutant KRAS was determined to be ~0.09% based on samples from healthy individuals.

Conclusion: The modification introduced in the ddPCR protocol facilitated the quantification of low-copy alleles carrying driver mutations, such as oncogenic KRAS, in localized and early-stage cancers using small blood volumes, thus offering a minimally invasive modality for timely diagnosis.

Contact Email Address: chelle884@yuhs.ac

Introduction: Benefit of second line chemotherapy (SL) after failed first-line chemotherapy (FL) for advanced pancreatic cancer has not yet been established. We intend to identify prognostic factors and ultimately devise a model of clinical parameters for decision of SL versus basic supportive care (BSC) after failure of FL chemotherapy.

Aims & Methods: 408 patients who received gemcitabine-based first-line chemotherapy for advanced pancreatic adenocarcinoma at Yonsei University Hospital between January 2010 and December 2014 were retrospectively reviewed. Significant clinical parameters regarding second line related survival were identified using a stepwise predictive factor analysis.

Results: 161 of 408 (39.5%) received SL therapy. Median overall survival from the beginning of SL (OS2) was 20.0 weeks (14.0 ~ 34.0). Significantly more SL patients presented higher body mass index (BMI) (p=0.001) and ECOG 0–1 (p=0.003) at diagnosis, lower rate of lung metastasis (p<0.001) and longer duration of FL (p<0.001). More SL patients had received gemcitabine-based concurrent chemo-radiation therapy (CCRT) (p=0.029) compared to FL only patients. Presence of liver metastasis was significant to OS2 were BMI at diagnosis (p=0.019, HR=0.870), duration of FL therapy (median duration 16weeks (8.0-28.00)) (p=0.004, HR=0.986), presence of peritoneal metastasis (p=0.002, HR=1.732) at diagnosis, malignant thrombosis during firstline chemotherapy (p=0.001, HR=0.428). Experience of CCRT was also a significant prognostic factor (p=0.001, HR=2.245); initial staging of the CCRT group was TNM stage3, which might be the ultimate factor impacting OS2.

Conclusion: Study suggests that SL chemotherapy may be beneficial for patients with longer duration of FL chemotherapy, higher BMI at diagnosis, patients without peritoneal metastasis at diagnosis, no malignant thrombosis event during chemotherapy and patient initially TNM stage3, who received Gemcitabine based CCRT.

Introduction: Rapid on site evaluation for endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) of the pancreas provides immediate information regarding cellular adequacy, avoiding repeated procedures.

Aims & Methods: The aim of this study was to evaluate the impact of ROSE in EUS-FNA of solid pancreatic lesions. Retrospective study of consecutive EUS-FNA of solid pancreatic lesions, in a tertiary center, between 2012 and 2016. A total of 259 EUS-FNA was performed on 197 patients with mean age of 63.4 (+/− 12.8) years. The anatomical distribution of the lesions was: 56.4% in the head, 17% in the body, 10% in the uncinate process and 5.8% in the tail. The mean number of passes was 3.3 (+/−1.4) and the needle size was 25G in 60.8% and 22G in 23.8%. ROSE was performed 34.7% of the punctures (23.6% along with the initial EUS-FNA), with a mean number of passes 3.4 (+/−1.9). The diagnostic yield of initial EUS-FNA without ROSE was 44.8% vs 83.6% when ROSE was performed (p < 0.001). When not conclusive, there was no significant differences in the diagnostic yield of the repeated EUS-FNA with (with and without ROSE). Beyond ROSE in the first puncture, higher levels of Ca 19.9 (199 vs 10ng/mL, p = 0.001), size of the lesion (31.6 vs 29.8 mm, p < 0.001), invasion of adjacent structures (64.6% vs 47.5%) and malignancy (73.2% vs 25.4%, p < 0.001) were associated with EUS-FNA diagnostic accuracy. In multivariate analysis, ROSE (p = 0.001) and the size of the lesion (p = 0.023) were independent predictors of adequate diagnostic samples. In this study, ROSE was able to improve the diagnostic yield in solid pancreatic lesions and should be considered whenever possible in the first procedure, until an overall adequate diagnostic yield (>70%) is achieved.

Introduction: Postoperative digestive fistula remain a challenging condition associated with a high morbidity-mortality, unsatisfactory healing rates and high refractoriness. The limitation of current approaches highlights the need for a better therapeutic strategy in terms of both long-lasting efficacy and safety. Mesenchymal stem cell (MSCs) are strongly involved in tissue injury repair. MSCs feature an immune-privileged status while displaying pro-angiogenic,
and antifibrotic properties. Increasing evidences point out MSC action via sub-cellular extracellular vesicles (EVs), MSC EVs recruit or reprogram the therapeutic properties of their cellular counterparts while offering remarkable advantages in terms of safety (no proliferation, no differentiation, no vascular occlusion following administration) and shelf life stability. Herein, we evaluated, in vivo, the role of the healing potential of MSC EVs delivered through a thermoresponsive gel (Pluronic F127) allowing the administration in a sol state through a catheter and gelation in situ at body temperature to retain EVs at fistula site.

Aims & Methods: Seventeen esophageal fistulas were surgically created by placing two plastic stents during 30 days into the neck of 9 pigs and randomized into control group (n = 6) and treated groups (gel alone n = 6 and gel-EVs n = 5). In the gel-EVs group, Pluronic F127 gel contained allogeneic EVs collected from the swine adipose stem cell conditioned medium, tested and radiological evaluation of fistula healing was performed at day 30 and day 45, before histological assessment.

Results: All fistulas were successfully induced at day 30. At day 45, the control group showed no improvement and external fistula secretion in all pigs. For this group, radiological evaluation showed open fistula tracts, which were confirmed by histology. In the gel group and gel-EVs groups, radiological examination showed a complete fistula closure in 67% (4/6) and 100% (5/5) of the animals, respectively. In the gel group, histological analysis confirmed a complete fistula for 3 from 6 cases while a partial closure was observed for 1 case from 6. In the gel-EVs group, histological complete fistula closure was reported for 4 from 5 cases while a partial closure was evidenced in 1 from 5 cases. In comparison with control group, treated fistulas showed a reduced inflammatory infiltrate and fibrosis and an enhanced angiogenesis, especially in the gel-EVs group.

Conclusion: This study provides the first evidence in the literature that MSC-EV's migration and angiogenic effect in a pre-clinical model. EVs were intravenously fully administered via a thermoresponsive Pluronic F127 hydrogel, gelling in situ to enable EV retention in the fistula tract. Besides, the gel further provided a pro-angiogenic and an anti-inflammatory effect. The combined action of MSC EVs and the pro-enhanced healing associated with EVs was confirmed by angiogenesis and fibrosis in the esophageal fistula model. This investigation paves the way towards a future sub-cellular localized fistula therapy merging safety and efficacy.

P0795 REAL-TIME MULTIPHOTON MORPHOLOGICAL IMAGING FOR DIAGNOSING GASTRIC ATYPICAL HYPERPLASIA AND ADENOCARCINOMA

K. He1, L. Zhao1, M. Wang1, X. Wang1, L. Liu1, Z. Fan1
The First Affiliated Hospital with Nanjing Medical University, Nanjing/China

Contact E-mail Address: fanzhining@njmu.edu.cn

Introduction: Compared with histopathology, real-time histology or virtual biopsy is important for clinical diagnosis, especially for endoscopic examination. Based on two photon fluorescence (TPF), multiphoton microscopy (MPM) imaging could demonstrate cell autofluorescence and second-harmonics generation (SHG) signal from collagen, which implied real-time information on tissue architecture and cellular morphology. More importantly, no contrast agent is needed for this live diagnosis. The aim of this study is to evaluate the feasibility of MPM to histologically diagnose gastric diseases, compared with other chromoendoscopy and H&E histopathology.

Aims & Methods: A pilot study was performed between March 2016 and August 2016. 30 gastric tissue slides (normal, low-grade dysplasia (LGD), high-grade dysplasia (HGD), and cancer) were examined under MPM. MPM and H&E images were compared by the experienced pathologist. Cellularity/nuclei ratio was analyzed to compare morphological features, while the major/minor axis was calculated to reveal cellular asymmetry.

Results: Near-infrared light (800 nm) was optimized and applied for multiphoton autofluorescence imaging in gastric tissue. Under MPM, gastric dysplasia tissue demonstrated enlarged, while cancer cells were characterized by irregular size and shape, enlarged nuclei, and increased nuclear-to-cytoplasmic ratio. All these were confirmed by H&E images. (Figure 1) The mean cellular/nuclear ratio for normal mucosa was 20.55±4.94, LGD 34.00±1.39, HGD 46.85±3.72, and cancer 56.80±3.37 (P<0.05). The mean major/minor axis ratio for normal mucosa was 1.31±0.09, LGD 2.02±0.16, HGD 1.70±0.18, and cancer 1.43±0.18 (P<0.05).

Conclusion: MPM-based optical biopsy was feasible and efficient to clinically diagnose gastric cancer. With miniaturization and integration of endoscopy, MPM can be applied to provide real-time histological diagnosis without invasive biopsy for gastric cancer in the future.

The prevalence of gastric peptic ulcer was 2.9% (30/1034) and gastric scar 0.9% (9/1034), but duodenal ulcer 2.3% (24/1034) and duodenal scar 5.9% (62/1034). In addition, three gastric adenocarcinoma cases (0.29%) have been identified during the upper endoscopy. The study showed statistically significant difference between the groups of individuals with normal and decreased pepsinogen tests with gastric polyps 3.6% vs. 9.2%, p = 0.02, gastric erosions 23.6% vs. 11.2%, p = 0.04, duodenal ulcer (scar) 6.5% vs. 1%, p = 0.02, duodenal lymphangiectasia 1.9% vs. 6.1%, p = 0.02 and reflux esophagitis A–B 18%, reflux esophagitis B–6%, reflux esophagitis C–1, 3% and histologically confirmed Barrett’s esophagus-1.3%. The most common main endoscopic finding was noted gastric erosions 232/1034 (22.4%). The prevalence of gastric peptic ulcer was 2.9% (30/1034) and gastric scar 0.9% (9/1034), but duodenal ulcer 2.3% (24/1034) and duodenal scar 5.9% (62/1034). In addition, three gastric adenocarcinoma cases (0.29%) have been identified during the upper endoscopy. The study showed statistically significant difference between the groups of individuals with normal and decreased pepsinogen tests with gastric polyps 3.6% vs. 9.2%, p = 0.02, gastric erosions 23.6% vs. 11.2%, p = 0.04, duodenal ulcer (scar) 6.5% vs. 1%, p = 0.02, duodenal lymphangiectasia 1.9% vs. 6.1%, p = 0.02 and reflux esophagitis A–B 18%, reflux esophagitis B–6%, reflux esophagitis C–1, 3% and histologically confirmed Barrett’s esophagus-1.3%.

Aims & Methods: To assess the influence of antithrombotic therapy on delayed bleeding rate after ESD, we prospectively investigated the delayed bleeding rate after ESD among the continuation of antithrombotic agents, the cessation of antithrombotic agents and heparin bridge therapy. 735 lesions in 665 patients were treated with ESD from January 2006 to December 2016. We compared the delayed bleeding rate in 153 patients receiving antithrombotic therapy with 512 patients without that. Furthermore, we compared the delayed bleeding rate in the patients continuing antithrombotic therapy with that in the patients with the cessation of antithrombotic therapy or with heparin bridge therapy. The patients who were taking two or more antithrombotic agents were treated with continuation aspirin or clopidogrel. The cessation period of antithrombotic therapy before ESD followed the guidelines for therapeutic endoscopy in antithrombotic agents-users from Japan Gastrointestinal Endoscopy Society. We defined delayed bleeding as hematemesis, a melena, or a decrease of Hb >2 g/dL.

Results: The delayed bleeding rate in the patients receiving antithrombotic therapy was 14.4% (22/153), which was significantly higher than that in the patients without antithrombotic therapy (5.7%: 29/512) (p=0.0007). The median timing of delayed bleeding in patients receiving antithrombotic therapy and that in patients without antithrombotic therapy were 5.7±4.6 days and 7.0±6.8 days, respectively, without significant difference (p=0.48). Of 153 patients taking antithrombotic agents continued and 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), and 30 switched to heparin therapy before ESD (heparin bridge group). One patient was excluded because of uncertain about the period of cessation. The delayed bleeding rate of continuation group, cessation group and heparin bridge group were 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference (p=0.63). The delayed bleeding rate of continuation group was 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference compared to that of total number of cessation and continuation group (13.1% (16/122), p=0.24). Deep vein thrombosis was observed in one patient in the cessation group.

Conclusion: Antithrombotic therapy increased the delayed bleeding rate. However, the delayed bleeding rate in the patients continuing antithrombotic therapy during ESD was similar to that in the patients discontinuing antithrombotic therapy. Therefore, it is inappropriate that the patients with high risk of thrombosis continue antithrombotic therapy on gastric ESD, but the heparin bridge therapy requires a further examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

esophageal squamous cell carcinoma at the endoscopic center of Xinhua Hospital, Third Military Medical University (Chongqing, China) from January 2015 to February 2017, were enrolled in this study. We collected specimens of autologous esophageal mucosal tissue from these patients. After undergone ESD, these mucosal tissues were given via the “ulcer surface” by hemoclips and then fixed by means of a covered metal mesh stent. The stent was removed on post-procedure day 7. All patients were monitored by endoscopy.

Results: In our ESD was safely achieved in all cases. The overall longitudinal diameter of resected specimens was 117.8 mm (range, 70 to 150 mm). Autologous esophageus mucosa was successfully transplanted to “ulcer surface” using an endoscope. The number of mucosal patches ranged from 8 to 28. Complete re-epithelialization occurred within a median time of 8.6 days with a graft survival rate at 93.06%. Postprocedural sticture accompanied by dysphagia occurred in seven patients on post-procedure day 24.7 (range, 18–34 days). The median sessions of EBD and intraluminal steroid injection was 3.3 (range 1–6). No other serious complications occurred in these patients, such as immediate bleeding and perforation. Eight patients were still alive during the mean follow-up period of 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

Conclusion: Transplantation of autologous esophageus mucosa appears to be a safe means of relieving the severity of esophageal stenoses following Circumferential ESD.

was reached in 290/301 (96%) procedures. A perforation occurred in 3/301 ER patients (1% CI 0.21%–3.8%). Two perforations were closed with clips, all three patients received intra-venous antibiotics and were admitted to hospital for 2, 3 and 9 days. Bleeding requiring intraprocedural hemostasis occurred during 15% of procedures. Significant post-procedural bleeding requiring an intervention occurred in 5 cases (2%). Dysphagia requiring endoscopic dilatation occurred in 7 patients (3%), after ER with a mean number of 4 ± 2.9 resected pieces. Mean total procedure time for ER using the new MBM device was 33 ± 17.1 minutes.

**Conclusion:** The new MBM device used in this study proved to be effective for resection of early neoplastic lesions in BE: successful ER was achieved in 96% of procedures. Perforations were seen in 1% and significant post-procedural bleeding in 2%, complications were effectively managed endoscopically.

**P0087 COST-EFFECTIVE ANALYSIS COMPARING STANDARD BIOPSY VS. DIGITAL BIOPSY BY CONFOCAL ENDOMICROSCOPY**

Gastroenterology, Instituto Ecuatoriano de Enfermedades Digestivas, Guayaquil, Ecuador

Contact E-mail Address: carlosouakm@yahoo.es

**Introduction:** Endoscopy has greatly influenced gastrointestinal disease diagnosis. However, most lesions can be suspected but not certainly diagnosed only on the basis of endoscopic findings and therefore, histology is needed. On the other hand the reliability of detecting lesions histologically depends on the site, number, and size of biopsy (Bx) specimens with a 20–30% probability of sampling mistakes. Probe based Confocal Lumer Endomicroscopy (p-CLE) allows endoscopist to perform cellular evaluation of the gastrointestinal (GI) tract with a high (90%) diagnostic accuracy. It allows to perform target Bx. Moreover, the NPV is >98%. There is no information in the literature regarding the economic impact of performing digital biopsies (DBx) by p-CLE.

**Aims & Methods:** The aim of this study is to perform a cost-effectiveness analysis comparing the diagnosis of upper GI tract pathologies using only standard Bx following the literature recommendations (LR) vs. the diagnosis with DBx using p-CLE. This was a retrospective study with prospective collection data of patients included from Jan 2014 to Nov 2016. The pathologies included for p-CLE evaluation are summarized in Table 1. The diagnosis costs using standard Bx was calculated following the literature recommendations (Table 2). The standard Bx costs included the histological process and physician honoraria per Bx (USD 50.00), and one biopsy forceps per patient (USD 38.00). The DBx costs by p-CLE included the probe, the processor and the physician honoraria (USD 500.00). Baseline characteristics, p-CLE indications, the diagnostic accuracy of p-CLE and costs were described.

**Results:** 78 patients were included, 51.2% were female. The mean age was 50.18 years old. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 cases (91.0%). Table 1 shows the procedure cost reached with the different pathologies by following the LR for initial diagnosis and follow-up. The efficacy of p-CLE in our study was 91.7% sensitivity, 89.8% specificity, 90.1% NPV and 90.1% accuracy for the diagnosis of the malignant upper GI tract pathology, by Digital Biopsy with p-CLE. Finally, the cost-effective analysis comparing the diagnosis of upper GI tract pathologies using only standard Bx vs. the diagnosis with DBx using p-CLE is detected if more than 10 biopsies are attempted by procedure.

**Table 1:** Cost analysis following the Literature Recommendations (LR) for initial diagnosis and follow-up

Bx: biopsies; LR: Literature Recommendations. a. For initial diagnosis. b. For follow-up. c. Cost includes histological process and physician honoraria per biopsy (USD 50.00), and the Bx forceps per patient (USD 38.00).

**Conclusion:** In our population, the digital biopsy by p-CLE proved to be more cost-effective, when ≥10 biopsies were indicated, like in cases of a Barrett’s Esophagus ≥4 cm, a Gastric Tumor, or in the context of two or more suspected pathologies (e.g.: esophageal and gastric disease).

**P0088 GASTRIC PER-ORAL ENDOSCOPIC PYLOROMYOTOMY (G-POEM) IN THE TREATMENT OF REFRACTORY GASTROPARESIS: EXPERIENCE OF THE FIRST 9 CASES IN A MEXICO**

O. V. Hernandez Mondragon, R. Palos Cuellar, G. Blanco Velasco, X. Li, Y. O. V. Mondragon, M. Hernández Reyes

Endoscopy, IMSS, Mexico City; Mexico

Contact E-mail Address: mondragonmd@yahoo.co.uk

**Introduction:** Gastroparesis is a syndrome characterized by a delayed gastric emptying, absence of a mechanical obstruction. Reduction in QOL scores has been observed. Etiologies include: idiopathic, diabetic, post-surgical. Diagnosis is based on the combination of symptoms and a delayed gastric emptying scintigraphy(GES) of >10% after 240 min. Multiple treatments have been used with temporary results or high morbidity, so new treatment options have been explored. G-POEM is a new endoscopic treatment which is based in the POEM treatment for achalasic patients and consist in a creation of a submucosal tunnel in order to perform an endoscopic pyloromyotomy. Initial results have been promising.

**Aims & Methods:** The aim of this study was to evaluate the safety and efficacy of G-POEM in a group of Mexican patients with refractory gastroparesis. This prospective study was carried out in a tertiary care center in Mexico city, between December 2016 and April 2017. We included patients with refractory gastroparesis defined as presence of symptoms such as: nausea, vomiting, early satiety with inability to finish a normal meal, bloating and upper gastrointestinal pain. These patients were on medical treatment and didn’t respond and have a positive gastroparesis cardiomagnetic index (GCSI) score combined with a >10% of retention at 240 min in the GES study. Exclusion criteria were malignancy, peptic ulcer disease, normal GES and coagulation disorders. Procedure steps were: performing a POEM procedure, beginning 5cms beyond pyloric arch with an longitudinal incision, then submucosal tunnel creation, myotomy of the pyloric arch up to the serosa and 2cms before this point and finally closure with clips. Follow-up included GCSI, endoscopy and GES at 3 months after procedure. Characteristics of procedure, and patients were documented. Stained pair-t test was used for comparisons between groups and p < 0.05 was considered as statistically significant.

**Results:** There were 9 patients included in this initial study, the mean age was 42.4 ± 8.5 years. 6 patients were female and 3 male. The most common etiology was posturgical 4/9 (44.4%), followed by diabetic 3/9(33.3%) and idiopathic 2/9 (22.2%). The mean G-POEM time was 61.4 ± 7.8 min, and complications were self-limited and presented in only 4 patients, the GCSI score decreased 68% between the pre-procedure levels as well as the GES which decreased 67% compared with levels at 3 months after G-POEM (34.3 ± 5.8 vs 13.1 ± 3.2 p = 0.003/ 20.74 ± 5.3 vs 6.83 ± 1.78 p = 0.001 respectively). 7/9 (77.7%) normalized the GES(<10% at 240 min). Endoscopy at 3 months after procedure didn’t show any complication (Table 1).

**Conclusion:** G-POEM is a safe and effective procedure in Mexican patients with refractory gastroparesis with a normalization of the GES in up to 77% of these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Foreign body (FB) ingestion including food bolus impaction is frequently encountered in clinical practice. Few studies with large sample size
towards endoscopic management of FBs had been reported. No direct evidence has demonstrated the relationship between duration of FB impaction and outcomes of endoscopic management. Moreover, it remained unclear whether endoscopic management of FBs under general anesthesia could improve endoscopic outcomes when compared with topical pharyngeal anesthesia.

Aims & Methods: The aim of the present retrospective study is to analyze our endoscopic outcome and explores the best timing and anesthesia methods of endoscopic intervention in FB ingestion with FB ingestion. All consecutive patients suspected of FB ingestion were enrolled. The demographic, clinical and endoscopic data were collected and analyzed.

Results: Totally, 1294 cases were recruited in this retrospective research. The ages ranged from 7 months to 94 years, with a median age of 47.0 (31-63) years. The majority of patients (1191/1294 cases, 92.0%) presented with some symptoms after FB ingestion, in order of frequency odynophagia (415 cases, 26.3%), foreign body sensation (340 cases, 23.6%) and sore throat (267 cases, 20.1%). The duration of FB impaction ranged from 4 hours to more than 2 years with a median time of 1.063-3 days. Bony FBs, jujube pit, food bolus and dental prosthesis were the most frequent FBs in population. Anatomically, FBs were mostly impacted in the oesophagus (n=1025, 68.9%), especially in the upper oesophagus (n=523, 32.5%), followed by stomach (n=95, 6.1%), duodenum (n=36, 3.0%) and pharynx (n=24, 2.0%). Nearly half of the patients (49.9%) developed FB-related complications, mainly including mucosal injuries (356 cases, 27.5%) and ulcers (210 cases, 16.2%). The most common underlying pathologies were oesophageal stricture (35 cases, 39.3%) and oesophageal cancer (11 cases, 15.5%). As the duration of FB impaction increased, positive finding and successful removal of FB by endoscopy significantly decreased (p < 0.001). Furthermore, complication rate significantly increased with time (p < 0.001). Age (OR=1.15, 95%CI: 1.20-1.91, p < 0.001), type and location of FBs (OR=4.51, 95%CI: 2.95-6.90, p < 0.001; OR=2.26, 95%CI: 1.48-3.46, p < 0.001), anaesthesia methods (OR=1.35, 95%CI: 1.05-1.75, p = 0.02) and duration of FB impaction (OR=1.74, 95%CI: 1.50-2.00, p < 0.001) were verified as risk factors for development of FB-related complication by logistic regression analysis. General anaesthesia could not improve FB detection (p = 0.181) or success rate of endoscopic management of FBs (p = 0.135), as well as decrease the complication rate when compared with topical pharyngeal anaesthesia (52.3% VS 47.5%, p = 0.033).

Conclusion: FB-related complication rate increased with time, endoscopic management under general anaesthesia could not improve therapeutic effects when compared with problem in endoscopic ESD. Patients suspected of FB ingestion should receive endoscopic management as soon as possible.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0810 CLINICAL OUTCOMES AFTER ENDOscopic RESection FOR ESOPHAGUSQUAMOUS CELL CARCINOMA COMPARING THE CASES WITH MM AND SM1 INVASION**

S. Yoshinizu1, T. Yoshi,2, K. Namikawa3, A. Ishiyama3, T. Tsuchida3, J. Fujisaki3

1Cancer Institute Hospital, Tokyo/Japan
2Gastroenterology, Cancer Institute Hospital, Tokyo/Japan
3Contact E-mail Address: toshiyuki.yoshis@jcr.or.jp

Introduction: Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal squamous cell carcinoma (ESCC) with muscularis mucosae (MM) and SM1 invasion as MM/SM1 invasive cancer is reported to have 8-20% of metastatic risks and is defined as relative indication for ER in guideline by Japan Esophageal Society. For them, we perform additional laparoscopic surgery such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients’ condition.

Aims & Methods: To know the difference of metastatic risk and local outcome, we retrospectively studied 121 cases of ESCC with pathological MM/SM1 invasion (MM/SM1:97/24) resected by ER from 2003 to 2013 in Cancer Institute Hospital. After pathological diagnosis of resected lesions, we performed additional therapy such as CRT, radiation therapy (RT) or operation, to the cases with lymphovascular invasion (LVI) or droplet infiltration (DI). Median observation period was 48 months.

Results: Enrolled cases included 112 males and 9 females and their median age was 66 (39-86). We resected ESCC by ESD in 71 cases and by EMR-C in 50 cases and their median size was 27 mm. Local recurrence was observed in 6 cases which were all after EMR (12%). As for local recurrence 5 cases were treated by resection and 1 case by APC, resulting in no re-recurrence. Of 97 cases of MM, 15 cases (15.5%) had LVI, 10 cases (10.3%) had DI. We recommended additional therapy in 21 cases (21.6%). Additional therapy was performed in 15 cases (15.5%) (ope/CRT/RT/9/5/1). No case died of ESCC and 22 cases (22.7%) died of other diseases. Of 24 cases of SM1, 9 cases (37.5%) had LVI, 5 cases (20.8%) had DI. We recommended additional therapy in 12 cases (50.0%). Additional therapy was performed in 9 cases (37.5%) (ope/CRT/RT/chemotherapy: 3/4/1/1). Three cases died of ESCC and 5 cases (20.8%) died of other diseases. Comparing both groups, tumor size and local recurrence rate were not different each other. The frequency of LVI was significantly higher in SM1 than in MM (p = 0.05) and the frequency of DI was higher in SM1, although not significant (p = 0.161). The metastatic recurrence was observed significantly frequent in SM1 than MM (16.7% vs 2.1%; p < 0.01). The 5-year overall survival (OS) did not different each other, but CSS in MM was significantly lower than in SM1 (p < 0.01).

Conclusion: ESCC with MM invasion was superior in metastatic recurrence and CSS than ESCC with SM1 invasion, although we treat MM/SM1 in the same way. Additional therapy should be considered more positively in cases of SM1 than in cases of MM, considering metastatic risk and patients’ conditions.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0811 GASTRIC ESD IN AN ANIMAL SURVIVAL MODEL USING THE ANUBIS-SYSTEM**

J. Bernhard1, H. Steffen2, P. Koehler3, S. Schneider-Kortath2, K. Ludwig2

1Dept. Of Endoscopy, Klinikum Suedstadt Rostock, Rostock/Germany
2Dept. Of Surgery, Klinikum Suedstadt Rostock, Rostock/Germany
3Friedrich Loeffler Institute, Neustadt/Germany

Contact E-mail Address: joern.bernhard@kliniksuend-rostock.de

Introduction: ESD is generally still under evaluation. The one-piece resection of lesions larger than 2 cm has many advantages against piece meal resection. One advantage of flexible preparation in ESD is to lift and prepare the specimen simultaneously. We used the ANUBIS-system for intragastric ESD.

Aims & Methods: The experimental study was conducted in a porcine model in general anesthesia. We started the study with 7 pigs in a survival model using the Anubusscope (Carl Storz, Germany). After insertion of the scope insufflations of the stomach was done using CO2. After the opening of the valves at the tip of the scope, an area of 5 cm in diameter was selected for resection. Injection was done with the two arms of the scope using a grasping and a hook-knife. Also the grasper could use for coagulation. The specimen was removed with the scope after closing its valves.

Results: The procedure was successful in all animals with operation time ranging from 102 to 189 minutes with a learning curve. After weight gain in all cases, the animals were sacrificed after postoperative day 2 and the workup showed competent healing with a star-like scar.

Conclusion: The use of an operating platform like the Anubuscope has the advantages of flexible preparation in opposite position of the instruments in ESD. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Also, it is not possible to reach all regions of the stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0812 USEFULNESS OF NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY AS A SCREENING TEST FOR GASTRIC CANCER**

T. Morishii

Gastroenterology, Kameda Medical Center, Chiba/Japan

Contact E-mail Address: moristatu@yahoo.co.jp
Introduction: Narrow band imaging with magnifying endoscopy (NBI-ME) is used for gastric cancer; however, whether NBI-ME is useful as a screening test for gastric cancers has not yet been determined. Additionally, it is important to consider the impact on the atrophy of the background gastric mucosa in gastric cancer screening because the incidence of gastric cancer depends largely on the degree of atrophy noted in the background gastric mucosa.

Aims & Methods: We aimed to determine the usefulness of NBI-ME as a screening tool for gastric cancer. We retrospectively studied 3515 patients who had undergone screening upper gastrointestinal endoscopy between April 2013 and March 2014. We excluded patients with advanced gastric cancer and those who had undergone gastrectomy. Thus, we studied 1080 patients who received NBI-ME and 2435 patients who had undergone conventional endoscopy. We classified the degree of atrophy of the background gastric mucosa using the Kimura-Takemoto classification. Severe atrophy was noted in 1620 patients (Group S), and mild atrophy in 1895 patients (Group M). We evaluated the biopsy rate, the detection rate of gastric neoplasms, and the accuracy of biopsy using NBI-ME compared to conventional endoscopy.

Results: The biopsy rate of NBI-ME and conventional endoscopy in Group M was 5.4 and 7.7%, respectively, while in Group S it was 14.9 and 14.8%, respectively. The biopsy rate did not differ significantly between those who received NBI-ME and those who had undergone conventional endoscopy. The detection rate of gastric neoplasms using NBI-ME and conventional endoscopy in Group M was 0 and 0.2%, respectively, while in Group S it was noted to be 4.2 and 1.8%, respectively. Thus, the detection rate of NBI-ME was significantly higher than that of conventional endoscopy in Group S (p < 0.01). The accuracy of biopsy with NBI-ME and conventional endoscopy in Group M was 0 and 3.2%, respectively, but in Group S it was noted to be 36.4 and 14.1%, respectively. Thus, the accuracy of biopsy using NBI-ME is significantly superior to conventional endoscopy in Group S (p < 0.01).

Conclusion: NBI-ME as a screening test for gastric cancer is useful for patients with severe atrophy of the background gastric mucosa because this technique has shown a higher detection rate of gastric neoplasms and better accuracy of biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.
cardiovascular diseases [3]. Thus, the verified risk prediction model of post-ESD bleeding may enable to determine preventive therapeutic options and restarting date of antplatelet agents.

Aims & Methods: The aim of this study is to develop the predictive risk model of post-ESD bleeding. A total of 3574 patients, who were taken ESD from January 2007 to November 2016 in a Korean tertiary hospital, were included in this retrospective study. To avoid overfitting of the prediction model, we divided the patients randomly into two groups, either a derivation group or a validation group. Preoperative and procedural-related variables were selected via univariate and multivariate analysis. A risk score was calculated to assess the bleeding prediction model of a patient in the derivation group and was discriminated in the validation group.

Results: Post-ESD bleeding occurred in 248 patients (6.4%). In the derivation group, multivariable logistic regression revealed renal disease or on diabetes (odds ratio [OR], 3.90; 95% confidence interval [CI], 1.48–9.09; P = 0.0029), anti-platelet agent (OR, 3.07; 95% CI, 1.44–6.05; P = 0.0002), and en-bloc resection (OR, 3.83; 95% CI, 1.34–9.34; P = 0.0059) as significant risk factors (C-statistic = 0.607; 95% CI, 0.52–0.61; P = 0.0054). In the validation group, the model also showed significantly discriminatory power (C-statistic = 0.580; 95% CI, 0.53–0.627). Based on the scoring system of odds ratio, bleeding risk was 4.1% in the low risk set (score ≤ 4), 7.0% in the high risk set (score > 4, P = 0.0003) (validation set).

Conclusion: Our study investigated a prediction scoring system of estimating the bleeding risk, including the patient, endoscopist factors. A risk score can be calculated before the procedure and the endoscopists can predict bleeding potency before the gastric ESD. Based on the scoring system, endoscopists may offer therapeutic plans such as prolongation of admission dates or medication schedules.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0816 USEFULNESS OF DUAL RED IMAGING IN ESOPHAGEAL AND GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

1Gastroenterology and Hepatology, Osaka City General Hospital, Osaka/Japan
2Hepatology, Osaka City General Hospital, Osaka/Japan

Contact E-mail Address: tomorrow_zaa@yahoo.co.jp

Introduction: Endoscopic submucosal dissection (ESD) remains difficult procedure due to bleeding and perforation. One of the reasons that these complications are occurred is unclear visibility of submucosal layer. Dual red imaging (DRI) is a new endoscopic imaging technique which is focused on deeper layer by using narrow long wavelength light than white light imaging(WLI). Therefore, DRI improves the visibility of vessels and demarcation line between the submucosal and muscle layers for colorectal ESD. The aim of this study is to evaluate the usefulness of DRI for esophageal and gastric ESD.

Aims & Methods: A retrospective analysis was performed on patients who underwent ESD for esophageal or gastric cancer in our institution. ESD was performed by circumferential incision using WLI at first. Submucosal dissection was performed using DRI in principle, and Ulcer bed was observed with DRI after resection. Total resection time (from incise to complete resection), perforation rate, and hemostasis rate after procedure were recorded. These parameters were compared with our matched previous procedures using propensity score (1: 2). We recorded paired endoscopic images using DRI and WLI at the same time during the dissection, then estimated the visibility of vessels and submucosa by using visual scale (0–100) by 5 endoscopists. We compared the visibility of DRI with WLI followed by the estimation.

Results: Twenty lesions (esophagus: 3, stomach: 17) of 18 patients were enrolled for this study. Total resection time was 67.0 ± 27.9 min, and was shorter than matched data (141.7 ± 113.5 min) significantly (p = 0.0054). Hemostasis rate after resection and perforation rate were not different significantly. The score of vessels visibility using DRI and WLI were 68.6 ± 17.5 and 62.3 ± 19.6, respectively. The score of submucosal visibility using DRI and WLI were 70.0 ± 18.0 and 64.9 ± 19.0, respectively. DRI was superior to WLI in both scores significantly (p < 0.0001).

Conclusion: Though our study is preliminary, DRI improves total resection time, visualisation of vessels and demarcation line between the submucosal and muscle layers significantly as previous study showed on colorectal ESD. DRI uses narrow long wavelength light. The light reaches slightly deeper layer than WLI. Therefore, we can see not only clear vessels but intact submucosa with this technique. Endoscopic procedure is done clearer by blood, fat, and fibrosis. We named this effect "noise cancelling effect" by DRI. This effect gets better the visibility better, therefore the esophageal and gastric ESD makes easier and safer.

P0818 RISK FACTORS OF COMPLICATION RELATED TO ENDOSCOPIC MANAGEMENT OF FOREIGN BODIES IN THE ESOPHAGUS: A PROSPECTIVE STUDY IN 595 CASES FROM MULTIPLE CENTERS IN CHINA

L. Wang, L. Wang
The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Contact E-mail Address: wanglj76@hotmail.com

Introduction: Foreign bodies (FBs) ingestion is a common medical emergency accounting for 4% of all emergency endoscopies, secondary only to the G1 bleeding.1-3 75% - 78% of FBs are located in the esophagus4,5. The need of endoscopic management reached up to 63 - 76%4,5,6 3% - 20% of incidence of complications.7 According to the latest guidelines from ESGE, emergent endoscopy is recommended for the impaction of sharp-pointed objects within 24 hours.8 However, there were still different opinions on the endoscopic methods with different FBs.

Aims & Methods: The study was performed from October 2015 to August 2016 among 595 patients with clinical suspicion of foreign body ingestion from 18 general hospitals in China. The patient data including age, gender, clinical features, and data about endoscopic management including types and locations of foreign bodies, retrieval devices, outcomes and complications were collected and analyzed.

Results: 1) The most common types of foreign bodies were fish bones (34.0%), chicken bones (22.1%), fruit nuclei (11.7%) and food bolus (14.6%). The majority of them were short objects (< 2.5 cm, 74.0%), subsequently followed by middle objects (2.5 - 6.0 cm, 24.5%) and long objects (> 6.0 cm, 1.5%). Most objects were lodged in the proximal esophagus (75.9%), followed by the middle segment (17.0%) and distal segment (6.9%) of esophagus. 2) 96.3% of all cases had obvious clinical symptoms. Clinical symptoms occurred more often in the proximal segment of the esophagus (98.1%) than any other segments of the upper gastrointestinal tract (92.6%) (P < 0.001). 3) The successful retrieval rate through endoscopy was 94.5%. It was even higher with general anesthesia (99.3%) than without it (92.7%) (P < 0.01). 4) Complication rate was as high as 34.0%, which was increased with long retention time and sharp objects (P < 0.001). The rate was increased by 2.2- and 6.1-folds after impacted for over 48 hours as compared to less than 24 hours. Logistic regression analysis indicated that sharp objects had obviously more complications than non-sharp ones (OR 3.36, 95% CI: 1.97-5.74). In particular, the incidence of perforation was 5.6%, which was strongly related with long retention time and sharp objects (P < 0.03), but not with locations or lengths of the objects (P > 0.05).

Conclusion: General anesthesia could largely improve the retrieval rate through endoscopy. Foreign bodies, especially sharp ones, should be removed as soon as possible within 24 hours, to further decrease severe complications.

P0819 BIOPSY STRATEGIES FOR ENDOSCOPIC SCREENING OF PRE-MALIGNANT GASTRIC LESIONS

Z. Neng
Department Of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China

Contact E-mail Address: zm1990pmorphine@163.com

Introduction: AG and IM are detectable precursor lesions of most gastric carcinomas. Early endoscopy examination may potentially result in early detection and treatment of advanced precursor lesions and cancer. The annual incidence of GA and IM among the general population in Europe, for GA was 0.1% and for IM was 0.25%. The histological assessment and biopsy sampling protocol has been standardized in the updated Sydney system and the recommended five gastric biopsies were widely applied in the staging system for gastric cancer risk stratification.1,2 Some believe that the GA risk screening requires consideration of the cost - suffering of patients as well as rational utilization of medical resources, so adopt five biopsy may be presumably less inappropriate in large-scale population gastric cancer risk screening. In this study, we evaluated the OLGA and OLGIM staging in a standardized five biopsy protocol through screening patients underwent endoscopy with abdominal pain and discomfort. In order to identify a more optimal biopsy strategy with quite high consistence with the standardized five biopsy protocol in OLGA and OLGIM staging and less number of biopsies during cancer risk assessment, we re-evaluated OLGA and OLGIM staging adopting different biopsy combinations (evaluated the appropriate biopsy locations and number of biopsies).

Aims & Methods: Gastric atrophy (GA) and intestinal metaplastic (IM) are precursor lesions of gastric cancer (GC), the extent and severity of which was intimate correlated with the occurrence of GC. Operative Linkon Gastritis Assessment (OLGA) and Operative Linkon Gastric Intestinal Metaplasia Assessment (OLGIM) with five biopsy samples are superordinate stages system during Gastric risk stratification. We analysis the degree of GA and IM in these five locations and screen out an more representative, simple and convenient biopsy samples composition for gastric risk screening.

Methods: 368 patients with abdominal pain and other discomfort undergoing endoscopy were enrolled in the study. Five biopsy pieces (two from antrum, namely lesser to the later curvature and corpus, one from corpus, larger and lesser curvature and one from incisura angularis) were acquired and graded by senior gastrointestinal pathologists according to the updated Sydney system. Gastric risk stratification was calculated by adopting OLGA and OLGIM staging system.

Results: GA and IM are respectively acquired in the incisura angularis mucosa than the both lesser and larger curve of antrum and corpus respectively (P<0.05), especially the moderate and severe degree. More GA and IM alternations happened in the lesser curve of the antrum and corpus than in the corpus and proximal corpus (P<0.05). The composition of the incidence anguish mucosa than the both lesser and larger curve of antrum and corpus, angularis biopsy) with quite accurate consistence with five biopsy pieces protocol using OLGA and OLGIM staging (94.0% and 92.9%), together with a rather low omission diagnostic rate of OLGA and OLGIM HI + N (5.8% and 7.2%).

Conclusion: The incisura angularis with more moderate and severe GA and IM should be recommended as conventional biopsy site during endoscopy. The three biopsies (corpus, larger curve of antrum and corpus) with more encouragement and more cost accuracy than five biopsy pieces protocol using OLGA and OLGIM staging system, and thus could be recommend in the further gastric risk screening applying OLGA and OLGIM staging.

Introduction: In gastrointestinal stromal tumors (GISTs) without a risk of metastasis to other organs, local resection is acceptable. In small GISTS, however, it is controversial whether surgical resection is necessary because a risk of recurrence/metastasis in these tumors are considered to be quite low. Laparoscopic endoscopic cooperative surgery (LECS) is a promising surgical technique as one of minimally-invasive, function-preserving surgeries. By using this technique, we are aggressively resecting gastric SMTs including relatively small ones.

Aims & Methods: To investigate necessity of surgical resection for small GISTS, we retrospectively assessed a malignant potential of these tumors which were resected nonexposed endoscopic wall-inversion surgery (NEWS) (nonexposure LECS technique) as well as feasibility and safety of this technique. Between August 2013 and October 2016, NEWS was conducted in 33 consecutive SMTs which met all of following conditions: possible GIST which was preoperatively diagnosed by histology or imaging modalities, less than 3 cm in size and inaccessible-growing type. NEWS was feasible, safe and therefore recommended for these tumors including Eckardt score, lower esophageal sphincter pressure, adverse events and recurrence.

Results: All patients underwent POEM successfully. Mean procedure time was 13.7 years-old and 23.3±8.4 mm, respectively. The procedure was successfully completed in all cases in a mean procedure duration of 206±43 min. The patients were discharged without severe adverse events 7.3±1.5 days after the procedure. The first endoscopy after the procedure was performed 5.8 months after discharge in 22 cases, which showed no residual food in the remnant stomach in all cases. Neither apparent impairment of food intake nor disease-related death occurred and a body weight loss was 0.9±2.3 kg during the mean observational period of 13.7 years.

Conclusion: Some small GISTS which could be retrieved transorally had a high malignant potential, NEWS was feasible, safe and therefore recommended for these tumors including ulcerated GISTs as a minimally-invasive surgical option to avoid an additional surgical scar for the retrieval of the specimen and a risk of intragastric tumor cell seeding into the peritoneum during the procedure.

PO822 LONG-TERM OUTCOMES OF PERORAL ENDOSCOPIC MYOTOMY FOR ACHALASIA IN PATIENTS OLDER THAN 70 YEARS

J. Zhu, Q. Li, P. Zhou
Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: zjyju@yahoo.com

Introduction: Achalasia is a rare esophageal motor disorder characterized by esophageal aperistalsis and incomplete relaxation of lower esophageal sphincter (LES). The Elderly patients have longer courses of disease, less perception of symptoms and similar manometric findings compared with younger patients. Peroral endoscopic myotomy (POEM) is a novel endoscopic therapy which recently has been described as an incisionless and less invasive scarless myotomy alternative for treating achalasia. However, very few studies concentrated on the long-term outcomes of POEM for achalasia patients, especially for elderly patients.

Aims & Methods: Peroral endoscopic myotomy (POEM) is a minimally invasive endoscopic myotomy for achalasia. But the long-term outcomes of POEM for achalasia in elderly patients are unclear. We therefore aim to evaluate the efficacy and safety of POEM for achalasia in patients older than 70 years. A total of 33 consecutive patients aged ≥70 years were enrolled in this study, who had undergone POEM for achalasia from May 2011 to March 2016 in the Endoscopy Center of Zhongshan Hospital. We retrospectively assessed the short and long term outcomes of these procedures including Eckardt score, lower esophageal sphincter pressure, adverse events and recurrence.

Results: All patients underwent POEM successfully. Mean procedure time was 50.7±22.0 mm and postoperative hospital stay was 2.8±1.5 days. No severe complications related to POEM were encountered. The mean follow-up period of 40.5±19.1 months (range from 12.2 to 70.9 months), the therapeutic success rate was 90.9% (30/33). Mean Eckardt score was 7.6±2.0 and 1.4±1.3 before and after POEM, respectively (P<0.001). Mean LES pressure decreased from 38.4±13.5 mmHg to 32.3±9.9 mmHg after POEM (P<0.001). Clinical gastroesophageal reflux occurred in 11 cases (33.3%) after the procedure which was successfully resolved by proton pump inhibitors.

Conclusion: POEM can be a safe and effective treatment option for achalasia in elderly patients older than 70 years with significant improvement in symptoms.

PO823 POST-POEM ESOPHAGITIS – REAL REFLUX ESOPHAGITIS OR JUST A HEALING PROCESS?

D. Erhartova1, J. Krajčová1, Z. Vacková1, Z. Rabekova1, P. Stíranda1, T. Hucl1, J. Czech2, D. Martínek3
1Departments Of HepaGastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

3Department Of Research And Development For Minimally Invasive Treatment, Division Of Research And Development For Minimally Invasive Treatment, Cancer Center, Keio University, School of Medicine, Tokyo/Japan

Introduction: POEM has become a standard treatment of achalasia based on its excellent efficacy and safety. However, unlike in laparoscopic myotomy, POEM is not accompanied by an antireflux procedure and thus the rates of both clinically relevant post-POEM reflux (measured by symptoms and/or 24 h pH monitoring) and post-POEM esophagitis are key questions of long-term POEM safety. Several studies have reported the rates of post-POEM reflux and post-POEM esophagitis being as high as 30–40%. The aim of this retrospective analysis was to analyze whether esophageal erosions, detected endoscopically early after POEM, represent real reflux esophagitis or rather signs of still ongoing healing process after POEM.

Aims & Methods: A single-center retrospective analysis of 192 patients who underwent POEM in our institution. Three months after POEM, 162 patients underwent both pH monitoring and endoscopy and treatment with PPIs was assessed. At 24–36 months, a control endoscopy was performed in 41 patients to screen for esophagitis. We reviewed all available video recordings of POEM procedures and subsequent control endoscopies to analyze whether the localization of erosions was limited to the site of submucosal tunneling (e.g. between 2–4 o'clock in patients after anterior POEM) or also outside this area (real reflux erosions). We also analyzed evolution of esophagitis in time and correlated it with pH monitoring and intake of PPIs.

Results: At 3 months, esophagitis was present in 64 out of 162 patients (39.6%). Of those, 21 (33%) were on PPIs by the time of endoscopy and 43 (67%) were not. Among 43 patients with esophagitis and available video recording, 29 (67.4%) had erosion(s) only on the site of submucosal tunnel and 14 (32.6%) had erosions also elsewhere. Among patients with erosion(s) only on site of the tunnel, 13 (44.8%) had normal acid exposure time (assessed by pH monitoring.
performed off PPIs). At 24–36 months, esophagitis was present in 9 out of 41 patients (p < 0.04 vs. 3.5 months). In 6 out of 10 patients with esophagitis present at 3 months, who underwent control endoscopy at 24–36 months, esophagitis resolved completely even though only 2 patients had been treated by a PPI.

Conclusion: After POEM, the majority of patients with esophagitis had erosions on site of submucosal tunnel and early esophagitis often occurred in patients without an abnormal acid exposure. These findings suggest that an ongoing healing process after POEM might interfere in findings of presumed post-POEM reflux esophagitis. Thus, the rate of real post-POEM reflux esophagitis may be lower than previously thought.

P0826 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR UPPER GI SUBMUCOSAL TUMOURS

Gastroenterology & Hepatology, Westmead Hospital, Sydney/Australia

Contact E-mail Address: halimawadie@gmail.com

Introduction: Submucosal tumours (SMT) in the upper gastrointestinal tract (UGI) impose diagnostic and therapeutic challenges. They may have malignant potential and endoscopic ultrasound (EUS) guided diagnosis is often inadequate. A substantial proportion may not involve the muscularis propria (MP) and thus may be amenable to endoscopic excision. Snare-based techniques are usually unable to completely excise such lesions, though without complete excision ongoing endoscopic surveillance may be necessary. Endoscopic submucosal dissection (ESD) offers the possibility of complete resection and definitive...
P0827 COMPARING APPROACHES TO SELF-EXPANDING METALLIC STENTS INSERTION

L. Mooney1, N. Church2, R. Sinha1, C. Basquill1
1Centre For Liver And Digestive Disorders, NHS Lothian, Edinburgh/United Kingdom
2Centre For Liver And Digestive Disorders, NHS Lothian, Edinburgh/United Kingdom

Contact E-mail Address: leanne.mooney@nhs.net

Introduction: The incidence of oesophageal cancer has increased significantly over the past two decades. The majority of these cancers are incurable at diagnosis. Therefore, the management is aimed at maintaining quality of life by ensuring adequate nutrition and palliation of symptoms, mainly dysphagia. Self-expandable metallic stents (SEMS) have a well-recognised role in the palliative management of patients with oesophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscope (FAE). There is little evidence to compare outcomes between these approaches.

Aims & Methods: The objective of this study was to compare the outcomes, using various performance indicators, in patients who underwent SEMS for palliation in oesophageal cancer via different approaches (EC or FAE) at the Royal Infirmary of Edinburgh (RIE). A retrospective observational study was conducted between May 2014 to April 2016; a total of 62 SEMS. The approach to stent insertion was subject to operator choice and availability of fluoroscopic assistance, and as such can be akin to randomized study. We compared early and late complications associated with two techniques. Early complications included pain, vomiting, bleeding, perforation and tachycardia. Late complications included tumour growth, oesophageitis, stent migration and stent malposition.

Results: Forty-seven stents were inserted by EC and fifteen by FAE. The mean age was 62 years with 19 male patients (63%). Mean lesion size was 18 mm. Twenty-five patients (83.3%) had completely resected lesions. Four patients (13%) had involvement of the MP which was identified during the resection, and one patient (3%) had MP injury which precluded complete resection. Three of five lesions of the incompletely EC procedures were in the proximal body of the stomach, however only two lesions of the completely resected lesions were in the proximal body (P=0.004). Otherwise, there were no significant differences between the patients and lesions characteristics. The histology of the SMT lesions were 9 NET, 6 leiomyoma, 5 Granular cell tumours, 4 inflammatory fibroid polyposis, 2 GIST, 2 dysplastic Lipoma, one myofibroblastic tumour and one Warthin’s like tumour. Nineteen patients had completed surveillance endoscopy (SE) without an endoscopic and histological recurrence (Median follow up 18 months). Six patients are pending SE. The four patients with deep MP involvement were referred for surgery.

Conclusion: EC for selected UGI SMT is an effective treatment. Long-term endoscopic follow-up confirmed the absence of recurrence endoscopically and histologically. MP involvement cannot be reliably excluded by prior EUS. This technique should be considered for UGI SMT lesions without MP involvement in experienced centres.

Contact E-mail Address: yoshikor@gmail.com

Introduction: A value of the combination of magnifying endoscopy of and image enhancement endoscopy (IEE) technology (e.g. NBI, BLI) is reported in a diag-nosis for the early gastric neoplasm. That method is useful, but in order to master it it is necessary to learn and familiarize complex classifications. Therefore, this diagnostic method is still more difficult for general endoscopists. Linked Color Imaging (LCI) was recently developed using a laser endoscopic system (Fujifilm Co., Tokyo, Japan). LCI acquires images by simultaneously using narrow-band short wavelength light and white light in an appropriate balance. This combina-tion of light provides more information about the vascular architecture and the mucosal surface than that obtained with typical white-light imaging. When we use acetic acid indigocarmine mixture (AIM) with LCI mode, we reported that the magnifying images of early gastric cancer are very clear, three-dimensional and near to real histology. So, we examined the examined the utility of this method.

Aims & Methods: This was a prospective observational study performed at a single tertiary referral center. The subjects are 120 lesions of 115 patients with gastric neoplasm. We are indicated the endoscopic submucosal dissection (ESD) and were given preoperative endoscopy in our hospital from September 2014 to February 2017. Firstly we observed the lesions by magnifying endoscopy with the BLI mode and diagnosed using VS classification system. Secondly we observed the lesions by magnifying endoscopy with LCI+AIM method and diagnosed using VS classification system. Furthermore, we classified tumor differ-entiation into high differentiation, moderately differentiated, and poorly differ-entiated by its surface pattern. Finally, we classified the visualization ability of the surface fine structure in Clear, Visible, and Invisible and evaluated it. We carried out ESD and compared the image with the histopathology.

Results: By the results, 92 lesions (79.1%) were gastric adenoma and 28 lesions were gastric adenoma. The differentiation ability of a cancer and the non-cancer (adenoma) did not have the significant difference between the BLI mode and the LCI+Aim methods. Diagnosis of differentiation of gastric cancer was correct in 87 of 92 cases (94.6%). In the classification of visualization ability, 32 lesions were Clear, 44 lesions were Visible, 44 lesions were Invisible by BLI mode, On the other hand, 45 lesions were Clear, 64 lesions were Visible, 11 lesions were Invisible by BLI mode. In the visualization ability of the surface fine structure, LCI+Aim method is significantly clearer than BLI mode (p < 0.001).

Conclusion: When we use AIM, indigocarmine accumulates in pit of the duct, and duct structures become clear by the acetic acid. By LCI mode, we can observe the vascular pattern of the lesion clearly. So by the combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images. By this method, we can compare histopathology with an endoscopic image intuitively, so we believe that a magnifying endoscopy diagnosis of the gastric cancer is enabled even if we do not use various confusing classifications.

P00831 RESULTS FROM THE FIRST UK VIRTUAL COMPLEX POLYP MD M. Chatterjee, M. Rutter
Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom

Contact E-mail Address: amitchattree@nhs.net

Introduction: Data from the UK Bowel Cancer Screening Programme (BCSP) has established that the assessment and management of large non pedunculated colocolar polyps (LNPCPs) varies markedly, leading to variable and often suboptimal outcomes, especially for the most complex lesions1. A multicentre complex polyp multidisciplinary team meeting was created within the North East of England BCSP with the aim of ensuring more robust decision making and managemment of complex LNPCPs.

Aims & Methods: A virtual multicentre MDM was conducted via audioteleconferencing within the North East of England between 2014-6 to discuss complex LNPCPs (LNPCPs with increased risk of malignancy or complexity associated with endotherapy, as defined in BSG/ACPGBI guidelines2). Non-complex LNPCPs were not discussed. Patient data was distributed securely via NHSmail. Outcomes were assessed prospectively using key performance indicators (KPIs) from the BSG/ACPGBI guidelines2.

Results: 61 complex LNPPC cases were managed via the MDM with 8 excluded from analysis (7: managed prior to MDM referral, 1: MDM advice not fol-lowed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery and 2 endotherapy to a finding and 1 to a follow up. 12 month recurrence was 8.7% with no reported complications. The rate of surgical man-agement using the BSG/ACPGBI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The en-bloc resection

Introduction: Patients of endoscopists with high (≥20%) adenoma detection rate (ADR) have less risk for interval cancer than those of low ADR (<20%). Lesion-related-factors, such as size, shape and histology influence the detection rate of physicians with high ADR tend to detect more full and spattered adenomas than those with low ADR.

Aims & Methods: Our study aim is to investigate the differences of size, shape and serrated histology of adenomas between low- and high-ADR group in our screening cohort. We analyzed 22,534 screening colonoscopies performed by 261 endoscopists between 2007 and March 2017 within the austrian certificate of screening colonoscopy. T-Test was used to assess differences.

Results: 39.1% of endoscopists were categorized in the ADR low- and 60.9% in the high-ADR group. Overall, mean ADR was 23.06% (SD 0.55) with a minimum of 0.39% and a maximum of 48.72%. In the low-ADR-group mean ADR was 14.56 (SD 0.42) and 28.51 (SD 0.50) in the high-ADR group. Regarding to size, there was a significant difference (p = 0.029) in detection of adenomas of 1–2 cm with a mean of 8.44% (SD 6.02) in low- vs. 10.22% (SD 6.64) of all adenomas in high-ADR group but no differences between adenomas <0.5 cm, 0.5–1 cm and those bigger than 2 cm. Regarding shape, proportion of pedunculated adenomas in low-group-ADR differ significantly higher (p = 0.002), with a mean of 19.36% (SD 14.60) vs. 17.40% (SD 9.55) but there were no differences between flat and sessile adenomas. With a mean proportion of 4.43% (SD 5.61) vs. 6.64% (SD 5.97), the proportion of sessile serrated adenomas (SSA) differ significantly between low-ADR vs. high-ADR group (p < 0.01).

Introduction: ESD is a complex procedure, mainly in non-Asian countries where the learning process is not well established. Results may be improved in Western countries with a careful selection of lesions for ESD and avoiding those with greater chance of technical difficulty. Factors predicting technically difficult ESD when it is performed by non-Asian endoscopists should be clarified.

Aims & Methods: We aimed to identify the potential risk factors that are associated with a higher technical difficulty during ESD in a Western European setting where there are no available Asian experts. We prospectively recorded consecutive ESD cases performed by members of the ESD Working Group of the Spanish Society of Digestive Endoscopy. Demographic and clinical characteristics of the patients, location and morphology of the lesions, and technical factors were collected. We defined difficult ESD as those aborted procedures, time-consuming (duration >180 min.) or when changing the technique to piecemeal resection was needed to remove the tumor. Analyses were carried out using IBM SPSS software for Windows (IBM Corp., Armonk, NY, USA). Parametric continuous variables are reported as the mean ± standard deviation (SD). A Kolmogorov-Smirnov test was used to evaluate normal distribution. Categorical variables are reported as either frequencies or percentages. Statistical differences between the groups were analyzed using a chi-squared test for categorical data. The meaningful variables with a p value <0.1 in the univariate analysis were included in the logistic regression model. Multivariate analysis was performed using binary logistic regression methods. Odds ratios (ORs) and 95% confidence intervals (CI) were calculated to assess the strength of the influence of each individual variable.

Results: We included 265 lesions in 265 patients [mean age ± SD: 69 ± 10; 150 males (56.6%)]. They were recruited in 15 Spanish University Hospitals between January 2016 and March 2017. Location of the lesions were: esophagus (n = 7; 2.6%), cardiac (n = 5; 1.8%); stomach (n = 48; 18.1%); duodenal bulb (n = 1; 0.3%); colon (n = 144; 54.3%) and rectum (n = 60; 22.6%). Mean lesion size was 38.8 ± 18.5 mm. Median duration of the procedure was 105 min. (8–375). In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n = 258; 97.3%), both situations, duration >3 h and a piecemeal resection, were noted in 21 (8.1%) patients. Duration >3 h in 25 cases (9.7%) and unsuccessful en bloc...
resection in 20.7% were observed in isolation, respectively. Table 1 shows the univariate and multivariate analysis of factors regarding technically difficult ESD.

### Conclusion
The factors independently associated with technically difficult ESD (abortive procedures, time-consuming or finished with a piecemeal resection) were: lesion size >30mm, poor manoeuvrability, recurrent lesions and intraprocedural bleeding. Except for the last one, the remaining factors can be identified during the first diagnostic endoscopy. Endoscopists who will start performing ESD should try to avoid these difficult procedures in the early part of their learning curves.

**Introduction:** We established the Laparoscopy Endoscopy Cooperative Surgery (LECS) procedure to overcome the limitation of colorectal endoscopic submucosal dissection (ESD). This procedure is a local full-thickness resection of the combined procedure of laparoscopy assisted colectomy (LAC) and ESD procedure. Also, it is the method that is epoch-making for minimal invasive treatment that kept an intestinal function.

**Aims & Methods:** The aim of this study was to investigate the feasibility and safety of LECS procedure applied with endoscopic submucosal dissection (ESD) technique obtained adequate surgical margin. We performed ESD on 1376 colorectal tumors in 1341 patients (male: female = 777:564; mean age, 66.1years). Among these cases, six cases had perforation (0.4%), and three of six cases required emergent surgery. We examined the cause of perforation and the limit of ESD from the view point of safety. We performed one-piece resection for 11 cases (male: female = 7:4; mean age, 63.5years) of colorectal tumors using LECS procedure. In the first, the indication of LECS is at high risk of the perforation by the treatment of ESD and EMR and is the lesion that safety cannot secure. In addition, the indication is the lesion which is curable by the local excision without lymph node dissection. Therefore, submucosal invasive (T1) cancer with the risk of lymph node metastasis does not become the indication for this full-thickness resection technique. From the above-mentioned basic concept, indications of the LECS procedure for colorectal tumors were thought to be: 1) Intramucosal carcinoma (Tis) and adenoma with high-grade atypia involved appendix or diverticulum. We examined the clinical pathological outcomes of 11 cases.

**Results:** Four of six cases that caused perforation in ESD were cases with fibrosis in the submucosal layer. Three cases of those were moderate to severe degree fibrosis cases, and a limit of ESD seemed to exist in these lesions from the viewpoint of safety and curability. We accomplished full-thickness resection successfully for 11 cases using LECS procedure as follows: 5 cases of Tis cancer, 4 cases of adenoma, 1 case of schwannoma, and 1 case of GIST. The reasons as we judged that the indication of LECS procedure were as follows: three cases accompanied by severe degree fibrosis, 2 cases involved diverticulum, 3 cases involved appendix, 2 cases of submucosal tumor, and 1 case of poor endoscopic operability. These cases were considered a limitation of ESD due to the high risk of perforation. An operative time was an average of 195.8 minutes (127 to 332), and the perioperative bleeding was an average of 8.9g (3 to 20). We experienced no complications, and average post-operative hospital stay was 7.7(6 to 12) days. Histological examination of the resected specimens revealed negative lateral and deep margins. The postoperative follow-up was carried out first a half year later, and it was every one year subsequently. In the above-mentioned follow-up schedule, blood examination, colonoscopy, CT scan were performed for clinical evaluation. The residual/local recurrence case was absent for 31.6 months (range 10-60 months) for the mean follow-up period. Also, without complications such as postoperative anastomotic stricture or adhesive ileus, we followed favorable course.

**Conclusion:** We developed a LECS procedure to overcome the limit of ESD, and completed full-thickness one-piece resection of the tumors considered as high risk of perforation in the endoscopic treatment.

**Introduction:** Endoscopic mucosal resection (EMR) and submucosal dissection (ESD) are effective procedures for reducing the need for colorectal surgery. Many studies have focused on major adverse events related to EMR and ESD such as bleeding and perforation. However, data on structured assessment of minor post-procedural adverse events remain scarce. We therefore evaluated the incidence of major and minor adverse events within 30 days of EMR or ESD.

**Aims & Methods:** We prospectively performed a single-center study on consecutive patients who underwent colorectal EMR or ESD between April 2014 and April 2016. We asked for permission to interview the patients 1 day, 14 days, and 28 days after their procedure. Four gastroenterologists performed all procedures. The assigned nurse performed the data and interviewed the patients in person on day 1 and day 14 ± 2 days, and via phone on 28 ± 2 days after their respective EMR/ ESD procedure. A standardized interview form was developed to assess the occurrence of (i) major adverse events (hospital visit required), (ii) minor adverse events, and (iii) working days lost due to adverse events. The primary outcome was the occurrence of all adverse events, which were classified as either “major” or “minor”.

**Results:** We enrolled 630 patients who underwent EMR or ESD. 615 (97.6%) (499 EMR, 116 ESD) were contacted. Male comprised 68.5% (n = 415), and the mean age was 57.9 years (±1.3). Major adverse events occurred in 31 (5%), 16 (2.5%), and 1 (0.2%) patients on days 1, 14, and 28, respectively. Minor adverse events occurred in 284 (46.1%), 344 (55.9%), and 25 (4.1%) patients on days 1, 14, and 28, respectively. Bleeding was the most common major event on days 1 and 14 ± 2 days, and abdominal bloating and bowel habit change were the most common minor events on days 1 and day 14, respectively. 11 (1.8%) and 20(3%) patients took leaves of absence due to adverse events on day 14 and 28, respectively. The detailed events are listed in Table 1.

**Conclusion:** Although the number of major adverse events was small, nearly half of the patients reported minor adverse events on 14 days following colon EMR/ ESD. Most minor adverse events subsided by the day 28.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Patient experience is increasingly recognised as a key measure of quality of care. Ensuring positive experience is important to patients and fundamental in maximising participation in screening programmes and re-attendance for surveillance procedures. Current measures of patient experience of gastrointestinal (GI) endoscopy are clinician derived. Patient Reported Experience Measures (PREMs) should be patient derived and incorporate pre-and post-procedure experience. We aimed to identify themes considered as important to patients undergoing GI procedures as a basis for developing PREMs.

**Aims & Methods:** We aimed to identify themes important to patients undergoing GI investigations, to enable questionnaire development. Patients who had undergone upper or lower GI investigations (gastroscopy, colonoscopy and CT pneumocolon) were invited to attend for a semi-structured interview. 32 interviewees were purposefully sampled to ensure diversity. Interviews were conducted by a research fellow trained in qualitative methods and were audio recorded and transcribed verbatim. Recruitment continued until saturation was achieved. Analysis used qualitative thematic methods focusing on anticipated and emergent themes, using constant comparison to ensure that all perspectives were included in the explanation of the data.

**Results:** 168 patients were approached. 32 interviews were completed (12 gastroscopy, 10 colonoscopy and 10 CT pneumocolon), with a male:female ratio of 18:14. The time interval from examination to procedure ranged from 5 to 44 days. Mean age was 63.1 years (SD 11.5) days. Mean age was 63.1 years (SD 11.5)

**Conclusion:** Despite heterogeneity between procedures consistent themes related to patient experience emerged. This work will be used to develop PREMs for Gastrointestinal Endoscopy.

**P0838 RANDOMIZED CONTROLLED TRIAL OF ABDOMINAL VIBRATION STIMULATION AND WALKING EXERCISE FOR BOWEL CLEANSING PRIOR TO COLONOSCOPY**

Gastroenterology, Ajou university School of Medicine, Suwon/Korea, Republic of

Contact E-mail Address: cknoh23@gmail.com

**Introduction:** Adequate bowel preparation is important to perform colonoscopy for accurate mucosa examination, lesion detection and treatment. Walking exercise is known to be effective for colon cleansing. However, it is difficult for patients with uncomfortable walking to improve the status of bowel cleansing.

**Aims & Methods:** Therefore, we prospectively evaluated the clinical feasibility and clinical validity of the abdominal vibration stimulation for bowel
preparation. In this randomized, prospective, investigator-blind study and single center setting, 141 inpatients for elective colonoscopy were randomized to two groups. PEG solution was used for bowel cleaning in all patients. The one is walking over 3000 steps and the other is having abdominal vibrator more than 30 minutes before colonoscopy. After examination we recorded procedure results, sedation information, patient's satisfaction and adequacy of bowel preparation by using the Boston Bowel Preparations Scale (BBPS).

**Results:** There were no significant differences between vibrator group (n=75) and walking group (n=66) in bowel preparation quality (Total BBPS 7.40 vs 7.23, p=0.519), withdrawal time (30.40 vs 30.03 mins, p=0.829), number of polyps (4.09 vs 3.17, p=0.085), patient satisfaction (4.39 vs 4.12, p=0.249) and number of diarrhea after taking PEG (11.49 vs 11.42, p=0.903). vibrator group was superior than walking group in time of first defecation after taking PEG (112.9 vs 123.42 mins, p=0.005) andecal intubation time (6.23 vs 8.52 mins, p=0.011).

**Conclusion:** Bowel preparation accompanied with abdominal vibration stimulation showed almost similar results to a walking group which was conventional methods for adequate bowel preparation. The patients with the condition which cause uncomfortable gait such as old age, CVA, Parkinsons, or joint disease, bowel preparation with abdominal vibrator is expected to help in proper bowel cleansing for therapeutic colonoscopy.

THE INCIDENCE OF SYNCHRONOUS ADVANCED NEOPLASIA OF RECTAL LATERALLY SPREADING TUMORS WITH A SKIRT

Department Of Gastroenterology, Saku Central Hospital Advanced Care Center, Saku, Nagano Japan

Contact E-mail Address: shou0122@hotmail.com

Introduction: A "skirt" is a slightly elevated flat lesion with wide pits occasionally observed at the margin of laterally spreading tumors (LSTs), and rectal LSTs had significantly more skirt lesion in comparison to colonic LSTs. Although the clinicopathological, endoscopic, and molecular characteristics of LSTs with a skirt have been reported [1], there are no reports concerning the incidence of synchronous neoplastic lesions of rectal LSTs with a skirt.

Aims & Methods: The aim of this retrospective study was to clarify the incidence of synchronous advanced neoplasia (AN) of rectal LSTs with a skirt. A total of 13,116 cases underwent colonoscopy in our hospital between January 2012 and June 2016. Of these, 101 consecutive rectal LSTs were examined to assess the incidence of synchronous AN detection rate and the number of AN according to the location of AN lesion; divided into the right colon, left colon and rectum. A skirt was defined on the basis of the following endoscopic findings: spreading across the margins of the LST, consisting of a slightly elevated flat lesion, and containing wide pits. AN was defined as the presence of any of the following features: adenomas larger than 10 mm, adenomas with villous histology or high-grade dysplasia including intra-mucosal carcinoma and invasive cancer.

Results: A skirt was observed in 25 of 101 rectal LSTs (24.8%). Rectal LSTs with a skirt (median age 69 years, 52% female, mean size 51.7 ± 21.1 mm) had 22 high-grade dysplasia and 3 submucosal carcinomas, and rectal LSTs without a skirt (median age 72 years, 34% female, mean size 24.7 ± 16.0 mm) had 8 low-grade dysplasia, 45 high-grade dysplasia, and 23 submucosal carcinomas, respectively. The overall AN detection rate in rectal LSTs with a skirt (20.0%) was significantly higher than in rectal LSTs without a skirt (6.0%).

Discussion: Endoscopic shielding technique with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model [3]. Lesions were performed in male Sprague-Dawley rats (400–450 g) under general anesthesia. Animals were randomized to receive one of the following shields onto the lesions: PRP + TriBio and PRP + TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers sites were macroscopically and histopathologically evaluated.

Introduction: Endoscopic resection of large lesions leads to extensive mucosal defects and submucosal exposure, with a substantial risk of adverse events. The prevention of these complications is inefficient with current methods. Endoscopic shielding, as a simple and safe technique, has been proposed to improve mucosal restoration, and therefore, the incidence of these events. Previous reports have confirmed the efficacy of the placement of hydrogels based on platelet-rich plasma (PRP) (1) or hialuronic acid with other substances (TriBio) (2), but never the combination of both hydrogels, in the prevention of delayed complications after mucosal damage.

Aims & Methods: To assess the efficacy of endoscopic shielding with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model (3). Lesions were performed in male Sprague-Dawley rats (400–450 g) under general anesthesia. Animals were randomly assigned to receive one of the following shields onto the lesions: PRP + TriBio and PRP + TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers sites were macroscopically and histopathologically evaluated.

Results: Animals treated with PRP + TriBio obtained the best results in comparison with other hydrogels (PRP and TriBio). Mucosal healing rate (percentage of mucosal restoration) at 14 days was significantly higher with PRP + TriBio (100% vs 82% and 90%; p < 0.05). Histological study confirmed these data, showing total restoration of mucosal layer with PRP + TriBio

Conclusion: The use of a combination of the two covering agents (TriBio and PRP) is the best approach to obtain mucosal healing in a rodent model of endoscopic thermal injury in colon

Results: Intratumoral injection was feasible in all animals with no adverse events. Biopsies obtained size of tumors ranged from 6 to 8 mm. Anti-VEGF in comparison with anti-EGF obtained the best results (significantly reduction in size and cell necrosis). However, only alfobceptor showed total acute tumoral necrosis.

Conclusion: Intratumoral injection of anti-VEGF in a drug-eluting platform is able to produce tumoral necrosis in an experimental model of CRC. This technique could open a new way to manage CRC.

P0844 A THREE-DIMENSIONAL IMAGING SYSTEM IMPROVES THE ENDOSCOPIC VISIBILITY OF NON-POLYPOID COLORECTAL NEOPLASMS

Department Of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba City, Japan

Contact E-mail Address: matsumura919@yahoo.co.jp

Introduction: Three-dimensional (3D) imaging techniques have been developed in the medical field. Previous research reports that simulated 3D colonoscopy improves the detection of colorectal lesions [1]. A novel 3D imaging system has been recently developed, which can create 3D virtual video images from conventional two-dimensional (2D) endoscopic images [2]. However, actual cases have not been studied.

Aims & Methods: This study aimed to investigate whether the 3D system can improve the visibility of colorectal neoplasms compared with conventional 2D endoscopy. We examined non-polypoid colorectal neoplasms and recorded their videos using conventional 2D endoscopy and the 3D system. The movies were evaluated by 8 endoscopists (4 experts and 4 non-experts) and 4 medical students. Each neoplasms was assigned a visibility score between 4 (excellent visibility) and 1 (poor visibility).

Results: The mean visibility scores were 3.35±0.58 for 2D endoscopy and 3.75±0.44 for the 3D system. The score was significantly higher for the 3D system than for 2D endoscopy (p<0.01). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p<0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.50±0.53 for 2D endoscopy and 3.87±0.35 for the 3D system, p=0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms, and this is more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pain is a subjective perception, which contributes to difficulties to provide adequate pain relief according to every patient’s needs. Colonoscopy is by many patients considered as a painful and strenuous procedure. Aims & Methods: To investigate congruence and differences between patients’ and caregivers’ report of pain during colonoscopy. Patients (≥18 years) undergoing an outpatient colonoscopy (all indications) have consecutively been included (n=862). Before the procedure the patients completed questionnaires regarding sociodemographic information and anxiety. After the colonoscopy the patients registered their pain experience on a six-grade scale, ranging from “no pain” to “extremely severe pain”. Caregivers (physicians and endoscopy nurses) estimated patient’s pain using the same scale.

Results: Data from 785 patients has been collected, mean age 52 (18–90) years; 486 (62%) were female and 51% of patients reported “moderate pain”, and a sub-group of 14% were not adequately relieved. These subgroup reported severe, very severe or extremely severe pain. 90% of the patients were given analgesics and sedation during the investigation. For patients who reported, “severe, very severe or extremely severe pain” (n=111), pain was underestimated by physicians and nurses in 58% of all assessments. This was most commonly seen among the youngest patients, 18-29 years (n=99), where pain was underestimated in 25.5% among the group. There was also a difference according to gender; physicians underestimated pain in 60% of men who reported “moderate pain” (n=66) while the nurses underestimated pain in 27% among the same group of men. Women’s pain was overestimated by caregivers in 26% (n=188) of all cases with mild pain. Patients undergoing colonoscopy for the first time (n=331), and reporting “moderate pain”, were underestimated by physicians in 58% and by nurses in 25%. 58% of the patient reports that they were anxious before the procedure. This group reported more pain than the group without anxiety (p<0.001). Presence of anxiety and a high level of anxiety among the group correlated better with the patient’s report and the patient’s pain report. The agreement between pain reports from patients and caregivers were poor to fair, with slight differences between nurses (Kappa =0.37; p<0.000) and physicians (Kappa =0.29; p<0.000) in total, congruent pain reports between patients and caregivers were seen in 36% of all assessments.

Conclusion: Agreement between caregivers’ and patients’ pain reports is far from perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient’s needs, which seems to be of special importance in specific groups of patients.

Introduction: The SCENIC consensus proposed recommendations for optimal detection and management of dysplasia during colonoscopic surveillance for IBD. Characterization of colonic lesions in IBD remains challenging even when using advanced endoscopic imaging modalities (high definition [HD], virtual chromoendoscopy [VCE] dye chromoendoscopy [DCE]). Aims & Methods: We aimed to develop a unified endoscopic classification of advanced imaging to predict histology of colonic lesions, and to validated by international experts (Frankfurt Advanced Chromoendoscopy IBD LESions-FACILE Group). We developed an endoscopic classification of IBD lesions, based on morphology, colour, demarcation, surface pattern, vessel pattern, sign of inflammation (table). A library of 60 colon lesions, including dysplasia, sessile serrated adenomas/polyps, invasive cancer and pseudopolyps collected at surveillance colonoscopy by using HD, DCE and VCE with i-scan or NBI were assessed. The diagnostic performance of the score was tested based on the final histopathology and the inter-observer variability of the eight examiners. The examiners have had to perform a pre-test (45 minutes) before analyzing the colonic lesions. Multivariate analysis with bootstrapping, of characteristics of the classification was performed to determine the strength of endoscopic predictors of dysplasia.

Results: Of the 60 IBD lesions, 33 (55%) were dysplasia, 6 (10%) cancer, 9 (15%) SSA/Ps and 12 (20%) pseudopolyps. Across the experienced academic raters sensitivity, specificity, PPV, NPV and accuracy in predicting histology, were 72%, 79%, 91%, 40%, 72%. Individual rater accuracy ranged from 66% to 77%. Sensitivity, specificity, PPV, NPV, accuracy, for predictions made with perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient’s needs, which seems to be of special importance in specific groups of patients. Disclosure of Interest: All authors have declared no conflicts of interest.

References
OR 0.31 (95% CI:0.17–0.54), vessel architecture OR 5.1 (95% CI: 2.7–10.2), sign of inflammation within the lesion OR 0.39 (95% CI: 0.18–0.85) were independent predictors of dysplasia, with vessel architecture and morphology being the best predictors. The sensitivity, specificity, PPV, NPV and accuracy at the multivariate analysis stage were 94% (95% CI: 90–96%), 51% (95% CI: 43–58%), 88% (95% CI: 82–92%), 69% (95% CI:62–75%), 85% (95% CI: 79–90%). Inter-rater agreement of the raters improved from the pre-test (Kappa = 0.27.95% CI: 0.19–0.38) to post test (Kappa = 0.34.95% CI: 0.23–0.45;P = 0.02) but was moderate.

Conclusion: We developed and validated the first endoscopic classification using all imaging modalities (HD, VCE, DCE) to characterize and differentiate dysplastic from non-dysplastic lesions in IBD. Non polypoid lesions, irregular surface and vascular pattern as well as inflammation within the lesions were predictive of dysplasia. The inter-observer variability of the score was moderate. The classification will be further refined based on the multivariate analysis and a prospective study is ongoing.

P0048 THE ROLE OF PROBE CONFOCAL LASER ENDOMICROSCOPY WITH IMAGE ENHANCED ENDOSCOPY IN CHARACTERISATION AND ENDOSCOPIC RESECTION OF DSYPOLYIC LESIONS IN INFLAMMATORY BOWEL DISEASE PATIENTS

M. Iacucci1, X. Gui2, S. Ghosh1

Introduction: Detection, characterization and therapeutic management of flat dysplastic lesions during surveillance colonoscopy in inflammatory bowel disease (IBD) can be a challenge. The recent SCENIC consensus has introduced a new terminology and concept “endoscopically resectable” when the distinct margins of a detected lesion could be identified. New endoscopic techniques and skills are required to recognize the margins reliably and assess the surrounding mucosa to plan endoscopic removal successfully and organ sparing. We report our experience of the use of probe confocal endomicroscopy (pCLE) combined with selective electronic virtual (VCE) and dye chromoendoscopy (DCE) for management of challenging dysplastic lesions during surveillance in IBD.

Aims & Methods: IBD patients underwent surveillance colonoscopy using high-definition (HD)-iSCAN (Pentax EC-3940F; Japan) VCE and DCE in combination with pCLE (Cellvizio, Paris, France). pCLE was applied following IV injection of fluorescein 5% 10 ml to assess the histological features of the lesion, the margins and the mucosa surrounding the visible colonic lesion. Biopsies eventually proved dysplasia or SSA of the colonic lesions. The study was approved by the Calgary Conjoint Health Services Research Ethics Board of the University of Calgary. All patients gave informed consent.

Results: Seven patients with IBD and disease duration of ≥8 years and in clinical remission [Eaden, 2001 #2] (mean age 55 years; 6 male, UC = 4 CD = 3) were prospectively included. They underwent surveillance colonoscopy using HD-iSCAN (Pentax EC-3940F; Japan). When a colonic lesion was detected, selective iSCAN - VCE was performed with or without DCE (five out of seven had DCE)

P0048 THE ROLE OF PROBE CONFOCAL LASER ENDOMICROSCOPY WITH IMAGE ENHANCED ENDOSCOPY IN CHARACTERISATION AND ENDOSCOPIC RESECTION OF DSYPOLYIC LESIONS IN INFLAMMATORY BOWEL DISEASE PATIENTS (continued)
with methylene blue 1% to characterize the surface, vascular pit pattern and the margins of the lesion. Each of the 7 patients had non polypoid colonic lesions, 4 were sessile (Paris Is) and 3 flat (IIa/IIb). Four of them were amenable to endoscopic therapy and were successfully removed using endoscopic mucosal resection (EMR) en-block or piecemeal technique. Interestingly, one patient with multiple scattered ‘pseudopolyps’ had a 8 mm sessile pseudopolypoid lesion with a suspicious areas of SSA in the midst that was confirmed by real pCLE.

The endoscopic, endomicroscopic and histological findings of all the lesions were described in Table 1.

**Conclusion:** This case series highlights the first successful use of pCLE in combination with VCE and DCE to predict, characterise and treat colonic neoplasia in IBD. pCLE may be an additional tool to aid the endoscopist in therapeutic management by deciding endoscopic resectability versus colectomy.

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms and conventionally utilizes an IT, hook, or needle knife. However, because these devices are used without fixation to target, it confers a potential risk of complications due to unexpected incision. To reduce the risk of complications from ESD performed using a conventional knife, we used a scissors-type knife (SB Knife Jr) in elderly patients. In the previous study, we reported that ESD performed using SB Knife Jr is a technically efficient and safe method for treating early colorectal neoplasms. However, the efficacy and safety of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

Aims & Methods: The aims of our study were to evaluate the efficacy, safety, and clinical outcomes of colorectal ESD using SB Knife Jr in patients aged ≥75 years in comparison with those in younger patients. We evaluated 291 lesions in 271 patients (male-to-female ratio, 148:123; median age, 70 years) treated with ESD using SB Knife Jr between October 2010 to March 2017 at Kure Municipal Medical Center and Chugoku Cancer Center. The patients were divided into two groups, an elderly group (A: age >75 years; 95 patients, 97 lesions) and a non-elderly group (B: age <75 years; 176 patients, 194 lesions). We evaluated the en block resection rate, complete resection rate, curative resection rate, resected tumor size, procedural time, complications, and long-term outcomes, including survival rate. The 3-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort, and the local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection.

Results: The mean age was 80.0 years in group A and 64.3 years in group B. The male-to-female ratios were 45:50 and 103:73 in groups A and B, respectively. Regarding histopathological findings, the prevalence rates of tubular adenoma were 37.1% (36/97) and 36.1% (70/194); T1a, 39.2% (38/97) and 44.8% (87/194); T1b, 10.3% (10/97) and 10.3% (20/194); and T1b, 13.4% (13/97) and 8.8% (17/194). The mean follow-up period: group A, 523 days; group B, 582 days. The 3-year overall survival and tumor-specific survival rates were 94.8% (89/95) and 94.4% (184/194); and the curative resection rates, 93.3% (91/97) and 93.8% (171/194) in groups A and B, respectively, showing no significant difference. The mean resected tumor size was 33.9 ± 16.6 mm in group A and 34.7 ± 15.2 mm in group B, and the median procedural time was 75.6 min (range, 10-420 min) in group A and 75 min (range, 10-533 min) in group B, showing no significant difference. The en bloc resection rates were 96.9% (94/97) and 99.0% (192/194); the complete resection rates, 94.8% (92/97) and 94.8% (184/194); and the curative resection rates, 83.5% (81/97) and 88.1% (171/194) in groups A and B, respectively, showing no significant difference. Regarding complications, no perforation during the procedure occurred in any of the cases. The delayed bleeding rate was 1.0% (1/97) in group A and 2.6% (5/194) in group B. Delayed perforation and delayed bleeding occurred in one patient each in group A and were treated conservatively. Regarding long-term outcomes, the local recurrence rate was 1.0% (1/97) in group A and 0.5% (1/194) in group B, and no distant recurrence was observed in the recurrence analysis cohort. Regarding survival analysis (mean follow-up period: group A, 523 ± 469 days; group B, 628 ± 582 days), the 3-year overall and disease-specific survival rates were respectively 98.8% and 100% in group A, and 93.3% and 98.3% in group B. One patient (0.5%, 1/194) died of colorectal cancer 26 months after ESD for other diseases in group B, while one patient (1.1%, 1/95) died of other diseases in group A.

Conclusion: ESD performed with SB Knife Jr is a technically efficient and safe method associated with favorable long-term outcomes in cases of early colorectal neoplasms in elderly patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sessile serrated polyps (SSA/Ps) are pre-malignant lesions that may lead to colorectal cancer in accelerated manner. These lesions are easily missed by endoscopists as these are difficult to detect in IBD patients. We aimed to assess the prevalence, detection rate and endoscopic findings of SSA/Ps in long standing IBD patients prospectively undergoing surveillance colonoscopy using dye (DCE) or virtual electronic chromoendoscopy (VCE) or high definition white light imaging (HD-WLE) colonoscopy. SSA/Ps are not an infrequent finding at surveillance colonoscopy in IBD patients. There was no difference in detection rates of SSA/P using HD-WLE, DCE or VCE. Endoscopic features were recorded in each group with regard to location, morphology (polypoid/non polypoid), size and mucosal pit pattern, and these were characterized using the Kudo modified classification and Paris classification. The histology was reported by modified Vienna classification.

Results: Thirty-three SSA/Ps were detected in 20 (11UC, 9 CD; 11 female, age range 34-72 y, median age 61 years) patients out of the 270 patients with IBD (median duration of the disease 14 years) undergoing surveillance colonoscopy were assessed by HD-WLE (n = 90), VCE (n = 90) or DCE (n = 90). Surveillance colonoscopy with HD imaging (High Definition) alone, or with iSCAN VCE or DCE was performed. Endoscopic features were recorded in each group with regard to location, morphology (polypoid/non polypoid), size and mucosal pit pattern, and these were characterized using the Kudo modified classification and Paris classification. The histology was reported by modified Vienna classification.

Conclusion: SSA/Ps are not an infrequent finding at surveillance colonoscopy in IBD. There are prevalent in the right colon location and these generally have Kudo pattern of IHO. SSA/Ps can be recognized endoscopically by Kudo pit landmarks or terminal ileum while the European and American guidelines suggest available photo documentation probably a panoramic view of the ileocecal valve and caecum. In this retrospective study we aimed to assess colonoscopists’ practice in photo documentation of colonoscopy completion.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The histological characterization of colorectal polyps using FICE (Fujinon Intelligent Color Enhancement) technology presents high diagnostic accuracy. However, the excellent results in histological prediction are a reflection of the clinical practice by trained endoscopists, and their application remains to be confirmed outside this context.

Aims & Methods: To evaluate the in vivo histological prediction accuracy of colorectal polyps <10 mm in size using FICE technology and compare with histopathology. We propose this tool for daily practice, involving all the endoscopists of our endoscopy unit.

Disclosure of Interest: All authors have declared no conflicts of interest.
null
Results: 1382 LSL in 1243 patients were analysed. 1155/1243 (92.9%) patients had a solitary LSL. The majority of patients with multiple LSL had two (77.3%) or three (15.9%) lesions. 889/1382 (64.3%) of LSL were G. G LSL were more likely to be solitary (87.0%) than NG LSL (77.5%, p < .001). G LSL were more commonly large (>40 mm in size) (49.5%) than NG LSL (26.0%, p < .001) and were more commonly found in the right colon (proximal to transverse colon) (54.2% versus 48.3%, p = .034). In 88 patients with multiple LSL the dominant LSL was G (49/88 (55.7%). A dominant G LSL was associated with fewer other LSL than a dominant NG LSL, p = .029.

Table 1: The morphology of the dominant (largest) laterally spreading lesion (LSL) predicts the presence and number of synchronous LSL. Morphology of the dominant lesion did not predict the others would be of the same morphology (p = .697). The dominant LSL was large in 43.2% of cases. Size of the dominant LSL predicted size of the other LSL (p < .001). 58.6% of dominant LSL were located in the right colon. In 65.9% patients all LSL were in the same colonic segment; this was not predicted either by the location of the dominant LSL (p = .860) or its morphology (p = .228).

### Dominant LSL Morphology

</tr>
</thead>
<tbody>
<tr>
<td>Granular (n = 49)</td>
</tr>
<tr>
<td>Non-granular (n = 29)</td>
</tr>
</tbody>
</table>

Conclusion: 7% of patients will have more than one LSL. In these patients the dominant lesion morphology predicts the presence and number of additional LSL (the Colonic Mucosal Phenotype). More than 20% of NG LSL are associated with an additional LSL whereas G LSL are predominantly large and solitary. Practitioners of endoscopic resection should be aware that NG LSL may be multiple and ensure full examination of the colonic mucosal surface, particularly since they are higher risk for MC than G LSL.

### P0860 WIDE-FIELD PIECEMEAL COLD SNARE POLYPECTOMY OF LARGE SESSILE SERRATED POLYPS WITHOUT A SUBMUCOSAL INJECTION IS SAFE

D. J. Tate, H. Awadie, F. Buhin, L. Desomer, R. Lee, S. Heitman, K. Goodrick, M.J. Bourke
Department Of Gastroenterology And Hepatology, Westmead Hospital, Sydney, Australia/NSW

Contact E-mail Address: dtjate@gmail.com

Introduction: Large series suggest endoscopic mucosal resection is safe and effective for the removal of large sessile serrated polyps ≥10mm (large SSP) but it exposes the patient to the risks of electrocutery, principally delayed bleeding.

Aims & Methods: We aimed to examine the feasibility and safety of piecemeal cold snare polypectomy (pCSP) for the resection of large SSP. Over 12 months sequential large SSP without endoscopic evidence of dysplasia referred to a tertiary endoscopy centre were considered for pCSP. The technique for pCSP was standardised. The lesion and its margins were assessed using high definition endoscopic imaging. Snare resection commenced at one margin including a 2–3mm rim of normal tissue. A thin-wire snare was used in all cases. Firm downward pressure and suction of luminal gas aided tissue capture. Subsequently the assistant closed the snare until resistance was felt, and then completely once the endoscopist was satisfied with the amount of captured tissue. If transection did not occur within five seconds gentle traction was exerted on the snare catheter against the tip of the colonscope. If transection still did not occur, the snare placement was revised. The mucosal defect was then expanded with a flushing pump containing 0.9% saline. Further resections were then performed aligning the snare with the cut edge of the expanding mucosal defect. Once the resection was completed the mucosal defect was inspected for residual serrated tissue. If residual was detected further generous snare resection was performed. Oozing of blood from the resection site was common and was not actively treated. Submucosal injection was not performed. High-definition imaging of the defect margin was used to ensure the absence of residual serrated tissue. Adverse events were assessed at 2 weeks and surveillance was planned between 6 and 12 months.

Results: 41 SSP were completely removed by pCSP in 34 patients. 7 patients had two lesions removed. The median size of SSP was 15mm (IQR 14.5–20), range 10–35mm. The median duration of procedures was 4.5 minutes (IQR 1.4–6.3). There was no evidence of perforation or significant intra-procedural bleeding. There were no significant adverse events at 2 week follow up including delayed bleeding and post polypectomy syndrome. 8/41 lesions underwent first follow-up at median 6 months with no evidence of recurrence.

### Table 1: Baseline characteristics and outcomes of the 34 patients and 41 SSP that underwent piecemeal cold snare polypectomy (pCSP).

Introduction: Polypectomy of adenomas reduces death due to colorectal cancer; therefore colonscopy is the gold standard to detect and treat adenomatous lesions. Most adenomatous lesions are less than 20mm in size. Therefore, these are not indication for endoscopic submucosal dissection (ESD). Recently, there are some reports about cold snare polypectomy (CSP). CSP is effective and easy to remove lesions of less than 5–10mm in size. On the other hand, in over 10mm lesions, many endoscopists would remove it by endoscopic mucosal resection (EMR) with monopolar snare. It is expected that the bipolar snare would decrease the incidence of perforation because of electric current flow peculiar to bipolar snare that does not flow through the wall of colon. So, by using bipolar snare, hot snare polypectomy (HSP) that can be easily resected in a short time may be safely performed for over 10mm colorectal lesions. However, there is no report about them.

Aims & Methods: We aimed to clarify removal method, procedure time and complications for over 10mm colorectal lesions endoscopically resected using bipolar snare. Consecutive patients with over 10mm colorectal lesions endoscopically resected using bipolar snare in National Cancer Center Hospital East between September 2016 and March 2017 were enrolled in this study, prospectively. The removal method rate of these lesions, each procedure time, complete resection rate, bleeding rate and perforation rate, and pathological finding were assessed.

Results: A total 92 lesions in 67 patients were analyzed. 47 patients (70%) were male, and the median age was 67 years (range: 44–88). The median lesion size was 15mm (range: 10–30). The macroscopic type was 33 (36%) polypoid lesions and 59 (64%) flat lesions. The location was 55 (60%) lesions in right colon, 31 (34%) lesions in transverse colon and 16 (18%) lesions in left colon.
in left colon and 6 (6%) in rectum. Pathological diagnosis was 22 (24%) hyperplastic polypl or SSA/P, 42 (46%) low grade dysplasia (LGD), 23 (26%) high grade dysplasia (HGD), and 1(1%) submucosal invasive cancer. In the removal methods, HSP was 71 (77%) lesions and EMR was 21 (23%). The median procedure time of HSP and EMR was 37 seconds (range: 7–430) and 167 (range: 60–450) (p < 0.001). The median lesion size of was HSP and EMR was 12 mm (range: 10–30) and 20 (range: 10–26) (p < 0.001). The immediate bleeding of HSP and EMR occurred in 7 (10%) lesions and 6 (3.3%) (p = 0.009). The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 (p = 0.143). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic polypl or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

**Conclusion:** Of over 10 mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

7 University of Sydney, Sydney/Australia

**Contact E-mail Address:** drmsidhu16@gmail.com

**Introduction:** The SMSA polyp scoring system is an objective method of stratifying the difficulty of polypectomy based on expert consensus opinion. The score is simple, intuitive and has previously not been evaluated in a large multicentre setting.

**Aims & Methods:** We aimed to determine the ability of the SMSA polyp score to predict robust endpoints after endoscopic mucosal resection (EMR) of colorectal laterally spreading lesions (LSL). The SMSA polyp score was applied to a prospectively collected multicentre database of LSL resected by EMR over eight years. This score describes the complexity of polypectomy with respect to four major domains (table 2) and is subsequently divided into four levels. Standard inject and resect EMR procedures were performed with detailed patient, procedural and outcome data recorded prospectively over the study period including all features of the SMSA. In patients who had multiple lesions resected the largest lesion was retained for analysis. The primary endpoints were correlation of SMSA score with completion rate, adverse event rate and adenoma recurrence.

**Results:** 2305 lesions in 2305 patients (47.4% M, 45%, 2% right colon) underwent EMR. The majority of lesions were SMSA 4 (50.2%) with a median lesion size of 30 mm (range 20–160 mm). Failed single session EMR occurred in 97 (4.2%) and this was predicted by increasing SMSA (p < 0.001). Intra-procedural bleeding was significantly more common with increasing SMSA (2, 19/229 (8.3%) versus SMSA 4 291/1158 (25.1%), p < 0.001). Clinically significant post EMR bleeding (CSPEB) was more common as SMSA increased with 17% in the SMSA 2 group and 90 (7.8%) in the SMSA 4 group, p < 0.001. Intra-procedural perforation and delayed perforation were no different between the groups. After EMR surgery at two weeks was more common in the SMSA 4 group (p < 0.001). Of those patients that underwent their first surveillance colonoscopy (SC1), endoscopic recurrence (EDR) was more common in the SMSA 4 group than the SMSA 2 group, 206 (23.7%) as compared to 9 (5.4%), p < 0.001. This was also the case for histologic recurrence (p < 0.001). The difference in EDR persisted to the second surveillance colonoscopy (SC2) with no recurrences in the SMSA 2 group versus 9.1% in the SMSA 4 group.

**Table 1:** Outcomes after endoscopic mucosal resection at the initial procedure, 2 weeks and subsequent surveillance procedures.

**Conclusion:** SMSA is a simple readily applicable clinical score that identifies a subgroup of patients who are at increased risk of EMR related complications including CSPEB and recurrence. This information is useful for planning EMR lists with respect to time and resource allocation. Moreover SMSA could have a major impact on training, both in identifying appropriate training cases and providing an objective benchmark against which to assess the progress of trainees in EMR.

**P0863 USE OF ACETIC ACID FOR EVALUATING SESSILE SERRATED ADENOMA/POLYP: A PILOT STUDY**

S. Yamamoto, M. Shafazand

Gastroenterology, Sahlgrenska University Hospital Östra, Göteborg/Sweden

**Contact E-mail Address:** shu0551suke@gmail.com

**Introduction:** Sessile serrated adenoma/polyp (SSA/P) has been accumulated increasing attention since its risk for developing to cancer had been clarified. These polyps are difficult not only to detect but also to determine their precise margin after detection especially in right side colon. Such a difficulty leads high recurrence rate after endoscopic resection. Magnifying function and narrow band imaging (NBI) is reported to be useful for evaluation of SSA/P but it needs special equipment, extra time, and expertise. Easier, uncomplicated, and non time consuming method is desired. The use of acetic acid or acetic acid-indigo carmine mixture have been introduced into endoscopic diagnosis in Barrett’s esophagus, early gastric cancer, and colorectal early cancer. However, there have been no reports on using this agent as aid for the optimal diagnosis of the margin of SSA/P. If this rather cheap agent were helpful for realizing the precise margin of SSA/P, it could decrease insufficient removal of the polyp and recurrence after that.

**Aims & Methods:** The aim of this pilot study is to assess whether the acetic acid could facilitate the recognition of the margin of SSA/P. We used acetic acid as a mixture with indigo carmine and compared it to conventional evaluating methods; narrow band imaging (NBI) and indigo carmine. From December 2016 to February 2017, patients in whom SSA/P more than 10 mm were found in right side colon in daily practical colonoscopy by single endoscopist in our institute were included. We used the standard scope without magnifying function. First we observed lesions with conventional white light and NBI. Second, we recorded pictures with indigo carmine (IC) spray alone on it. Finally, we sprayed the mixture of acetic acid and indigo carmine mixture (AIC) directly through the endoscopic working channel without using catheter onto lesion. Using recorded pictures during these procedures, ability for recognizing the margin of polyps were compared between IC and AIC, or NBI and AIC by 3 endoscopists, and the concordance rate of diagnosis among these three were assessed as Kappa statistics.

**Results:** 9 SSA/P lesions in 7 patients were investigated. In all cases, AIC was helpful to recognize the margin of polyps without causing any obstructive effect. We also observed disappearance of mucous on the surface, dilated crypts caused by acid contact, and aceto-whishit reaction on the surgical glands in all lesions. In comparing the ability for recognizing the margin of the lesions, 6.3 in 9 lesions (mean among 3 practitioners) were thought to be as AIC better than IC, and...
similarly 7.3 in 9 were better than NBI. Kappa value among participants was 4.8; moderate agreement (p = 0.0016). All polyps were removed endoscopically after evaluation. All lesions were histologically diagnosed as SSA/P without dysplasia.

**Conclusion:** Acetic acid was useful and promising to facilitate the endoscopic recognition of the precise margin of SSA/P in right side colon. Strength of this method is that it is very simple and needs no special equipment nor skill.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Aims & Methods:**

From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood. A total of 80 patients who underwent endoscopic tattooing using India ink or autologous blood were included in this study. From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood at a single tertiary medical center, and the outcomes were collected prospectively. As a comparison, we retrospectively reviewed the medical records of a further 40 consecutive patients who underwent endoscopic tattooing using India ink before February 2016. The primary outcomes were the visibility of the tattooing in the peritoneal cavity and related adverse events.

**Results:** Endoscopic tattoos produced using India ink were visible in 38 (95%) patients, and tattoos created using autologous blood were visible in 36 (90%) patients. In the autologous blood group, the tattoo could not be identified in four patients due to excessive peritoneal fat, bleeding tendency, congenital anomaly, and tattooing to an inadequate depth. Eight (20%) patients in the India ink group and four patients (10%) in the autologous blood group experienced endoscopic tattooing-related adverse events.

**Conclusion:** Preoperative endoscopic tattooing using autologous blood is a feasible and safe modality for the preoperative localization of colorectal lesions.

**Conclusion:** Our western series confirm similar rates of submucosal adenocarcinoma according to the type of LST as compared to Asian series. LST-G with large nodule, and LST-NG with depression were associated with a higher risk of submucosal invasion and invasive pit pattern was the stronger predictor of malignancy. Endoscopic submucosal dissection should be systematically performed in these cases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

References
Introduction: Endoscopic submucosal dissection represents the standard of care for large superficial colo-rectal neoplasms in Japan. In Europe, only few studies reported diagnostic results, essentially in the rectal location. Colonic ESD is more technologically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is although more risky because perforations are most often non-clinically apparent in the rectal location (under peritoneal reflection) contrary to the colonic location. Here we reported our results of two years of colonic ESD performed by two French expert teams that began colonic ESD after a strong animal training and a strong experience in rectal and upper-digestive tract ESD.

Aims & Methods: Retrospective bicentre study of all cases of colonic ESD performed between 01/2016 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and extended curative resection rate (Curative resection + non-curative due to positive horizontal margins and without recurrent disease on endoscopic control). Secondary endpoints were to compare these results with results of rectal ESDs performed during the same period.

Results: 2674 cases were performed in two French centers between 01/2015 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. During the same period 93 rectal ESDs were performed for superficial pre-cancerous or cancerous neoplasms. Descriptive results: male 54 (61%), mean size of the specimen: 49 mm, mean duration of procedure 125.1 min, mean speed of ESD: 18.9 mm²/min, perforation rate: 9 (10.3%), post procedural bleeding rate: 2.3%, secondary endpoints were compared with those of rectal ESDs performed during the same period.

Conclusion: Colonic ESD could be performed with similar results than rectal ESD in French expert teams with prior strong experience in animal ESDS and rectal ESDs. It allows en bloc resection of large superficial colorectal neoplasms with a very low risk of recurrence. RTs comparing colonic ESD to piece-meal EMR are needed to determine the appropriate place of each technique in Europe.

Disclosure of Interest: All authors have declared no conflicts of interest.
needed. We recorded endoscopic diagnostic accuracy according to Baron criteria, time to reach the caecum, and the patient’s pain/discomfort and operator’s difficulty.

Results: We studied 12 patients (7M/5F), mean age 41 yrs and disease duration 5.33 yrs. 53 colonic segments out of the 54 evaluated had the same assessment of disease activity (absent = 0 points, mild = 1 pt, moderate = 2 pts and severe = 3 pts) with a mean difference score with 0.3 pts (SD 0.33 pts) (SD 0.60) with S, without significant difference. The caecum was reached in 11/12 cases by S in an average of 29.42 min (SD 28.94), and in 10/12 cases by R, in an average of 46.67 min (SD 24.98 min), with a mean difference of 17, 25 min., not statistically significant. Incomplete colon explorations with R clustered in Milan, probably because of smaller experience. An average of 1.45 (SD 0.79) mg of midazolam were used during S while 0.41 (SD 0.38) mg during R. Mean pain/discomfort on a 0–10 scale was 2.08 (SD 1.67) for R and 4.17 (SD 1.74) for S, with a statistically significant difference (p = 0.006) favouring R. Mean perceived operator’s difficulty on a 0–10 scale was 4.44 (SD 1.78) for R, and 4.08 (SD 1.44) for S, with a mean difference of 0.42 pts favouring S, not statistically significant.

Conclusion: R appears to be a promising method for disease staging in patients with ulcerative colitis, because of comparable accuracy and reduction in pain and discomfort. A tool channel to obtain biopsies and perform therapeutic endoscopy, together with images of higher definition (CMOS digital Camera HD ready) and virtual chromo-endoscopy, useful for follow-up and screening for dysplasia in patients with long duration of disease are now available in the latest version of R. The “column” connected to the latest version of the robot is the size of a portable suitcase, and suitable for remote operation. Further studies with newer versions of R are needed to assess the role of this technology from an economic point of view and in special settings like failed colonoscopies, dysplastic lesions in UC, bed-side colonoscopy, colonoscopy in rural areas.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The LST classification and Paris classification systems are internationally used to describe polyp morphology. Differences between Japanese and Western endoscopists in the use of classification systems, have been observed. We aimed to evaluate the inter-observer agreement of LST classification amongst Western & Japanese experts.

Aims & Methods: A total of 40 endoscopic video clips depicting LSTS (10% minor LST) were sent by 6 expert endoscopists: 3 from Japan and 3 from the West. Assessments included LST classification (LST-G homogeneous, LST-G mixed, LST-NG flat, LST-NG pseudodepressed), Paris classification, invasiveness, treatment suggestion and mean size of lesion. We calculated the interobserver agreement with weighted kappa and Chi square.

Results: Japanese endoscopists diagnosed more lesions as LST-G than Western (62.7 vs. 45.4%), Western diagnosed more LST-NG than Japanese (54.6 vs. 37.3%; p = 0.007). The interobserver agreement of the LST classification amongst all six experts was good according to the weighted Kappa of 0.61 (IC 95% 0.45–0.78) for Japanese, and moderate at 0.45 (IC95% 0.27–0.64) for Western. Difference in concordance between the two cohorts was not statistically significant (p = 0.22). When only two categories were considered (LST-G vs NG), agreement was very good according to Japanese (weighted Kappa of 0.81; 95% CI 0.65–0.97) and good for Western endoscopists (0.65; 95% CI 0.46–0.85). Again, difference in concordance was not statistically significant (p = 0.22).

Piecemeal Endoscopic Resection was suggested in 34, 7% cases by Western, but never by Japanese endoscopists, whereas Endoscopic Submucosal Dissection was recommended in 50.4% and 16.1% cases by Japanese and Western experts respectively (p < 0.0001).

Conclusion: This study is the first to validate the LST classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A scoring system based on size, morphology, site and access (SMSA score) was established for determining the complexity of polypectomy and endoscopic treatments. It could predict outcome of endoscopic interventions.

Aims & Methods: The aim of this study was to assess the usefulness of the SMSA scoring system relating the difficulty level with outcomes and complications of EMR and to compare it with a subjective classification of difficulty. We conducted a prospective multi-center study with 1997 consecutive patients with large (>20mm) non-pedunculated colorectal lesions (LNPLC) treated by EMR (n = 2198) at 23 hospitals belonging to the Spanish Endoscopy Society Endoscopic Resection Group, from January 2013 to October 2016. We
calculated the SMAS score of difficulty and assessed the ability of SMAS to identify 5 outcomes: 3-months recurrence, 1-year recurrence, global recurrence (endoscopy not effective after 2 or more treatments), delayed bleeding and perforation. We compared results with those obtained using a subjective classification of difficulty: easy or medium vs difficult. Comparisons were conducted using chi-squared tests and complemented with logistic regression models.

Results: The SMAS scoring system classified 690 polyps (39%) as level 4 and 1098 (61%) as level 3, whereas the subjective classification system classified 392 (22%) as difficult and 1389 (78%) as easy or medium. The agreement between measures of difficulty was weak (k = 0.33). 255 patients (19.9%) had recurrence 3 months after EMR, 84 (11.6%) had recurrence at 1 year, 78 (3.5%) suffered delayed bleeding and 5 (1.6%) perforation. Using the subjective indicator of difficulty, recurrence was also delayed bleeding (p = 0.001) but not for perforation.

Conclusion: The SMAS grading tool is a predictor of outcomes or recurrences and bleeding following resection of LNPLC. However, in our multi-center sample, it does not appear to overcome the ability of a subjective indicator of difficulty. This was evidenced during the EMR. It seems that this score can be used to facilitate planning, training or competency assessment, but efforts should be focused on validating the scoring system in a real situation, adjusting the score of variables or including new ones.

P0872 NARROW BAND IMAGING GUIDED BIOPSY IMPROVES THE YIELD OF HISTOLOGY FOR THE DIAGNOSIS OF GASTROINTESTINAL TUBERCULOSIS (GITB)
Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: sarojksinha@hotmail.com

Introduction: Accurate diagnosis of gastrointestinal tuberculosis (GITB) is challenging due to pauci-bacillary nature of disease and poor sensitivity of histopathology. Role of tissue acquisition using narrow band imaging magnification (NBI-M) to improve yield of histopathology over high-definition white light endoscopy (HD-WLE) has not been assessed. Aim: We aimed to test the utility of narrow band imaging with magnification versus high-definition white light imaging guided endoscopic biopsy for diagnosis of gastrointestinal tuberculosis. In this prospective study from July 2015 to November 2016, adult cases of clinically suspected GITB were recruited. All patients underwent randomised test, contrast enhanced computed tomography of abdomen, esophagogastroduodenoscopy and/or colonoscopy using both HD-WLE and NBI-M and guided biopsies using both were taken. Histopathological examination was done by two independent pathologists. A final diagnosis of GITB was made if acid-fast bacilli were seen in tissue or grown in culture, histopathology showed caseous necrosis with granulomatous inflammation or clinical/radiological and endoscopic features were suggestive of tuberculosis and clinical response to antitubercular therapy. Results: A total of 35 cases of clinically suspected GITB were recruited. A final diagnosis of tuberculosis was made in 32 cases (daedalor n = 4, ileocolic n = 28). Concomitant evidence of active or healed pulmonary tuberculosis was seen in 21% of cases. The mean age, haemoglobin and erythrocyte sedimentation rate of patients with tuberculosis were 36.4±14.6 years, 10.2±2.4 g/dl, 37.8±15.3 mm/hour respectively. The mean duration of symptoms was 10.9 months. The most common symptoms were pain abdomen (78%), weight loss (62.5%), and loss of appetite (40.6%), fever (37.5%), vomiting (34%) and diarrhea (22%). Mantonius test was positive in 40.6% cases. The most common endoscopic findings were ulcerations (75%), nodularity (46.8%), distorted ileocecal valve (28%) and strictures (21.8%) (Table 1). The most common radiological findings were mural wall thickening (65.6%), mesenteric lymphadenopathy (56%) and strictures (40%) (Table 1). NBI-M guided biopsy confirmed the diagnosis of GITB in 46.88%, while HD WLE guided biopsy confirmed diagnosis of GITB in 28.12% (P = 0.04). The two sets of biopsies together confirmed diagnosis of GITB in 53.1%. The area under curve for NBI-M plus HDWLE, NBI-M alone and HDWLE alone were 0.770 (63.87–0.73) (0.60–0.85) and 0.64 (0.50–0.77) respectively. Patients were started on anti-tubercular therapy for nine months. Four patients underwent surgery for intestinal obstruction while on anti-tubercular therapy. Twenty eight completed full therapy and improved.

Conclusion: NBI-M guided biopsy improved the yield of histology for diagnosis of GITB.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancer is a leading cause for cancer related mortality. Adenomatous poly, the precursor lesion, can usually be endoscopically resected to prevent cancer. Currently, there are no criteria for surgical vs. endoscopic resection and decision is individually made by the treating physician.

Aims & Methods: We aimed to evaluate factors associated with short-term efficacy and safety of endoscopic resection of large ≥20 mm and giant (≥40 mm) adenomas. Consecutive cases that underwent endoscopic resection of adenomas larger than 20 mm were included. Endoscopic, clinical and histological details of polyps and of the endoscopic procedure were recorded as well as the need for further surgery.

Results: Total of 351 resections were included. Average diameter was 30.34 ± 10.66 mm. Surgery was indicated in 21 (5.98%) cases. In a multivariate analysis for efficacy, two variables were independent risk factors for surgery: adenoma size (OR 95%CI 1.08 (1.04–1.12) and cecal location (OR 95%CI 5.97 (1.60–22.33)). Post-polypectomy complications were documented in 85 cases (24.2%): bleeding - 69 (19.7%, 54/69 managed during procedure), perforations - 8 (2.3%) and significant discomfort up to early termination of procedure - 15 (4.3%). Only 21 (6.0%) developed serious complications requiring further hospitalization. In multivariate analysis for safety, independent risk factors for post-polypectomy complications were: adenoma size (OR 95%CI 1.04 (1.01–1.06), poly morph morphology (sexile OR 95%CI 2.55 (1.45–4.51), flat OR 95%CI 2.40 (1.04–5.52) and submucosal adrenaline injection (OR 95%CI 1.87 (1.11–3.20)). Every increment of 1 mm in adenoma diameter above 20 mm, increased the need for surgery by 8% and the risk for complications by 4%.

Conclusion: Resection of large or giant adenomas is generally a safe procedure when performed by an experienced endoscopist. Although adenoma size is the most significantly related to efficacy and safety, each case of giant adenoma should be evaluated in a referral center for feasibility of endoscopic resection.

Contact E-mail Address: palmela.carolina@gmail.com

Introduction: Clinical delayed bleeding is the most frequent adverse event following endoscopic colorectal mucosal resection. Observational and interventionist studies on the efficacy of prophylactic closure (PC) following endoscopic mucosal resection (EMR) showed conflicting results.

Aims & Methods: The primary objective of this review is to evaluate the effectiveness in preventing bleeding and post-polypectomy syndrome (PPS) or perforation of PC of colonic mucosal defects following endoscopic resection. We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) from MEDLINE.

Results: 269 articles were initially screened: 5 were RCTs, 4 of them were pooled in the quantitative analysis. A total of 555 patients and 557 resection lesions (proximal colon: 220; distal: 337) were included. Endoscopic procedures: 459 loop polypectomies and 98 submucosal dissections. A total of 298 lesions were randomized to PC versus 259 to non-closure (NC). Number of events on PC group: delayed bleeding (n = 3), PPS and perforation (n = 61). Number of events on NC group: delayed bleeding (n = 13), PPS and perforation (n = 14). Prophylactic mucosal defect closure was effective in reducing delayed bleeding risk (OR: 0.206, 95%CI 0.045-0.77; p = 0.020; I² = 0.0%; 2 RCT and 452 lesions included). There was a non-significant trend for PPS/perforation risk reduction after PC (OR: 0.349, 95%CI 0.114-1.070, p = 0.066; I² = 0.0%; 2 RCT and 374 lesions included).

Conclusion: Prophylactic closure of mucosal defects after EMR of flat or sessile colorectal lesions ≥ 10 mm reduces the risk of delayed bleeding. Further studies are needed to evaluate the effect on PPS/perforation prevention.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0875 RECTAL ESD IN VERY OLD PATIENTS (>80 YEARS): A FRENCH MULTICENTER RETROSPECTIVE STUDY**

Introduction: Endoscopic Submucosal Dissection has become the standard of care for large superficial rectal precancerous and cancerous lesions. It allows an en-bloc resection of large superficial lesions that increase the quality of pathologic staging. Endoscopic Submucosal Dissection has become the standard of care for large superficial rectal precancerous and cancerous lesions. It allows an en-bloc resection of large superficial lesions that increase the quality of pathologic staging.

Results: 58 rectal ESDs were performed in four French centers between 06/2010 and 12/2016 for superficial pre-cancerous or cancerous neoplasms in patients older than 80 years. Four French teams that performed more than 150 ESDs in the last 5 years. Primary Endpoint was to evaluate the ESD. R0, curative resection rate and complications in patients older than 80 years. Secondary endpoints were to compare these results with rectal ESDs performed during the same period for patients younger than 80 years.

Conclusion: ESD is feasible and efficient in very old patients. However, ESD resection and R0 resection are less frequent than in younger patients probably due to more challenging lesions (more frequent cancer on the pathological analysis). ESD should be the treatment of choice for large rectal superficial neoplasms of the rectum in very old patients in view of its oncological efficiency and its safety in comparison to the surgical alternative.

Introduction: Split-dose bowel preparation (SD) is more effective in bowel cleansing quality in patients from a district hospital. The implementation of a split-dose bowel preparation protocol in bowel cleansing quality in patients from a district hospital.

Aims & Methods: The main objective of the study was to explore the impact of a SD protocol in bowel cleansing quality in patients from a district hospital. This was an exploratory observational study of patients who underwent total colonoscopy between Jun/2016-Mar/2017 with polyethyleneglycol bowel preparation before and after SD protocol implementation. Bowel cleansing quality was assessed prospectively (using Boston Bowel Preparation Score) and compared between SD and PD groups. Tolerance was assessed using a patient questionnaire.

Results: A total of 344 patients were included, 53% were male, mean age of 61.8 ± 13.6 years. Bowel preparation: 66% SD and 34% PD. Overall, 72% of colonoscopies occurred in morning shifts. Mean interval between finishing bowel preparation and colonoscopy was 4h50 (SD) and 8h09 (PD). Adequate bowel cleansing was found in 51% of patients (SD 83% vs. PD 79%; p = 0.34). There was an association between adequate bowel cleansing and a shorter interval between finishing preparation and colonoscopy (5h40 vs. 7h15; p = 0.010). Split-dose preparation was associated with a better cleansing in the right colon (2.17 ± 0.69 vs. 2.03 ± 0.65; p = 0.047) and a trend for better overall cleansing (6.70 ± 1.87 vs. 6.32 ± 1.90; p = 0.067). On morning shifts, there was a significant association between SD prep and better overall cleansing (p = 0.030) and also right colon cleansing (p = 0.034). After adjusting for morning shifts, we found an association between SD preparation and better bowel cleansing (risk difference 0.406; 95%CI – 0.023–0.834; p = 0.063). There was no difference between groups on bowel urgency (SD 2.6% vs. PD 1.7%; p = 0.718). SD preparation was associated with worse sleep quality (SD 25% vs. DA 7%; p = 0.004).

Conclusion: The implementation of a split-dose bowel preparation protocol in our hospital was associated with better bowel cleansing, especially on the right colon. Split-dose preparation was not associated with higher bowel urgency, although there was a worse sleep quality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0877 EQUAL ADENOMA DETECTION RATE IN COLON PATIENTS WITH SPINAL CORD INJURY AND CONTROLS – A CASE-CONTROL STUDY
A. Blanco Belver1, M. Auchar2, W. Schmiegel1, T. A. Schildhauer2, R. Meindl2, T. Brechmann1
1Department Of Gastroenterology And Hepatology, Berufsgenossenschaftliches University Hospital Bergmannsheil Gmbh, Bochum/Germany
2Department Of General And Anaesthesia Surgery, Spinal Cord Injury Unit, Berufsgenossenschaftliches Universitätsklinikum Bergmannsheil gGmbH, Bochum/Germany

Introduction: Spinal cord injury (SCI) is a devastating event that occurs with a discharge incidence of 199 per million, which results in an estimated prevalence of up to 2525 per one million [1]. Cancer is a major cause of death in patients with spinal cord injury (SCI) [2]. Preventive strategies claim increasing attention, but must deal with special problems. Most SCI patients suffer from neurogenic bowel abnormality, a loss of bowel control, sweats, reduced skin sensibility, constipation or evacuation difficulties. Therefore, bowel preparation requires modified and intensified regimens and more intensive care to prevent pressure ulcers and optimum skin management [3, 4, 5]. Colonoscopy itself may be associated with increased morbidity in SCI patients, since a poorer quality of bowel cleansing or failure to reach the caecum could diminish adenoma detection rates (ADR) [6, 7], while complication rates could increase due to severe morbidity.

Aims & Methods: The primary objective was to determine the adenoma detection rate (ADR) in general, right and left hemicolectomy. Secondary objectives were polyp, advanced adenoma and carcinoma detection rates, size of adenomas and polyps in either localization, intensity and effect of bowel preparation, rate of complete colonoscopies, need for re-endoscopy, duration of colonoscopic procedures, deepest point of insertion and complication rates. We reviewed retrospectively consecutive SCI patients who underwent colonoscopy from 2003 to 2013 and assigned an age-, gender- and year of performance-matched control group.

Results: In 236 SCI, compared to 414 control patients, bowel preparation lasted longer (3.57 ± 1.5 vs. 1.15 ± 0.6 days, p < 0.001), achieved insufficient cleansing rate more often (23.7 ± 3.6%) and caused more adverse events (OR: 0.37 ± 2.6). Colonoscopy needed longer time (36.9 ± 25.0 min, p < 0.001), remained incomplete more often (24.6 ± 4.6%), resulting in more re-colonoscopies (14.8 vs. 4.3%), and caused more adverse events. Colonoscopy itself might achieve a comparable quality.

Disclosure of Interest: None declared.

P0879 CONTRIBUTION OF COLONOSCOPY IN ELDERLY PATIENTS OLDER THAN 70 YEARS
A. El Mekkaoui2, A. Taimy1, A. Zazour4, W. Khannoussi1, G. Kharrass1, Z. Ismaili2

3Avicenne, Faculty of medicine Oujda, Oujda/Morocco
4Medical School, Casablanca/Morocco

Introduction: The elderly patients are considered as a particular population. Colonoscopy has an important place at this population because of the limited number of normal paraclinic examinations and the high incidence of tumor disease, specially the colo rectal cancer.

Aims & Methods: The aim of this study was to determine the indications and results of colonoscopy in people older than 70 years We performed a retrospec- tive descriptive study over a period of 2 years from the beginning of the endo- scopic unit until February 2017, conducted in the department of hepatogastroenterology of our university hospital. All patients over the age of 70 years who have underwent colonoscopy have been included.

Results: A total of 1095 colonoscopes were performed, 10.3% were indicated for people older than 70 years. The mean age was 74.15 years with a median age of 75 years and a maximum age of 91 years. The prevalence of males was 51%, 10.5% of cases (n = 10) were diabetic, 12.6% (n = 12) hypertensive, 12.6% (n = 12) with ischemic heart disease 8.4% (n = 8) had cardiac insufficiency and 9% (n = 9) had a digestive neoplasia. Colonoscopy was indicated for hematochezia 40% (n = 38), transit disorders in 33.6% (n = 32), abdominal pain in 14.7% (n = 14), IBD in 3.1% (n = 3), radiographic abnormalities in 13.6% (n = 13), iron defi-
cency anemia in 4.2%, and for patients with a family history of colorectal cancer in 1% of cases. Colonoscopy was abnormal in 83% (n = 93), with polyps in 48.3% (n = 45), suspected lesions of malignancy in 16.1% (n = 15), Diarrhea in any culture positive results (n = 15), cirrhosis in 19.3% (n = 18), IBD in 3.7% (n = 3). There were two recurrences (13.3%) at 3-months within the 15 cases with piecemeal resection, treated endoscopically, which were noted in en-bloc (ESD or EMR) resection patients (p = 0.044). Three (7.7%) and one (1.3%) patients had an indication for surgery in case-control groups (p = 0.107).

Conclusion: The presence of certain factors should be assessed during the procedure to identify patients who are high-risk for ESD conversion regardless of size or location, particularly the duration of the dissection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are limited data concerning risk factors and consequences of colorectal endoscopic submucosal dissection (ESD) conversion to mucosal resection (EMR) in western centers.

Aims & Methods: Hospital-based frequency-matched case-control retrospective study. All patients were identified from a database of 223 consecutive dissections between 2013 and 2017. The cases were those with ESD conversion to EMR for a >20 mm colonic lateral spreading tumor (LST). The controls were randomly selected by frequency 1:2 matching for tumor size (±0.5mm) and location (rectum/non-rectum). The presence of different factors were evaluated to deter-

P0880 ENDOSCOPIC CLOSURE OF ACUTE IATROGENIC PERFORATIONS OF THE GASTROINTESTINAL TRACT AND PREDICTORS OF NEED FOR EARLY SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Acute iatrogenic perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the
burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: To assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used. Also, to identify factors predicting success as a first line treatment, and failure of endoscopic treatment.

References:
2. Voemans, R., Moine, O., and Von Rentlen, D. (2012). Efficacy of endoscopic closure (NBI) allows, after training, "in-vivo" classification of colorectal polyps. Recent guidelines propose a "do not resect" strategy. However, the results may have been affected by the addition of an additional category (1s) to the NICE classification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0882 “O-RING SIGN” AS A NOVEL COLONOSCOPIC FINDING WITH NARROW-BAND IMAGING FOR DETECTING DEPRESSED-TYPE COLORECTAL LESIONS
T. Fujii
Dept. Of Gastroenterology, TF Clinic Dept. of Gastroenterology, Tokyo/Japan

Contact E-mail Address: tfclinic@tkki.com

Introduction: In recent years, colorectal cancer (CRC) has become a focus of attention as likely representing “missed” or “rapidly-growing” lesions in colorectal screening for colorectal cancer (CRC). Currently, lesions thought responsible for CRCV (carcinoma including neoplastic colorectal polyps) and flat lesions occurring on the right side of the colon, and there is an increasing need for endoscopic modalities to prevent overlooking these lesions. Colorectal screening using narrow-band imaging (NBI) during colonoscopy withdrawal from the cecum, which was started at our clinic since November 2008, suggested that the NBI colonoscopy was superior to white-light imaging (WLI) colonoscopy in detecting flat and depressed-type lesions (1). With NBI, the depressed area of a lesion is recognized as “whitish” and the surrounding ring-like mucosa as “brownish”, which constitutes the “O-ring sign”.

Aims & Methods: We aimed to evaluate the incidence and characteristics of the “O-ring sign” in depressed-type colorectal lesions. A total of 227 endoscopically resected and histologically confirmed depressed lesions (375 156, 71) were included for analysis. The colorectal lesions of these were retrospectively examined for “O-ring sign” positivity and intensity (grade 0, negative; grade 1, mildly to moderately positive; and grade 2, highly positive). Of these, 16 were included as evaluable and a total of 211 evaluable lesions were analyzed. Results: Of the 211 lesions (IIa + Hc; 40, IIc; 71 analyzed, 84 (Hc + Hc; 60, Hc; 24), 105 (IIa + Hc; 69, IIc; 36), 22 (IIa + Hc; 12, IIc; 10, found to be in grades 0, 1, and 2, respectively, with 60.2% of these shown to be “O-ring sign”-positive (127,211), with IIa + Hc and IIc accounting for 57.4% (81,141) and 65.7% (46,70), respectively, of these lesions. While an examination by tumor size and location revealed no clear tendency in “O-ring sign” positivity, an examination by grade revealed a higher “O-ring sign” positivity rate among those with high-grade dysplasia (84.6%; 11,13) than those with low-grade dysplasia (59.2%; 116,196).

Conclusion: NBI colonoscopy screening for the “O-ring sign” as an index appears to improve the detection of depressed-type colorectal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) has been acceptable as a minimally invasive therapy and providing en-bloc resection for early malignant and pre-malignant lesions of gastrointestinal cancer. Colorectal ESD has some difficulties such as a risk of perforation and its severity compare to gastric ESD. Hence, Colorectal ESD is more challenging than gastric ESD in endoscopic technique. In Japan, where has high incidence of gastric cancer, endoscopists

Introduction: Narrow-band imaging (NBI) allows, after training, "in-vivo" classification of colorectal polyps. Recent guidelines propose a "do not resect" strategy for rectosigmoid hyperplastic polyps with a degree of confidence, with >90% negative predictive value (NPV) for adenoma.

Aims & Methods: We aimed to evaluate the impact of the training for the simulta-
neous evaluators (International Colorectal Endoscopic Classification) and WASP (Workgroup Serrated Polyps and Polyposis) classifications. Prospective, single-center study of patients undergoing elective colonoscopy (colonscropy-CF-H1908, Olympus, in two periods: P1: January-February/ 2016 and P2: January-February/2017. Endoscopists had no prior experience in NBI in P1, except for an interactive session of 20 minutes, and after P1 applied the technique during 2016 at their discretion. Polyps were assessed for its location, size and morphology (Paris classification); NICE/WASP. 1 (hyperplastic), 2 (serrated), 3 (adenoma), 4 (deep submucosal invasive cancer); confidence level (low: <90% vs high: >90%) of the predictions. NICE/WASP classifications were compared with histology. Learning impact evaluated by P1 and P2 comparison. Statistics: Software-R (version 3.1.2).

Results: 95 patients were selected (P1: n = 192; P2: n = 98), average size 6.4 mm (2.5 mm), 60% located in the left colon, 71.0% 0h. No difference in size, location, morphology and histology between P1 and P2 groups. An improvement of global accuracy in the application of NICE/WASP classification (P1: 72.5% vs P2: 75.5% of the predictions: 78.5% (95% CI: 71.1%–84, 8%) vs 90.5% (95% CI: 81.5%–96.1%) (p = 0.044). In the P2 data subanalysis, NICE/WASP classification for adenoma showed specificity, sensitivity, positive predictive value and NPV of 82% (70–99%), 94% (80–99%), 96% (87–100%) and 72% (56–85%), respectively; for rectosigmoid polyps ≥5mm, with high confidence level (n = 35), NPV for adenoma was 80% (59–93%).
could have many experiences of gastric ESD that may be beneficial for the future work of the new trainee. Little knowledge about the learning curves of the young endoscopists who perform the colorectal ESD first.

Aims & Methods: We conducted multi-center retrospective observational study to elucidate the safety and learning curve of the trainee who perform the colorectal ESD. Trainee endoscopists were comprised of 261 cases of colorectal ESD performed by three endoscopists in Nippon Medical School Hospital and Machida Icho Hospital from 2010 to August 2016. The ESD devices were Flush knife BT (Fujifilm), Dual knife (Olympus), Hook knife (Olympus) or a combination by operator’s discretion. The endoscopist A and B, who had over 10000 examinations of colonoscopy and experiences of gastric ESD as (expert group), and endoscopist C had about 1000 colonoscopies and 200 large bile duct stones was accepted by the trainee endoscopist who had no experience of gastric ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0884 LARGE BALLOON DILATION VERSUS MECHANICAL LITHOTRIPSY AFTER ENDOSCOPIC SPHINCTEROTOMY IN MANAGEMENT OF LARGE COMMON BILE DUCT STONES AMONG CIRRHOTIC PATIENTS

M. I. Radwan1, M.H. Emara Elzanan2, I. M. Ibrahim3, M. E. Morsy3

1Department of Gastroenterology, Rambam Health Care Campus, Haifa/Israel
2Department Of Gastroenterology, Rambam Health Care Campus, Haifa/Israel
3Department Of Gastroenterology, Rambam Health Care Campus, Haifa/Israel

Introduction: Removal of large common bile duct (CBD) stones is one of the challenges during ERCP and it seems more difficult in cirrhotic patients due to superstition of the complications in cirrhotic patients under ERCP because of liver cirrhosis can tolerate ERCP to treat their biliary tract or pancreatic diseases. Patients with liver cirrhosis are three times more susceptible to cholelithiasis, than the non-cirrhotic population and liver cirrhosis is an independent risk factor for cholecystitis and other diseases and that is why ERCP is increasingly performed for patients with cirrhosis. Endoscopic sphincterotomy (EST) has become a standard step in the management of CBD stones and introduction of both mechanical lithotripsy (ML) and large balloon dilation (LBD) facilitated extraction of the large CBD stones. Despite the increasing use of both techniques, a head-to-head comparison of the two groups was not reported. Therefore, the aim of this study was to evaluate the efficacy of large balloon dilation group showed more success in stone retrieval rate, the difference was statistically significant (P value 0.04).

Conclusion: The training of colorectal ESD first was acceptable by the trainee endoscopist, who had no experience of gastric ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.
PO886 A NOVEL METHOD OF PREVENTING DUODENOBILIARY REFUX BY MEANS OF SUSPENDED OVERLENGTH BILIARY STENTS IN PATIENTS WITH BILIARY STRICTURE

Y. Huang, X. Yan, H. Chang, Y. Zhang, W. Yao, K. Li
Gastroenterology & Hepatology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 13911765322@163.com

Introduction: Endoscopic insertion of plastic or metal stents is a well-established treatment for malignant or part of benign biliary obstruction. The major limitation of this technique is stent occlusion. Duodenobiliary reflux has been considered as a key contributor to stent occlusion. No appropriate method can so far prevent duodenobiliary reflux. Different strategies to prolong the patency of plastic stents included changing stent size, stent design, but stent sludge due to duodenal biliary reflux remains an unsolved problem. We have been using a novel suspended overlength biliary stents (reformed with nasobiliary tube) as substitution for ordinary biliary plastic stent to prevent the reflux from January 31, 2016. To December 31, 2016.

Aims & Methods: The aim of the study is to evaluate the efficacy and patency of the suspended overlength biliary stents. The suspended overlength biliary stents (SOBS) were placed in intrahepatic bile duct in 61 patients with extrahepatic bile duct strictures who were followed up at least three months from January 1, 2016, to December 31, 2016. Nasobiliary tube of 7.5Fr or 8.5Fr with multiple side holes were cut 30 cm with operation knife from the top on sterile operating table. The purpose of the set of 30 cm length is to ensure the tail reaches the duodenal horizontal part. The SOBS were placed in the intrabiliary hepatic duct by using conveyer under the fluoroscopic guidance at the end of ERCP. Radiography of the Meglumine Diatrizoate was performed in each patient of SOBS group to evaluate the existence of duodenal biliary reflux. 74 patients who were performed at least two or more ERCP with extrahepatic bile duct strictures treated with ordinary plastic stents (OBS group) from last ten years were compared with SOBS group.

Results: (1) The mean age of SOBS and OBS were 68.8±15.6yrs and 60.4±14.7yrs (P = 0.002), respectively. (2) 35 (57.4%) and 34 (45.9%) patients were malignant biliary obstruction in SOBS and OBS group, respectively (P = 0.227). Malignant obstruction included bile duct cancer and biliary duct invasion of pancreatic cancer. Benign obstruction included autoimmune pancreatitis, chronic pancreatitis, post operation stenosis, inflammatory stenosis due to cholelithiasis. (3) The mean first and second patency was 4.5 months and 5.6 months in OBS groups. All the patients in OBS group experienced at least three months to 15 months (mean patency was 5.2 months). The mean follow-up was 80 days to 12 months (mean patency was 5.2 months). The mean follow-up period of the other 50 patients in SOBS groups was 6.5 months. (range from 3 months to 15 months). No evidence of duodenal biliary reflux were detected in SOBS group.

Conclusion: Suspended overlength biliary stents can prolong the patency and reduce the occlusion rate effectively due to duodenobiliary reflux in both malignant and benign biliary stricture.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: To analyze the frequency of probable causes of asymptomatic hyperamylasaemy and acute pancreatitis after ERCP and their prevention. Two groups of patients were covered: a retrospective (340) and prospective (154) group. Patients had evidence of bile ducts impaired passability of varying etiology. In these cases ERCP is the final stage in the diagnostic and therapeutic algorithm. All ERCPs were carried out by one expert endoscopist. Patients from the prospective group were administered intramuscularly with Diclofenac (75 mg) before and after the manipulation. The methods used in the study were: demographic data; history and physical examination; laboratory data; imaging methods; ERCP; clinical course and statistical methods for processing data received.

Results: The most common indication for ERCP in all patients was cholestasis constellation (88.1%). In a minority of patients ERCP was purely diagnostic (6.1%), while at 93.9% it was also therapeutic. Of all patients at 47 of cases (9.5%) hyperamylasaemy was observed, and at 12 or 2.4% - acute pancreatitis was observed. Patients who developed acute pancreatitis often have acute calculous cholecystitis. Due to the small number of patients with acute pancreatitis, however, these results should be carefully commented. Patients who developed acute pancreatitis were found to have a lower level of alkaline phosphatase and ES and higher values of leukocytes on the 72nd hour. The univariant logistic regression analysis identified the following risk factors for developing hyperamylasaemy: cholethiasis; sclerosing papilloiditis of ERCP; normal values of serum total bilirubin and elevated CRP levels in receiving. In order to establish a predictive model a multiple logistic regression analysis was performed. The model includes: average total bilirubin at entry and cannulation of the pancreatic duct more than 3 times. The estimated true percentage for predicting lack of hyperamylasaemy with this predictive model is very good - 97%. Univariate logistic regression analysis identified the following risk factors for the development of acute pancreatitis: cannulation of the pancreatic duct and the presence of calculous cholecystitis when entering.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0889 ACUTE PANCREATIS AND HYPERAMYLASAEMY DEVELOPMENT AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY – CHALLENGES AND PREVENTION

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most technically complex procedures performed by gastroenterologists. After a significant increase in the indications for implementing ERCP, gastroenterologists began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and increased experience of endoscopists, the rate of complications has not declined significantly.

Aims & Methods: To analyze the frequency of probable causes of asymptomatic hyperamylasaemy and acute pancreatitis after ERCP and their prevention. Two groups of patients were covered: a retrospective (340) and prospective (154) group. Patients had evidence of bile ducts impaired passability of varying etiology. In these cases ERCP is the final stage in the diagnostic and therapeutic algorithm. All ERCPs were carried out by one expert endoscopist. Patients from the prospective group were administered intramuscularly with Diclofenac (75 mg) before and after the manipulation. The methods used in the study were: demographic data; history and physical examination; laboratory data; imaging methods; ERCP; clinical course and statistical methods for processing data received.

Results: The most common indication for ERCP in all patients was cholestasis constellation (88.1%). In a minority of patients ERCP was purely diagnostic (6.1%), while at 93.9% it was also therapeutic. Of all patients at 47 of cases (9.5%) hyperamylasaemy was observed, and at 12 or 2.4% - acute pancreatitis was observed. Patients who developed acute pancreatitis often have acute calculous cholecystitis. Due to the small number of patients with acute pancreatitis, however, these results should be carefully commented. Patients who developed acute pancreatitis were found to have a lower level of alkaline phosphatase and ES and higher values of leukocytes on the 72nd hour. The univariant logistic regression analysis identified the following risk factors for developing hyperamylasaemy: cholethiasis; sclerosing papilloiditis of ERCP; normal values of serum total bilirubin and elevated CRP levels in receiving. In order to establish a predictive model a multiple logistic regression analysis was performed. The model includes: average total bilirubin at entry and cannulation of the pancreatic duct more than 3 times. The estimated true percentage for predicting lack of hyperamylasaemy with this predictive model is very good - 97%. Univariate logistic regression analysis identified the following risk factors for the development of acute pancreatitis: cannulation of the pancreatic duct and the presence of calculous cholecystitis when entering.

Conclusion: We detected a low incidence of asymptomatic hyperamylasaemy (9.5%) and acute pancreatitis (2.4%) in the group of patients which were subjected to ERCP. Clinical and laboratory parameters characterizing the patients who developed these complications, and risk factors for acute pancreatitis and asymptomatic hyperamylasaemy were determined. The effect of intramuscular Diclofenac administered before and after ERCP has no effect.

P0890 MOST ADVANCED ENDOSCOPY TRAINEES DO NOT MEET COMPETENCE FOR NATIVE PAPILLAE CANNULATION IN ERCP: RESULTS FROM A PROSPECTIVE MULTICENTER STUDY

S. Wani1, M. Hall1, V. Simon1, S. Han1, D. Early2, R. Keswani3
1University of Colorado Anschutz Medical Center, Aurora/United States of America
2Washington University in St. Louis, St. Louis/United States of America
3Northwestern University, Chicago/United States of America

Contact E-mail Address: sachin.wani@ucdenver.edu

Introduction: Advanced endoscopy trainees (AETs) achieve ERCP competency at variable rates and specific case volumes do not ensure competence. However, training and credentialing guidelines continue to utilize an absolute procedure volume to determine competence. There are limited data on whether current training composition and volumes ensure ERCP competence in the US.

Aims & Methods: (i) To define ERCP learning curves, utilizing a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). (ii) To critically examine the composition of current ERCP training in AETPs. ASGE-recognized AETPs were invited to participate and AETs were graded on every ERCP after completion of 25 hands-on ERCP exams. Grading was performed using our previously developed and validated tool [The EUS and ERCP Skills Assessment Tool (TEESAT)] which assesses technical and cognitive competence in a continuous fashion. Grading for each skill was done using a 4-point scoring system: 1-no assistance, 2-minimal verbal cues, 3-multiple verbal cues or hands-on assistance and 4-unable to complete. A comprehensive data collection and reporting system was built using REDCap, a web-based data collection software, and SAS to create learning curves using cumulative sum (CUSUM) analysis for overall and individual technical and cognitive components of ERCP. Individual results and comparison to peers were sent to AETs and trainers quarterly. Acceptable and unacceptable failure rates were set a priori. AETs with <20 evaluations were excluded and success was defined as a skill score of 1 or 2. Individual and combined graphs to assess change in cannulation success rates were constructed and the Cochran-Armitage trend test was used to assess improvement in success rates.

Disclosure of Interest: No conflicts of interest.
Results: Of the 62 programs invited, 20 AETPs participated and 20 AETs were included in the final analysis. At the end of training, median numeric of ERCPs performed/AET was 350 (15–500). Overall, 2649 ERCP exams were graded; the rates of PERCPP in E1 and A1 were 2.3% (3 patients) and 1.7% (2 patients) respectively. One 84-year-old patient of E1 with a presumed malignant common bile duct (CBD) stricture had PERCPP and died 17 days after ERCP, having opted for palliation. The remaining 4 patients had uneventful conservative management of PERCPP. E1 had one patient with immediate bleeding post-sphincterotomy controlled with a CBD stent whilst A1 had 2 patients requiring adrenaline injection for haemostasis. In addition, E1 had one patient with retroduodenal perforation managed conservatively and A1 had one patient with CT evidence of intramural duodenal haematoma which was uneventful. Both E1 and A1 had one case each of uncomplicated hyperamylasaemia. A summary of complications, with patient and procedural characteristics, is listed in Table 1.

Conclusion: In our observational study, which was not intended or powered for statistical analysis, there was no overt difference in the rates of PERCPP when comparing between endoscopist- or assistant-controlled wire-guided CBD cannulation. The overall complication rate was similar and although there were some differences in procedural characteristics between the two endoscopists, there were no characteristics predisposing to PERCPP overtly skewed towards either endoscopist’s case load. Furthermore, randomised trials, or a crossover study, provided the endoscopists and assistants are equally competent in both methods of wire cannulation, are needed to clarify the safety profile of either technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Most endoscopic retrograde cholangiopancreatography (ERC) -related procedures are performed under “conscious sedation”, a drug-induced depression of consciousness during which patients are comfortable and able to maintain purposeful responses to verbal or tactile stimulation, and cardiorespiratory function generally remains intact 1. Meanwhile, we sometimes observe adverse events related to conscious sedation after ERC such as aspiration pneumonia 2. So far, it is unknown whether immediate recovery from conscious sedation with antagonists is necessary or not.

Aims & Methods: We aimed to reveal the efficacy of flumazenil, an antagonist to benzodiazepines, on the prevention of adverse events, especially, aspiration pneumonia related to conscious sedation which is most frequent after ERC. One hundred ninety patients who underwent ERC between January to December

P0891 SIMILAR POST-ERCPT PANCREATITIS RATES IN ENDOSCOPIST- VS ASSISTANT-CONTROLLED WIRE-GUIDED BILE DUCT CANNULATION: A SINGLE CENTRE OBSERVATIONAL STUDY

M. Hu, A. Bhagwat, M. Hayat
Dept Of Gastroenterology, Northumbria Healthcare NHS Foundation Trust, North Shields/United Kingdom

Contact E-mail Address: maxworth.hu@gmail.com

Introduction: A recent randomised study by Buxbaum et al1 demonstrated a significantly lower rate of post-endoscopic retrograde cholangiopancreatography (ERC) pancreatitis (PERCPP) in endoscopist- versus assistant-controlled bile duct cannulation. We set out to audit the rates of PERCPP at our centre based on this finding.

Aims & Methods: All ERCPs performed by two endoscopists between April 2015 and March 2016 were audited retrospectively. The two endoscopists practiced endoscopist- (E1) and assistant-controlled (A1) wire-guided cannulation exclusively. Both E1 & A1 had access to the same medications, sphincterotomes, equipment, and teams. Data was obtained and anonymised from electronic patient records and endoscopy reporting software. PERCPP was defined as abdominal pain with hyperamylasaemia at least three times the upper limit of normal (ULN) 24–48 hours after ERCP with or without corresponding imaging findings within 7 days; or abdominal pain with a further rise in pre-existing hyperamylasaemia to at least three times ULN 24–48 hours after ERCP with or without corresponding imaging findings within 7 days. Additional data was collected for CT evidence of post-ERCPP complications, hyperamylasaemia without pancreatitis, bleeding, and post-ERCPP cholangitis. Patient and procedural characteristics predisposing to pancreatitis were also recorded.

Results: A total of 250 procedures were audited. E1 performed 132 procedures (54% female; median age 63.5) and A1 performed 118 procedures (67% female; median age 63). The rates of PERCPP in E1 and A1 were 2.3% (3 patients) and 1.7% (2 patients) respectively. One 84-year-old patient of E1 with a presumed malignant common bile duct (CBD) stricture had PERCPP and died 17 days after ERCP, having opted for palliation. The remaining 4 patients had uneventful conservative management of PERCPP. E1 had one patient with immediate bleeding post-sphincterotomy controlled with a CBD stent whilst A1 had 2 patients requiring adrenaline injection for haemostasis. In addition, E1 had one patient with retroduodenal perforation managed conservatively and A1 had one patient with CT evidence of intramural duodenal haematoma which was uneventful. Both E1 and A1 had one case each of uncomplicated hyperamylasaemia. A summary of complications, with patient and procedural characteristics, is listed in Table 1.

Conclusion: The results of this study confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence. We report the feasibility of establishing a centralized national database to report individualized ERCP learning curves using a novel web-based comprehensive data collection and reporting system. Using strict definitions, a minority of AETs achieved competency in native papilla cannulation which may, in part, be due to limited cannulation time provided to AETs. Selective native papilla deep cannulation needs to be an important benchmark for assessing competence. Methods to improve native papilla cannulation rates and strategies to increase AET exposure to advanced ERCP techniques are required.

The aim of this study was to evaluate the impact of this hydration protocol (AHP) for patients undergoing ERCP in order to prevent pancreatitis (PEP). In our department we implemented an aggressive retrograde cholangiopancreatography (ERCP). Some studies have shown that the distributions of used b-blockers (midazolam/diazepam) were 64/8/17/26 in the F group and 30/11/16/18 in the non-F group. There was no significant difference of patients' characteristics between both groups. The mean procedure times were 36.7 minutes in the F group and 30.3 minutes in the non-F group, respectively. There was no significant difference between the incidence and severity of PEP. Our AHP didn't reduce the incidence of PEP or its severity. Indeed, the non-F group had a lower incidence of PEP (4.1% vs. 6.7%) and a lower severity of PEP (3 cases Vs. 5 cases). Conclusion: Flumazenil did not have any preventive effect on the occurrence of aspiration pneumonia related to conscious sedation after ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0895 PROSPECTIVE STUDY OF EARLY PRECUT VS. UTMOST PRECUT PANCREATIC STENT IN INITIAL PANCREATIC DUCT CANNULATION
E.T. Park, B.C. Yun, S.U. Lee, B.H. Han
Internal Medicine, Kosin University, Gospel Hospital, Busan/Korea, Republic of

Contact E-mail Address: eunparkhan@hanmail.net

Introduction: In biliary access, repeated biliary cannulation attempts are a risk factor for post-ERCP pancreatitis (PEP). Early precut is an effective technique for success of biliary cannulation and can significantly reduce the incidence of PEP. The aim of this study was prospectively to evaluate clinical efficacy the performance of utmost early precut with pancreatic stent in the patients whom pancreatic duct cannulation was performed initially.

Aims & Methods: When guidewire was placed in the pancreatic duct initially by chance, the patients were randomized into early precut (Group A) or utmost early precut sphincterotomy with pancreatic stent (Group B). In Group A, pancreatic duct cannulation within 5 times and attempted precut papillotomy with outstanding difficulty. In Group B, from the first, pancreatic stent was inserted and then precut with an incision over a pancreatic stent was done. Main outcome measurements were frequency of successful CBD cannulation and post-procedure related complications.

Results: From January 2015 to August 2016, the two groups were similar with regard to patient demographics. A total of 50 patients were enrolled. 26 patients were assigned to the Group A and 24 to the Group B. Successful CBD cannulation was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of 24 (95.8%) patients in the Group B. The mean cannulation time was 16 minutes in the Group A and 14.8 minutes in the Group B. Post-procedure hyperamylasemia was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B (P < 0.05).

Conclusion: In patients with pancreatic duct cannulation initially by chance, compare to early precut group, utmost early precut with pancreatic stent over the guidewire can easily facilitate biliary cannulation and the success rate but also promise low incidence of post-ERP pancreatitis. In experienced hands, utmost early precut technique can dramatically reduce the trauma of ampulla and risk of PEP compared with conventionally persistent cannulation attempts.

P0896 POST-ERCP BLEEDING IN THE ERA OF MULTIPLE ANTIPLAQUE AGENTS
H. Oh, J.S. Choi1, H. Kang, S. Sherman2
1College Of Medicine, Chung-Ang University, Seoul/Korea, Republic of
2Department Of Pathology, SoonChunHyang University School of Medicine, Bucheon and Seoul/Korea, Republic of

Contact E-mail Address: ohche@cau.ac.kr

Introduction: Antithrombotic therapy with antiplatelet agents (APA) has been increasingly utilized during the last few decades. This study aimed to determine the risk of post-ERCP bleeding among those patients who are taking APAs, especially in the era of multiple agents.

Aims & Methods: From July 2012 to May 2016, the patients who underwent 1st therapeutic ERCP were identified from the ERCP database of 3 institutions in USA and Korea. The primary outcomes were the frequency, type, and severity of ERCP-related bleeding according to the use of APA.

Results: The frequencies of post-ERCP bleeding among the four different groups were 16 of 203 (8.0%) in No drug group, 12 of 256 (4.7%) in Aspirin group, 3 of 48 (6.3%) in Single APA group, and 4 of 48 (8.3%) in Multiple APA group (p < 0.001). Most cases of post-ERCP bleeding were mild (29/35, 88%). In the univariate analysis, post-ERCP bleeding was associated with age, pull-type sphincterotomy, and APA, and inversely associated with balloon dilatation of the biliary papilla. In the multivariate analysis, pull-type sphincterotomy odds ratio [OR] 7.829, 95% confidence interval [CI] 1.41–43.453, p = 0.019) and country (Korea; OR 0.124, 95% CI 0.042–0.361, p < 0.001) were associated with post-ERC bleeding.

Conclusion: The frequency of post-ERCP bleeding was statistically higher in patients on any APAs within 6 days prior to ERCP. However, in the multivariate analysis, APA use was not associated with post-ERCP bleeding. Until a large study is sufficiently powered to show differences in bleeding rates, caution is recommended when considering invasive procedures during ERCP in patients on APAs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In a recent, a digital version of single-operator cholangioscope (SpyGlass DS) and direct POC (DPOC) using a multibending ultrasound endoscope were introduced as improved forms of each POC, especially in image quality and technical difficulty, respectively.

Aims & Methods: In this study, we prospectively compared the procedure success rates of SpyGlass DS and DPOC for diagnosis and treatment of BD lesions. A total of 15 patients with BD lesions (diameter of CBD >8mm) requiring evaluation or treatment using POC were enrolled prospectively. All patients received POCs using SpyGlass DS and multibending ultrasound endoscope for DPOC. According to the presence of obstructive lesion, all patients were classified as obstructive type or non-obstructive type, respectively. Procedural success defined as an ability to advance the cholangioscope to the desired target and get adequate cholangioscopic visualization for the targeted lesion.

Results: The overall technical success rates of SpyGlass DS and DPOC were 100% and 93.3%, respectively (P = 0.5). In DPOC, 1 patient was failed to insert the endoscope into the CBD. In SpyGlass DS, 2 patients were failed to visualize the targeted lesion. The procedural success rates of SpyGlass DS and DPOC according to the type of lesion were not different in 9 obstructive type (100% vs. 88.9%, P = 0.5) and 6 non-obstructive type (66.7% vs. 100%, P = 0.227). The successful diagnostic and therapeutic procedures by DPOC and SpyGlass DS were observed in 8 of 8 patients (100%) and 7 of 9 patients (77.8%) (P = 0.265), respectively.

Conclusion: Both advanced image quality of SpyGlass DS and improved technical difficulty of DPOC by a multibending ultrasound endoscope showed comparable and high procedure success rates in patients with dilated BD. Future prospective studies focused on overall cost savings and long-term clinical outcomes are seems to be required for deciding adequate indications of each POC systems.

P0899 THE DILEMMA OF MANAGEMENT BORDERLINE COMMON BILE DUCT STONE. DOES STONE SIZE MATTER?: A PROSPECTIVE RANDOMIZED STUDY
E. Abdellatif, E. ElHanafy, A. Elnakkeb
Surgery, Gastroenterology Surgical Center, Mansoura/Egypt

Contact E-mail Address: dr.ehab.atif@icloud.com

Introduction: Management of common bile duct stones (CBDs) in patients with borderline CBD presents a surgical challenge. The aim of this study was to compare conservative treatment with endoscopic stone extraction for the treatment of borderline CBD with stones.

Aims & Methods: This prospective randomized controlled trial includes patients with CBDs in borderline CBD (<10mm) associated with gallbladder stones who were treated with conservative treatment or endoscopic stone extraction followed by laparoscopic cholecystectomy (LC) and intraoperative cholangioscopy (IOC). The primary outcome was successful CBD clearance. The secondary outcomes were the overall complications, cost, and hospital stay.

Results: LC and IOC revealed complete clearance of CBDs in 48 (96%) cases in the endoscopic retrograde cholangiopancreatography (ERCP) group (52% of patients by ERCP, and 44% of patient passed the stone spontaneously), and in the remaining two patients, the CBDs was removed by transcytoscopy exploration. In the conservative group, LC and IOC revealed complete clearance of CBDs in 90% of cases, and in the remaining 10% of patients, the CBDs was removed by endoscopic sphincterotomy. Post-ERCP pancreatitis (PEP) is noticed significantly in the ERCP group (2% [4%] versus 8 [16%]; P = 0.04). The average net cost was significantly higher in the ERCP group. Recurrent biliary symptoms developed significantly in the ERCP group after 1 year (10% versus 0%; P = 0.02) in the form of recurrent cholangitis and recurrent CBDs.

Conclusion: Management of CBDs in patients with borderline CBD represents a surgical challenge. Borderline CBD increases the technical difficulty of ERCP and increases the risk of PEP. Conservative management of CBDs in borderline CBD not only avoids the risks inherent in ERCP and unnecessary preoperative ERCP, but it is also effective in clearing CBDs. The hepatobiliary surgeon
Aims & Methods: This study aimed to identify the incidence rate of and risk factors for PEP in a prospective large cohort study. This is a prospective multicenter study. In the present multicenter prospective study, SOSUI, we investigated the potential predictors of severity.

Aims & Methods: Of 2078 subjects who underwent ERCP between February 2015 and May 2016 at five high-volume centers, 1932, excluding those who were complicated by pancreatitis, undergone biliary tract reconstruction, or had papilla not reached, were included. Of the 1932 patients, 163 developed PEP were compared between the mild and severe cases to examine potential predictors of severity. PEP was diagnosed based on two or more of the following three conditions: (1) serum amylase elevation (above the upper limits of each center), abdominal pain lasting more than 24 hours, and (2) pancreatitis on CT. Severity was assessed based on the severity criteria of the Ministry of Health, Labour, and Welfare. Continuous variables, the Mann-Whitney U test was employed. For binomial comparison, univariate analysis was conducted using a chi-square test. Results: Twenty-five severe (1.3%) and 138 mild (7.1%) PEP patients were included. Patient and procedural factors were examined, demonstrating that the AMY values at 2 hours after ERCP were significantly higher in the severe cases than in the mild ones (P = 0.005). ROC analysis was conducted on the AMY values at 2 hours as a predictor of severe PEP, demonstrating that the cutoff value was 3.7 times higher than the upper limits of each center (sensitivity: 64%; specificity: 70%; and AUC: 0.65). In multivariate analysis using logistic regression by dividing the AMY values at 2 hours after ERCP into higher or lower than 3.7 times the reference value of each center, abdominal pain immediately after ERCP and AMY values at 2 hours after ERCP were identified as independent factors. Conclusion: Severe PEP should be diagnosed as early as possible for intervention. However, it may take a long time to assess clinical courses or examine images after examination. In the present study, abdominal pain immediately after ERCP and AMY values at 2 hours were identified as predictors of severity, being useful for facilitating early therapeutic intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

5. Hall RC. Is natural orifice transluminal endoscopic cholecystectomy as safe and simple approach for performing an endoscopic cholecystotomy? Aims & Methods: The aim of this study was to evaluate the accuracy of T1 stage subdivision of ESCC by higher frequency EUS probe prior to ESD treatment. The overall 5-year survival rate of ESCC is 12–15%. It is import to diagnose ESCC in early stage and receive curative treatment. Endoscopic submucosal dissection (ESD) is a well-developed skill to complete resect gastrointestinal (GI) tract early cancer. The limitation of ESD is cancer invasion to submucosal layer and increasing the risk of lymph node metastasis (10–45%) of ESCC.\n
Reference: EUS-Endoscopic ultrasonography (EUS) is an examination for detecting the pancreas and other solid internal organs. EUS elastography was performed by 2 operators, using a linear echoendoscope. The mean SR value was significantly higher in the malignant tumors comparing with the benign tumors (55.56 vs 23.93, p=0.001). The sensitivity and specificity of SR for differentiation of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%.

Conclusion: Quantitative EUS elastography presents good accuracy in the differentiation between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnosis and follow-up of these patients.

P0903 ENDOSCOPIC ULTRASOUND-BASED TRANSUDODENAL CHOLECYSTOLOYTOMY VIA DOUBLE-FLANGED FULLY COVERED METAL STENT WITH HOT STENT DELIVERY S. Sun Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/China Contact E-mail Address: sunsiyuncu@aliyun.com

Introduction: Laparoscopic cholecystectomy (LC) has become the 'gold standard' for the treatment of symptomatic gallstones. However, before clinical implementation, instruments still need modification, and a more convenient treatment is still needed.

Aims & Methods: The aim of this study was to evaluate the transudodenal tractcholecystectomy technique in the treatment of gallbladder disease without cholecystectomy, being patient with cholesterol gallstones and high surgical risks were enrolled between January 2015 and March 2017. Endoscopic ultrasound (EUS)-guided cholecystostudodenotomy by deploying a double-flanged fully covered metal stent with hot stent delivery was performed and endoscopic sphincterotomy (EST) was also performed during this procedure for those patients with accompanying common bile duct stones. One or two weeks later an forward-viewing endoscope was advanced into the gallbladder via the stent, and cholecystolithotomy or polypectomy was performed. After the stents were removed, a pigtail-type naso-cholecystic drainage catheter was inserted into the gallbladder over the guide wire and removed 2 days later. Four weeks later gallbladder was assessed by abdominal ultrasound.

Results: EUS-guided cholecystostudodenotomy with double flanged metal stent deployment was successfully performed in all of 26 patients (Male/Female, 11/15; mean age, 61 ± 16.19ys). After the procedure, fistulas had formed in each of the patients and the stones of 7 patients expelled themselves completely. Endoscopic ultrasound (19) and polyectomy (2) were successfully performed through the stents, and then the stents were removed. Common bile duct stones were also successfully removed in 6 patients. EGD showed all the fistula closed completely after 3 days. The ultrasound examination of the gallbladder 4 weeks later showed no stones remaining and also showed satisfactory functioning of the gallbladder. The mean follow-up period was 11 months (range: 1–27months). Cholesterol gallstones recurrence were not detected in any patient during follow-up.

Conclusion: The EUS-guided placement of a novel metal stent with hot stent delivery is a safe and simple approach for performing an endoscopic cholecystostudodenotomy, which can subsequently allow procedures to be performed for treating biliary disease, including cholecystolithotomy.

Introduction: Quantitative second generation endoscopic ultrasound (EUS) elastography allows the quantitative analysis of tissue stiffness and can be a useful auxiliary tool in the differential diagnosis of pancreatic solid tumors (1)(2).

Aims & Methods: The aim of this study was to evaluate the accuracy of the quantitative EUS elastography in the differential diagnosis of pancreatic solid masses, discriminating malignant from benign masses, using strain ratio (SR) analysis. A prospective study was performed for 15 months and included 29 consecutive patients who underwent EUS for the evaluation of solid pancreatic masses. EUS elastography was performed by 2 operators, using a linear echoendoscope. The mean of 3 measures was considered as the SR final result for each lesion. EUS-fine-needle aspiration of the lesions was performed after SR assessment and the final diagnosis was based on the cytology or histology results. Accuracy of the elastography was obtained by the analysis of ROC curves.

Results: Included 29 patients in a total of 30 lesions with conclusive histological/cytologic diagnosis (8 inflammatory masses, 19 adenocarcinomas, 2 neuroendocrine tumors and 1 undifferentiated carcinoma). The mean SR value was significantly higher in the malignant tumors comparing with the benign tumors (55.56 vs 23.93, p=0.001). The sensitivity and specificity of SR for differentiation of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%.

Conclusion: Quantitative EUS elastography presents good accuracy in the differentiation between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnosis and follow-up of these patients.

3Department Of Pathology, Kyungpook National University School of Medicine, Daegu/Korea, Republic of

Contact E-mail Address: sekk319@hanmail.net

**Introduction:** Determining the cause of suspected biliary strictures is always a difficult problem in clinical practice. Although EUS-guided tissue sampling (EUS-TS) revealed a better diagnostic yield in suspected malignant biliary obstructive lesions compared to ERCP-guided tissue sampling (ERC-P-TS), there was few studies for which techniques are better dependent on primary tumor. Aim of our study is to compare the diagnostic yields between EUS-TS and ERC-P-TS in patients with suspected malignant biliary obstructive lesion according to primary tumor sites. By reviewing medical records, we enrolled patients who underwent same-session examination of EUS and ERC-P for the evaluation of suspected pancreatobiliary obstructive lesion.

For cytopathologic diagnosis, endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) or biopsy (EUS-FNB) and ERC-P-TS using brush cytology and/or forceps biopsy were performed. The diagnostic performances were compared between two techniques according to primary tumor sites.

**Results:** From January 2011 to September 2016, we enrolled 125 patients and 32 patients were excluded due to the following reasons: loss of follow up in 8, ERC-P-TS of pancreatic duct in 23, and ERC-P-TS from peripancreatic biopsy in 4. Among the enrolled patients (93 patients; 62 males, mean age 65.8 years, 86 (92.5%) had malignant tumor such as cholangiocarcinoma in 39, pancreatic cancer in 37, and other malignant tumors in 10 patients. And 7 (7.5%) patients had benign lesion. EUS-TS revealed higher rate of overall diagnostic accuracy comparing to ERC-P-TS (82.8% vs. 60.2%, p = 0.001). Depending on primary lesions, the diagnostic accuracy for pancreatic lesions was statistically higher in EUS-TS than ERC-P-TS (84.4% vs. 51.1%, p = 0.003). Conclusion: EUS-TS is superior to ERC-P-TS for the evaluation of suspected malignant pancreatobiliary obstructive lesions. Especially, if the biliary obstruction was caused by pancreatic cancers, EUS-TS would need to be a priority for cytopathologic diagnosis.

**P0907 PREVALENCE OF POSTERIOR MEDIASTINAL LYMPHADENOPATHIES IN PATIENTS UNDERGOING ENDOSCOPIC ULTRASOUND-INDUCED MALIGNANT INDICATIONS: A PORTUGUESE SINGLE-CENTRE PROSPECTIVE STUDY**

J. Veloso Du Carmo, S. C. Marques, M. Bispo, C. Chagas

Gastroenterology, Hospital Egas Moniz – Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: joanavcarmo@gmail.com

**Introduction:** Significant heterogeneity in geographic distribution in the prevalence of mediastinal lymphadenopathies have been documented in CT studies. Awareness of the geographic prevalence and characteristics of lymphadenopathies will be relevant when performing endoscopic ultrasonography (EUS) for malignant neoplasia. EUS is considered the gold standard method for the evaluation of suspected malignant lymphadenopathy and frequently follow-up. Endoscopic ultrasound with fine-needle aspiration is the most accurate diagnostic method in these lesions. The role of repeated EUS-FNA with cystic fluid analysis in follow-up of PCNs is not clear.

**Aims & Methods:** 1. To document the prevalence and characteristics of mediastinal lymphadenopathies in patients submitted to EUS for non-malignant extra-thoracic disease. 2. To identify predictive factors for the presence of mediastinal lymphadenopathies. A prospective, unicentric study was performed between July and December 2016. Mediastinal stations 9, 8, 7, 6, 5, 4L and 2 were systematically evaluated using a linear echoendoscope in all patients undergoing EUS due to benign extra-thoracic pathology, without history of oncologic disease. Demographic, clinical and EUS features were analysed, including location, number, shape, dimensions and echogenicity of the lymphadenopathies.

**Results:** We analysed 75 patients: M/F; 32/43; Mean age; 63. The majority (72%) of the patients presented lymphadenopathies in at least one mediastinal station and 59% in 2 or 4L. Only 6% of these had short axis diameter >10 mm, most were oval (59%) or triangular (37%) and 40% had a hyperechogenic center. The prevalence of lymphadenopathies was higher in smoker patients (83% vs 64%, p=0.024), with a higher average number of lymphadenopathies per patient in this group (2.1 vs 1.6; p=0.017). Similar findings were documented in patients with relevant occlusational or environmental respiratory exposure (prevalence 83% vs 71%; average number 3 vs 1.7). By logistic regression analysis, none of the variables addressed was associated with the presence of mediastinal lymphadenopathies.

**Conclusion:** This prospective Portuguese study documented a higher prevalence of mediastinal lymphadenopathies than previously reported in northern Europe, in smokers and in patients with relevant occupational exposure, may negatively influence the specificity and positive predictive value for malignancy of mediastinal lymph node (N) staging by EUS, with particular relevance in esophageal and pulmonary cancer staging.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Contact E-mail Address: julianamecosta87@gmail.com

**Introduction:** Recent studies demonstrated the positive impact of neoadjuvant treatment for gastric adenocarcinoma T ≥ 2 and/or N+. Aims & Methods: We aimed to assess the accuracy of endoscopic ultrasound in the selection of patients with gastric adenocarcinoma for neoadjuvant therapy. A unicentric retrospective analysis of patients with the anatomicopathological diagnosis of gastric adenocarcinoma between 2011 and 2016, who performed endoscopic ultrasound for staging and underwent surgery without prior neoadjuvant treatment. The concordance (kappa) and accuracy [sensitivity (S) and specificity (E)] of the endoscopic ultrasound for T ≥ 2 and/or N + (criteria for neoadjuvant treatment) were assessed using the anatomicopathological staging of the resected surgical specimen.

**Results:** The final sample included 144 patients (64.6% male) with a median age of 68.5 ± 12.2 years. In most cases (80.6%), the neoplasia was distal (antrum, incisura angularis and body). The neoplasia was of the intestinal type, diffuse and mixed in 63.5%, 18.8% and 16% of the cases, respectively. After examination of the resected surgical specimen, 53.5% of patients had criteria for neoadjuvant treatment (T ≥ 2 and/or N+). The overall kappa, specificity and sensitivity of the endoscopic ultrasound for T ≥ 2 and/or N + were 0.720 (p < 0.001), 85.2% (95% CI: 75.6-92.1%) and 87.3% (95% CI: 76.5-94.4%), respectively. The overall kappa, sensitivity and specificity of the endoscopic ultrasound for T ≥ 2 and/or N + were higher in proximal lesions (cardia and JEG) (k = 0.924, 94.4% and E-100%) compared with distal lesions (k = 0.671, 82.5% and E-84.9%) and in intestinal type lesions (k = 0.765, 84.9% and E-92.7%) compared with diffuse type lesions (k = 0.682, 88.4% and E-80%) or mixed (k = 0.566, 81.8% and E-75%).

**Conclusion:** In one of the largest series of patients, we showed that endoscopic ultrasound was an overall high agreement and accuracy in the selection of gastric adenocarcinoma patients for neoadjuvant therapy, although they higher for proximal and intestinal lesions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0909 IS IT USEFULL TO REPEAT ENDOSCOPIC ULTRASOUND WITH FINE NEEDLE ASPIRATION OF PANCREATIC CYSTIC LESIONS? A RETROSPECTIVE STUDY**

2Pathology, IEO Lisboa, Lisboa/Portugal

Contact E-mail Address: sandrafas1@hotmail.com

**Introduction:** Pancreatic cystic neoplasms (PCNs) require initial imaging characterization and frequently follow-up. Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) for CEA measurement and cytology of cystic fluid is the most accurate diagnostic method in these lesions. The role of repeated EUS-FNA with cystic fluid analysis in follow-up of PCNs is not clear.

**Aims & Methods:** To determine if patients with pancreatic cysts with a second repeated EUS-FNA for cystic fluid analysis for CEA and cytology had a change in cyst classification or on clinical decision. Retrospective analysis of a EUS FNA database, with 284 patients who had EUS-FNA for pancreatic cyst evaluation from 2007–16, of which 35 had 2 EUS procedures, and of these, 22 had 2 consecutive EUS-FNA procedures.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: We enrolled in the study all the patients who underwent and avoid unnecessary surgery. Recently intracystic fluid glucose has been proposed as a pancreatic cyst marker. Some pancreatic cysts still remain challenging. There has been an increasing interest in non-mucinous cysts (7.7 mg/dl vs 95.7 mg/dl, p < 0.0001). In the diagnosis of cystic pancreatic neoplasms, mucinous cystadenomas; 12 intraductal papillary mucinous neoplasms (SCN) in five cases, mass-forming pancreatic cysts in four cases, and autoimmune pancreatitis (AIP) in 40 cases. Just after EUS-FNA, tissue sample in the FNA needle was flushed out into petri dish with saline. The specimen was carefully examined to ensure diagnostic criteria were met. Histology was assessed using formalin-fixed and processed for pathological evaluation. All residual liquid specimen in whole was immediately immersed in liquid-based fixation medium (CytoRichTM Red) at the bedside. The liquid was centrifuged and processed for LBC in pancreatic cell samples obtained by EUS-FNA. Sufficient material rate of cytology was retrospectively evaluated in all cases, and diagnostic yield between cytology and histology in patients with malignant diseases was compared. In addition, availability of immunohistochemistry (IHC) and ICC was assessed retrospectively.

Results: Sufficient material rate in cytological evaluation was 96.6% in all enrolled specimens (282/292). 10 insufficient materials were obtained from PC in 4 cases, and AIP in 3. In the diagnostic cytology between the two groups. The mean time between the two EUS-FNA procedures was significantly shorter in the surgical patients group. Diagnostic cytology was not confirmed using rapid onsite evaluation. Accuracy of cytology, histology, and combination of cytology and histology were 84.4%, 72.9%, and 90.0%, respectively. In the study of samples with mucinous cystic neoplasms, sufficient material rate of cytology and histology were 99.1% (223/225) and 98.3% (201/205). Positive predictive values of cytology and histology were 81.7% (184/225) and 67.6% (152/225). 65.8% (48/73) of pathologically non-diagnosed cases could be diagnosed as malignant cystic neoplasms. In 26 specimens where IHC was needed, IHC was available in 23 of the 26 specimens (88.5%) and ICC was available in all specimens. In the three specimens, ICC was not available owing to pathological insufficiency. Cytology in pancreatic cystic lesions obtained by EUS-FNA may be useful for reducing insufficient material rate and conducting ICC as well as in samples in other medical fields.

Conventional EUS-guided fiducial placement requires back-loading each fiducial through the tip of the FNA needle. Thus, delivery of multiple fiducials can be cumbersome and time-consuming.

Aims & Methods: We aimed to evaluate the feasibility, safety, and performance characteristics of fiducial deployment in PC patients using a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needles. This was a single-center pilot study of 10 consecutive PC patients undergoing EUS-guided fiducial placement for SBRT. The fiducial delivery system contains a 22-gauge EUS needle pre-loaded with 2 gold markers with knurled design. After the 2 markers were deployed, the EUS fiducial needle insert was exchanged out for a second pre-loaded EUS fiducial needle insert through the exchangeable FNA system for total deployment of 4 markers in each patient. All patients underwent CT after fiducial placement as part of SBRT to evaluate successful deployment and complications. The primary endpoint was procedure success, defined as deployment of at least 3 fiducials into the desired target area. Secondary endpoints were total procedure time, fiducial delivery time, and safety.

Results: Fiducial placement was attempted in 10 consecutive patients with PC (mean age 61.7 years, males 60%). The tumor was located in the head (n = 6), neck (n = 2), and the body (n = 2) of the pancreas. Mean size of the tumor was 2.7 cm (range 1.6–5.3). Procedure success was achieved in all 10 (100%) patients. All 10 patients successfully received fiducials. Mean total procedure time was 12.2 minutes (range 5–18). By comparison, using historic controls of the first 10 patients who underwent conventional EUS-guided fiducial placement, the mean total procedure time was 26 minutes (range 16–44, p < 0.002). Mean fiducial delivery time was 4.2 minutes (range 1–8). There were no immediate or delayed (7 days) complications.

Conclusion: EUS-guided fiducial placement with a novel exchangeable FNA system and pre-loaded 22-gauge EUS fiducial needle is quick, technically feasible and safe. This system may theoretically decrease the risk to the clinical staff by eliminating the need for back-loading fiducials through exposed needle tip and handling of potentially dirty needles. Given the potential safety and time advantages, further prospective studies are warranted for validation.

P0918 AGE AND GASTRIC EMPTYING TIME ARE PREDICTIVE FACTORS FOR INCOMPLETE CAPSULE ENDOSCOPY: RESULTS OF A MULTIVARIATE ANALYSIS IN A LARGE STUDY POPULATION

E. Macías1, I. Fernández-Urrien Sainz2, J.F. Juamartínet2, I. Elizalde3, A. Borda4, G. Ezpeleta5, J.J. Vila6
1Gastroenterology, CHN, Pamplona/Spain

Introduction: Capsule endoscopy has been demonstrated to be a first-line tool for small bowel visualization. However, it has some limitations such as incomplete examinations - i.e. the capsule does not reach the cecum - leading to missing lesions.

Aims & Methods: To evaluate those factors that can predict incomplete examinations, to identify those patients at risk for incomplete procedures and to define those approaches that may improve the efficiency of the examination reducing the time of the diagnostic process as well as the need to repeat procedures. A total of 1918 patients who underwent capsule enteroscopy at our center between 2008 and 2015 were retrospectively analyzed. We evaluated variables such as age, sex, anthropometric parameters, comorbidity, drugs, outpatient care, analytical parameters, indication of the test and transit times. Initially, a univariate analysis and then, a multivariate analysis using a logistic regression model were carried out.

Results: In the univariate analysis, the following variables showed a statistically significant association with the rate of incomplete examinations: age, gender, indication of procedure, outpatient care, history of abdominal surgery, heart disease, capsule ingestion posture, hematoglobin levels, renal failure and both gastric and small bowel transit times. These variables were included in the multivariate analysis and less than 286 minutes (OR = 1.78, 95% CI: 1.72–3.93) and small bowel transit time > than 286 minutes (OR = 3.52 95% CI: 2.26–5.48) showed a statistically significant association with the risk of incomplete examination.

Conclusion: Complete capsule endoscopy is predictable. Patients older than 65 years and/or a gastric emptying time greater than 42 minutes are independent predictive factors for incomplete procedures. In these clinical scenarios, pharmacological preventive measures or endoscopic introduction should be taken into account to avoid incomplete examinations.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bubbles can impair the visualization of the small bowel (SB) mucosa during capsule endoscopy (CE).

Aims & Methods: Our aim was to develop and to validate a computed algorithm, with the purpose to evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as "scarce in" or "abundant in" bubbles (random order. Each still frame was categorized as "scarce in" or "abundant in" bubbles). Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as "scarce in" or "abundant in" bubbles. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos.

Validation step
Algorithm 1: GLCM 94.38 93.58 95.32 92.31 0.9852 0.040
Algorithm 2: Fractal dimension 84.27 82.57 86.54 79.78 0.9269 10.1
Algorithm 3: SURF 94.74 94.23 95.15 93.75 1.45
Algorithm 4: SURF 94.74 94.23 95.15 93.75 1.45

Conclusion: GLCM detector strategy had the best diagnostic capabilities, with Se and Sp over 90%) and a perfect reproducibility (coefficient), sensitivity (Se), specificity (Sp), Receiver operating characteristic (AUROCC) of four algorithms for evaluation of bubble abundance in small bowel capsule endoscopy still frames (development step).

P0919 A NOVEL CAPSULE TECHNOLOGY PLATFORM FOR SPECIFIC LOCALIZED COLON DRUG DELIVERY

1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Rambam Health Care Campus, Haifa/Israel
3Borow Medical Center, Bnei Shearim/Israel
Poor cases had significantly lower CCE sensitivity compared with fair, good and excellent cases, for 6 mm polyps (P-value = 0.007). When stratifying cases based on the current adequacy cutoff, sensitivity for 6mm polyps was considered a match, if the size measured by the capsule (≥50%) range overlapped the size measured by the colonoscopy (≥50%) range, and polyp location estimates by the 2 methods were in the same or adjacent segments[2]. Results: The mean age of the analyzed cohort was 57.1 (SD 5.8) with 342 males (44.6%).

Conclusion: This analysis indicates, that when utilizing 4 liter PEG and oral suflate solutions for CCE procedure preparation, current cleansing assessment scale and methodology may need to be re-evaluated - to better correlate with polyp detection. Currently, “fair” cleansing may not indicate inadequate cleansing for polyp detection.

P0921 COLON CAPSULE ENDOSCOPY MAY REDUCE COLONOSCOPY MISS RATE – A MULTICENTER STUDY
S. Perek1, N. Schwartz2
1Medicine A, Rambam Health Care Campus, Haifa/Israel
2HaEmek Medical Center, Afula/Israel

Contact E-mail Address: shayperek@gmail.com

Introduction: Colonoscopy miss rate is an area of intense focus, as it directly correlates with colorectal cancer incidence rate. Previous studies reported a colonoscopy miss rate of 2%–22%, depending on polyp size and histology [1]. Colon Capsule Endoscopy (CCE) is a visualization diagnostic modality of the colon mucosa, which has demonstrated high sensitivity for polyps and adenomas [2]. Determining the nature of polyps detected by CCE but missed by the imperfect gold standard (colonoscopy), may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Aims & Methods: Characterize polyps detected by CCE, which were missed by colonoscopy. 695 screening population participants, from 17 sites in the United States and Israel, underwent CCE procedure followed by a blinded colonoscopy. The overall colonoscopy adenoma detection rate in this study was very high – 39% [2]. Following the blinded colonoscopy, the patient’s CCE report was assessed. Based on the findings in this report, the colonoscopy performing physician decided whether or not to immediately follow up with a second colonoscopy. 70 of the CCE findings were detected by the second colonoscopy. These 70 polyps were compared with 683 polyps detected by blinded colonoscopy, using logistic regression model. Adjusted Odds Ratios (Adj.OR) and corresponding Confidence Intervals (CI) were estimated.

Results: Of the 70 polyps missed by first colonoscopy and detected by second colonoscopy, 20 (29%) were 6mm or larger (based on colonoscopy size estimation). 19 (27%) were either adenomatous or sessile serrated lesions and 16 (23%) were described as either flat or sessile-flat by colonoscopy performing physician. Stratification of polyps based on location:

Poor cases had significantly lower CCE sensitivity compared with fair, good and excellent cases, for 6 mm polyps (P-value = 0.007). When stratifying cases based on the current adequacy cutoff, sensitivity for 6mm polyps is similar in inadequate (“poor” + “fair”) cases compared to adequate (“good” + “excellent”) cases (70.1%, 78.5% respectively; P-value = 0.147).
Multivariate logistic regression revealed that after adjusting to polyph’s size, cecal and rectal segments were associated with increased chance of CCE additive value to colonooscopy (cecum vs. ascending or transverse colon: Adj.OR = 3.2 [95% CI: 1.3–7.6] and Adj.OR = 4.3 [95% CI: 1.4–14.6] respectively; rectum vs. ascending or transverse colon: Adj.OR = 2.6 [1.1–5.8] and Adj.OR = 3.6 [95% CI: 1.2–11.4] respectively). There were 59 patients (8.49% of study population), with at least one CCE additive value to colonooscopy event.

Conclusion: CCE has the ability to detect polyps missed by traditional colonooscopy, especially lesions in the cecum and rectum.

Conclusion: Among the three types of stents, the 7Fr soft tip was suitable for ECPC. The ideal stent in the phantom and animal models was the fully covered self-expandable metallic stent (cSEMS). The ideal stent needs to be technically feasible and safe for EUS-BD and possibly reduce adverse events.

Aims & Methods: We examined six type II perforations associated with ERCP. We retrospectively evaluated the clinical findings, the length of hospital stay, the need for surgery and death.

Results: Of the 3250 ERCP procedures performed from March 2010 to November 2016, only six (0.18%) resulted in perforations (male/female, 2/4; median age: 69 years; age range: 54–80 years). ERCP procedures were performed with carbon dioxide insufflation. Five patients underwent ERCP for biliary stenosis due to pancreatic or duodenal strictures and one patient was being evaluated for clinical. Successful closure of persistent sphincterotomy-related duodenal perforation using FCSEMS was obtained in all patients. One patient developed ERCP-related pancreatitis, successfully treated with medical therapy. Three FCSEMS were successfully removed after a median of 18 days, the remaining three fell out spontaneously. The median length of hospital stay was 8.5 days (range 4–20 days). There were no deaths or need for surgery.

Conclusion: The placement of FCSEMS is easy, safe and quick. In our cohort of patients, FCSEMS is the effective endoscopic approach for management of type II perforations recognized during ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Duodenal obstruction is often seen in patients with advanced pancreatic cancer. Endoscopic duodenal stenting (DS) has become increasingly popular due to its less invasiveness compared with surgical gastrojejunostomy. With recent new advances in chemotheray and radiation therapy, conversion surgery after neoadjuvant therapy are performed in some cases with APC.

Aims & Methods: To evaluate the efficacy and safety of DS as palliative treatment and bridge to surgery in patients with APC. We retrospectively analyzed patients who received DS placement between March 2012 and March 2017. Twenty-three patients (11 men/12 women median age, 65.6; 46–82 years) with APC. GOO scoring system (GOOSS) was used as an index of clinical success.

Results: A total of 23 Patients consisting of 6 patients treated with chemotherapy and 11 patients treated with neoadjuvant chemoradiotherapy were included in this study. Obscrted parts of the duodenum were D1 in 2, D2 in 5, D3 in 12, and D4 in 5 patients. Technical success of DS was achieved for all patients. The mean GOOSS before DS and after DS were 0.5 and 2.6 respectively (p < 0.001). The median time to restart solid meal after DS was 2.9 days. Biliary obstruction was seen in 13 patients and managed with endoscopic biliary stenting. Adverse events occurred in 6 patients, including 1 with cholangitis, 1 with bleeding and 3 with stent occlusion. The intervention technical and clinical success rates were 100% (5/5) and 80% (4/5), respectively. The median survival time after DS was 159 days. In neoadjuvant chemoradiotherapy patients, 4 patients were performed surgery for APC.

Conclusion: DS in patients with APC was effective and safe. The findings of this study suggest that DS is worth considering as the bridge to surgery in patients receiving neoadjuvant therapy.

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMS) has become widely accepted for an alternative to emergency surgery in the management of malignant large bowel obstruction (LBO) after the initial introduction of SEMS in 1991. Recent years, advance in procedural equipment and accumulation of experience have improved technical success rate in colonic stenting for malignant LBO. However, there is still a divergence in the success rate of SEMS.

Aims & Methods: The aim of this study is to clarify the factors that reduce clinical success rate of stent placement. This study was conducted by a retrospective chart review at a single center. The endoscopy database and clinical records from the University of Tokyo Hospital, Tokyo, Japan, were reviewed retrospectively between May 2007 and February 2017. Patient’s symptoms, characteristics, clinical data were obtained from electronic medical record. The obstructions were diagnosed clinically and radiologically and were evaluated by the colorectal surgeons. The Clinical and Endoscopic Scoring System (CROSS) was used for the assessment of clinical success. The technical success was defined as deployment of a stent across the entire length of the stricture on the first attempt. Clinical success was defined as resolution of symptoms and radiological relief of the obstruction within 24 hours, as confirmed by radiographic observations.

Results: A total of 172 patients (91 males, 81 females; mean age 68 years) underwent colorectal stenting for malignant LBO. This procedure was performed to 80 colorectal cancer (CRC) patients (48%) and to 92 patients (52%) with cancer of other etiology. Stenting was performed as a bridge to surgery (BTS) therapy in 33 patients (19.2%), whereas stenting was planned palliative. Technical and clinical success rate was 98.8% and 89.5%, respectively. Clinical success rate dropped from 98.9% (91/92) to 78.8% (71/90) when the patient had obstruction of distal colon or rectum vs in 139 patients (80.8%). Sixty-seven patients (39%) had a tumor causing obstruction in the proximal colon, and 105 patients (61.0%) in the distal colon or rectum. The mean length of obstruction was 6 cm, and obstruction of 60 patients (34.9%) longer than 6 cm. The clinical and technical success rate was 98.3% and 89.5%, respectively. Clinical success rate dropped from 98.9% (91/92) to 78.8% (63/80) when the obstruction caused by extra-colonic malignancy (ECM) (p < 0.05). The clinical success rate of colonic stenting was 85.7% (90/105) and 95.5% (64/67) (p < 0.05) when the patient had obstruction of distal colon or rectum vs in proximal colon. In multivaria analysis, placement in distal colon or rectum, obstruction by ECM, and obstruction longer than 6 cm were independent risk factors associated with lower clinical success rate (odds ratio [OR] 3.19; 95% CI 0.96–10.6, [OR] 24.5; 95% CI 3.19–189.3, [OR] 31.7; 95% CI 3.22–223.7).

Conclusion: The placement of SEMS for malignant LBO is safe and effective, but clinical success rate drops in the cases with obstructions of distal colon or rectum, longer than 6 cm, or caused by ECM. Considering the indication of colonic stenting for malignant LBO, these factors should be evaluated before procedure.

P0931 THE CLINICAL Efficacy OF MITOMYCIN-C injection Therapy in Refractory benign esophageal Stenosis: A Preliminary Study
S.G. Lim1, J. Kim2, K.M. Lee3
1Gastroenterology, Ajou University School of Medicine, Suwon/Korea, Republic of Korea

Contact E-mail Address: mldsk75@gmail.com

Introduction: Refractory Esophageal Stenosis (RES) definition differs among studies. Unresolved benign esophageal stenosis even after 5 or more sessions of endoscopic dilation therapy in most studies. Until now, there have been no treatment showing the satisfactory results. Mitomycin C (MMC) inhibits DNA synthesis reduces fibroelastic collagen formation. Tried in RES in several studies. The meta-analysis about treatment of refractory gastrointestinal stenosis with MMC in total 24 studies. The most commonly reported site esophagus (79%). Only 9 recruited adult patients (n = 98). Of these, 23 patients were RES.

OF COMPLETE AND PARTIAL LOWER GI ANASTOMOSIS

P0932 TREATMENT WITH MULTIPLE REABSORBABLE STENTS

1 colorectal surgery. Colostomy or ileostomy and later redo anastomosis or Hartmann’s procedure are the mainstay of therapy, but edema and inflammation (median 6.7 months). Presence of adhesions can prevent adequate management, and therefore alternative salvage repair methods may be required. Reabsorbable polydioxanone stents are a proposed method but with still debatable results in terms of correct placement, clinical success, early and late stenosis, stent migration, perforation, bleeding, fecal incontinence and local pain.

Aims & Methods: We report here on the use of reabsorbable polydioxanone stents (RPS) in colorectal anastomotic stenosis or dehiscence. We treated with RPS placement, endoscopic dilation and daily mesalazine enemas and/or suppos-

Contact E-mail Address: kimemurica@gmail.com

Introduction: The prevalence of post-ESD esophageal strictures is non-negligible, with a critical impact on the patients’ quality of life. Balloon-dilation may be the first-line therapy. However, factors associated to a successful dilation in post-ESD strictures remain unclear.

Aims & Methods: This is an observational and analytical retrospective study. Sixty-eight consecutive patients (mean age: 65±11, 76.5% men) who underwent endoscopic dilation because of post-ESD symptomatic esophageal strictures between 2006 and 2016 were included. They had Barrett’s esophagus (n=46, 67.6%), epidermoid carcinoma (n=21, 30.9%) and other (n=1). Patients with a critical impact on the patients’ quality of life. Balloon-dilation may be the first-line therapy. However, factors associated to a successful dilation in post-ESD strictures remain unclear.

Disclosure of Interest: All authors have declared no conflicts of interest.

Service De Gastroentérologie, Assistance Publique - Hôpitaux de Marseille, CHU Nord, Marseille/France

Contact E-mail Address: alban.benezech@ap-hm.fr

Introduction: Refractory or recurrent esophageal benign strictures (REBS) are frequent, and defined as the impossibility to reach or maintain a diameter of 14 mm after 5 sessions of endoscopic dilation (ED). Because of a lack of guidelines, their management remains challenging, sometimes leading to radical surgical procedure.

Aims & Methods: The aim of this study was to define the efficacy of long-term and repeated ED in the management of REBS. This was a monocentric retrospective study involving patients managed in our tertiary center between January 2002 and April 2017 for REBS. All the endoscopic dilations were performed using Savary bougies or hydraulic balloons, depending on the operator’s choice. Demographical and clinical data were recorded for each patient. The endoscopic management was detailed with the number of procedures, the endoscopic device used, the diameter of dilation, and potential concomitant treatment (as self-expanding metal stent, steroid injection or incisional therapy). The primary endpoint was the efficacy of sustained and recurrent ED, defined as the absence of further dilation within 3 months of the last procedure or an interval between the 2 last ED greater than 3 months. A failure was considered in case of death, need for surgery, permanent enteral feeding tube or an interval between the last 2 procedures lower than 3 months. The secondary endpoints were to document the characteristics of dilation procedures and concomitant treatments, the decreasing of the number of dilations per trimester, and to elucidate potential predictive factors for success of ED.

Results: A total of 39 patients (23 men) with a mean age of 47.5 ± 20.7 years were included. The etiologies of strictures were anastomotic (46.1%), caustic (28.2%), peptic (10.3%) or other etiologies (radiation injuries, esophageal diverticuloty, severe viral esophagitis, 15.4%). A clinical success of repeated ED was achieved in 27 patients (69.2%). Twelve patients (30.8%) experienced failure, among them seven (17.9%) required frequent dilations, two (5.1%) underwent surgery, two (5.1%) maintained an enteral feeding tube, and one patient (2.6%) died consecutively to inhalation pneumonia. A mean of 9.4 ± 4.2 ED sessions were performed per patient, with a mean treatment duration of 22.6 ± 20.1 months. Regarding concomitant treatments, 16 patients (41%) had at least one fully-covered metallic stent implantation, incisional therapy was performed in 11 patients (28.2%), and 3 patients (7.7%) received corticosteroid injections. The number of dilations per trimester gradually decreased over time. No significant predictive factor of success was found, such as etiology of stricture or the use of concomitant treatment, particularly. Nevertheless, an greater number of dilations during the first trimester could promote the success of the management (3.2 ± 2.2 dilations in the success group vs 2.2 ± 0.8 in failure group, p = 0.056).

Conclusion: Repeated and maintained endoscopic dilations are effective (70%) in the management of REBS, regardless of the etiology of stricture. A prolonged management up to 2 years, and the initial rhythm of endoscopic procedures may favor the final success. A systematic schedule for ED would improve the efficacy of this management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0935 EFFICACY AND SAFETY OF NEWLY DEVELOPED ENDOSCOPIC COLONIC STENTS WITH AN INCREASED EXPANDABLE FORCE: A RETROSPECTIVE COMPARISON WITH CONVENTIONAL COLONIC STENTS

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMSs) is a widely accepted procedure for treating malignant colonic obstruction. This procedure was covered by the National Health Insurance of Japan in January 2012, and the WallFlex colonic stent and Niti-S colonic stent can currently be used in Japan. In the previous study, we reported that the WallFlex colonic stent has more expanded force than the Niti-S colonic stent. On the other hand, the risk of stent-related perforation was lower when using the Niti-S stent due to its structure. Currently, we newly developed an SEMS (Niti-S structure, with 18-mm diameter with increased expanded force compared with the conventional type), which comprised the benefits of both WallFlex and Niti-S. In this study, we compared the efficacy and safety of the newly developed colonic stent with the conventional colonic stents.

Aims & Methods: This study aimed to compare the efficacy and safety of the newly developed colonic stent with the conventional colonic stents (the WallFlex colonic stent and the Niti-S colonic stent). Overall, 91 patients (96 lesions, male/female: 48/43, average age: 73.2 years) underwent endoscopic SEMS placement between November 2012 and March 2017 at Kure Medical Center and Chugoku Cancer Center. The WallFlex colonic stent was used in 36 patients (38 lesions: Group W), the Niti-S colonic stent in 51 patients (53 lesions: Group N), and the newly developed colonic stent in 5 patients (5 lesions: Group D). Stratified analysis of the clinical background, technical success rate, procedure time, clinical success rate, and complications was performed to compare Group W, Group N, and Group D.

Results: Endoscopic SEMS placement was attempted in 96 lesions as a bridge to surgery (BTS) in 52 lesions (54%) and as palliative therapy (PALT) in 44 lesions (46%). In Group W, SEMS was placed in 19 lesions (50%) as BTS and in 19 lesions (50%) as PALT; in Group N, SEMS was placed in 32 lesions (60%) as BTS and in 21 lesions (40%) as PALT; and in Group D, SEMS was placed in 1 lesion (20%) as BTS and in 4 lesions (80%) as PALT. The technical success rate was 100% in all groups. The overall clinical success rate was 93.7% (90/96): 89.5% (34/38) in Group W, 96.2% (51/53) in Group N, and 100% (5/5) in Group D. Complications within 7 days included abdominal pain (3/38, 8%), poor
expansion (1/38, 3%), and lever (1/38, 3%) in Group W and perforation due to overdistension (2/35, 6%) in Group N. In Group N after the surgery, the integrated stent-related perforations (4/38, 11%) and stent occlusion (1/38, 3%) in Group W and stent occlusion (2/35, 4%) in Group N. All 4 patients with stent-related perforations had undergone palliative stenting with the WallFlex colonic stent, and the stent-related perforation rate in Group W was significantly higher than that in Group N (P < 0.05). In Group D, there were no complications and no stent occlusion.

Conclusion: The technical and clinical success rates were extremely high in all groups. The details of the stent-related perforations were also retrieved. Multiple regression models were fitted to the data to test the association between potential predictors and preoperative lymphoma and lymphopenia on POD1 as parameters of immune suppression.

Results: The preoperative lymphocyte count was 1, 240/ml (IQR: 0.895–1.700) in the POEM group. The lymphocyte count on POD1 was 0.670/ml (IQR: 0.500–0.982), p < 0.001; on POD3, it was 0.800/ml (IQR: 0.580–1.070), p < 0.001; and on POD7, it was 0.825/ml (IQR: 0.550–1.180), p < 0.001. In a model that also included the interval between the end of neoadjuvant therapy and the esophagectomy, the number of surgical access (laparotomy, thoracotomy and cervicotomy) and the number of nodal metastasis, only the final dose of radiotherapy resulted to be an independent predictor of lymphocytes count on POD1.

Conclusion: Patients with esophageal and esophagogastric junction cancer present a significant postoperative immunosuppression that lasts at least for the first postoperative week. The total amount of radiation received by the mediastinum is the only predictor of the preoperative and postoperative lymphocyte count.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: The aim of this review was to determine the optimum choice and the route of conduit after oesophagectomy in adults. PubMed, MEDLINE and the Cochrane Library (January 1985 to January 2017) were systematically searched for studies which reported outcomes of colonic interposition after oesophagectomy in adults. The primary outcome measure was overall morbidity and secondary outcome measure was operative mortality.

Results: Twenty-seven studies, involving 1849 patients (median age 60 years, 1177 males, 697 malignant disease) who underwent colonic interposition were analysed. The overall pooled morbidity rate of left vs. right colonic conduit was 9.6% [95% CI (6.24-12.87), p < 0.0001] vs. 16.5% [95% CI (11.07-22.02), p < 0.0001] respectively. The overall pooled mortality rate of left vs. right colonic conduit was 5.6% [95% CI (3.59-7.60), p < 0.0001] vs. 10.3% [95% CI (7.23-13.27), p < 0.0001] respectively. Retrosenal route placement was associated with the lowest overall pooled morbidity of 9.2% [95% CI (6.48-11.99), p < 0.0001], and lowest overall pooled mortality of 4.8% [95% CI (3.74-5.89), p < 0.0001]

Conclusion: Left colon is the conduit of choice for colonic interposition after oesophagectomy in adults and the retrosternal route should be favoured.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
CS group, 16 patients had unresectable disease (due to lack of remnant liver volume or hilar biliary area, or both) and 7 to three hepatic segments and 9 initially had unusable disease (progressive primary disease or suspicion of other distant metastasis); therefore, upfront chemotherapy was selected.

**Results:** The frequency of adverse prognostic factors tended to be higher in the CS and S groups (mean ± SD: 3.7 ± 1.7 and number of metastatic lymph nodes (4.2 ± 6.3 vs 2.7 ± 2.3). Nevertheless, overall survival (OS) in the CS and S groups since primary tumor resection was equivalent (3-year survival rate: 43.1% vs 54.1%, Log-rank P = 0.14) and much better than that in the C group (3-year survival rate: 40.2%). Although liver-limited relapse-free survival (RFS) since hepatectomy tended to be worse in the CS group than in the S group (3-year survival rate: 45.5% vs 62.7%, Log-rank P = 0.14), RFS after hepatectomy was equivalent in the C group and S group (3-year survival rate: 33.3% vs 21.6%, Log-rank P = 0.97). Early tumor shrinkage (ETS) was found to be a stronger prognostic factor for liver resection after chemotherapy than existing prognostic factors in univariate and multivariate analyses, and RFS was much better in patients with ETS than in those with non-ETS (3-year survival rate: 62.5% vs 77.5%, Log-rank P = 0.05).

**Conclusion:** OS and RFS in the CS group compared favorably with those in the S group despite the high frequency of poor prognostic factors; patients with ETS had a better prognosis after liver resection. Liver resection after chemotherapy revealed comparatively favorable prognosis in well-selected patients with cSCLM, and early responsiveness to chemotherapy was useful in determining the indication for liver resection in patients receiving chemotherapy for cSCLM.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0943 PERIOPERATIVE ADMINISTRATION OF BROAD SPECTRUM ANTIBIOTICS REDUCES THE INCIDENCE OF SURGICAL SITE INFECTION FOLLOWING PANCREATODUODENECTOMY**

**Department Of Gastroenterological Surgery 2, Hokkaido University Graduate School of Medicine, Sapporo/Japan**

**Contact E-mail Address:** komikak121@gmail.com

**Introduction:** Pancreatoduodenectomy (PD) is one of the operations associated with high risk of surgical site infection (SSI). The one of the reasons is said that SSI is associated with the preoperative biliary infection caused by preoperative examinations or drainage of biliary tract. In our clinical trial [1]; SSF after pancreatoduodenectomy could be decreased by using the perioperative selective antibiotics based on preoperative biliary culture. The bacteria cultured from SSI were Enterobacteriaceae such as Enterococcus and Enterobacter species with high frequency.

Recently, however, most of the patients who had planned to undergo PD received internal biliary drainage preoperatively. It means preoperative collection of the bile juice is hard for the patient with internal biliary drainage. In order to solve this problem, we compared the conventional perioperative prophylactic antibiotics (Cefmetazole: CMZ) and the broad-spectrum antibiotics covering the Enterobacteriaceae (Piperacillin/Tazobactam + Vancomycin: PIPC/TAZ + VCM), retrospectively. The aim of this study is to assess the impact of two types of perioperative antibiotics usage in patients undergoing PD.

**Aims & Methods:** Sixty-nine patients underwent PD at Hokkaido University Hospital (Japan) between April 2015 and March 2016, when prospective surgical site infection surveillance was performed. Thirty-eight patients were administered CMZ as perioperative prophylactic antibiotics from April 2015 to March 2016, and 31 were PIPC/TAZ + VCM from April 2016 to March 2017. CMZ was injected intravenously every three hours from the start of operation, and once after the operation. PIPC/TAZ was injected intravenously every three hours from the start of operation and twice three times on the next day after the operation, whereas CMZ was injected intravenously in the morning of operation (20 mg/kg) and just after the operation (15 mg/kg).

Comparison between CMZ group and PIPC/TAZ + VCM group was performed by chi-square test, Student t-test, unpaired t-test, nonparametric test and contingency coefficient, and each of them was performed in terms of case series of a single surgeon at three Japanese tertiary referral centers.

**Results:** There were no significant differences in clinical features and operative outcomes between the two groups. The patients with PIPC/TAZ + VCM received significantly shorter duration of postoperative antibiotics administration than the patients with CMZ (5.9 ± 8.5 vs. 13.0 ± 18.2 days; p = 0.048). Significantly lower incidence of SSI was revealed in patients with PIPC/TAZ + VCM (9/31(29.0%) vs. 3/16 patients in CMZ group) (p = 0.048). Especially, significantly lower incidence of incisional SSI was revealed in patients with PIPC/TAZ + VCM (23/316.5%) than in those with CMZ (14/38(36.8%) (p = 0.004). The redneck syndrome as one of the side effects of CMZ was observed in 5/31 patients (16.1%). No multifocal recurrence of bacteria were identified. The occurrence of multifocal recurrence of bacteria were investigated, as well.

**Conclusion:** The broad-spectrum perioperative antibiotics covering Enterobacteriaceae such as Enterococcus and Enterobacter species could decrease the incidence of SSI and duration of postoperative antibiotics administration compared to CMZ. More strict indication to select the patients who should be administered VCM, because the occurrence of side effects of VCM was relatively high.

**Introduction:** Gallbladder cancer is the most frequent malignant tumor of the biliary tract. The most frequent symptomatic form of gallbladder cancer is a symptomatic gallstone disease. The prevalence of gallbladder cancer is up to 0.3% worldwide with a median age at the time of diagnosis of 70 years. The 5-years survival rate is approximately 20% (up to 40% in T1a). Therefore, gallbladder cancer is currently considered as a curable disease. The mainstay of treatment is complete removal of the diseased gallbladder with lymphadenectomy. The treatment of choice for small gallbladder cancer (T1a) is minimally invasive surgery. The question of whether to perform a lymphadenectomy in patients with T1a is a matter of debate.

**Aims & Methods:** Sixty-five T1a patients underwent gallbladder cancer with lymphadenectomy were identified. The group was divided into two groups (with/without lymphadenectomy). The groups were compared in terms of clinicopathological characteristics, surgical outcome. The SPECTRUM ANTIBIOTICS COVERING ENTEROBACTERIACEAE

**Results:** The redneck syndrome as one of the side effects of VCM was observed in 5/31 patients (16.1%). No multifocal recurrence of bacteria were identified. The occurrence of multifocal recurrence of bacteria were investigated, as well.

**Conclusion:** The broad-spectrum perioperative antibiotics covering Enterobacteriaceae such as Enterococcus and Enterobacter species could decrease the incidence of SSI and duration of postoperative antibiotics administration compared to CMZ. More strict indication to select the patients who should be administered VCM, because the occurrence of side effects of VCM was relatively high.

**P0944 PARADIGM SHIFT? SHOULD A LYMPHADENECTOMY ROUTINELY BE PERFORMED ALSO AMONG GALLBLADDER CANCER PATIENTS WITH T1A DISEASE?**
Introduction: Pancreatic cancer is the fifth most common gastrointestinal malignancy and the most common of all biliary tract cancers. Overall, it is associated with a poor prognosis. Consensus guidelines suggest that patients with T1a cancers can be observed with cholecystectomy alone while patients with T1b or greater lesions should undergo lymphadenectomy in the hepatoduodenal ligament. Extent of surgery is especially important for those patients given efficient systemic therapy is lacking.

Aims & Methods: The aim of this study was to critically explore whether those surgical and patient population-based factors that given that current evidence is mainly based on small patient series. Especially we assessed the rate of T-stage specific lymph node positivity and the impact of lymphadenectomy on long-term outcomes. The National Cancer Data Base of the United States was reviewed from 2004 to 2012 to identify non-metastatic gallbladder cancer patients with T1a, T1b, or T2 stage primary tumors. Patients were grouped by whether a dedicated lymphadenectomy was performed or not while those with missing information were excluded. Groups were compared for baseline characteristics. Pathologic lymphadenectomy was defined by univariate and multivariable adjusted logistic regression with adjustment for important patient- and tumor characteristics. Overall survival was assessed using Cox proportional hazard regression analyses before and after full bivariate pairwise propensity score matching.

Results: Of the 3879 patients included, 287 (7.4%) had T1a, 661 (17.0%) T1b, and 2931 (75.6%) T2 gallbladder cancer. Most patients were female (n = 2751, 70.9%), median age was 72 years (range 21–90). Among patients with T1a, T1b, and T2 disease, 102 (35.5%), 278 (42.1%), and 1526, (52.1%) underwent a dedicated lymphadenectomy, respectively. Over the study period, the rate of lymph node excision increased from 43% to 58% (p for trend = 0.005). The rates of positive lymph nodes were 11.8%, 16.2%, and 42.5% for T1a, T1b, and T2-stage, respectively. 5-year overall survival rate was 31.6% for patients without and 44.6% for patients with a dedicated lymphadenectomy and 58.6%, 43.9%, and 34.5% for T1a, T1b, and T2-stage, respectively. After multivariable adjustment, the risk of longer lymphadenectomy increased with tumor stage compared to T1a disease (vs. T1b: OR: 1.37; CI: 1.01–1.86, vs. T2: OR: 1.95; CI: 1.48–2.57). Compared to their counterparts, patients who underwent lymphadenity for gallbladder cancer were more likely to have had an R0 resection status or radiation therapy, were diagnosed in later years, were younger, had a lower Charlson-Deyo-comorbidity score, were operated in high volume centers and traveled a longer distance to the treatment facility. In univariate analysis, no survival benefit of lymphadenectomy was found for T1a disease (HR 1.04, 95%CI 0.70–1.54) while lymphadenectomy improved overall survival in T1b (HR 0.72, 95%CI 0.58–0.90) and T2 stage (HR 0.59, 95%CI 0.53–0.65). Given significant bias of undergoing lymphadenectomy, full pairwise propensity-score matching was performed. A trend towards overall survival benefit was also found for T1b disease (HR 0.44, 95%CI 0.25–0.79). Overall survival benefit remained for T1b (HR 0.68, 95%CI 0.51–0.91) and T2-stage (HR 0.63, 95%CI 0.55–0.71).

Conclusion: Our results support current consensus guidelines that T1b and T2 gallbladder cancer patients should undergo LA. However, based on the high rate of nodal positivity among patients with T1a disease and the trend towards overall survival improvement among T1a patients who underwent lymphadenectomy, we suggest to rethink this dogma and advocate to perform lymphadenectomy also in surgically fit patients with T1a disease.

P0945 RECTAL SWAB CULTURE CAN DIRECT ANTIMICROBIAL PROPHYLAXIS AND PREDICT THE RISK OF INFECTIONAL COMPLICATIONS AFTER PANCREATICO-BILIARY SURGERY: A PROSPECTIVE SCORING SYSTEM MATCHING RETROSPECTIVE STUDY

Department Of Gastroenterological Surgery, Fukuoka University Faculty of Medicine, Fukuoka/Japan

Contact E-mail Address: kanae60519@yahoo.co.jp

Introduction: Surgical site infections (SSIs) after gastrointestinal surgery cause significant morbidity, prolong hospitalisation and increase health care costs. Thus, SSI prevention is critical. To prevent bacterial colonisation in suture material, which disables local mechanisms of wound decontamination, triclosan-coated sutures were developed. We retrospectively analysed the efficacy of triclosan-coated polydioxanone sutures in abdominal fascia and skin closure using a propensity score matching analysis.

We further analysed the surgery types for which these sutures are best suited.

Aims & Methods: The study protocol followed the principles of the Declaration of Helsinki and received ethical approval from the Ethics Committee of the Fukuoka University (approval no. 12-7-96). At our department, we used conventional abdominal closure methods during gastrointestinal surgery before August 2012. Thus, we retrospectively collected surveillance data over a 1.5-year period for the control group. From September 2012, we began using triclosan-coated sutures for closure. Here, we collected data for the study group from September 2012 to September 2013. In total, we included 1768 patients (control group, n = 640; study group, n = 1128) who underwent gastrointestinal surgery. Baseline differences and selection bias were adjusted using propensity score matching.

Results: Before matching, the SSI incidence differed significantly between the control and study groups for all gastrointestinal surgeries [12.4% (140/1128) vs. 5.7% (28/455); p = 0.001] and hepato-biliary-pancreatic [16.4% (11/64) vs. 4.3% (5/116); p = 0.045]. In hepato-biliary-pancreatic surgery, 18.2% (40/220) vs. 7.8% (5/64) (p = 0.045) for hepato-biliary-pancreatic procedure, 12.7% (26/204) vs. 10.5% (12/114) (p = 0.347) for upper gastrointestinal (GI) surgery, 14.6% (43/294) vs. 5.3% (10/190) (p = 0.001) for lower GI surgery, 8.8% (24/274) vs. 4.1% (7/169) (p = 0.045) for hepato-biliary-pancreatic surgery, 18.2% (40/220) vs. 7.8% (5/64) (p = 0.030) for emergency surgery and 5.1% (7/136) vs. 1.0% (1/103) (p = 0.074) for others. Of 1768 cases, 483 pairs were matched using propensity score matching. No parameter used for the propensity score differed between the groups. After matching, a significant difference in the SSI incidence between the control and study groups for all gastrointestinal surgeries [9.7% (47/436) vs. 5.7% (28/455); p < 0.001]. We found a significant difference in the SSI incidence between the control and study groups for lower GI [17.0% (168/878) vs. 14.3% (21/149); p = 0.018] and hepato-biliary-pancreatic [16.4% (11/64) vs. 4.3% (5/116); p = 0.049] surgeries. No significant difference was found between the groups for upper GI surgery, emergency surgery and others. Multivariable logistic regression analysis showed that triclosan-coated suture use for lower GI surgery was the independent factor affecting the SSI incidence (p = 0.017). The sutures demonstrated a significant efficacy in lower GI surgery.

Conclusion: Few studies have focussed on the types of surgery best suited for triclosan-coated sutures. Our findings suggest that abdominal fascia and skin closure using these sutures reduces the SSI risk, particularly for lower GI surgery.

**Introduction:** In recent years, laparoscopic proximal gastrectomy (LPG) has been actively performed in our institution to reduce invasiveness. However, proximal gastrectomy is sometimes followed by reflux. Until February 2015, we performed esophagogastrosentery with a circular stapler (CS) accompanied by fundoplication in LPG. However, in March 2015, to avoid the postoperative complication, we have been using esophagogastrosentery with the double-flap (DF) technique. This DF technique in LPG for gastric cancer. Aims & Methods: We conducted this study to examine whether DF can reduce the reflux and eliminate reflux ulcers and thus be possible to reduce postoperative complications. From February 2012 to February 2017, 47 LPGs were performed at Keio University Hospital.  

First, surgical time, bleeding, incidence of postoperative complication, postoperative hospital stay, and incidence of Anastomotic stenosis were examined as surgical factors and compared between the DF and CS groups. Second, gastroesophageal reflux finding on endoscopy, condition of the remnant stomach according to residue, gastritis, bile (RGB) classification at postoperative 6 months and 1 year, and proton pump inhibitor (PPI) intake were examined as postoperative factors. Finally, albumin and hemoglobin levels at postoperative 6 months and 1 year were examined as nutrient factors. Gastroesophageal reflux was assessed with scores of 0–5 in accordance with the Los Angeles (LA) classification.  

**Results:** Twenty-three LPGs with DF and 24 LPGs with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 55.5 vs 241.1 ± 26.7 min, p < 0.01). Other surgical factors showed no statistically significant differences between the two groups. For as postoperative factors, although no significant differences in PPI intake, LA classification, and RGB classification were found, the DFT group showed a significantly lower score than the CS group (p < 0.01). Postoperative nutrition scores showed no significant differences between the two groups. Conclusion: Although LPG with DF required a longer surgical time than LPG with CS, DF is thought to be a safe reconstruction method in LPG. In addition to its safety, DFT can reduce postoperative reflux in patients who undergo LPG.

**Introduction:** Gastrointestinal (GI) leaks and perforations are difficult to manage and often mandate laparotomy and extensive surgical interventions for their treatment. Endoscopic Negative Pressure Therapy (ENPT) has been developed to treat leaks such as fistula and perforations. However, ENPT has only been utilized in the management of rectal and esophageal leaks. By modifying the delivery catheter we were able to adapt ENPT to treat duodenal defects, that otherwise would have required surgery or more invasive methods to be used.  

**Aims & Methods:** Herein, we report ENPT using open-pore Polyurethane-foam and Film Drainage in a series of 10 patients with duodenal leakages. This is an innovative variant of ENPT. In 7 patients we used the OPD device, in one patient OFD, and in two patients OPD and OFD. All leakages (100%) were successfully closed after a treatment period of 11 days in median (range 7-19 days). Nine patients were treated with intraluminal and one patient with intracavitary variant of ENPT. In 7 patients we used the OPD device, in one patient OFD, and in two patients OPD and OFD. All leakages (100%) were successfully closed allowing early enteral feeding and thus reducing hospital stay.  

**Conclusion:** ENPT using small diameter tube with open-pore film was effective to treat duodenal leakages. Advantage of OFD is the small diameter which allows easy endoscopic placement through small openings and nasally insertion. OPD and OFD are placed accurately at the site of leakage and perforations using common endoscopic techniques and thus represent a potential addition to the armamentarium to treat these difficult lesions.

**Introduction:** The main relesser for development of multifacile failure syndrome is multivital organ failure, which often occur after surgical complications and more than in 70% of cases leads to lethal outcomes. Increase of an endotoxemia leads to development of the expressed pathological processes and to a fast descomposition of bodies of natural detoxication system at the subsequent development of a multifacile failure. Increase in detoxication ability of sorbents can happen due to change of chemical composition, or due to collimating of padding properties to them by their modification by various agents by means of an immunization on their surface of endotoxine. In this plan especially important role is got by the researches directed to development of sorbents with oxidizing activity.  

**Aims & Methods:** Aim of study is to estimate effectiveness of the modified hae-mosorbtor application for patients about the MOFS. The experimental part of work was conducted on 14 not purebred dogs with the acute liver failure modelled by bandaging of distal department of the CBD. After development of pathological process animals were divided into 2 groups. To the first group of animals the procedure of a haemosorbtion was carried out by a reference technique on use of a haemosorbtion of SKN-2K. To the second group of animals the haemosorbtion was carried out by the developed technique with the same sorbent, but the solution of a neutral anolyte subjected to oxidizing modification. For this purpose, in the flowing mode carried out a half-hour incubation of a sorbent from 2 l of solution of a neutral anolyte.  

**Results:** Results showed that at animals of the 2nd group in comparison with group of comparison improvement of a condition of an organism was expressed in a greater degree. After performing detoxication therapy by the developed technique a normalization of all studied parameters is registered. The same tendency is revealed also concerning nontoxic components. It is necessary to pay special attention to dynamics of a ratio of the common protein and an index average molecules/the common protein, pointing to synthesis process activation. The carried-out all-clincal blood test revealed the considerable improvement of indexes of white blood. In group of comparison it was not succeeded to achieve the complete normalization of the studied indexes. On the basis of what the conclusion was drawn on high effectiveness of the developed technique, and expediency of its introduction in clinical practice. Under our observation there were 45 patients needing carrying out getter detoxication in the postoperative period. The control group (25) was created by a random sample of case histories of patients with the MOFS who was earlier on treatment in our clinic and receiving a course of a haemo perfused therapy by a reference technique. The analysis of results of treatment of patients of a basic group showed that the positive dynamics of clinical indexes expressed in decrease of manifestations of an intoxication syndrome, improvement of health and labora-tory indexes is noted in earlier terms, and degree of expressiveness of positive changes at them was much higher. Dynamics of decrease in endogenic intoxica-tion is reflected by data of laboratory researches. We are showed that it is possible to increase quality of detoxication by a pretreatment of a haemo sorbent solution of a neutral anolyte. As a result of it the sorbent gains padding, oxidizing properties. At such modification there is an inclusion of oxygen-containing and acid groups in struc-ture of a sorbent, which besides the fact of sorbent protecive groups of carboylic and phenolic types thanks to which the oxidized coals gain the expressed cation-exchange ability are formed. Therefore, besides actually manifestations of an intoxication syndrome, improvement of health and labora-tory indexes is noted in earlier terms, and degree of expressiveness of positive changes at them was much higher. Dynamics of decrease in endogenic intoxica-tion is reflected by data of laboratory researches. Introduction: Laparoscopic cholecystectomy is the gold-standard for the treatment of gallbladder stone disease. Single-incision laparoscopic (SILS) cholecystectomy was introduced with the aim of reducing the invasiveness of classic laparoscopic surgery. Despite satisfactory cosmetic results of SILS cholecystectomy and its repute of a painless procedure, there are few published studies comparing early and long-term perioperative period of laparoscopic SILS cholecystectomy versus laparoscopic four-port cholecystectomy.

Aims & Methods: The aim of this study is the comparative evaluation of SILS cholecystectomy and laparoscopic four-port cholecystectomy. Early and long-term perioperative period has been analyzed in 240 patients who underwent laparoscopic cholecystectomy including 120 cases of single-port technique and 120 cases of four-port technique. Both groups were compared in surgical time, pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients' satisfaction of surgical results and their aesthetic effect.

Results: It was revealed that SILS cholecystectomy is associated with lower severity of postoperative pain, quick recovery of daily activity and return to physical work, high satisfaction rate of cosmetic results and significantly shorter hospital-stay as compared with four-port cholecystectomy. Disadvantages of SILS cholecystectomy include longer duration of surgery, high incidence of postoperative umbilical hernia. However, hernia was predominantly observed during the period of surgical technique development.

Conclusion: Further studies to standardize, evaluate the safety and benefits of SILS cholecystectomy are necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aim to present the experience using CSDCD for gastric leaks secondary to BS. In this retrospective study, patients with leaks secondary to gastric bypass (GBP) or sleeve gastrectomy (SG) from 4 centers were included. Data collected from november 2012 to january 2016 included sex, age, type of surgery, previous treatment, tract path, size of the leak opening and defect closure. Leaks were grouped according to the International Sleeve Gastroectomy Expert Panel Consensus in acute (post-operative days 1-7), early (1-6 weeks), late (after 6 weeks) and chronic (> 12 weeks). Biliary catheters were adapted to introduce the CSDCD through the gastroscopies working channels. Clinical success was defined as complete elimination of abdominal or thoracic drainage with imaging documentation of closure (CT with contrast or upper GI contrast study) after 2 months.

Results: 62 patients with leaks were included (31 SG, 11 GBP). Three acute leaks, 5 early, 2 late and 12 chronic. Prior failed therapies included: SEMS and enteral tube feeding (ETF), SEMS alone, SEMS and gastrostomy of excluded stomach, OTSC, ETF alone, jejunostomy and none (3 acute leaks had CSDCD as the primary treatment). Tract path was grouped as gastric-cutaneous (37), gastric-pleural (3) and gastric-bronchial (2). Median follow-up was 34, 8 weeks. All 3 patients with acute leak failed to close the defect. The CSDCD were removed within 7 days and SEMS were placed instead leading to defect closure. The 5 patients with early leaks had initial good response but within 30 days drainage recurred. The CSDCD were removed and replaced for a larger diameter device leading to permanent defect closure. Clinical success was achieved on 38 patients (90, 5%). In one patient with late leak the tract path was connected to an undrained cavity. Evolution was unsatisfactory and total gastrectomy accomplished.

Conclusion: CSDCD are effective to treat post bariatric surgery late and chronic leaks despite of the failed previous endoscopic treatment. Although early leaks finally healed it seemed advisable to maintain conservative treatment and wait for the leak to become late or chronic before CSDCD placement. Acute leaks must be managed with a combination of SEMS, ETF, OTSC as first step.

Tuberculosis is still a problem of public health in Tunisia, which is a country of endemicity. The epidemiological situation of the disease is marked by the rise of the extrapulmonary forms especially abdominal tuberculosis.

Aims & Methods: The aim of this study was to analyze the epidemiologic, clinical, diagnostic, therapeutic and effective features of abdominal tuberculosis in a series of 150 patients. This was a descriptive and prospective monocentric study of 150 cases of abdominal tuberculosis conducted from 2004 to 2014 in a tunisian center. Diagnosis of tuberculosis was based on histological evidence or other on a biopsy of arguments.

Results: There were 150 patients enrolled. The mean age was 37.2 (17–72 years). Ninety seven (64.6%) were females. Symptoms were ascites 107 (71.3%), abdominal pain 28 (18.6%), weight loss and reduced appetite 80 (53.3%). Un tableau pathologique surgical was performed in one case. Patients (66.6%) had a lymph node involvement. Diagnosis of abdominal tuberculosis was histology and microbiology (surgical and biopsy).

Conclusion: Abdominal tuberculosis is one of the most common site of extra-pulmonary tuberculosis. No single test is adequate for diagnosis of abdominal tuberculosis. Therefore, in all patients an ongoing diagnostic dilemma requiring a high index of clinical suspicion.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. van Empel PJ et al. Mapping the Maze of Minimally Invasive Surgery Training. 48 medical students completed three tasks in a laparoscopic virtual reality simulator, a validated Minimally Invasive Surgical Trainer. Prior to the task, they performed a visuospatial test and answered questions regarding baseline characteristics (e.g. PC-gaming experience, age, gender, previous simulator experience). The data were analyzed regarding different parts of the simulation (time, economic value of carrying out radiological, endoscopic and histo-bacteriological investigations). The main operative findings in patients with coelioscopy or exploratory laparotomy were: Whist granulations (98%), adhesions (43.1%) and agglutination loops (1.5%). The presence of tuberculous granuloma was observed in 52 patients (81%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

TLR3-deficient and emulsifier-treated mice demonstrated that these models of gut injury characteristically depended on disruption of the epithelium that maintains microbiota dependency of intestinal inflammation reflects an inability to manage pathobiont bacteria, such as Adherent-Invasive E. coli (AIEC).

Aims & Methods: Our goal was to examine extent to which microbiota mismanagement and associated inflammation in TLR3-deficient and emulsifier-treated mice would manifest in a limited pathobiont-free microbiota. WT and TLR3-deficient mice were maintained in gnotobiotic isolators containing altered Schaedler flora (ASF), a community of eight bacterial species. Mice were treated with either WT or inoculated with AIEC LF82 [4]. Feces were assayed for bacterial loads, microbiota composition, and inflammatory marker lipocalin-2. Fecal LPS and flagellin bioactivity were measured via a cell-based reporter assay, and morphologic and metabolic parameters were determined.

Results: Neither CMC nor P80 induced evidence of intestinal inflammation nor metabolic syndrome in WT ASF animals. Analogously, relative to similarly maintained WT mice, loss of TLR3 did not result in low-grade intestinal inflammation or metabolic syndrome under ASF conditions. Concomitantly, the ASF microbiota community was not disturbed by CMC nor P80 and, moreover, was similar between WT and TSKO animals. Inoculation with AIEC strain LF82 resulted in profound alteration of the ASF community in TSKO mice compared to WT. Within an ASF LF82 inoculated in an ASF TSKO mouse model.

Conclusions: A limited complexity pathobiont-free microbiota, loss of the flagellin receptor TLR5 or emulsifier consumption does not impact microbiota composition nor its ability to promote inflammation. Addition of AIEC to this eutrophic microbiota composition, increases levels of lipopolysaccharide (LPS) flagellin, but only modestly promotes gut inflammation and adiposity, suggesting that the phenotypes previously observed require disruption of complex microbiota.

Introduction: Lamina propria represents a thin layer of connective tissue rich in lymphoid cells and macrophages, underlying the epithelium of mucous membranes. Lamina propria mononuclear cells (LPMCs) are immune system’s first line of defense in the intestine characterized by the ability of differentiating invading pathogens from beneficial intestinal flora and swiftly removing them. Disrupted regulation of LPMCs is implicated in pathology of a group of diarrheal and inflammatory bowel disease (IBD). Two major types of IBD are ulcerative colitis, limited to the colon and chronic’s disease affecting any segment of the gastrointestinal tract. Chronic’s disease and ulcerative colitis were shown to be mediated by Th1-polarized helper (CD4+) T-cells, and Th2-polarized CD4+ T-cells. Conversely, while Th17-polarized cells are involved in pathogenesis of both diseases, therefore, research into biology and regulation of LPMCs is of essential importance for development of treatments for IBD symptoms.

Aims & Methods: The aim of this study was to develop a robust method for isolation and characterization of LPMCs from human colonic mucosa, compatible with further ex vivo cell culturing and research. Mucosal tissue samples contained the tissue not affected by tumor, removed during tumor surgery of patients consented to donation of tumor and the surrounding resected tissue. The tissue may be considered as healthy in terms of IBD. We have employed an isolation method consisting of disruption of epithelial cells by incubation of mucosa in a DTT and EDTA containing solution, followed by enzymatic and mechanical digestion of tissue and purification of mononuclear cells by density gradient centrifugation. Isolated cells were characterized by flow cytometry (FACS) detection of cell-type specific surface antigens and cytokine analysis.

To examine the plasticity of isolated cells in terms of polarization towards IBD-associated phenotypes, the cells were seeded at conditions mediating Th1, Th2 and Th17 differentiation of CD4+ T-cells and analyzed for activation of differentiation-specific gene expression and cytokine production by qPCR and ELISA assays. Aliquots of cells were cryopreserved and further analyzed for the effect of cryopreservation on distribution of surface antigens and CD4+ T-cell responses.

Results: Approximately 95% cell viability and 90% leukocyte (CD45+) cell purity was determined by FACS analysis of isolated LPMCs. According to cytokine analysis, CD45-negative cells may represent CD45-negative population of plasma cells: no contamination with epithelial cells was detected. Within CD45+ cell population, 26–47% T-lymphocytes, 17–24% B-lymphocytes, 8–17% macrophages and 21–46% monocytes were detected by FACS and cytokine analyses (N=3). Cryopreservation did not significantly affect cell viability and surface marker distribution. Isolated cells successfully polarized towards Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by INF-γ gene expression and cytokine production for Th1, IL13 gene expression and IL5 cytokine production for Th2 and IL17 cytokine production for Th17 differentiated cells. Differentiation was confirmed via cryopreserved cells, with lower level of phenotype-specific cytokine production.

Conclusion: Method for LPMC isolation from human colonic mucosa tissue samples was successfully established with approximately 95% viability of isolated cell population. No detectable epithelial cell contamination was observed. Within CD45+ cell population, 26–47% T-lymphocytes, 17–24% B-lymphocytes, 8–17% macrophages and 21–46% monocytes were detected. Isolated cells were successfully polarized towards IBD-associated Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by activation of phenotype-specific gene expression and cytokine production. Cryopreservation of isolated LPMCs did not significantly affect cell viability, distribution of cell-type specific surface antigens or polarization towards Th1, Th2 and Th17 CD4+ T-cell phenotypes.

Introduction: The Inflammatory Bowel Disease-Disability Index (IBD-DI) has recently been validated to measure disability in IBD.

Aims & Methods: We aimed to assess disability in IBD outpatients using IBD-DI and to determine the sociodemographic, clinical and psychological factors that are associated with greater disability. Between August and October of 2016, patients with an established diagnosis of Crohn’s Disease (CD) or Ulcerative Colitis (UC) for at least 3 months and followed up at our outpatient clinic were invited to participate. Socio-demographic and clinical data were collected from electronic health record and interview. Optimism and disability were evaluated employing, personally or by phone, the validated Portuguese versions of the Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The association between sociodemographic, clinical and psychological variables (optimism) and IBD-DI (scale 0-100, proportional to the reported disability) was determined by univariate and multivariate analysis.

Results: A total of 143 patients (70 DC and 73 UC; 50.3% females) with a mean age of 38 ± 13 years were included. Most (85.5%) was in clinical remission. The mean IBD-DI-PT score was 17.9 ± 10.7, with a significant difference between DC and UC (p = 0.944). In univariate analysis, female gender, high level education, number of days off from work, articular manifestations, number of comorbidities, use of psychotropic drugs and pessimism (low LOT-R score) were significantly associated with higher disability (IBD-DI-PT score). In multivariate analysis, only female gender (β = 0.150), number of comorbidities (β = 0.186) and pessimism (β = 0.370) were significantly associated with higher disability. Clinical activity was associated with higher disability only for CD patients (β = 0.321).

Conclusion: IBD outpatients reported low levels disability associated with their disease, which can be explained by the high percentage of patients in clinical remission. Comorbidities and psychological factors (optimism) emerged as the main predictive factors of greater disability, reinforcing the importance of multidisciplinary approach to these patients. Clinical activity seems more important to CD than UC patients in terms of disability.

P0960 BIOLOGIC THERAPY REDUCES T CELL ACTIVATION IN PATIENTS WITH CROHN’S DISEASE

Experimental Research, Hospital Israelita Albert Einstein, Sito Paulino/Brazil

Contact E-mail Address: dargeniole@gmail.com

Introduction: Imbalance of immune bowel environment is associated with development of many diseases, such as Crohn’s disease (CD). Although the pathogenesis of CD remains unclear, a key feature of CD is dysregulation of immune responses and include, in addition to other cells, CD4+ and CD8+ T cells, which comprises adaptive phase and require proper inflammatory cues for their development. Corticosteroids are the mainstay of the abating phase. CD4+ T cells express markers that give them powerful functional abilities (Abbas et al., 1996). CD38 and HLA-DR besides being classically markers of cellular activation, are also known as markers of diseases progression (Lovealce et al., 2017). Some studies shows that CD4+ T cells play a key role in the immune inflammatory response leading to CD but this cells are poorly characterized in the blood of the patients.

Aims & Methods: This study aimed to characterized CD4+ and CD8+ T cells in the blood of patients with CD. The study was performed in individuals with CD (n = 40) and healthy controls (n = 38). Blood of healthy donors and patients with CD was collected in clinical laboratory from Hospital Albert Einstein. CD4+ and CD8+ T cells was quantified by multiparametric flow cytometry. Dosage of corticosteroid and ASCA was performed by commercial Elisa kit. The groups were compared for numerical measures using Student’s t-tests.

Results: The highest prevalence in both group was female, aged between 19 and 66 years with a median of 37.5 years. Among clinical exams, 61% of cases present a value greater than 200 in the dosage of Calprotectin, whereas in the control group this rate was 43.84% (p < 0.001) and IgA (p < 0.001) were also higher in age of cases when compared to control group. The population of CD3+ cells in peripheral blood of healthy controls and patients with CD was evaluated both in biological and corticoid treatment. A significant increase in the proportion of patients receiving corticosteroids (p = 0.02) compared to healthy controls. In the population of CD4+ a significant increase was observed in patients undergoing treatment with corticosteroids in relation to patients undergoing biological treatment (p = 0.0027). In CD4+ population, no statistical difference was observed between the groups. The markers CD38, CD62L and HLADR were also evaluated. In relation to CD38 (p = 0.0022) and CD62L (p = 0.015) in subpopulation of CD4+ T cells, a significant increase in the expressions was observed in the group of patients receiving corticosteroids in relation to the group receiving biological therapy. Regarding HLADR, statistical difference (p = 0.01) was observed between the group undergoing biological treatment and the group of healthy controls. In the subpopulation of CD8+ T cells, a significant increase (p = 0.02) was observed in the CD38 expression between the groups. Significant differences were recorded. In all experiments the levels of inflammation markers: myeloperoxidase (normalized number of reads in control samples reached 0.2 and was less than 0.06 in samples of patients with ulcerative colitis).

Conclusion: This study suggests that the use of biological therapy suppresses activated immune responses and include, in addition to other cells, CD4+ T cells, which comprises adaptive phase and require proper inflammatory cues for their development. Corticosteroids are the mainstay of the abating phase. CD4+ T cells express markers that give them powerful functional abilities (Abbas et al., 1996). CD38 and HLA-DR besides being classically markers of cellular activation, are also known as markers of diseases progression (Lovealce et al., 2017).

Introduction: Advancing of sequencing technologies in the first decade of the XXI century gives the opportunity to realization of large scale projects such as the 1000 human genomes project. This project provides enormous amount of the data for H.sapiens population genetics studies and different GWAS studies aimed to investigate connection of the human genetics variations with different diseases. It is especially interested to study the connection between the human genetics, the microbiome metagenomes of mucosa and different pathological conditions. Previously revealed, the size of the summary gut microbiome metagenome is on order more than the size of a human genome. The most of works devoted to the study of the connection between human and microbial genome changes with different pathological conditions based on the investigation of fecal samples. On our opinion, in the case of ulcerative colitis it is more effective to study the mucosal microbiome of the affected regions.

Aims & Methods: The aim of our work was to study the composition of mucosal microbiomes in the colon mucosa biopsies from patients with ulcerative colitis by using the target high throughput sequencing of bacterial 16S rRNA genes. Biopsies from four caucasoid race patients with left-sided ulcerative colitis in the abating activity. Meyo endoscopic index = 3, Rachmelevich clinical index = 4 and two patients from control group with irritable bowel syndrome were collected. The DNA was extracted from mucosal biopsies and 16S rRNA genes from it’s were target sequenced by using Illumina MiSeq sequencer. Sequencing reads were quality checked by the FastQC software and trimmed by using the trimmomatic software. To characterize the composition of the microbiota, trimmed reads were analyzed by the QIIME software. The obtained results were compared with the earlier published data: SRA Project - ERP001780 (96 samples from patients of control group, 44 samples from patients with ulcerative colitis)[1] and SRA Project - SRP056002 (703 samples from patients with ulcerative colitis).

Discussion: More than 124 bacterial genera were found in biopsies of four patients with ulcerative colitis. The analyzed samples of patients with ulcerative colitis were split in two groups by using the PCA analysis. The first group was characterized by decreasing of the concentration of the Firmicutes type bacteria (p-value <0.005) and increasing the concentration of Bacteroidetes (p-value <0.005). For the second group, It was founded decreasing of the concentration of the Actinobacteria type bacterias (p-value <0.05), 70-fold excess of Bacteroidetes vulgatus species bacteria concentration was revealed for one sample of the first group (normalized number of reads in control samples was less than 0.003, and reached 0.21 in samples of patients with ulcerative colitis). Additionally, the concentration of Escherichia coli species bacteria was increased in the 40 times for that sample (normalized number of reads in control samples was less than 0.003 in samples of patients with ulcerative colitis). Although, the predominance of Proteobacteria genus bacteria was not founded. The concentration of Faecalibacterium prausnitzii species bacteria was decreased by three orders of the magnitude for samples from the first group (normalized number of reads in control samples reached 0, 2 and was less than 0, 06 in samples of patients with ulcerative colitis).

Conclusion: The concentration increase of the conditional-pathogenic mucosal microflora (a mostly Bacteroidetes type bacteria) was discovered, which playing a prominent role in the development of ulcerative colitis and its pathological damage. Also, the deficiency of Faecalibacterium prausnitzii species bacteria was discovered, which decrease resistance of mucosa to the conditional-pathogenic microflora.

Introduction: The role of incretin hormone, GLP-1, in inflammatory bowel diseases (IBD) development and exacerbations is still poorly understood. GLP-1 decreases blood glucose levels and in patients with IBD delays the onset of pro-inflammatory cytokines and excessive administration of diabetogenic drugs. We hypothesize that the possible mechanism underlying this phenomenon is related to changes in the levels of incretin hormones.

Aims & Methods: The primary aim of this study was to investigate, in the mouse model of coexisting colitis and experimental diabetes, the role of incretin hormones as an underlying factor. Experimental diabetes was induced by administration of streptozotocin for 5 consecutive days (50 mg/kg, i.p.). Mice with experimental diabetes and receiving neither GLP-1, nor GIP were considered as diabetic. To develop a chronic and relapsing colonic inflammation, mouse model of colitis induced by intracolonic administration of TNBS (first dose: 150 mg/kg at day 1, booster dose: 75 mg/kg at days 12, 23, 34, 45, 56) was used. On day 60 mice were sacrificed and macroscopic score, ulcer score, colon length and bowel thickness were recorded. In all experiments the levels of inflammation markers: myeloperoxidase (MPO) activity, TNF-α and IL-1β expression were determined. The

**Introduction:** Pathogenesis of inflammatory bowel disease (IBD) is multifactorial and establishing diagnosis requires a performance of series of variable tests. The alternative, non-invasive, markers of IBD are intensively searched for. Eosinophils are acidophilic multifunctional granulocytes that remain outside the mainstream research on IBD. However, they are a rich source of cytotoxic proteins, pro- and anti-inflammatory cytokines, chemokines and growth factors and are likely to contribute to both inflammatory and regenerative phases of the disease. Accordingly, peripheral eosinophils of IBD patients are primed and pre-activated. They display increased responsiveness, adhesiveness, migration, and degranulation and are characterized by up-regulated secretion of their mediators. Locally, increased number and activation of eosinophils have been repeatedly observed in areas of active inflammation. Despite the acknowledged contribution of eosinophils to the disease pathogenesis, available data on cytokines closely related to the development and activity of peripheral eosinophils in IBD patients are either scattered or non-existent.

**Aims & Methods:** Aim of the study was assessment of the circulating eosinophil-associated cytokines and growth factors as differential markers and indicators of mucosal healing in inflammatory bowel disease. Study population consisted of 277 individuals: 101 patients with Crohn’s disease (CD), 77 with ulcerative colitis, 16 with irritable bowel syndrome (IBS) and 83 healthy controls. The disease severity was assessed using the Crohn’s Disease Activity Index (CDAI) for CD and the Mayo Disease activity index for UC. Results: The development of hyperglycemia in mice treated with TNBS was delayed compared to a non-inflected group, what was associated with significantly higher level of GLP-1 in blood. Surprisingly, the levels of GLP-2 were significantly reduced in diabetic mice with colitis, suggesting that two distinct mechanisms are involved in the regulation of the incretin hormones in response to intestinal inflammation. There were no significant differences in macropscopic score, colon length, and bowel thickness in diabetic mice with or without colitis. Nevertheless, significantly increased in diabetic mice with colitis compared to diabetic mice with no inflammation. No changes in MPO, TNF-α, IL-1β were observed between these groups.

**Conclusion:** We propose that GLP-1 production may be stimulated in response to colitis, contributing to the post-inflammatory regeneration phases of the disease.

**Introduction:** Interleukin(IL)10 is an important anti-inflammatory cytokine for the maintenance of gut homeostasis. Defects in the IL10 signaling pathway in macrophages leads to disregulation of regulatory (M2) type macrophages and subsequent inflammatory bowel disease (IBD). IBD patients are frequently successfully treated with anti-TNFα antibody therapy, although not all patients are responders.

**Aims & Methods:** We determined the effect of anti-TNFα therapy in both IL10 knock-out (KO) mice and in the CD4+CD45RBh high T-cell transfer model of colitis. Macrophage populations were quantified using qPCR analysis for CD206 and the macrophage marker F4/80 and flow cytometry for CD206. IL10 mRNA and protein levels were analysed with qPCR and ELISA.

**Results:** Colitis in the IL10 KO mice was completely resistant to anti-TNFα therapy, in sharp contrast to the colitis in SCID or Rag1 KO mice upon transfer with CD4+CD45RBh high T-cells, which was significantly reduced by anti-TNFα therapy. Successfull anti-TNFα therapy was accompanied by an increase of IL10 levels and an increase of regulatory (M2) type macrophages in the intestine. Blocking IL10 signaling, with an IL10 Receptor blocking antibody, diminished the therapeutic efficacy of anti-TNFα therapy. Anti-TNFα therapy was also unresponsive to anti-TNFα therapy upon receiving CD4+CD45RBh high T-cells. In these mice there was also no increase of intestinal M2 macrophages.

**Conclusion:** IL10 signaling in macrophages is pivotal for the therapeutic efficacy of anti-TNFα therapy in animal models for IBD. Defects in the IL10 pathway may also play a role in anti-TNFα non-responders which is subject of further investigation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Epidemiological studies revealed that antibiotics exposure increases the risk of inflammatory bowel diseases (IBD) development (Hviid, 2011, Shaw, 2011, Kronman, 2012). However, mechanisms of this association are not fully understood. Recent studies revealed sustained alterations in gut microbiota after antibiotic treatment (Rashid, 2015, Dethlefsen, 2011), the full consequences of which remain unknown.

**Aims & Methods:** We investigated long-term effects of antibiotic treatment on gut microbiota, short-chain fatty acids (SCFAs) production, transport & sensing, mucosal and mucus layer functional state, surface mucus layer and epithelial barrier integrity. Male Wistar rats (n = 178, 140-160 g) were treated for 14 days with broad-spectrum antibiotic cefazolin (CT) (300 mg/kg, i.m.) or vehicle; euthanized in 1, 14 or 56 days after CT withdrawal. The fecal microbiota was analyzed by bacteriological culture methods; fecal SCFAs – by gas chromatography; colorectal localization and levels of FFAs & FFA3 receptors and MCT1, MCT4 & SMCT1 transporters of SCFAs – by immunohistochemistry; levels of FFAs, FF3, ERK1/2, p38, HIF1α proteins in colon mucosa – by Western blot analysis; reactive substances, mucus glycoproteins and their carbohydrate composition – by colorimetrically; epithelial permeability was evaluated by Evans blue permeation and bacterial translocation.

**Results:** CF injection leads to compositional changes of fecal microbiota which progress over time. In 56 days, we found increased level of Clostridium spp., E. coli, conditionally pathogenic and hemolytic bacteria. Levels of Bifidobacterium...
& Lactobacillus were unchanged during the study. Moreover, the concentrations of amino acids and short-chain fatty acids were decreased in UC mice, 0.4-, 8.5-, 4.8-fold (P < 0.05), respectively, the first day after Cf withdrawal. These changes were accompanied by decreased immunoreactivity for the FFA2, FFA3 receptors, SMCT1 and increase MCT1 & MCT4 transporters of SCFAs in colon mucosa. In 56 days, concentration of SCFAs and level of FFA3 was still below control values. These changes evoked a significant shift in colonic mucosal homeostasis. We revealed increased level of TBA-active substances, decreased the activity of SOD and catalase antioxidant enzymes with increased HIF1α, activation of P2Y2 receptor subtype P2Y2R, which are induced via α-defensin and oxidative stress development were associated with increased permeability of colon epithelium and bacterial translocation to blood in 56 days after Cf withdrawal. Moreover, the levels of mucus glycoproteins, hexoses and fucose decreased while sialation of mucus glycoproteins increased which is typical for IBD development. These changes were accompanied by increased activity of MMP-9 and decrease – MMP-2 in rats colon mucosa.

Conclusion: We showed for the first time that antibiotic treatment induced long-termed changes in SCFAs composition, levels of their receptors and transporters in colonic mucosa. It was associated with alterations in mucus composition, increased epithelial permeability that might increase susceptibility to IBD development.

Disclosure of Interest: All authors have declared no conflicts of interest.

subsequently analyzed for STAT3 signaling (western blot), NFkB signaling (NFkB Transcription Factor Assay, western blot) and cytokine secretion (ELISA).

Results: Peripheral blood CD4+ T cells from IBD patients could be characterized by a significantly increased P2Y2R expression compared to healthy controls, with higher expression levels of the P2Y4 receptor subtype turned out to be comparable between both groups. Further subdividing the group of included IBD patients into Crohn’s disease and ulcerative colitis patients, we could not observe a significant difference in the P2Y2R levels between both disease entities. Interestingly, the increased P2Y2R expression in the lymphocyte compartment of IBD patients seemed to be limited to CD4+ T cells, as CD8+ T cells of those patients even showed decreased P2Y2R levels. Regarding potential regulators of P2Y2R expression in the context of IBD, our data identified IL-6 and TGF-beta as major inducers of P2Y2R expression in human CD4+ T cells. Interestingly, high extracellular UTP levels resulted in a decreased expression of the TGF-beta1 receptor on CD4+ T cells, implicating a potential negative feedback loop in which P2Y2R signaling might inhibit TGF-beta1 induced P2Y2R expression over time. However, the impact of P2Y2R on the pro-inflammatory capacity of human lymphocytes, our data indicate that the selective P2Y2R agonist 2-Thio-UTP is able mediate NFkappaB as well as STAT3 activation and to induce secretion of the pro-inflammatory cytokines IL-6 and IL-17 in stimulated human monocyte cell lines.

Conclusion: The observed increased expression of P2Y2R in CD4+ T cells of IBD patients together with the demonstrated pro-inflammatory effects of P2Y2R signaling in human T cells markedly strengthen the role of P2Y2R as a promising molecular target in IBD.

Introduction: Environmental hypoxia has been increasingly recognized as an important environmental factor associated with Inflammatory Bowel Disease (IBD). Hypoxia allows the stabilization of hypoxia inducible factor (HIF) complexes and has been linked to the activation of autophagy. HIF-1a is induced in the inflamed mucosa from IBD patients and mouse models of colitis, but its role in intestinal inflammation is still controversial since both, positive and negative effects have been reported.

Aims & Methods: We aim to elucidate the effects of HIF-1a stabilization in autophagy and the development of intestinal inflammation in a murine model of colitis. Female C57BL/6J mice between 8-10 weeks of age were exposed to 2% O2 in drinking water for 7 days, and received 8 mg of the hydroxylase inhibitor dimethyloxaloylglycine (DMOG) intraperitoneally every second day. Mice were killed at day 9, mucosal damage was assessed by colonoscopy and mucosal endoscopic score of colitis severity (MEICS) was calculated. H&E staining was performed to analyze the histological damage. Expression of TNF, IL-6, IL-1β and Nlrp3 was analyzed by qPCR and protein expression of p-NFkB and Nrf2, as well as HO-1 by western blot. Chemoattractant C5a was measured with the ELISA.

Results: DMOG administration induced a significant lower reduction of body weight in DSS-treated mice compared to DSS-treated mice administered with vehicle. Furthermore, mice administered with DMOG presented less reduction of the colon length, a significant reduction in the MEICS and histological scores of colitis. The mRNA expression of the pro-inflammatory factors TNF, IL-6, IL-1β and Nlrp3 was significantly reduced in mice treated with DMOG compared to vehicle-treated mice. At a protein level, DMOG administration reduced the expression of NLRP3. DMOG-treated mice also showed activation of autophagy, as evidenced by a decrease in p-mTOR and p62 expression and an increase of LC3II. In vitro, hypoxia induced a significant accumulation of lysosomes, as measured by LysoTracker Yellow-HCK-123 to monitor lysosomal accumulation. Chromatin immunoprecipitation (ChIP) analysis was performed using an antibody against HIF-1a and pCR was performed using the promoter-specific primers for the p62 promoter binding sites of HIF-1a.

Results: DMOG administration induced a significant lower reduction of body weight in DSS-treated mice compared to DSS-treated mice administered with vehicle. Furthermore, mice administered with DMOG presented less reduction of the colon length, a significant reduction in the MEICS and histological scores of colitis. P0972 THE PATHOGENIC MECHANISM OF ARYL HYDROCARBON RECEPTOR MEDIATED ABNORMAL DIFFERENTIATION OF INTESTINAL ILC3/ILC1 IN CROHN’S DISEASE

X. Zhao, H. Zhang
Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China
Contact E-mail Address: zhaoxj91718@163.com

Introduction: The abnormal differentiation of intestinal innate lymphoid cells ILC3 and ILC1 exist in autoimmune disease. ILC3 decreased and ILC1 increased in Crohn’s disease (CD) patients, suggesting that CD patients have abnormal intestinal ILC3/ILC1 alteration.

Aims & Methods: The present study investigated the aberrant colonic mucosal ILC3/ILC1 in active CD patients and 2, 4, 6-trimethylbenzene sulfonic acid (TNBS)-induced colitis mice. The expressions of aryl hydrocarbon receptor (AhR) in colon of active and quiescent CD patients were detected by western blot and immunofluorescence. The ILC3/ILC1 were investigated in CD patients and 2, 4, 6-trimethylbenzene sulfonic acid (TNBS)-induced colitis mice (AhR−/−, AhR+/+).

Results: Compared to quiescent CD patients, the expression of aryl hydrocarbon receptor (AhR) in the intestinal tissue in active CD patients was decreased. Meanwhile, the number of ILC3 in active CD patients and AhR knockout mice was decreased while ILC1 increased. The intestinal inflammation in AhR knockout mice given TNBS was more severe than wild-type mice.

Conclusion: These findings suggest that AhR may mediate abnormal differentiation of ILC3/ILC1, and the production of inflammatory cytokines, finally, promotes the pathogenesis of CD.

P0973 PREVALENCE AND GENETIC DIFFERENCES IN ADHESION-RELATED GENES AMONG COMMENSAL AND ADHERENT-INVASIVE E. COLI STRAINS

C. Campbru-Font, A. Seguí-Roig, N. Maeso-Sánchez, M. López-Siles, M. Martínez-Medina

Contact E-mail Address: c.campbru@gmail.com

Introduction: Long polar fimbriae (Lpf(A)), FimH adhesion and ChiA chitinase have been related with adherent-invasive E. coli (AIEC) pathogenesis. Controversial results have been found regarding the prevalence of LpfA in AIEC vs non-AIEC (1, 2). Some FimH amino acid variants were reported to be specific for AIEC (3) whereas other variants were associated with phylogroup disease origin of the strains (4). Differences in the ChiA sequence were reported between LF82 and K-12 strains but this gene has not been studied in other AIEC yet (5).

Aims & Methods: The prevalence of LpfA and the distribution of FimH and ChiA variants in AIEC collection of AIEC and non-AIEC from different disease origins - Crohn’s disease (CD), ulcerative colitis (UC) and colorectal cancer (CRC) - was studied with the purpose to determine if these genes could be used as molecular markers for AIEC identification and disease diagnostics. In a collection of 7 AIEC and 29 non-AIEC isolated from CD, UC, CRC patients and controls, LpfA gene was PCR-amplified to assess its presence and fimh and chia genes were sequenced to identify point mutations. For comparison of FimH and ChiA protein sequences, UPGMA phylogenetic tree and allele identification was performed using MEGA5. The genetic differences were annotated as reference for the K-12 strain. Then, they were analysed statistically according to AIEC pathotype, phylogroup, and disease origin by the χ2 test and non-parametric tests were used to evaluate amino acid variability regarding the adhesion and invasion indices.

Results: Low gene frequency for lpfA1441 and lpfA1545 was reported (11.7% and 16.7% respectively). LpfA1545 was only found in strains from A (22%) and B1 phylogroup (86%) and no relation with AIEC phenotype or disease was observed. Two main clusters of FimH were obtained by phylogenetic analysis, classifying the strains according to the presence of S78N mutation. S78N and S78N variants were characteristic from strains of B2 and D phylogroups as none of the A or B1 strains presented it. Despite statistical significance was not observed, the strains with S78N, S78N, V163A, R166H mutations showed the highest adhesiveness. Regarding ChiA, two main clusters defined by the presence or absence of an insertion in 312–314 residues were observed. None of the five previously mutations found in FimH in LF82 strain were associated with AIEC strains whereas the V415A variant was found specifically in AIEC (20%) (p = 0.049). Of note, among the strains harbouring the 312–314 insertion, a subcluster that shared identical amino acid sequence included the LF82 strain and the 44% of AIEC strains but only the 10% of the non-AIEC (p = 0.019). No differences between FimH/ChiA variants and origin of isolation was observed.

Conclusion: In contrast with other studies, no relation of lpfA presence nor in FimH mutations with AIEC pathotype or disease was observed. Nonetheless, a variant in ChiA sequence more frequently found in AIEC isolates was reported being an interesting signature sequence for the detection of at least a subgroup of AIEC strains. Further confirmation in a wider strain collection would be required.

Introduction: Primary sclerosing cholangitis (PSC) is a progressive disorder of the biliary tree which can lead to end-stage liver disease, liver transplantation or even death1. Colitis accompanying PSC is considered to be a phenotype of IBD (inflammatory bowel disease) distinct from ulcerative colitis (UC) and is often referred to as "PSC-IBD"2.

Aims & Methods: Our aim was to compare the gut bacterial microbiota of patients with PSC and UC. Stool samples were prospectively collected and relevant clinical data obtained from 106 study participants, 43 PSC patients with (n = 32) or without (n = 11) concomitant IBD, 32 UC patients, and 31 healthy controls (HC). Sequencing of the 16S rRNA gene including the V3 and V4 regions was performed on Illumina MiSeq platform to cover low taxonomic
levels. Data were further processed in QIIME employing MoAsLin and LESe to generate final output data.

Results: Microbial profiles in both PSC and UC were characterized by low bacterial diversity and significant change in global microbial composition. *Rothia*, *Enterococcus*, *Streptococcus*, *Veillonella*, and three other genera were markedly overrepresented in PSC regardless of concomitant IBD. *Rothia*, *Veillonella* and *Streptococcus* were tracked to the species level to identify *Rothia mucilaginosa*, *Streptococcus infantis*, *S. acuclotylicus,* and *S. equil* along with *Veillonella parvula* and *V. dispar*. PSC was further characterized by decreased abundance of *Alistipes* and *Prevotella corpori*. Decrease in genus *Phascolarctobacterium* was linked to presence of colonic inflammation regardless of IBD phenotype. *Akkermansia muciniphila*, *Butyrivibrio plicatocororum* and *Clostridium colinum* were decreased in UC along with genus *Roseburia*.

Unclassified *Actinomyces* species were markedly increased in overlap syndrome of autoimmune hepatitis (AHI) and PSC. Low levels of serum albumin were significantly correlated with enrichment of order Actinomycetales. PSC–IBD. Several bacterial taxa clearly distinguished IBD phenotypes (PSC–IBD). Ulcerative colitis (UC) as well as PSC from PSC/AIH.

Disclosure of Interest: All authors have declared no conflicts of interest.

2. Chapman RW, Arbogth BA, Rhodes JM, Summerfield JA, Dick R, Scheuer PJ, Sherlock S. Primary sclerosing cholangitis: a review of its clinical fea-
Results: 28 patients with Ulcerative Colitis, duration of disease 4 months to 31 years were included. 22 Healthy population were recruited to the study. Half of the patients had active disease as assessed by Ulcerative Colitis Severity Score. Disease severity positively correlated with frequency of mucosal TH17 (CD4+IL-17a+) and IL-17f. Breaches in tight junction protein expression were greater in severity: Claudin 1 (p < 0.006), Claudin 4 (p < 0.0016) and occludin (p = 0.03). The serum marker of bacterial translocation, lipopolysaccharide binding protein (LBP) was increased in UC compared to controls (p = 0.0078) and was positively correlated with breaches of Claudin 1 and Occludin (p = 0.018 and p = 0.012 respectively) Staining colon biopsies for the presence of lipopolysaccharide in the lamina propria demonstrated positive findings in healthy controls, supported by data from 16s rDNA analysis of blood from healthy controls. In the Ulcerative Colitis cohort in clinical remission the absence of lipopolysaccharide in the lamina propria was associated with elevated levels of LBP and increased breaches of Occludin (p = 0.0022).

Conclusion: Breaches of tight junction proteins in the colon of patients with stable clinical remission can be detected and are associated with perturbations of mucosal immunological function and markers of bacterial translocation. Lipopolysaccharide presence in the lamina propria of patients in remission appears to be associated with less tight junction breaches and reduced local and systemic evidence of bacterial translocation. These findings require further study, specifically to examine the role of mucosal immune tolerance to lipopolysaccharide and other bacterial cell products that may be present in the healed mucosa of ulcerative colitis.

P9979 EFFECT OF FIBER AND FAT CONSUMPTION ON DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

School Of Medicine, University of Crete, Heraklion/Greece

Contact E-mail Address: medp2011775@med.uoc.gr

Introduction: Diet may influence intestinal inflammation via various pathways but the evidence regarding the role of fiber or fat intake in patients with inflammatory bowel disease (IBD) is controversial.

Aims & Methods: The aim of this study was to investigate the association between dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients. We prospectively collected food frequency questionnaires (FFQ) from consecutive IBD patients at outpatient visits. The European Prospective Investigation into Cancer and Nutrition (EPIC) Study FFQ for Greece population with the MAFF photographic food atlas were used in order to collect information for dietary habits of IBD patients. Moreover, disease activity with the simple colitis activity index (SCCAI) (for ulcerative colitis (UC)) and information for dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients diagnosed in 2010 in Eastern and Western European centres. Patients were followed prospectively for five years and clinical data were captured throughout the follow-up period. Disease behaviour was defined according the Montreal classification as B1: non-stricturing, non-penetrating, B2: stricturing; B3: penetrating based on endoscopy, cross-sectional imaging or surgery. The risk of surgical resection was analysed by Cox regression analyses using the proportional hazard assumption including multiple covariates (age, gender, disease location, diagnostic delay, smoking status, change in behaviour, geographic region and treatment with biologics within 6 months from diagnosis).

Results: A total of 488 incident CD patients were included in the study, of which 347 (71%) had B1. A total of 141 (29%) patients had complicated CD at diagnosis. After 3 years’ follow-up, this number increased to 190 (39%) (Table 1). Of patients diagnosed with B1, 35 (10%) progressed to B2 while 14 (4%) progressed to B3 after a median of 21 months (range: 0–62). The proportion of B1 patients changing behaviour was highest during the 1st year of disease (5%) but stable during the remaining follow-up period (approx. 2%·year). Colon location (L2) was associated with a higher risk of transition to B3 (HR 0.3 CI95%: 0.1-0.8), extra-intestinal manifestations at diagnosis (HR 0.2 CI95%: 0.1-0.8), and the need for early biologics (HR: 2.5 CI95%: 1.2–5.1) were associated with progression in behaviour. During follow-up, a total of 107 patients had a resection. Of patients with B1 as initial behaviour a total of 37 (11%) patients had a resection. A change in behaviour from B1 to B2/B3 (HR 6.8 CI95%: 3.0-15.6) and early biologics (HR 0.5 CI95%: 0.2-0.5) was
associated with the risk for resection. No difference in the results was found between Eastern and Western European patients.

Conclusion: In this European population-based inception cohort of unselected CD patients 14% of patients with B1 progressed to B2 or B3 after five years of follow-up. The risk of surgery was increased in patients with B1 who progressed to B2/B3. No clinical predictors for progression in behavior including smoking and treatment with biological therapy could be identified.

P0982 COLORECTAL CANCER IN INFLAMMATORY BOWEL DISEASE: RISK FACTORS IN A PROSPECTIVE MULTICENTER NESTED CASE-CONTROL IG-BIBD STUDY

1Nest Hospital, Rome, Rome/Italy; 2Giordano Hospital, Turin, Turin/Italy; 3Sapienza University, Rome, Rome/Italy; 4Sapienza University, Rome, Rome/Italy; 5University of Rome "Foro Italico", Rome, Italy; 6University of Pisa, Pisa, Pisa/Italy; 7University of Palermo, Palermo, Palermo/Italy; 8Fondazione Policlinico Universitario "La Sapienza" (Sapienza University), Rome, Rome/Italy; 9University Hospital of Padova, Padova, Padova/Italy; 10University of Cagliari, Cagliari, Cagliari/Italy; 11University of Lecce, Lecce, Lecce/Italy; 12University of Bari, Bari, Bari/Italy; 13University of Palermo, Palermo, Palermo/Italy; 14University of Naples, Naples, Naples/Italy; 15University of Rome "Tor Vergata", Rome, Rome/Italy; 16University of Rome "La Sapienza", Rome, Rome/Italy; 17University of Rome "La Sapienza", Rome, Rome/Italy; 18University of Cagliari, Cagliari, Cagliari/Italy; 19University of Rome "Tor Vergata", Rome, Rome/Italy

Abstract: P0982

The role of IBD phenotype vs thiopurines (IS) and/or anti-TNFs use as risk factors for CRC was also evaluated. From Jan. 2012 to March 2017, all incident cases of CRC in IB-IBD pts referring to 16 IG-IBD Units were recorded. Each IB-IBD pt with CRC (IBD-CRC) was matched with 2 IBD pts with no cancer (IBD-C) for: IBD type (Crohn’s Disease, CD vs Ulcerative Colitis, UC), gender, age (<5 yrs. vs B2/B3). No clinical predictors for progression in behavior including smoking and treatment with biological therapy could be identified.

Disclosure of Interest: All authors have declared no conflicts of interest.
pts with CRC were younger at diagnosis of IBD than their IBD-C (UC-CRC vs UC-C: median yrs 39 [15–76] vs 46 [20–81]; n [%]: 31 [51%] vs 27 [33%]–40 yrs: 20 [49%] vs 55 [67%]; p = 0.04; CD-CRC vs CD-C: median yrs 27 [6–67] vs 37 [10–67]; n [%]: 19 [76%] vs 26 [52%]–40 yrs: 6 [24%] vs 24 [48%]; p = 0.04). The median age at diagnosis of CRC was comparable between UC pts using or not IS and/or anti-TNFs (CRC-UC vs CRC-UC: IS monotherapy 6 [15%] vs 17 [21%]; Anti-TNFs monotherapy: no CRC; Combi-therapy: 5 [12%] vs 6 [7%]; no IS/no anti-TNFs: 11 [27%] vs 23 [28%]; p = 0.03). There were also observed less UC pts between CD pts treated or not with IS and/or anti-TNFs (CRC-CD vs CRC-CD: IS monotherapy: 4 [16%] vs 9 [18%]; Anti-TNFs monotherapy: 2 [8%] vs 3 [6%]; Combi-therapy: 10 [40%] vs 23 [46%]; no IS/no anti-TNFs: 16 [64%] vs 33 [70%]; p = 0.59). CD pts with CRC showed a higher frequency of pattern B1 (B1 vs B2: IS and/or anti-TNFs: 14 [56%] vs 3 [12%]; 8 [32%]/p = 0.019). Risk factors for CRC considered in Multivariate analysis included: age (<40 vs ≥40 yrs), IBD duration (<10 vs ≥10 yrs), smoking habits (Yes/No), IS, IS/anti-TNFs (Y/N), IBD-related surgery, UC extent (extensive vs distal; subtotal vs distal), CD pattern (I3 vs B1, I2 vs B1), perianal CD. In UC, the only significant risk factor was UC duration (OR [95% CI]: OR 3.33 [1.44–9.11], as the other risk factors were not significant: OR 0.94 [0.36–2.98], 1.28 [0.48–3.04], 0.96 [0.36–3.08], 1.78 [0.60–4.66], 1.36 [0.66–2.89], 0.38 [0.08–1.23], respectively). In CD, perianal disease was the only significant risk factor for CRC (OR 3.11 [1.16–8.31], as not all significant risk factors were identified (OR 2.21 [0.70–9.87], 1.66 [0.62–4.96], 0.56 [0.19–1.41], 0.39 [0.14–2.52], 0.54 [0.23–1.43], 0.83 [0.26–2.55], 0.23 [0.04–0.83], respectively).

Conclusion: In a prospective, multicentre, nested-case control IG-IBD study, incident cases of CRC were more frequent in UC than in CD. In our cohort, UC duration and perianal CD, but not immunomodulators use, were identified as independent risk factors of CRC.

P0984 IMPACT OF ANORECTAL COMPLAINTS ON QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE - A SURVEY OF THE DUTCH NATIONAL CROHN’S AND COLITIS ORGANISATION

P. F. Vollebregt1, A. A. Van Bodegraven1, G.L. Markus-De Kwaadsteniet2, D. Van Der Horst3, R. J. Felt-Bersma4
1Gastroenterology And Hepatology, VU University Medical Centre Amsterdam, Amsterdam/Netherlands
2Dutch Crohn’s and Colitis organisation, Woerden/Netherlands

Contact E-mail Address: v.vollebregt@vumc.nl

Introduction: Anorectal complaints occur in a considerable group of patients with IBD. There is a dearth of evidence relating to the impact of these complaints on IBD patients’ lives. We aimed to survey the effect of anorectal complaints on quality of life in a large cohort of patients who engaged in the Dutch Crohn’s and Colitis organisation (CCUVN).

Aims & Methods: In October 2016, the CCUVN had a membership database of 10,487 patients. A comprehensive study questionnaire was sent out online by the CCUVN in January 2015 and October 2016 to a voluntary panel, which consisted of 1710 CCUVN patients. The panel is represented by patients who volunteered to participate in online surveys with regard to disease related subjects. Inclusion criteria: Patients over 18 years old and either diagnosed with CD (Crohn’s disease), UC (ulcerative colitis), or IBD-U (a (usually unmet and) clear need to treat). More patients were exclusively found in pouchitis which included FAP, CD and UC.

Results: A total of 1094 patients (64%) responded the online survey. Mean age was 48.7 years (range 18-87). CD diagnosis was predominant (62% CD patients (57%), 431 UC patients (39%) and 42 IBD-U patients (4%)) and diagnosis was established for a mean period of 13 years (interquartile range 3–19 years). Active perianal disease was present in 243 CD patients (39%) and perianal surgery was performed in 137 (21.3%) CD patients. Active perianal disease was present in 243 CD patients (39%) and perianal surgery was performed in 137 (21.3%) CD patients. Multivariate regression analysis (adjusted for gender, diagnosis and previously performed perianal surgery) showed a reduced total SF-36 score in patients with faecal incontinence (β = −8.57 [−11.33; −5.81]; p < 0.0001) and active perianal disease (β = −4.13 [−7.33; −0.91]; p = 0.01). A better score was reported in UC patients compared to CD patients (β = 3.53 [0.48:6.58]; p = 0.02). Previously performed perianal surgery was not associated with SF-36 score in the multivariate analysis.

Conclusion: Anorectal complaints have a substantial impact on the quality of life in patients with IBD, with a (usually unmet and) clear need to treat. More awareness for this highly distressing and most common cumbersome treatable disease manifestation is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0985 CURRENT UNDERSTANDING OF POUCH MICROBIOTA IN HEALTH AND DISEASE; A SYSTEMATIC REVIEW

Introduction: The human gut microbiome is made up predominantly of four major bacterial phyla, Firmicutes, Bacteroidetes, Proteobacteria and Actinobacteria. Changes or imbalance of these phyla is termed dysbiosis. Specifically, in inflammation bowel disease (IBD), key changes have been identified such as a reduction in beneficial bacterial species including Faecalibacterium prausnitzii and increases in more pathogenic species including members of the Enterobacteriaceae. Currently it is not understood if dysbiosis is the cause of, or the effect of, intestinal inflammation. It is difficult to chronologically assess the microbiota changes prior to developing IBD as currently we are unable to predict those individuals who will develop the disease. The pouch is a potential model to study pathogenesis of inflammatory disease as 40% of those that develop pouchitis do so within 12 months. The relative short time from pouch formation to inflammation allows the longitudinal study of the microbiota which gives insight into potential microibota patterns occurring both in disease and non-diseased states. Interestingly, inflammation within the pouch is rarely seen in patients who have this operation for Familial Adenomatous Polyposis (FAP), thus raising the possibility that pouchitis shares a similar pathogenesis to the inflammation that is seen in ulcerative colitis.

Aims & Methods: 1. To understand changes in pouch microbiota over time. 2. To understand pouch microbiota that is associated with pouch formation A computer assisted search of the on-line bibliographic databases MEDLINE and EMBASE was carried between 1966 and February 2016. Randomised controlled trials, cohort studies and observational studies were included. Inclusion criteria: Studies which reported microbiota analysis on either faecal samples or tissue from the ileo-pouch anastomosis. Studies that provided information on specific bacterial taxa. Exclusion criteria: Studies which did not report on patterns of individual bacterial taxa differences in the pouch. Studies on the microbiota of Crohn’s disease or UC in isolation without any data on pouch patients. Studies with less than ten patients.

Results: The search strategy found 844. There were a total of 27 papers included in the analysis. Microbiota in pouchitis: Bacteroidetes, Enterococccaceae, Lachnospiraceae, Faecalibacteriaceae, Ruminococcaceae, Streptococci, Alcaligenaceae and Bifidobacterium were reduced in patients with pouchitis. Whereas Enterobacteriaceae, including E. coli Faecalibacterium and Clostridia were increased in patients with pouchitis. One study highlighted bacteria that were exclusively found in pouchitis which included Lepotospira, Pseudomonas, Desulfovirgulis, Micrococcus, Methylbacter. Chronic pouchitis was associated with a significant increase in Staphylococcus aureus and it has been suggested that this may be a responsible pathogen for chronic pouchitis. Furthermore, Enterococcus, F. prausnitzii, Lachnospiraceae and Insertae Sedis XIV and have been shown to be significantly reduced in chronic pouchitis patients. These differences were largely due to a decrease in sequences from members of the genera Ruminococcus, Dorea, Clostridium, and Eubacterium.

Conclusion: The microbiota undoubtedly plays an important role in both the inflamed and the healthy pouch. However, a direct causal relationship has not yet been established between individual microbiota changes and inflammation. There are many studies that highlight changes in bacterial composition, but studies are limited by heterogeneity of and in particular, analysis techniques and sampling strategies. Studies used a variety of methods to define microbial diversity which can be broadly split into culture vs culture-independent approaches. Culture-based studies are likely to have a bias towards cultivating more aerobically friendly microbes than exist in a true pouch environment, thus over-representing aerobic bacteria whilst possibly under-representing anaerobic bacteria. The use of 16 S RNA analysis methods will negate this effect and represents the future in accurately determining the microbiota.

Disclosure of Interest: All authors have declared no conflicts of interest.

but often performed before 6 months. Information to pregnant IBD women is because of a bad bowel preparation for 4 times. In 13 patients (72.2%) no mum: 1). 2 patients refused next colonoscopy, one patient was not controlled not resectable and referred to surgery. 31 lesions were resected in 21 patients: 22 dysplasic lesions were identified in 25 patients; 5 lesions were judged endoscopic control was done at 6 month than every one year.

Results: 36 dysplasic lesions were identified in 25 patients; 5 lesions were judged endoscopically in ulcerative colitis. In this prospective study of 27 patients with longstanding ulcerative colitis were assessed for their resecability, 23 patients (85%) and was administered before 6 months in 15 children (14%). One local anti TNF was discontinued before 26 gestational weeks in 66 (53%) women during pregnancy, 18 (15%) women were treated with steroids. Recent guidelines recommend the complete endoscopic resec-

Endoscopic Ally Resected Dysplasic Lesions in Ulcerative Colitis

Introduction: Anti TNF cross placenta during pregnancy and are detectable in the newborn in the first 6 months at least. Along this, European consensus recommends to avoid live vaccines within 6 months of live in newborn exposed in utero to anti TNF treatments. Moreover, anti TNF treatments are low of risk for breastfed infants but data are scarce. The aim of our study was to evaluate the rate and tolerance 1) of live-vaccines before and after 6 months of life in newborn exposed in utero to anti TNF and 2) of breast feeding under anti TNF. Aim of this study was to perform an observational study in 22 French departments of gastroenterology from February 2016 to April 2017. Included patients were inflammatory bowel disease (IBD) women, pregnant under anti TNF, giving birth to alive newborn and agree to answer a questionnaire concerning 1) live vaccines (BCG, rotavirus, MMR) in their child during pregnancy.

Results: 124 pregnant women treated with anti TNF were included. The mean age of women was 31 year (IQR 5). 96 (77%) patients had a flared of IBD during pregnancy, 18 (15%) women were treated with steroids. Anti TNF was discontinued before 26 gestational weeks in 66 (53%) women and resumed after delivery in 112 (90%) patients. 35 women (45%) breastfed their newborn, this continuation was noted among 69 women who did not perform lactation, 42 (63%) did not for personal choice and 25 (37%) because not recommended by the gastroenterologist. Concerning vaccination questionnaires, 96 responses were obtained. BCG was performed in 29 children (30%) and was administered before 6 months in 15 children (14%). One local abscess was reported with favorable evolution. Rotavirus vaccination was performed in 7 children (7%) before 6 months in 5 (5%) cases. One case of fever was reported. MMR vaccination (Measles, Mumps and Rubella) was performed in 62 children (65%): before 6 months in 5 cases. Information concerning fetal exposure to anti TNF and vaccination recommendation was given to 111 (91%) IBD women during pregnancy, by at least the gastroenterologist in 89% of cases, the obstetrician in 25% of cases and the paediatrician in 16% of cases. Immunoglobulin in 105 (86%) cases and tetrax in 39 (32%) cases.

Conclusion: Half of women breastfed their child with no reported complication. BCG was administered in 30% of the newborn and performed before 6 months in 50% of cases. There was only one case of local abscess. Rotavirus vaccination is rare but often performed before 6 months. Information to pregnant IBD women is only given by gastroenterologist in the majority of cases. Information in maternity by obstetrician and pediatrician should be improved.

P9097 Outcome of Endoscopic Ally Resected Dysplasic Lesions in Ulcerative Colitis

Introduction: The aim of this study was to determine the outcome of dysplastic lesions resected endoscopic ally in ulcerative colitis. In this prospective study between January 2008 and January 2015, dysplastic lesions detected in patients with longstanding ulcerative colitis were assessed for their resectability, then when they were resected. The patients were followed, and an endoscopic control was done at 6 months every one year.

Results: 36 dysplastic lesions were identified in 25 patients; 5 lesions were judged not resectable and referred to surgery. 31 lesions were resected in 21 patients: 22 low-grade dysplasia, 7 lesions indefinite for dysplasia, and 2 high-grade dysplasia. 18 patients (85.7%) had endoscopic control: mean 2.8 (maximum: 5 minimum: 1). 2 patients refused next colonoscopy, one patient was not controlled because of a bad bowel preparation for 4 times. In 13 patients (72.2%) no dysplasia was detected after a mean follow up of 30.16 months (range: 7.56–

P9098 CYTOMEGALOVIRUS INFECTION IS ASSOCIATED WITH A POOR OUTCOME IN PATIENTS WITH UC: TREATED WITH VEDOLIZUMAB

X. Robin1, L. Brichet1, S. Pillier2, E. Del Tedesco3, J. M. Phelip3, B. Pozzetto2, N. Willems3

Introduction: The aim of this study was to analyze the outcome of UC patients treated with Vedolizumab and to analyze the risk factors for CMV disease associated with Vedolizumab therapy.

Aims & Methods: We performed a retrospective case-control study of all patients with UC treated with Vedolizumab from June 2014 to April 2017. The CMV disease was defined as CMV DNA load was found undetectable for all 6 patients. Treatment change was more frequent in the CMV disease group (HR = 3.15 [1.02–9.7], p = 0.03507) with only 16.7% patients who continued Vedolizumab treatment versus 65.4% in the control group (p = 0.0052). Coleotyam was also more frequent in the CMV group (33.3% versus 7.7% p = 0.0064). By multivariate analysis, the only factor associated with the occurrence of CMV disease was a fecal calprotectin less than 600 mcg/g stools at the beginning of the vedolizumab treatment. A previous history of colitis infection also was more frequent but not statistically significant. There was no association between CMV infection and Vedolizumab levels in the sera.

Conclusion: The occurrence of CMV disease, documented with high CMV DNA load on colonic biopsy samples, in UC treated with Vedolizumab is responsible for a negative impact on the natural evolution of UC, with more therapeutic failure and surgical treatment, even after an efficient antiviral treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P9099 F-CALPROTECTIN USE IN INFLAMMATORY BOWEL DISEASE IS CHARACTERIZED BY IMPROVED DIAGNOSTIC ACCURACY, LESS PATIENT HARM AND DECREASED COSTS, COMPARED WITH CONVENTIONAL SEROLOGICAL MARKERS AND COLONOSCOPY. THE SPANISH SCENARIO

B. Muscalino1, A. A. Vora2

Introduction: Gastrointestinal disorders may exhibit overlapping symptoms making diagnosis difficult in the primary and specialty care settings. Inflammatory bowel disease (IBD), with a prevalence of <0.5% in the general population[1], is characterized by chronic inflammation of the gastrointestinal tract, non-specific elevation of conventional inflammatory markers such as ESR and CRP and may present with extra-intestinal manifestations. Irritable bowel syndrome (IBS), in contrast, is a functional disorder without gastrointestinal inflammation and with an estimated prevalence of 10-20% [2]. Endoscopy is the gold standard for detecting and quantifying IBD vs. IBS, but due to the low prevalence of IBD, is negative in the majority of cases. Furthermore, it is invasive, expensive, and uncomfortable for the patient and not without risks. Moreover, inadequate bowel preparation prior to colonoscopy is known to
increase the burden of disease from both the clinical and the economic perspec-
tive: shorter intervals between repeated procedures, higher missed rates, patient
inconvenience, and increased risk of complications are reported in the scientific
literature. F-Calprotectin (FC) is a fecal marker of intestinal inflammation; IBD
patients exhibit FC levels significantly higher than the general population; IBS
patients, however, have FC levels higher than healthy controls, but significantly lower than
IBD patients [3]. Therefore, FC can be used as a pre-endoscopic test to differ-
entiate between IBD and IBS. The present study aims at evaluating the cost-
effectiveness of FC compared to the combined usage of CRP and ESR, and the
gold standard to distinguish IBD from IBS in Spain.

Aims & Methods: An 18-week Markov model was developed for each diagnostic
strategy, simulating 1000 patients presenting to a primary care physician with
non-specific gastrointestinal symptoms. In the model, 1.6% of the colonoscopies
brought about complications [4], which may result in Emergency Room visits
and surgery. Inadequate colon preparation (23%)[5] and consequent repeated
colonoscopies (30.3%)[6] were also included in the calculations. Outcomes include cost savings, cost per corrected IBD diagnosed, and colonoscopy reduc-
tion. Uncertainty was addressed with sensitivity analysis.

Results: FC is cost-effective when compared to CRP and ESR, and to colonoscopy
(Table 1): It results in more correctly IBD diagnoses at a lower price; It reduces the number of unnecessary endoscopies, increasing the number of correctly diag-
osed IBD (N = 63) and IBS (N = 26) patients.

Clinical and health economics results

<table>
<thead>
<tr>
<th>FC-Calprotectin</th>

<td>0</td>
</tr>
<tr>
<td>Savings ascribable to the avoided colonoscopies</td>
<td>336.3</td>
<td>305.0</td>
</tr>
</tbody>
</table>

Conclusion: Results show that the usage of FC as pre-endoscopic diagnostic tool is
associated with fewer colonoscopies and correctly identifies more disease while
decreasing the costs compared to the alternatives. Consequently, FC demonstrates
superior value both from patient and payer perspective, while simultaneously
decreasing diagnostic efficacy.

Introduction: The increased use of immunomodulators and biological agents for the
treatment of patients with inflammatory bowel disease (IBD) is associated with
a key safety concern considering potential serious infection. Healthcare
workers are at a special risk for acquiring such infections due to daily and close interactions with infected patients and asymptomatic carriers of
pathogens.

Aims & Methods: We performed a retrospective observational study, collecting
data from the Group of Etude Thérapeutique des Affections Inflammatoires du
tube Digestif (GETAD) from January 2015 to June 2016, on all 482 consecutive
patients with IBD (68.5% with rohn’s disease, 28.4% with ulcerative colitis and
3.1% with IBD undetermined) who work as healthcare workers (27.2% of phys-
sicians, 33.6% of nurses, 13.1% of nurses’ aides and 26.7% of other healthcare
personnel working in interaction with in-hospital patients), in 17 tertiary centers
in France and Belgium. We selected a control group of patients with IBD who do
not work as healthcare personnel from the monocentric MICISTA database.
Controls were matched on age (±2.5 years), sex, IBD type and date of IBD
diagnosis (±2.5 years). Serious infection was defined as (1) Clostridium difficile
infection (2) community-acquired pneumonia (3) Mycobacterium tuberculosis
infection (4) any community-acquired infection that required hospitalization.
Serious infection-free survival was studied with Kaplan-Meier method, log-
rank test and Cox regression model. In each patient, the duration of IBD was
divided into semesters which were independently analyzed regarding the occur-
rence of serious infection too take into account the influence of various treatments.

Results: 482 patients (126 male; median age: 24.0 [IQR 19.9–32.1] years) were
included in the present study. The median follow-up period was 9.3 [4.6–16.2]
years. A total of 74 serious infection was recorded in healthcare workers includ-
ing 14 Clostridium difficile infection, 19 EBV or CMV-related serious viral infec-
tion, 8 tuberculosis infection including 4 tuberculosis and 4 tuberculous primo-
fection, 8 community-acquired pneumonia and 25 miscellaneous serious infec-
tion. The probabilities of serious infection-free survival were 1.0%, 6.1%, 10.8% and
14.1% at 1, 5, 10 and 15 years. No difference was found between healthcare
workers and control patients regarding the occurrence of serious infection in
time-dependent analysis and in independent semester analysis. However, a
increased risk of tuberculosis infection was found in healthcare workers (OR = 4.27, p = 0.002).

Conclusion: Although there is an higher exposure to potential pathogens in
healthcare workers, this is not associated with an higher risk of serious infection as
compared with controls with the exception of tuberculosis infection. Prospective studies are needed to confirm that the level of occupational exposure
to potential pathogens should not be taken into account when discussing the introduction of immunomodulator or biological agents with the exception of
the risk of tuberculosis infection.

the MES was 0.848, for the DS 0.801 and for the MMES 0.815, and there was no
were not superior to Mayo Endoscopic Score.
Calprotectin, the correlation between scores that take into account the extension
lation was found with the DS. There was no significant correlation between ESR
45.3
60 patients were included, 46.7% female patients with mean age
l and Calprotectin 354
100 g/g. This was a retrospective study, including patients with
diagnosis of left or extensive UC who underwent colonoscopy between 2015 and
2016. The biomarkers were obtained with a maximum interval of one week in
relation to colonoscopy and without introduction of new therapy. The Spearman
test calculated the correlation between scores and biomarkers. ROC curves
(AUC) were obtained for each score to predict Calprotectin >100 g/g.
Results: 60 patients were included, 46.7% female patients with mean age
45.3 ± 12.8 years with mean values of ESR 4.4 ± 12.8 mm, CRP 5.2 ± 6.00 mg/
1 and Calprotectin 354 ± 430 g/g. The correlation between Calprotectin and
Mes was rs = 0.623 p < 0.001, for DS rs = 0.548 p < 0.001 and for MMES
rs = 0.588 p < 0.001. Regarding CRP, a correlation with the MES was
rs = 0.414 p = 0.015; and with the MES was rs = 0.404 p = 0.001, but no corre-
lation was found with the DS. There was no significant correlation between ESR
and endoscopic scores. To predict values of Calprotectin >100 g/g the AUC for
the MES was 0.848, for the DS 0.801 and for the MMES 0.815, and there was
no statistically difference between the curves.
Conclusion: Although there is a good correlation between endoscopic scores and
Calprotectin, the correlation between scores that take into account the extension
were not superior to Mayo Endoscopic Score.

P0992 IBD – IS IT A RISK FACTOR FOR THE DIAGNOSIS OF HEPATIC STEATOSIS?
C. Ariera1, S. Monteiro2, S. Xavier1, F. Dias De Castro1, J. Magalhães3, M.J. Moreira1, J. Cotter2
1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Guimarães/Portugal
2Pt Government Associate Laboratory
3ICFSJ’s 3R’s, Braga/Guimarães/Portugal
Contact E-mail Address: catia_arieira@hotmail.com
Introduction: Although it is not yet established, recent studies suggest an increase
prevalence of hepatic steatosis (HS) in patients with inflammatory bowel disease
(IBD). Factors such as chronic inflammation, previous surgeries, drug-induced
hepatotoxicity, malnutrition and intestinal dysbiosis seem to be involved in the
pathogenesis of this disease.
Aims & Methods: We aimed to assess the frequency of HS in IBD patients
quantified by CAP (controlled attenuation parameter) and by clinical-analytical
methods: Hepatic Steatosis Index (HSI) and Fatty Liver Index (FLI). A second-
ary aim is to investigate risk factors associated with HS in IBD patients. This
was a retrospective study that included consecutive patients that were observed
in our department between January and March 2017. Patients with known liver
disease or alcohol habits were excluded. HS was defined as HSI ≥ 36 or FLI ≥ 60
or CAP ≥ 248.
Results: 149 patients included with mean age 40.7 ± 13 years, 83 female (55.7%),
59.7% with Crohn’s disease (CD). 62 patients (41.7%) had CAP ≥ 248.20
(13.4%) FLI > 60 and 40 (26.8%) HSI > 36. There were no differences in the
mean CAP value (244 ± 54.2), HSI (33.3 ± 5.8), and FLI (31.5 ± 25.3) among
patients with CD and inflammatory Crohn’s disease. We found that patients with
CAP ≥ 248 were more frequently obese (27.4% vs 0% p < 0.001), males (54.8% vs.
36.8% p = 0.029) and presented more frequently metabolic syndrome (25% vs 4.6%
p < 0.001). Regarding the IBFD factors, patients with HS had a higher frequency
of previous surgeries (30.6% vs16.1% p = 0.035). There were no differences
between hospitalization, duration of the disease, use of corticosteroids or other
IBD treatments.
Conclusion: In our cohort the frequency of HS varied between 13.4% and 41.7%
defined by non-invasive methods. We found that the presence of metabolic syn-
drome and obesity were more frequent in patients with HS. Regarding factors related
to IBD, patients with previous history of surgery were more frequently
diagnosed with HS.

P0993 BONE HEALTH IN CROHN’S DISEASE IN THE ERA OF TNF-ALPHA INHIBITORS
S. Hakimian1, J. Kheder2, D. Cave3, B. Hyatt4
1Internal Medicine, University of Massachusetts, Worcester/United States of
America/M
2Gastroenterology, UMass Medical Center, Worcester/United States of America
Contact E-mail Address: shahrad.hakimian@umassmemorial.org
Introduction: Osteoporosis and fractures are common in Crohn’s disease (CD).
Recently, several inflammatory cytokines, including tumor necrosis factor
(TNF)-alpha have been linked to increased bone resorption. Therefore, it is
hypothesized that anti-TNF therapy may influence osteoporosis and fracture
risk. However, few studies have evaluated osteoporosis and fracture risk in the
CD population.
Aims & Methods: The aim of this study is to gain a better understanding of the
epidemiologic risk factors for osteoporosis and vitamin D deficiency in the era of
TNF-alpha inhibitors. We conducted a retrospective review of 714 consecutive
patients with CD in our GI clinic between 2008 and 2015 to identify 464 patients
who met the inclusion criteria for the study comprising of all adults older than 18
years with confirmed CD based on labs and endoscopic findings. Data extracted
for analysis included demographics data, disease phenotype, duration of disease,
measures of disease activity, imaging and endoscopic data. Statistical analysis
was performed using student t-test and chi-square test.
Results: We reviewed the charts of 290 patients with CD treated with TNF-alpha
inhibitors (TNF) and 174 patients who are anti-TNF-naïve (NB). There were 207
(45%) males and 257(55%) females in this cohort. TNF patients tended to be
younger (average age of 43+/−15 and 54 +/− 18 years in TNF and NB groups
respectively). Mean duration of disease was 14.9 +/- 10.2 years for TNF and 18.6 +/-
19.2 for NB group. Approximately half of the patients had a smoking history.
Average BMI was 27.6 +/- 6.6. Rates of vitamin D deficiency, insufficiency and
normal vitamin D-25-OH levels were not significantly different between TNF
and NB groups. Vitamin D level was not associated with age, duration of disease,
or inflammatory markers (ESR). However, there was a weak positive correlation
between nutritional status (lowest albumin) and vitamin D level (Pearson’s R
=0.420). Concomitant use of TNF and corticosteroids was recorded in 168 patients
which included 100 patients in the TNF group and 68 patients in the NB group.
There was similar rate of osteoporosis (16% vs 18%), osteopenia (53% vs 57%) and
normal bone density (31% vs 25%) between the TNF and NB groups respectively.
Furthermore, there was no statistically significant difference in T-scores at the hip
(−1.2 vs −1.3), the spine (−1.0 vs −0.95), or the lower T-scores (−1.5 vs −1.4) between
TNF and NB patients. However, Z-scores at the spine (−0.47 vs −0.05), the hip (−0.55
vs −0.49) and the lowest Z-scores (−0.91 vs −0.67) were lower in the TNF group,
but only reached significance at the spine (P=0.03). Interestingly, a significantly
higher proportion of TNF patients under 60 years of age met the criteria for
osteoporosis (T-score < −2.5 below the mean) as compared to NB patients (15%
vs 3.6%). Additionally, rates of osteoporosis in the NB group were very different
between before and after age 60 (3.6% vs 30%)[table 1]. There was no correlation
with bone density and vitamin D level, nutritional status (based on lowest albumin
level), or degree of inflammation (highest ESR or CRP levels). However, there
was a moderate positive correlation with BMI and bone density (Pearson R
= 0.39) and a negative correlation with age (R = −0.25).
Table 1: Osteoporosis rates in patients on anti-TNF therapy (TNF) and those
naive to biologic medications (NB) before and after age 60.

</tbody>
</table>

Conclusion: Rates of vitamin D deficiency, and osteoporosis were similar among
patients on anti-TNF medications to those on no biologics. TNF group patients
were diagnosed with osteoporosis at an earlier age compared to NB group.
Patients on anti-TNFs also had statistically lower Z-scores at the spine. Prospective
studies are necessary to further determine the role of anti-TNF medications
in osteoporosis.

Conclusion: In our cohort the frequency of HS varied between 13.4% and 41.7%
defined by non-invasive methods. We found that the presence of metabolic syn-
drome and obesity were more frequent in patients with HS. Regarding factors related
to IBD, patients with previous history of surgery were more frequently
diagnosed with HS.
Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Infliximab (IFX) trough levels (ITLs) have emerged as a promising tool for the management of inflammatory bowel disease (IBD) patients and they correlate with clinical response and endoscopic remission. However, its use in clinical practice is still under debate, particularly in clinically stable patients.

Aims & Methods: 1) to describe real-life ITLs in clinically stable IBD patients; 2) to identify subjective factors associated with intra-therapeutic ITLs; and 3) to evaluate the impact of ITLs availability by comparing the CCD with TLGD. The decisions between experts were also compared. Both comparisons were calculated by the linear Cohen’s Kappa (κ) index. IBD patients on maintenance IFX therapy were prospectively included from June 2015 to June 2016. Demographic, clinical and biological data including C-reactive protein (CRP) levels from the same infusion day were collected. At each IFX infusion, patients were visited by their physician; a “current clinical decision” (CCD) was taken regarding clinical data and CRP. Infliximab levels measured just before the IFX infusion were considered as infratherapeutic if <2 μg/mL. Once ITLs were known, 3 experts took a hypothetical decision on treatment based on the same clinical and biological data plus ITLs (ITL-guided decision – TLGD).

Results: A total of 224 IFX infusions from 74 patients (76% Crohn’s disease) were analyzed. Median (IQR) disease and IFX therapy duration was 10 years (5-18) and 23 months (7-61), respectively; 87% received concomitant immunosuppressant therapy; 70% were on standard dosing, whereas 10% were scheduled every 4-6 weeks. Median (IQR) ITLs were 1.79 μg/mL (0.53-3.74), with 52% of patients having infratherapeutic ITLs. In the multivariate analysis, the only risk factor for infratherapeutic ITLs was the presence of biological activity. Concordance between experts A-B/B-C/A-C respectively. Moreover, concordance between experts was moderate (κ = 0.40 [95%CI:0.26–0.55]) between experts A-B/C-B/A-C respectively.

Conclusion: Our results highlight the impact of the inflammatory burden on ITLs and the importance of their therapeutic range in patients clinically stable. Both the clinical and economical impact of ITL-assisted decision-making in IBD patients should be evaluated in prospective cohorts.

P0995 THE DIAGNOSTIC UTILITY OF LINKED-COLOR IMAGING IN THE EVALUATION OF MUCOSAL INFLAMMATION IN PATIENTS WITH ULCERATIVE COLITIS

Dietetic And Lifestyle Diseases, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan

Contact E-mail Address: h-hitomi@m3.kufm.kagoshima-u.ac.jp

Introduction: Recent studies recommend the histological mucosal healing of the intestinal tissue as a treatment goal in ulcerative colitis (UC). The intestinal tissue modality using white-light imaging (WLI) to detect histological findings is considered as the leading modality to detect histological findings. However, findings are not always correlated with the histological findings. Linked-color imaging (LCI) is a new endoscopy system that enhances the color differences of the gastrointestinal mucosa. We investigated the efficiency of LCI in the evaluation of the intestinal activity, including the histological activity, in patients with UC.

Aims & Methods: UC patients underwent colonoscopy from August to December 2016. Twenty-one UC patients, who were evaluated using an EC-L600ZP endoscope with the LASEREO system (FUJIFILM Co., Tokyo, Japan), were enrolled. All of the target lesions were observed by WLI and LCI, and biopsy specimens were obtained from the lesions with the reddest tones in each view. A total of 96 lesions were biopsied. We quantified the color tones L* a* b* values (LCI-L, LCI-a, LCI-b), where L* a* and b* represent lightness, red color and yellow color, respectively. We also quantified the color tones LCI-L, LCI-a, LCI-b (WLI-L, WLI-a, WLI-b) on the L* a* b* color values. The endoscopic images were classified according to the Mayo endoscopic score (MES), and biopsied specimens were classified according to the Geboes score. The endpoint of this study was to measure the correlation between the L* a* b* color values and the (1) MES, (2) Geboes score, (3) mucosal healing, and (4) histological healing.

Results: Furthermore, we defined MES 0 as inactive endoscopic disease, mucosal healing, and a Geboes score of ≥2 as inactive histological disease, histological healing.

Contact E-mail Address: manubarreiro@hotmail.com

Introduction: Inflammatory Bowel Disease (IBD) patients live situations that may trigger negative feelings and psychological malaise. ENMENTE Project globally to improve identification and early management of psychological impact in IBD patients followed in Spanish hospital gastroenterology clinics. The aim of the study was to describe possible differences among perceptions from physicians and patients about the clinical situations triggering anxiety in patients with IBD.

Aims & Methods: During April 2016 two surveys were available on-line, one for IBD patients, in the ACCU Spain website (Confederation of IBD Spanish Patients’ Associations) and another one for physicians members of GETECCU (Spanish Group for IBD treatment). Both invited their members to participate by email and the patients’ survey was announced in social networks. The scientific committee (3 gastroenterologists, 2 psychologists, 1 nurse and 1 patient) decided which potentially stressful clinical situations were considered. Physicians and patients rated these situations on a scale from 1 to 10 as potential triggers of anxiety for the patient. A Mann-Whitney test was used to compare perceptions from patients and physicians taking 151 valid questionnaires from physicians and a randomized sample of 151 valid questionnaires from patients.

Results: The survey was completed by 912 patients (mean age 39±10 years, 67% women) and 170 patients (mean age 44±10 years, 58% women). Having an ostomy, fecal incontinence in public or surgery are important triggers agreed by physicians and patients and (table). Patients, however, experience anxiety from a possible new flare or being fatigued, whereas physicians are more concerned about anxiety due to telling about a new IBD diagnosis and about pregnancy in IBD patients (table).

Mean scores from physicians and patients about clinical situations triggers anxiety or depression

A new auto-injectable treatment 5.6 5.3 ns
A new intra-venous treatment 5.9 5.3 ns
A surgery 6.7 6.5 ns
Healing an ostomy 6.9 6.0 p<0.05
A pregnancy 5.9 4.0 p<0.05
The pain 6.3 6.1 ns
An episode of public inconvenience 6.8 6.6 ns
A new flare 6.2 6.5 p<0.05
Changes in the body image 6.3 5.9 ns
Tiredness, fatigue, reduction in performance 6.0 6.3 p<0.05

Conclusion: The main anxiety triggers in patients were having an ostomy, fecal incontinence in public, a surgery, a new flare and the feeling of fatigue. These last situations
two situations were scored higher by patients than by physicians. Teaching the patients how to manage a new condition and the treatment of fatigue are aspects that would help to reduce the anxiety feeling and should be taken into account in clinical practice Acknowledgements. Funded by Merck Sharp & Dohme of Spain and endorsed by ACCU España and by GETECCU

Introduction: Flixabi, an infliximab biosimilar referencing Remicade®, was developed by Samsung Bioepis, the joint venture between Samsung BioLogics and Biogen. SB2 received approval in EU for all approved indications of the reference infliximab. Many decision algorithms based on the measure of Infliximab (IFX) trough levels and antibodies to infliximab (ATI) have been increasingly used to optimize infliximab in Crohn’s disease and ulcerative colitis. The aim of our study was to appreciate if the biosimilar SB2 could be efficiently monitored using the Lisa-Tracker infliximab and anti-infliximab immunoassays developed by Theradiag (France).

Aims & Methods: During this evaluation, standard curves of Infliximab and two different batches of SB2 were compared and then accuracy of the Lisa-Tracker IFX kit in detecting the spiked concentration of SB2 was measured using the SB2 batch 1 and SB2 batch 2. All samples and standards were tested in duplicate. Regression lines were compared to the standard curve R² between R² = 0.95 and the slope to be comprised between 0.9 and 1.1. Intra-run and inter-run precision were also measured with spiked samples of different known SB2 (from 2 to 12 μg/mL) amounts. Capacity of polyclonal antibodies directed against infliximab to block the detection of SB2 using the Lisa-Tracker infliximab assay and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Results: We demonstrated the perfect equivalence of infliximab standard curve to the Lisa-Tracker standard curve is suitable for the quantification of SB2 in human serum samples (R² = 0.99); the levels of infliximab of the 20 samples were calculated according to the 3 standard curves (inflimab, SB2 batch 1 and SB2 batch 2) and the CV between the R² ranged from 2.1 to 12.6%). Quantification of SB2 was shown by the mean matrix and 1% recovery were comprised between 82% and 113%. High intra-run and inter-run precision were obtained with the Lisa-Tracker infliximab assay for the quantification of SB2 (CV ranged from 3.3 to 17.9%). Finally, the capacity of polyclonal antibodies to infliximab to block the detection of SB2 in 5 spiked samples and the % of recovery were comprised between 80% and 97%. The capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Conclusion: In conclusion, Lisa-Tracker Inflimab and Anti-Inflimab assays are suitable for the monitoring of patients treated with SB2. Acknowledgements: Biogen provided the SB2 drug for this study. Biogen reviewed the contract and provided feedback to the authors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0998 THE MEASURE OF TROUGH LEVELS OF INFLIXIMAB IS LINKED TO THERAPEUTIC RESPONSE IN IBD PATIENTS

X. Robin1, A. Berger2, G. Boschetti1, B. Flourie3, S. Nancey4, S. Paul2

Contact E-mail Address: xavier.robin@chu-lyon.fr

Introduction: If the association between trough levels of infliximab (TLI) and clinical remission or mucosal healing is demonstrated, we don’t really know the cause and effect between TLI and target value to obtain this association. So, the aim of our study was to evaluate the causality or the association between TLI and clinical remission and mucosal healing in IBD patients.

Aims & Methods: We prospectively included all IBD patients treated in our IBD unit and in clinical remission (CDAI < 150 for Crohn’s Disease (CD) or partial Mayo score < 3 for ulcerative colitis (UC)) with biomarker normalization (fecal calprotectin < 250 μg/g stools) or in deep remission (clinical remission with fecal calprotectin <50 μg/g stools). We analyzed median of TLI and fecal calprotectin at the inclusion (M0) and 6 months before eligibility (M-6). We excluded patients with deep remission at M-6.

Results: 111 patients were included (60 CD, sex ratio M/F: 0.8, 51 patients in deep remission at M0). All these patients were in clinical remission at M-6. Median fecal calprotectin at M-6 were similar in the two groups of patients (210 μg/g) in the group of patients who achieved deep remission at M0 vs 220 μg/g in the group of patients who achieved only biomarker remission respectively (p=0.04). Conversely, the median TLI at M-6 was significantly lower in patients who did not achieved deep remission at M0 (2.8 vs 4 μg/L respectively; p=0.01). A ROC curve analysis was not able to isolate a cut-off value associated to deep remission achievement. (AUROC = 0.61). Next, we analyzed separately median of TLI and fecal calprotectin levels 6 months before eligibility (M-6) of patients in deep remission at M0 (51 patients). The median TLI was significantly lower at M-6 than at M0 (4.1 μg/L vs 5.9 μg/L respectively; p=0.03). Conversely, median fecal calprotectin was significantly higher at M-6 in comparison to M0 (190 vs 35 μg/g stool; p=0.01). A negative and weak significant correlation between fecal calprotectin and TLI was observed (Spearman’s rank correlation coefficient (q) = -0.25; p = 0.045).

Conclusion: Although TLI may increase with decreased drug clearance due to deep remission, we show for the first time that the residual rate is the causal element for achieving clinical remission.

P0999 SMOKING STATUS INFLUENCES FECAL VOLATILE ORGANIC COMPOUNDS COMPOSITION

J. De Swart1, N. Van Gaal1, D. J.C. Berkhout2, S. Bosch1, T.G. J. De Meij3, K. H.N. De Boer1

1Gastroenterology And Hepatology, VU University Medical Center, Amsterdam/Netherlands
2Department Of Pediatric Gastroenterology, VU University Medical Center, Amsterdam/Netherlands
3Netherlands

Contact E-mail Address: bosch.sofie@gmail.com

Introduction: Fecal volatile organic compounds (VOCs) are gaseous carbon-bound metabolic products considered to reflect intestinal microbiota composition. Comparison of VOCs may serve as markers for a broad range of gastrointestinal diseases. As smoking leads to a substantial shift in intestinal microbial composition in healthy and diseases persons, the aim of this study was to assess the effect of smoking status on fecal VOC pattern.

Aims & Methods: In this cross-sectional pilot-study adult smokers, non-smokers and former smokers scheduled for colonoscopy at the VU University medical center were instructed to collect a fecal sample prior to bowel cleansing. Patients were included if no abnormalities were found during colonoscopy. Exclusion criterion was use of antibiotics three months prior to participation. All participants completed a questionnaire on standard demographics, BMI, diet and smoking habits. Fecal VOC profiles were measured using an electronic nose device (Cyanosense 3200).

Results: Fecal samples from 56 subjects (11 smokers, 21 non-smokers, 24 former smokers) were analyzed. Median age was 62 years (27–82 years). Furthermore, there were no significant differences between groups for the variables age, sex, BMI, diet, sample weight, chronic diseases and medication and supplement use. Fecal VOC profiles differed between smokers and non-smokers (PC1: p-value = 0.003). Smokers could be distinguished from non-smokers based on fecal VOC profiles was possible with an overall accuracy of 75% and corresponding sensitivity and specificity values of 72.7% and 76.2%. No significant differences between fecal VOC profiles from smokers and former smokers (PC1: p-value = 0.083) and between profiles from non-smokers and former smokers (PC1: p-value = 0.61). Next, we analyzed separately smokers and non-smokers.

Conclusion: This study showed that smoking status has a significant influence on fecal VOC profiles. This implicates that the smoking status should be taken in account when performing (fecal) VOC analysis. The finding that VOC profiles diverged (6 month – 43 years) in smoke-free time in former smokers group. Smoking cessation induces profound changes in the composition of the intestinal microbiota in humans.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Clinic Of Gastroenterology, Medical University, Varna, UHMAT’S, Marina” Varna, Varna, Bulgaria

Contact E-mail Address: anianassova@abv.bg

Introduction: The prevalence of Clostridium difficile infection (CDI) in patients suffering from inflammatory bowel disease (IBD) has increased rapidly over the past several decades. However, the exact global epidemiology remains unclear because of insufficient data from developing countries.

Aims & Methods: The goal of our study is to examine the incidence of CDI in patients with IBD. A retrospective, observational study evaluating IBD patients in a referral center was performed to evaluate the incidence of Clostridium difficile. Diagnosis was confirmed with stool toxin analysis. Demographic information, diagnosis, anatomic location, IBD therapy, antibiotic exposure, hospital stays and recurrences were recorded. For a period of 3 years, 202 IBD patients were studied, 105 of which have UC and 97 - Chron’s disease (CD). We used the Clostridium difficile Glutamat Dehydrogenase + Toxin A + B based on the principle of quantitative immunochromatographic assay for the determination of Clostridium difficile Glutamat Dehydrogenase, Toxin A and Toxin B in stool samples.

Results: The results show that all patients with a positive CDI test have a clinical picture, which resembles a relapse of the disease (p < 0.05). There’s a tendency towards growth in the incidence of IBD patients who are positive CDI. Their number in 2016 is significantly higher than that in 2014. In 2014 it was ~5.90% with CD and 12.30% with UC, whereas in 2016- 12.20% with CD and 27.80% with UC. The results show that the incidence of CDI cases in UC is significantly higher than in patients with CD, respectively 18.1% vs 9.30% (p < 0.05). There is a strong correlation between CDI incidence in patients with IBD and the severity of their disease. Patients positive for CDI have a much more severe course of the disease, UC (46.40%) and CD (24.20%) (p < 0.05).

Conclusion: There is an increase in incidence of CDI, and patients with UC are more affected by it. The results of our study are confirmed by other authors as well. A significant part of patients with CDI have a severe disease that needs extra prospective researches to determine the incidence and influence of the infection amongst patients with IBD, who receive different therapy regimens and also to understand how the CDI affects the evolution of the disease.

Disclose of Interest: All authors have declared no conflicts of interest.

P1001 DEVELOPMENT OF A NEW SCORE PREDICTIVE OF SUSTAINED CLINICAL REMISSION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE UNDER INFliximAB- AZATHIOPRINE COMBOTHERAPY
B. Sivard1, N. Willer2, J. Thépil3, E. Del Tedesco4, S. Paul5, X. Roblin1
1Hepato-gastroenterology, university hospital of Saint-Etienne, Saint-Priest en Jargeau, France

Contact E-mail Address: xavier.roblin@chu-s-etienne.fr

Introduction: There is no blood test predictive of sustained clinical remission in patients with Crohn’s Disease (CD) or Ulcerative colitis (UC) under Infliximab (IFX) - azathioprine (AZA) combotherapy.

Aims & Methods: All patients with CD or UC, consecutively treated by the combination of IFX-AZA between August 2015 and March 2017, were included in this monocentric study. Clinical, biological (blood cells count, liver function enzymes, C-reactive protein (PCR)) were retrospectively collected at baseline, at week 14 (W14) and at 6 months (W24) from the start of combination therapy.

Results: Trough level of IFX (TLI) at W14 was also recorded. Sustained clinical remission was defined as clinical remission for 6 months under combotherapy with no need of AZA dose modification, nor therapeutic switch or need for surgery. A predictive score before combotherapy was developed basing on receiver operating characteristic (ROC) curves and logistic regression analyses.

Conclusion: This new score is a promising tool for the prediction at baseline of sustained clinical remission in inflammatory bowel disease patients who start combotherapy. It may help to identify easily patients that would benefit of IFX monotherapy. toddler population.

Disclose of Interest: All authors have declared no conflicts of interest.

Introduction: As surgical resection is not curative in Crohn’s disease (CD), post-operative recurrence (POR) remains a crucial issue. The POCE r trial (1) has operated recurrence (POR) remains a crucial issue. The POCE r trial (1) has

Aims & Methods: To assess the performances of MRI and faecal calprotectin to detect endoscopic POR in CD patients. Adult CD patients from two tertiary centers who underwent ileal or ileocolonic resection were conpared to the two other modalities (P = 0.043), related contrast

Results: Overall, 30 CD patients were enrolled in the study. Among them, 15 (50.0%) were female and 7 (23.3%) were active smokers. Disease location was ileal, colonic or ileocolonic in 15 (50.0%), 1 (3.3%) and 14 patients (46.7%), respectively. The patients included in this study were treated with no medication (20.0%), 5-ASA (6.7%), thiopurines (56.7%) or anti-TNF agents (20.0%) in preventing endoscopic POR. Within the first year after surgery, endoscopic findings were assessed and Rutgeerts index was noted for 8 patients (26.7%), 11 for 5 patients (16.7%), 12a for 4 patients (13.3%), 12b for 6 patients (20.0%), 13 for 5 patients (16.7%) and 14 for 2 patients (6.7%). In defining endoscopic POR as Rutgeerts index ≥12, ADC value (2.2 vs 2.12; p = 0.35), related contrast enhancement (RCE) (77% vs 119%, 0.056), Clermont score (5.3 vs 7.9; p = 0.11), MRI score (p = 0.57) and MaRIA (5.3 vs 6.4; p = 0.21) were not significantly different in patients with endoscopic POR. Using Rutgeerts index ≥12 as cut-off value to define endoscopic POR, ADC mean value was lower in patients of preparations. The groups were comparable concerning the clinical characteristics of the patients were collected before more 1 L PEG before the capsule (PEG), liquid diet the evening before the capsule. The cleanness scores were compared on the whole small bowel and on each segment.

Conclusion: There were no statistically significant differences in patients with endoscopic POR defined as ≥12. In contrast, MaRIA (5.0 vs 7.3; p = 0.15) and MRI scores (p = 0.17) were not significantly higher in patients with endoscopic POR ≥12b. In case of severe endoscopic POR (≥13), RCE (87% vs 135%; p = 0.046) was increased while none of the following MRI parameters was significantly different: ADC (2.05 vs 2.20; p = 0.18), Clermont score (7.5 vs 7.5; p = 0.94), MaRIA (5.3 vs 7.8; p = 0.25) and MRI score (p = 0.11). Faecal calprotectin values were significantly higher in patients with endoscopic POR defined as ≥12 (87.8 vs 314.9 µg/g; p = 0.0064), ≥12b (92.6 vs 366.1 µg/g; p = 0.0075) or in patients presented with severe endoscopic POR ≥3 (98.8 vs 544.4 µg/g; p = 0.0003). CRP value was not significantly higher in patients with endoscopic POR defined as ≥12 (2.5 vs 3.9; p = 0.01) and ≥12b (3.2 vs 6.2; p = 0.43), but was increased in patients with severe endoscopic POR (3.0 vs 9.8; p = 0.02). Using ROC curves, we determined the best thresholds and their performances to detect endoscopic POR (Table 1).

Introduction: PEG preparations reduce the acceptability of endoscopic explorations but remains recommended before performing a small bowel videocapsule (SBVC). No study has evaluated its impact on the small bowel cleanness compared to other modalities in patients with Crohn’s disease (CD). The objective of this study was to compare three methods of preparation, one using polyethylene-glycol and two simplified methods in adult patients with CD.

Aims & Methods: Three methods of preparation i.e. low-residue diet the evening before more 1 L PEG before the capsule (PEG), liquid diet the evening before the capsule (LD) and Water (Water) (P = 0.102). The endoscopic activity of the capsule. The cleanness scores were compared on the whole small bowel and on each segment.

Results: Between January 2015 and August 2016, 97 patients (38 men, mean age 40.8yrs) were included and performed 105 capsules with 35 capsules in each group of preparations. The groups were comparable concerning the clinical and demographic characteristics (sex ratio, disease duration, history of intestinal resection, phenotype, treatment, indication of the capsule). The mean duration of the small bowel transit time was comparable between the three groups (198 min (PEG), 245 min (LD), 226 min (Water) (P = 0.102). The endoscopic activity of the disease was comparable between the 3 groups (P = 0.358). The capsule intubation rate was significantly lower in the PEG group 66% versus 91% (LD) and 94% (Water) (P = 0.04). No capsule impaction was observed. The mean quantitative cleanliness score for the whole small bowel was not significantly better for the PEG group (5.7) compared to the other modalities LD (6.3) and Water (6.5) (P = 0.262). In the first tertile, the quantitative score was significantly better in the LD (7.9) and Water (7.6) groups compared to the PEG group (6.8) (P = 0.043). The preparation by water was considered qualitatively better compared to the two other modalities (P = 0.04).

Conclusion: Faecal calprotectin and MRI are reliable tools to detect endoscopic POR in CD patients and could be used as non-invasive alternative options to colonoscopy.

Introduction: PEG preparations reduce the acceptability of endoscopic explorations but remains recommended before performing a small bowel videocapsule (SBVC). No study has evaluated its impact on the small bowel cleanness compared to other modalities in patients with Crohn’s disease (CD). The objective of this study was to compare three methods of preparation, one using polyethylene-glycol and two simplified methods in adult patients with CD.

Aims & Methods: Three methods of preparation i.e. low-residue diet the evening before more 1 L PEG before the capsule (PEG), liquid diet the evening before the capsule (LD) and 1.5 L of water at the time of the capsule (Water) were compared. All patients were prospectively included and had an SB3 (Medtronic) capsule after the ingestion of a Patency Agle™ capsule. The small bowel was identified between the 1st duodenal and the 1stecal images or the last recorded image and was separated into 3 equal segments. A standardized quantitative cleanliness score was calculated rating the luminosity, the presence of bubbles, turbid liquids, food residues and the percentage of visible mucosal surface in the entire small bowel and in each terri-
Conclusion: This is the first study evaluating the relevance of PEG preparation in a large population of adult patients with CD. Our study has demonstrated that there is no benefit in using PEG for the preparation of the small bowel before the capsule in patients with CD. Quantitatively, the two simplified preparation methods were more efficient than the preparation with PEG and qualitatively, the preparation using water was considered as the most efficient.

Aims & Methods: Totally, 10 consecutive patients with inactive or mildly active UC were enrolled, and fifty-three areas were assessed by LCI. All examinations were conducted with a LASEROE endoscopic system (FUJIFILM Co., Tokyo, Japan). During the colonoscopy, each region of interest (ROI) of terminal ileum, cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum was imaged by the use of wide-field endoscopic imaging (WLI) and LCI. The Commission international de l’éclairage (CIE) LAB color differences (ΔC) were calculated among WLI and LCI in each ROI. After ROIs were imaged by colonoscopy, the biopsy specimen was taken in each ROI. Inflammatory cell infiltration, crypt atrophy, crypt distortion, and goblet cell depletion were assessed by the histologic findings of acute inflammation. For evaluation of chronic inflammation, crypt atrophy, crypt distortion, and basal plasmacytosis were assessed. The correlation between ΔC and Mayo endoscopic sub-score was assessed, indicating that the higher ΔC mean easier color difference for recognition.

Results: The mean age of patients who were enrolled in the present study was 45.6 ± 17.7 years. The sex ratio (Men/women) was 4:6. The type of extent of UC (ulcerative proctitis/left-sided UC/extensive UC) was 0:3:7. 1. Correlation between ΔC and Mayo endoscopic sub-score was significantly lower than that of ROI with inflammatory cell infiltration (ΔC: 15.9 ± 6.8 vs. 13.0 ± 4.8, p = 0.046). The mean ΔC was not affected by histological findings of erosions, crypt atrophy, goblet cell depletion, crypt atrophy, crypt distortion, and basal plasmacytosis. LCI distinguished colon mucosal white color compared with WLI with use of three-dimensional color space, indicating the remission-colon mucosa of UC with no inflammatory cell infiltration in ROI was easily detected by LCI. 2. Correlation between ΔC color differences and UC Mayo endoscopic subscore. Low Mayo endoscopic sub-scores tended to be inversely proportional to high ΔC (ΔC: 15.9 ± 6.8 vs. 13.0 ± 4.8, p = 0.046), but not significantly different in the present evaluation. The colon mucosa with the low Mayo endoscopic sub-scores were relatively easily detected by LCI compared with WLI.

Conclusion: The present pilot trial indicated that the inactive UC mucosa could be easily detected as the white area by the LCI mode compared with WLI, suggesting that LCI might be one of novel approaches for evaluating the disease activity.

P1005 57SeHCAT IN THE DIAGNOSIS OF BILE ACID MALABSORPTION IN CROHN’S DISEASE WITH CHRONIC DIARRHEA
B. Gros1, L. Mena2, J.M. Benitez-Cantero1, E. Carmona2, E. Iglesias-Flores3, F.R. Maza1, P. Martín4, R. Mora1, V. García-Sánchez1, 1Gastroenterology, Hospital Reina Sofia, Córdoba/Spain, 2Internal Medicine, Hospital Reina Sofia, Córdoba/Spain, 3Gastroenterology, Hospital Universitario Reina Sofia, Córdoba/Spain, 4Gastroenterology, Instituto Maimó´nides de Investigacio ´n Biome´dica, Córdoba/Spain

Contact E-mail Address: begrosal@gmail.com

Introduction: Bile acid malabsorption (BAM) is a well-known disorder associated to inflammatory bowel disease patients, however, it is underdiagnosed in clinical practice. The 57SeHCAT test is the current clinical gold standard for diagnosing bile acid diarrhea widely used in Europe.

Aims & Methods: We aimed to analyze the incidence of BAM in Crohn’s disease (CD) patients with chronic diarrhea through 57SeHCAT and to assess whether there is a relationship between the malabsorption degree and the presence of ileal resection. 30 patients with CD and chronic diarrhea with and without ileal resection during the period between August 2015-April 2016. In all patients, an inflammatory activity was previously discarded before. Seven-day measurements were compared with 3 hours activity to calculate the abdominal retention percentage. The interpretation of the retention results was made considering ≥10% BA is consistent with a normal result. Mild BAM is considered 7–10%, moderate 4–7% and severe <4% retentive at seventh day measurements. Epidemiological and clinical data were collected from the local database ENEIDA.

Results: Twenty-five women and 15 men with mean age of 46.5 years old (26–58). The median duration of the disease was 13 years (2–27). At diagnosis, ileal location was present in 50% of the patients, ileocolonic 40% and colonic in 10%. According to the behavior of the disease, 50% presented non-stricturing non-penetrating, 25% strictureing and 25% penetrating pattern, and 43% patients had perianal disease. In relation to smoking status, 34% were active smokers.

During the evolution of the disease. Median time from CD diagnosis to surgery of the patients had undergone ileal resection. Median length of intestinal resection was present in 50% of the patients, ileocolonic 40% and colonic in 10%.

Conclusion: 50% of the patients were controlled with only immunosuppressants. In relation with smoking status, 34% were active smokers. According to the behavior of the disease, 50% presented non-stricturing non-penetrating, 25% strictureing and 25% penetrating pattern, and 43% patients had perianal disease. The median duration of the disease was 13 years (2–27). At diagnosis, ileal location was present in 50% of the patients, ileocolonic 40% and colonic in 10%. According to the behavior of the disease, 50% presented non-stricturing non-penetrating, 25% strictureing and 25% penetrating pattern, and 43% patients had perianal disease. In relation with smoking status, 34% were active smokers.

Aims & Methods: We studied 15 women and 15 men with mean age of 46.5 years old (26–58). The median duration of the disease was 13 years (2–27). At diagnosis, ileal location was present in 50% of the patients, ileocolonic 40% and colonic in 10%. P1007 THE ROLE OF SENSE OF COHERENCE IN DETERMINING HEALTH RELATED QUALITY OF LIFE AND DISABILITY IN INFLAMMATORY BOWEL DISEASE
G. Wild, M. Vitagliano, I. Albuneau, K. Shirlow
Gastroenterology, McGill University Health Centre, Montreal/Canada

Contact E-mail Address: gary.wild@mcgill.ca

Introduction: There is an ever growing body of evidence that indicates that Health Related Quality of Life (HRQoL) is significantly impaired in IBD. While clinical variables and disease activity status influence HRQoL, a host of psychosocial and personality variables also play an important role. This contention is supported by evidence of impaired quality of life (QoL) in patients with Crohn’s disease (CD) and ulcerative colitis (UC). QoL is related to the absence of demonstrable disease activity. Moreover, individual differences may play a key role in the psychological adaptation to living with IBD and coping with the psychological distress associated with the disorder. Sense of coherence (SOC) is an emerging theoretical and dynamic construct that seeks to explain why some individuals in the face of adversity experience illness while others do not. Antonovsky’s theory of SOC suggests that individuals with strong SOC are better able to adapt to health stressors and have less motivation when confronted with challenges that their health. While a number of studies have shown that SOC appears to have an impact on HRQoL, data regarding this association in IBD are limited.

Aims & Methods: The goal of the current study was to examine the associations between an individual’s sense of coherence, and their overall health-related quality of life. The first part of this study examined whether sense of coherence among water was considered as the most disability level, and an individual’s illness perception was, as compared to other reported psychosocial factors. The second part of this study evaluated whether sense of coherence, as well as illness perception, were associated with an individual’s self-reported quality of life, and if this interaction was moderated by an individual’s level of disability. Additionally, the correlations between sense of coherence, and self-efficacy, as well as self-reported emotional intelligence were also further evaluated. This is a cross-sectional observational cohort of IBD patients attending MUHC (McGill University Health Center) IBD outpatient clinics. The patients population. The number of subjects was: ≤ 42.4 ± 12.44, gender (46.6% male), disease type (58.4% CD, 33.7% UC), disease activity (27.7% active, 65.3% inactive). Patients completed multiple validated questionnaires pertaining to a variety of psychosocial parameters. Data was analyzed by multiple linear regression using statistics software (SPSS version 17.0).

Results: Preliminary analyses of this patient population revealed that 40.2% of the variance in level of disability is explained by sense of coherence. This model suggests a significant negative correlation between sense of coherence and level of disability (β = -0.64, p < 0.05). A smaller, albeit significant contribution of sense of coherence with illness perception was additionally found (14.1% of the variance, and β = -0.39, p < 0.05). Furthermore, 32.3% of the variance in self-
reported quality of life was explained by sense of coherence ($r=0.43$, $p<0.05$) and illness perception ($r=-0.28$, $p<0.05$). However, the individual's report of anxiety did not moderate this relationship. Significant positive correlations between sense of coherence and self-efficacy were also seen in this patient population ($r=0.61$, $p<0.01$), as well as with self-reported emotional intelligence ($r=0.52$, $p<0.01$).

Conclusion: This was the first pilot study to assess the potential of the faecal amino acid profile as a non-invasive biomarker for disease activity of paediatric inflammatory bowel disease. We aimed to cross-sectionally investigate the correlation between faecal amino acid profiles and clinical, biochemical as well as endoscopic activity in Greek IBD patients. Consecutive IBD patients on maintenance treatment with IFX, were included. IFX-TLs and ATIs were measured using ELISA (Eagle Biosciences, Nashua, NH, USA) on serum samples drawn before infusion. At the same time quality of life using short IBD questionnaire (SCAI) for ulcerative colitis (UC) and Crohn's disease (CD).

All levels are displayed in nmol/mg.

Conclusion: This was the first pilot study to assess the potential of the faecal amino acid profile as a non-invasive biomarker for disease activity of paediatric inflammatory bowel disease. We observed remarkable differences in faecal amino acid composition between IBD patients and healthy controls, and between the IBD phenotypes. Whether these differences reflect decreased absorption or increased loss by inflamed intestines needs to be elucidated. Currently, we are awaiting the results of a larger proof-of-concept study on these faecal amino acid profiles.

P1001 EVALUATION OF PET-MRI AND FECAL BIOMARKERS TO PREDICT DISEASE ACTIVITY IN PATIENTS WITH ULCERATIVE COLITIS

Departments For Internal And Integrative Medicine, Klinikum Essen-Mitte Integrative Gastroenterology, University Hospital of Essen, Essen/Germany

Introduction: Endoscopy is the gold standard diagnostic tool in ulcerative colitis (UC). However noninvasive methods like cross-sectional imaging and fecal biomarkers are needed for interval clinical assessments and assessing response to medical treatment. The combination of positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) with magnetic resonance imaging (MRI) as integrated PET/MRI in one examination is a new cutting-edge technology for the non-invasive assessment of the inflammatory activity in UC. In addition a panel of noninvasive biomarkers like Lactoferrin and Calprotectin are increasingly popular and used in all-day patient care.

Aims & Methods: To compare the performance of non-invasive biomarkers to PET/MRI and colonoscopy in patient with UC. In every patient a PET/MRI including the maximum standardized uptake value ratio gut/liver (SUVQuot) and a colonoscopy including an endoscopy index (EI) was performed within 48 hours and the Disease Activity Index Mayo score (DAI) was calculated. Fecal Lactoferrin (LF), Calprotectin (PMN), Calgranulins (CalP), S100A12 and CRP were also measured. PET and MRI were performed using integrated PET/MRI scanners. All analyses were performed using SPSS (IBM SPSS Statistics for Windows, release 22.0).

Results: 32 patients (21 female), mean age 44.4 ± 10.63 years (range 23–67) with diagnosed UC were included in the study. Mean time since diagnosis was 11.41 years (SD = 6.42). EI and SUVQuot (r = 0.45; p < 0.009), EI and DAI (r = 0.32; p = 0.000) as well as DAI and SUVQuot correlated significantly (r = 0.40; p < 0.022). SUVQuot was significantly correlated with LF (r = 0.32; p = 0.046), EDN (r = 0.29; p = 0.05), and CRP (r = 0.32; p = 0.009), but not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated significantly with PMN (m = 36.1) and Cal (all p < 0.05). LF and CRP were significantly correlated with PMN (m = 36.1) and Cal (all p < 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated with PMN (m = 36.1), S100A12 and Cal (all p < 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05).

The median levels (inactive/active) were: LF: 1.75/20.13 μg/g; Cal: 0.15/0.75 mg/dl. Sensitivity, specificity, diagnostic accuracy (confidence interval) and optimized cut-off for LF was 87.5%/87.5%/87.5% (CI 72.1%/100%/77.5%), 4/27 g/g; CalP: 62.5%/62.5%/58.5% (CI 38.9%/97.5%/56.1%); m = 36.1; Cal: 62.5%/62.5%/58.5% (CI 36.7%/86.2%); m = 36.1; EDN: 63.9/23.5 μg/g; PMN: 83.3%/75.0%/81.25% (CI 60.5%/99.9%); 0.805 g/g; S100A12: 75.0%/75.0%/75.0% (CI 56.9%/94.1%); 60.40; EDN: 75.5%/75.0%/75.0% (CI 80.5%/100%); 1, 30 μg/g; CRP: 70.8%/75.0%/71.5% (CI 53.5%/94.9%); 0.35 mg/dl.

Conclusion: Using EI as gold standard reference we found that fecal biomarkers LF, EDN, PMN and S100A12 can reliably distinguish between active and inactive UC. However, Cal did not perform well in this study. LF and CRP were significantly correlated to the SUVQuot which was significantly correlated with EI and DAI. In conclusion, Lactoferrin and Eosinophil-derived Neutrophil (EDN) were significantly correlated with LF and DAI and SUVQuot correlated significantly (r = 0.40; p < 0.022). SUVQuot was significantly correlated with LF (r = 0.32; p = 0.046), EDN (r = 0.29; p = 0.05), and CRP (r = 0.32; p = 0.009), but not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated significantly with PMN (m = 36.1) and Cal (all p < 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05). LF was correlated with LF (r (32) = 0.41; p = 0.001), and not with PMN (m = 36.1), S100A12 and Cal (all p > 0.05).

Introduction: At present, drug response to infliximab is monitored by trough levels of anti-drug antibody (ATI) and anti-drug factor levels. However, there are other pathways of drug degradation that have been hypothesized since MMP3 and MMP9 were found to be able to cleave IgG, like infliximab, in both animal and human experimental studies (1).

Aims & Methods: We collected serum samples in 102 patients (27 Crohn’s Disease and 75 Ulcerative Colitis) treated with stable doses of infliximab for at least 6 months (t0) and 6 months thereafter (t1). In each patient, TL, AT and MMP3 levels were assessed at t0 and t1 by ELISA. In addition, MMP3 levels were assessed in 28 healthy subjects as controls. Clinical (HBI or Mayo score) and biochemical (CRP, fecal calprotectin) markers were assessed to define disease remission/activity. TL were considered therapeutic if >3.8 mcg/ml. AT were considered positive if > 10 mcg/ml. Data are presented as mean ± Standard Error Mean (SEM). Comparison among groups was performed by non-parametric tests.

Results: MMP3 levels were similar at t0 and t1 in patients which maintained therapeutic TL (14.5±1.7 pg/ml and 15.0±1.6 pg/ml, respectively) and in those who discontinued TL (23.0±2.1 pg/ml and 22.2±1.7 pg/ml, respectively). Patients whose TL decreased had significantly higher MMP3 levels compared to the group with low TL and AT positive (33.2±3.0 and 20.0±2.7 respectively, p=0.0003), showing another pathway of drug degradation. 21 patients lost response between t0 and t1: 15 out of 21 patients demonstrated high levels of MMP3 (22.0±2.1 pg/ml) already at t0; in addition, 17 of these 21 patients were in clinical remission at t0, while at t1 all patients had disease activity.

Conclusion: Serum MMP3 levels are useful in predicting loss of response to anti-TNFa in patients with low TL but without AT. High MMP3 levels predict with 90.5% accuracy loss of response over the next 6 months.

P1013 USEFULNESS OF A MULTIDISCIPLINARY APPROACH COMBINING BOTH RHEUMATOLOGY AND GASTROENTEROLOGY FOR THE ASSESSMENT AND TREATMENT OF INFLAMMATORY BOWEL DISEASE PATIENTS

M. Barreiro-De Acosta1, E. Pérez-Pampín2, R. Ferreiro Iglesias3, R. Mejuto1, A. Mera1, J.E. Domínguez-Munóz3

1Gastroenterology, University Hospital of Santiago, Santiago de Compostela/Spain
2Rheumatology, University of Santiago de Compostela, Santiago de Compostela/Spain
3Contact E-mail Address: manubarreiro@hotmail.com

Introduction: More than one third of inflammatory bowel disease patients (IBD) present symptoms and/or manifestations, which are more common, clearly more the complicating and which more alter the quality of life of IBD patients. These patients could benefit from a multidisciplinary approach for quicker diagnosis and for optimizing treatments.

Aims & Methods: The aim of the study was to evaluate the impact of a multidisciplinary approach carried out by both a rheumatologist and a gastroenterologist in the management of these patients. Therapeutic changes after the consultation were also evaluated. From April 2015 to April 2017, all IBD patients reporting articular pain to the IBD-dedicated gastroenterologist in the management of these patients.

Results: 112 consecutive IBD patients were remitted from the IBD Unit and analyzed by the committee. Mean age 38 years (ranging from 18 to 73). Most patients were women (67%), 19% were smokers and 23% former smokers. 51% of patients had Crohn’s disease and 49% ulcerative colitis. The main causes for derivation from IBD were a suspicion of inflammatory arthropathies in 43% and of arthromyalgias in 40%. The more frequent diagnosis after the consultation was rheumatoid arthritis and the committee meeting were inflammatory arthropathies associated with IBD in 41% (51.5% presented arthralgias and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%. Regarding treatment changes, after the multidisciplinary committee with a rheumatologist and a gastroenterologist, changes were made in 28% of patients. Of those, in 35% of patients methotrexate was added in patients with biochemical treatment (in some of them patients were in monotherapy, but in others the drug was introduced for replacing thioaurines). In 24% of patients sulfasalazine was introduced instead of mesalamine. In the other patients either other biologies like adalimumab (with IBD in 41% (51.5% presented arthralgias and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%).

Conclusion: A multidisciplinary consultation combining inflammatory bowel disease and rheumatology allows both an earlier detection of inflammatory arthropathies associated with IBD and earlier changes in treatment, thereby helping to optimize the hospital resources. Fibromyalgia is common among IBD patients, though it is important that it is detected it should not be confused with the other conditions.

Introduction: Adalimumab (ADA) is an anti-TNFα drug approved for patients with refractory luminal Crohn’s disease (CD). Recently, mucosal healing (MH) emerged as a major therapeutic goal in inflammatory bowel disease. Few data are available on ADA trough levels (TL), anti-ADA antibodies (AAA) during long term follow-up of CD patients, and their potential association with MH and disease outcome.

Aims & Methods: The aim of our prospective study was to evaluate a possible association between achievement of MH, ADA TL, and AAA in CD patients. Moreover, we assessed the possible association between clinical outcome and MH. We prospectively enrolled moderate to severe CD patients who were primary responders to ADA treatment. Blood samples were withdrawn at standardized time points during treatment (0-, 2-, 6-week and every 8 weeks thereafter), before ADA administration. ADA TL were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Disease activity was assessed by means of Harvey-Bradshaw Index (HBI, remission defined by HBI < 5). As to endoscopic activity, we defined MH in case

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
of a value of Crohn’s Disease Endoscopic Index of Severity below 8, so far we included 47 complete MH and 16 partial MH, as a minimal residual endoscopic activity. Endoscopic evaluation was performed within two weeks of blood sampling, and at least after 6 months of ADA treatment.

Results: In our prospective study we enrolled 22 CD patients primary responders to ADA therapy (13 males, median age 43 years, range 23–67 years) who had a median treatment duration of 52 weeks (range 24–121 weeks). ADA TL were significantly higher ($P = 0.0002$) in patients who achieved MH (12.1 mcg/mL, range 6.8–17.2 mcg/mL) as compared to patients without MH (4.50 mcg/mL, range 0.9–9.9 mcg/mL). Receiver Operating Characteristic curve identified an ADA TL cut-off of 6.43 mcg/mL as the threshold with the highest accuracy for identification of patients who achieve MH (AUROC 0.934, sensitivity 100%, specificity 81.8%, PPV 84.6, NVP 100). Moreover, achievement of MH was associated with absence of AAA ($P = 0.012$). Lastly, HBI was significantly lower ($P = 0.0002$) in patients with MH (4, range 3–8) than in patients without MH (11, range 4–17).

Conclusion: In our cohort of CD patients, we observed a clear association between better clinical and endoscopic activity, with particular attention on novel, ADA cut-off of 6.43 mcg/mL, has been identified as the best cut-off to obtain endoscopic remission or at least a minimal residual endoscopic activity. Moreover, we observed that CD patients on ADA therapy who achieved MH had a lower disease clinical activity. Thus, we data support the use of therapeutic ADA monitoring for the management of CD patients in order to obtain clinical and endoscopic remission of the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Conclusion: The proposed ultrasonic and elastographic signs of restricting CD features predict disease activity and differentiation, with a high diagnostic of fibrotic and inflamatory strictures, helping to choose appropriate surgical treatment.

Introduction: IBDs are disabling conditions that negatively affect physical, psychological, familial and social dimensions of life. The concept of quantifying disability has become established for the evaluation of many other chronic diseases. Thus, specific tools have been used to assess the impact of disease and its treatment options on relevant end-points such as health-related quality of life (HRQL), measured by the IBD-Questionnaire (IBD-Q). Recently, the IBD-Disability Index (IBD-DI) has been developed to evaluate the entire spectrum of limitations in functioning in patients with IBD. This index is inspired to the International Classification of Functioning, Disability and Health (ICF). The aim of the present study was to assess the relationship between the IBD-DI, clinical characteristics, and IBD-Q in a cohort of Sicilian patients with ulcerative colitis (UC) and Crohn’s disease (CD) followed up in a referral center.

Aims & Methods: IBD-Q and IBD-DI questionnaires were administered to consecutive UC and CD adults outpatients from July 2016 to April 2017. The IBD-DI consists of 28 items that evaluate the 4 domains of body functions, activities and participation, body structures and environmental factors. IBD-Q consists of 32 questions grouped into 4 dimensions: bowel, systemic, social, emotional.

Results: Data from UC and CD patients were analysed separately. 100 UC patients (59% males, median age 49 years) were enrolled; 17% were smokers. 83% had inactive or mild disease, 17% moderate disease. None of the recruited patients had severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients (50%), immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 32 patients (28%). The mean IBD-DI score was 20.17 (IQR: 15.7–25.1) and 14.37 (IQR: 10.1–19.2) in UC and CD patients respectively (P = 0.005). By linear regression analysis, IBD-DI was significantly associated with IBD-Q (R² = 0.573, P < 0.001). Interestingly, 5% (n = 5) of patients with inactive or mild disease had severe disability (≥50) and 5% (n = 5) with active disease had minimal disability (<5). Analysis of UC patients revealed that 59% males, median age 41 years were enrolled; 22% were smokers. 94% had mild disease, 17% severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 22 patients (40%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 32 patients (60%). The mean IBD-DI score was 20.17 (IQR: 16.2–25.1) while only 2 patients had high DI (>50). No correlations were found between IBD-DI and gender, disease duration, disease extension (Montreal Classification) and immunosuppressive therapy. IBD-DI was related to clinical disease activity (p = 0.001) and extraintestinal manifestations (P = 0.005).

Conclusion: Our preliminary results show that the IBD-DI is significantly related to HR-QoL both in UC and CD. IBD-DI is also related to disease activity and prevalence of extraintestinal manifestations. However, most of our patients were in clinical remission. A larger sample with different grades of disease activity could provide a more accurate evaluation of the reliability of this tool in measuring functional status and disability in IBD. IBD-DI could become a major end-point in RCTs targeting the course of IBD.

Introduction: DPP-4 is a membrane-bound glycoprotein expressed on the cell surface of enterocytes and lymphocytes. It is released in plasma, maintaining its proteolytic activity and inactivating cytokines, chemokines and neuropeptides.

Aims & Methods: We aimed to investigate the diagnostic and prognostic value of DPP-4 in patients with inflammatory bowel disease (IBD). A total of 203 adult patients (n = 149 IBD patients; n = 42 healthy controls; n = 12 immune controls - systemic lupus erythematosus (SLE) in remission) were prospectively recruited. Plasma DPP-4 was analysed in all groups; faecal samples from IBD patients were collected to perform a DPP-4 and calprotectin analysis.

Disease activity was assessed by the Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD), the partial Mayo Score (pMS) for Ulcerative colitis (UC) and the Systemic Lupus Erythematosus Disease Activity Index for SLE. A multi-biomarker model was used deriving logistic regression to evaluate predictors of disease activity and Cox regression to evaluate predictors of treatment escalation (disease outcome).

Results: Disease activity was defined as the need for escalation to immunomodulatory/biologic therapies or intestinal resection surgery, as a consequence of a disease flare.

In UC, median plasma DPP-4 values were lower in remission vs UC in remission [103 ng/mL, IQR: 78–156 ng/mL vs 174 ng/mL, IQR: 106–240 ng/mL; P = 0.001] and with faecal calprotectin (FC) (r = 0.46, P = 0.001), C-reactive protein (CRP) (r = 0.60, P < 0.001) and HBI (r = 0.56, P < 0.001), but no differences were found between immune and healthy controls. Median faecal DPP-4 values were much lower in active UC vs UC in remission [121 ng/mL, IQR: 59–1682 vs 7814 ng/mL, IQR: 2555–7985; P = 0.001], but no differences were found between inactive and active UC.

In CD, plasma DPP-4 correlated strongly with faecal calprotectin (FC) (r = 0.61, P < 0.001) and CRP (r = 0.32, P < 0.05), strongly with pMS (r = 0.52, P < 0.001) and with faecal DPP-4 (r = 0.52, P < 0.001). The multivariable logistic regression model showed that plasma DPP-4 and CRP are independent predictors of CD activity (OR: 62.10; 95% CI: 2.93–1315.62; P = 0.002 and OR: 48.19; 95% CI: 3.35–692.76; P = 0.004). At follow-up (median 578 days; IQR: 426–688), plasma DPP-4 and CRP independently predicted treatment escalation in CD [hazard ratio (HR) 9.09; 95% CI: 1.77–46.57; P = 0.008 and HR 7.80; 95% CI: 1.60–38.04; P = 0.010, respectively).

Conclusion: Plasma DPP-4 correlated well with plasma DPP-4 in ulcerative colitis, but not in Crohn’s disease.

P1021 ROLE OF PET-CT TO ASSESS DISEASE ACTIVITY IN ULCERATIVE COLITIS AND ITS CORRELATION WITH CLINICAL AND BIOLOGICAL MARKERS

Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: nehaberry86@hotmail.com

Introduction: Disease activity in ulcerative colitis (UC) is best assessed clinically by Mayo score and endoscopy. Positron emission tomography -computerized tomography (PET-CT) is a non-invasive imaging technique to assess disease activity, extent, treatment response in UC, specially in pediatric population, sick patients and those unwilling for endoscopy.

Aims & Methods: We conducted a prospective observational study at our tertiary care centre with the aim of assessing and correlating UC disease activity by clinical criteria, endoscopy, histology, serum and fecal biomarkers and PET-CT. 60 eligible patients of UC were enrolled into 3 groups (26 remission, 24 moderate and 10 severe activity) as per Mayo score and 18F FDG PET-CT was performed within 72 hours of endoscopy. ESR, CRP and fecal calprotectin levels were determined for all patients.

Results: Of 60 enrolled patients, 10% patients had proctitis, 43.3% had left-sided colitis and 46.7% had extensive colitis. ESR, CRP, fecal calprotectin levels and rectal PET activity were significantly higher in patients with moderate and severe disease activity as compared to those in remission. Rectal PET activity showed a significant correlation with the Mayo score (r = 0.465, p < 0.001), endoscopic sub-score (r = 0.526, p < 0.001), histological score (r = 0.496, p < 0.001), and fecal calprotectin levels (r = 0.279, p < 0.031). Extent evaluation by PET-CT and colonoscopy also showed a significant correlation (r = 0.582, p < 0.001) with each other. We found that CRP at a cut-off level of < 12 mg/L had a sensitivity of 70.59% and specificity of 92.3%, and fecal calprotectin at a cut-off level of < 1400 µg/g had a sensitivity of 88.35% and specificity of 84.60% to predict remission. Besides, PET-CT identified sacroiliitis in 1, mesenteric lymphenodo-pathy in 5, mesenteric stranding in 4, and adenocarcinoma in 1 patient.

Conclusion: PET-CT is a reliable non-invasive tool for assessing disease activity in UC with good correlation with the Mayo score, endoscopic score, histology and fecal calprotectin. It is an accurate measure to determine disease extent, and a good predictor of remission. Thus, with a better patient compliance, it holds promise in replacing colonoscopy where it is refused or difficult to perform.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1023 THE IMPACT OF AN INFLAMMATORY BOWEL DISEASE EDUCATION CLINIC ON PATIENT OUTCOMES AND RESOURCE UTILISATION

Contact E-mail Address: weihong.on@gmail.com

Introduction: Patient education and awareness in those who have inflammatory bowel disease (IBD) is an important aspect of care. To date, there has not been any published data on the impact of an IBD education clinic on resource use or patient outcomes. Aims & Methods: We aimed to evaluate the impact of the education clinic on resource use in patients who attended the clinic compared to patients who did not. A retrospective analysis was done of patients who were diagnosed with IBD between January 2013 and May 2015. 40 patients were identified and divided equally (20 patients each) into clinic attenders (CA) and non-attenders (NA). Resource use was determined at 12 months from diagnosis in the NA group and 12 months from attendance in the CA group. The median time from diagnosis to clinic attendance in the CA group was 7 months. Data was obtained from our hospital’s electronic database system. Statistical analysis was carried out with the student’s t-test.

Results: The median age was 37 in the CA group and 33 in the NA group. In the CA group, 10 patients had ulcerative colitis (UC), 9 patients had Crohn’s Disease (CD) and 1 patient had unclassified IBD. In the NA group, 13 patients had UC and 7 patients had CD. The median of resource use and patient outcomes over a 12 month period (from diagnosis in the NA group and from clinic attendance in the CA group) is detailed in the table below.

Conclusion: In our cohort of patients, patients who attended the IBD education clinic were more likely to utilise our open access IBD telephone helpline service. There was a trend towards increased frequency of outpatient clinic appointments and blood tests in patients who did not attend the IBD education clinic although this was not statistically significant. There were no differences in the rates of hospital admissions or steroid courses in either group. The limitations of our data include the small sample size and short follow-up period.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1024 EMERGING ROLE OF IL-33/ST2 LEVELS IN PREDICTING MUCOSAL RESPONSE TO ANTI-TNF THERAPY IN ULCERATIVE COLITIS

L.R. Lopetuso1, V. Petito1, C. Graziani2, T. T. Pizzarro3, F. Scaldafferi1, A. Gasbarrini1

Introduction: Tumor necrosis factor (TNF) inhibitors (anti-TNF) are considered to be the first-line treatment for moderate-to-severe ulcerative colitis (UC). The role of IL-33 and its receptor, ST2, in intestinal inflammation is incompletely understood, with both pro-inflammatory and regulatory properties described. Recent evidence has shown that anti-TNF is able to modulate the IL-33/ST2 axis in inflammatory conditions.

Aims & Methods: The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC. Endoscopic Mayo score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). UC patients (Mayo score at T0 ≤2) grouped into responders and non-responders to anti-TNF at T2 (MAYO score ≥2) were enrolled. Healthy controls underwent routine colonoscopy for tumor screening which were also enrolled. At each time point, serum samples were collected and ELISA performed to assess IL-33/ST2 protein levels. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization.

Results: IL-33/ST2 protein levels were significantly increased in responders vs. non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders vs. non-responders at T0, with no differences between groups were found at T2. Among responders, ST2 staining was even more evident in non-responders at both time points.

Conclusion: Our results suggest that the IL-33/ST2 axis in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF therapy. Further studies are underway to determine the impacts of anti-TNF therapy on the IL-33/ST2 axis in UC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1025 INFlixIMAB TROUGH LEVELS IN THE INDUCTION PHASE ARE ASSOCIATED WITH PROLONGED REMISSION IN CROHN’S DISEASE PATIENTS

M.D. Martin-Arranz1, M. Jaquotot Herranz2, E. Martín-Arranz2, A. Martínez Peito1, M. Diaz-Almirón1, C. Suárez Ferrer, J. Poza Cordon1, S. Gómez Seneres1, L. García Ramirez1, M.P. Arcuela1, D. Pascual-Salcedo1

2Pathology, Case Western Reserve University, Cleveland/United States of America/Ohio

Contact E-mail Address: mmartinarranz@sahad.madrid.org

Introduction: Higher infliximab (IFX) serum concentrations have been associated with higher rates of clinical remission in inflammatory bowel disease patients. On week 22, 44.8% patients were in remission; on week 54, 40% were in remission.

Aims & Methods: To assess, in a prospective study, the correlation between clinical, endoscopic and histologic activity scores in a cohort of IBD patients (pts) undergoing colonoscopy. Secondary end-point was to assess the role of histologic scores in clinical practice. From Feb. to Dec. 2016, pts undergoing colonoscopy were included in a prospective observational study. The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC. Endoscopic Mayo score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). UC patients (Mayo score at T0 ≤2) grouped into responders and non-responders to anti-TNF at T2 (MAYO score ≥2) were enrolled. Healthy controls underwent routine colonoscopy for tumor screening which were also enrolled. At each time point, serum samples were collected and ELISA performed to assess IL-33/ST2 protein levels. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization.

Results: IL-33/ST2 protein levels were significantly increased in responders vs. non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders vs. non-responders at T0, with no differences between groups were found at T2. Among responders, ST2 staining was even more evident in non-responders at both time points. Healthy controls showed significantly lower levels of both IL-33 and ST2 compared with other groups. IHC confirmed these observations. In particular, IL-33 and ST2 staining was more evident in healthy controls. In responders, ST2 was more evident in the mucosa and in close proximity to adherent inflammatory infiltrate. IL-33 and ST2 staining was even more evident in non-responders at both time points. Healthy controls showed significant differences between responders and non-responders at both time points. Healthy controls showed significant differences between responders and non-responders at both time points. Healthy controls showed significant differences between responders and non-responders at both time points.

Conclusion: Our results suggest that the IL-33/ST2 axis in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF therapy. Further studies are underway to determine the impacts of anti-TNF therapy on the IL-33/ST2 axis in UC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1027 THE RELATIONSHIP BETWEEN SERUM INFILXIMAB AND ADALUMAB CONCENTRATIONS AND THEIR CORRESPONDING ANTI-DRUG ANTIBODY LEVELS: ANALYSIS OF OVER 50,000 PATIENT RESULTS USING LAB-DEVELOPED CHEMILUMINESCENT IMMUNOASSAYS

K. Y. Chun1, J. Yang2
1Esoterix Specialty Medicine, Labcorp, Calabasas/United States of America/CA
2Medical Affairs, Labcorp, Calabasas/United States of America/CA

Contact E-mail Address: chunk@labcorp.com

Introduction: Assays to measure TNF inhibitors and anti-drug antibodies (ADAb) in patient serum are being utilized to manage failure to respond and loss of response. These monitoring assays may also be used to proactively titrate doses and dosing intervals. Here, 36,477 infliximab (IFX) and 21,284 adalimumab patient results from the past 4 years were analyzed.

Aims & Methods: Measurements of drug and ADA levels were performed by lab-developed chemiluminescent immunoassays.[1] Lower limits of quantitation are 0.4 µg/mL for IFX and 0.6 µg/mL for adalimumab. ADA assays are drug specific and performed in the presence of up to 100 µg/mL of drug. Clinical histories and blood collection timing are unknown.

Results: Of 36,477 measured IFX samples, 56% (20,355) were ADA-free and 44% (16,224) had measurable ADA ranging from 22 to 3.5 million ng/mL. In the absence of ADA, IFX concentrations were from 0.4 to 15 ng/mL, with the majority (>60%) between 3.0 to 20 µg/mL. In the presence of ADA, an inverse relationship between IFX concentrations and anti-IFX antibodies is evident (Table 1). As a reference, an ADA-free mean drug level was determined from samples with IFX between 0.4-30 µg/mL. Decreasing mean IFX concentrations (column 3) with increasing ADA (column 1) are demonstrated where low ADA (<200 ng/mL) appears to have minimal impact on mean drug levels while high ADA (>1000 ng/mL) is invariably associated with severely diminished IFX (10% or less than the mean). A similar drug - ADA relationship was observed with adalimumab (Table 2). Interestingly, even lower tier anti-adalimumab antibodies are associated with a diminished mean adalimumab (3.4-5.6 µg/mL) where the baseline mean adalimumab (6.1 µg/mL) was calculated from 10,784 ADA-free samples with adalimumab from 0.6-15 µg/mL. Anti-adalimumab antibody levels >300 ng/mL are associated with free adalimumab concentrations <30% of the mean. Of all adalimumab patient samples, 60% (12,873) were free of ADA, and 40% (8411) were ADA positive, ranging from 25 to 2.8 million ng/mL. For adalimumab in Table 2, as ADA levels increase (column 1), their corresponding mean drug concentrations diminish (column 3), similar to IFX results in Table 1.

P1028 REAL-WORLD USE OF IMMUNOSUPPRESSIVES AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH VEDOLIZUMAB

M. Rahy Callado1, R. Carroll2, R. Curtis2, M. J. Khalid2, H. Patel2
1Evidera, London/United Kingdom

Contact E-mail Address: hari.patel@takeda.com

Introduction: Immunosuppressives (IM) are often used as maintenance therapy to reduce the risk of relapse among patients with inflammatory bowel disease (IBD). Vedolizumab (VDZ), a monoclonal antibody that targets α4β7 integrin, has been approved for the treatment of moderately-to-severely active Crohn’s disease (CD) and ulcerative colitis (UC).

Aims & Methods: The aim was to assess the real-world use of IM therapy and compare outcomes in IBD patients with, versus without a history of IM use, who initiated treatment on VDZ in the United States. The Explorys Universe database was used to identify all IBD patients >18 years of age who: (1) initiated VDZ therapy between May 20, 2014, and February 22, 2016 (the date of VDZ initiation was the assigned index date); and (2) had 365 days of available data pre- and post-index date (follow-up). Patients were stratified based on the use of IM at any point in their treatment history before the index date. Key outcomes in the follow-up period included the use of IM, and the incidence of IBD-related surgeries, hospitalizations, and flares (defined as the use of intravenous corticosteroids, IBD-related surgeries, or hospitalizations).

Results: A total of 567 patients were included, of which 68.4% had CD, and 31.6% had UC. Mean (standard deviation [SD]) age at index was 44 (15.0) years; 59.6% were female. Overall, 54.6% had a history of prior IM use, and 64.6% received anti-TNFs before starting VDZ therapy. On average, patients initiated VDZ 4.5 (3.6) years following their initial diagnosis. Of the 54.6% of patients with a history of IM therapy, 61.0% did not use IM during maintenance treatment with VDZ during follow-up. Of the 45.4% of patients without a history of IM use, 87.0% did not initiate IM therapy during follow-up. Amongst VDZ patients with a history of IM vs. without history of IM use, there was a trend of increased flares (38.7% vs. 30.0%, p = 0.034), hospitalizations (21.9% vs. 19.8%, p = 0.60), and surgeries (10.6% vs. 6.6%, p = 0.103). Findings for UC and CD patients are presented in Table 1.

Conclusion: The majority of patients with a history of IM use did not use IM therapy after initiating VDZ in a real-world clinical practice. The use of IM after initiating VDZ was also low amongst patients without a history of IM use. Lower rates of healthcare resource utilization were observed amongst patients without a history of IM use. Further research is needed to better understand the degree to

P1029 MOLECULAR SURROGATES OF HISTOLOGIC ACTIVITY IN CROHN’S DISEASE

C. Monast1, K. Li2, E. Myshkin2, C. Brodermelker3, J. Friedman4, F. Baribaud5

Introduction: Biomarkers of inflammatory bowel disease activity have been researched for decades but objective markers of disease severity that support clinical decision-making are still needed. Well-established markers include serum C-reactive protein and fecal calprotectin, but their use as a standalone surrogate for disease activity has been controversial. We hypothesize that novel objective markers of tissue inflammation are best identified at the site of disease with a tissue-level assessment of disease activity.

Aims & Methods: Biopsy samples were obtained from patients in the UNITI trials of ustekinumab in moderate-to-severe Crohn’s disease. The UNITI induction trials included two cohorts, patients who failed ≥1 TNF antagonists (UNITI-1) or patients who failed conventional therapies (UNITI-2). Pairs of adjacent biopsies were taken from the rectum, splenic flexure, and ileum. DNA from each biopsy from each pair was assessed by Global Histology Disease Activity Score (GHAS) while the other was submitted to microarray analysis. Partial least squares regression and random forest were used to identify biomarkers associated with histological severity in the UNITI-1 cohort. Robustness of the resulting models was assessed using cross-validation within the training set and multiple external validation sets (defined within the UNITI-1 and UNITI-2 cohorts).

Results: In UNITI-1, a single multivariate model comprising 16 genes was identified that predicted histological activities in rectum or splenic flexure biopsies. This model was characterized by R²=0.78 for the training set, and R²=0.59, 0.54, and 0.32 on external validation sets also from UNITI-1. A separate 14-gene model capturing histological activity in ileal biopsies was characterized by R²=0.5 for the training set and R²=0.45 in the external validation set. In general, both models contained genes related to tissue degradation, barrier function, and immune regulation, including CXCL11 (I-TAC). Both models retained performance in external validation datasets from UNITI-2 but exhibited lower performance. De novo models generated from UNITI-2 also exhibited lower performance. Indeed, weighted gene co-expression network analysis indicated weaker associations between gene expression and histology scores for UNITI-2 compared to UNITI-1 subjects.

Conclusion: Our analysis supports the ability of biopsy transcriptomics combined with machine learning approaches to capture disease-relevant variability in Crohn’s disease and, more importantly, supports the use of similar approaches to identify additional surrogate markers. Interestingly, this approach was more successful in the TNF antagonist failure cohort compared to the conventional therapy failure cohort. We hypothesize that this is related to increased strength of the transcriptional signal in the TNF antagonist failure cohort. We identified specific genes that could be used together as surrogates for histologic measurement, which may not be susceptible to the subjectivity inherent in GHAS scoring. Finally, the specific genes identified by our analysis provide insight into the molecular processes driving histological disease activity in Crohn’s disease.

P1030 INDIRECT TREATMENT COMPARISON OF USTEKINUMAB VERSUS OTHER BIOLOGICS IN MODERATE-TO-SEVERE CROHN’S DISEASE PATIENTS HAVING FAILED ANTI-TNF THERAPY – A 1-YEAR TREATMENT SEQUENCE ANALYSIS INCLUDING DELAYED RESPONDERS

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work proposing a solution to challenges inherent to CD data to compare one year efficacy of biologics in CD patients having failed anti-TNF therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional doses) to generate more comprehensive estimates of biologics’ relative efficacies.

Aims & Methods: A systematic literature review identified randomized controlled trials in CD patients having failed anti-TNF therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI <150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were summed to obtain overall response and remission rates. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study, adjusted for responder and remitter induction rates. Bayesian analyses generated relative

Note: IM therapy included use of azathioprine, 6-mercaptopurine, methotrexate, mycophenolate mofetil, cyclosporine, and Tacrolimus
odds ratios (OR), credible intervals (CI), and posterior distribution probabilities for superiority of UST.

**Results:** Accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were 30% of patients receiving UST every other week and 33% of patients receiving ADA every other week or weekly. Based on a one-year treatment sequence analysis, probabilities for UST to be better than ADA for achieving and maintaining response and remission were 99% (OR[CrI]: 1.94[1.07;3.48]) and 98% (OR[CrI]: 1.82[1.00;3.26]), respectively. UST had higher likelihoods of remission than ADA given weekly (OR[CrI]: 1.36[0.72;2.58] or every other week (85%, OR[CrI]: 1.14[0.70;2.48]).

**Conclusion:** This approach deals with methodological issues inherent to CD trial data. In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihood of response or remission than adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab have demonstrated benefits in delayed responders compared to other biologics. Previous research is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients’ response to biologics and better informs clinical practice.

Introduction: The use of immunosuppressors, including Azathioprine (AZT) in inflammatory bowel disease (IBD) is considered reference treatment. They are indicated especially in the case of corticoadherence, corticoreistance and in postoperative recurrences. Their efficacy is primarily judged on clinical evaluation and relapses. Few data are available on long-term healing during Crohn’s disease (CD). The aim of this study is to evaluate the long-term clinical effectiveness of AZT in luminal Crohn’s disease and in prevention of postoperative recurrence with endoscopic evaluation.

Aims & Methods: In this retrospective study, 135 consecutive patients followed for CD at the IBD Center with or without anoperative involvement were included between 1/1/2016 and 31/03/2016. All patients with Rutgeerts score greater than or equal to 2 received AZT. All patients were under AZT for at least 12 months, maintaining remission for luminal involvement or preventing

STAY OF INFLAMMATORY BOWEL DISEASE PATIENTS

P1036 INFliximab dose banding shortens length of stay of inflammatory bowel disease patients

J. Ollivier1, F. Pouliolot2, A. Berroirne3, S. Djabarou4, F. Xuerba5, F. Zerbi5, D. Laharie5, D. Breili5

Introduction: According to infliximab (IFX) license in inflammatory bowel diseases (IBD), infusion doses are based on patient weight. In daily practice, treatment is prepared by pharmacist after clinical patient assessment, leading to an increased duplication of hospital stay and consequently costs. A pharmacoeconomic study (1) has shown that a weight-based dose (WBD) strategy does not reduce interindividual variability of IFX trough levels when compared to fixed doses. According to these findings, our hospital implemented dose banding (DB) of IFX infusions, defined by doses rounded up or down according to one of eight pre-determined standard doses with a maximum theoretical deviation of +/– 5%, that allowed to prepare infusions at the pharmacy before patient admission.

Aims & Methods: The aim of the study was to compare hospitalisation length of stay (HLOS) in IFX DB as compared to those treated with IFX WBD. From February to March 2017, we conducted a prospective, case-control study in our unit, including all IBD patients admitted for an IFX infusion. Patients who should receive an IFX dose between 250 and 800 mg were included in the DB group (treatment pre-prepared at the pharmacy, sent to the hospital unit before patient admission and administered just after the clinical validation). Patients who should receive an IFX dose below 250 mg or above 800 mg were included in the WBD group (treatment prepared after clinical validation including weight, and then sent to the hospital unit). Patients were analysed only when precise length of stay could be obtained and measured in minutes. Primary objective was to compare the length of stay at hospital in both groups. Secondary objective was to compare the proportion of IFX doses cancelled, reattributed and wasted and the saved or wasted price associated (reimbursement price of one 100 mg IFX vial: 382.28 €). Two out these three infusions (3.5%) were cancelled in the DB group (treatment pre-prepared at the pharmacy, sent to the hospital unit before patient admission and administered just after the clinical validation). The median time to obtain response was 4.0 days (95% confidence interval (CI): 1.0, 4.0) and the median time to remission was 7.0 days (95%CI: 4.0, 14.0).

Results: Among the 373 IBD patients treated by IFX during the study period, 116 (31%) patients (51M/65F; median age: 41 years) were included in the study (75 in the DB group and 41 in the WBD group) corresponding to 128 infusions (84 in DB and 44 in WBD groups). Mean length of hospitalisation stay were 238 ± 21 min in the DB group and 308 ± 32 min in the DBW group, respectively (p < 0.001). DB was associated with a mean reduction of length of stay of 23%, corresponding to 70 minutes per patient. DB reduced significantly the mean duration of stay by decreasing the waiting time between clinical assessment and start of the infusion: 16 min vs. 84 min with WBD (p < 0.001). During the study, none of the 44 (6%) infusion in the WBD group was cancelled while 3/84 (3.5%) were cancelled in the DB group (p=0.55). Two out these three infusions could be reattributed to other patients, saving 2801€.

Conclusion: When used routinely in IBD, IFX DB is associated with a shortened length of hospital stay as compared to WBD, with a mean reduction of 70 minutes per patient. As IFX DB seems having similar efficacy to weight-based doses, it may improve functioning of daily hospitalisation units.

Introduction: Rapidity of response to treatment in CD is now considered a field of major interest, due to the importance of achieving the highest benefit in the shortest possible time. There are no studies specifically designed to evaluate the rapidity of response to ADA neither other anti-TNF therapies. The aim of this trial was to evaluate the rapidity of onset of clinical response to ADA therapy.

Aims & Methods: Adult anti-TNF naïve patients with active luminal (Harvey-Bradshaw Index (HBI) ≥ 8) moderate-to-severe CD (excluding penetrating and stricture disease), with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants, were enrolled in this international, prospective, open label, single arm and multicenter clinical trial. Patients received standardized ADA treatment (160 mg – 80 mg – 40 mg eow). The HBI was evaluated to determine the response at day 4 and week 1; and clinical remission at weeks 2, 4 and 12. Response was defined as a decrease of, at least, 3 points in the HBI global score and remission was defined as HBI global score ≤ 5. CRP (C Reactive Protein) and fecal calprotectin (FC) were analyzed at baseline, day 4, week 1, 2, 4, 12. The modified intention to treat (mITT) population was the primary population for efficacy analysis and consisted of those patients enrolled in the study who had received at least one dose of ADA. Treatment-emergent serious adverse events (AEs) were recorded to assess safety throughout the study until 70 days after last treatment dose. All patients who received at least one dose of ADA were included in the safety population.

Statistical analyses were performed by the t-test or the Wilcoxon signed rank test, as applicable. Time to clinical response was analyzed using a Kaplan-Meier survival analysis model.

Results: 86 anti-TNF naïve patients were analyzed. A response at day 4 and week 1 was experienced by 60.5% and 74.4% of patients, respectively. Remission was achieved by 53.5% of patients at week 2, 61.6% at week 4 and 54.7% at week 12. The median time to obtain response was 4.0 days (95% confidence interval (CI): 1.0, 4.0) and the median time to remission was 7.0 days (95% CI: 4.0, 14.0).

During the study, 42.5% of the patients suffered from any adverse event (AE). Only 3 patients (3.5%) showed a serious AE.

Conclusion: ADA produces rapid clinical remission and response since day 4 in patients with moderate-to-severe CD unresponsive to therapy with corticosteroids and/or immunosuppressants.

No ADRs of hypophosphatemia were reported. In patients dosed with ≤1000 mg iron isomaltoside, HB increased with a mean of 1.72 (95% confidence interval (CI) 0.12 g/dL from baseline to week 3, 0.00 (0.12) g/dL to week 4, and 2.32 (0.13) g/dL to week 8. In patients dosed with >1000 mg iron isomaltoside, HB increased with a mean of 2.04 (0.10) g/dL from baseline to week 3, 2.51 (0.09) g/dL to week 4, and 3.01 (0.12) g/dL to week 8. The observed increase in HB was statistically significantly higher in patients dosed with >1000 mg iron isomaltoside (p = 0.04). In the IBD subgroup, a similar dose-depended statistically increase in HB was observed at week 3 and onwards (p < 0.02).

Conclusions: No dose-response for ADRs was observed with administration of high cumulative doses of iron isomaltoside whereas HB increased more after 3 weeks with doses >1000 mg. Thus, high doses (>1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in HB in patients with gastrointestinal symptoms.

CONCLUSION
Golimumab was effective and safe in induction of response in UC patients in daily clinical practice.

P1041 PHARMACOKINETIC SIMILARITY OF ABP 710 TO INFLEXIMAB: RESULTS FROM A RANDOMIZED, SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS

Contact E-mail Address: vchow@amgen.com

Introduction: ABP 710 is being developed as a biosimilar to infliximab, an anti- tumor necrosis factor monoclonal antibody. Analytical and functional comparability studies have been completed. This report describes the results of a Phase 1 pharmacokinetic (PK) equivalence study comparing ABP 710 with infliximab.

Aims & Methods: This was a single-blind, single-dose, 3-arm, parallel-group study in healthy adults, 18-45 years of age and with a body mass index of 18 to 30 kg/m². Subjects were randomised to receive a 5 mg/kg intravenous (IV) infusion of ABP 710 or infliximab sourced from the EU and the US after pre-treatment with an antihistamine and acetaminophen 30 minutes prior to start of infusion. The primary objective was demonstration of PK similarity of ABP 710 with infliximab EU and with infliximab US based on area under the serum concentration-time curve from time 0 to infinity (AUC₀→∞) as the primary endpoint. The criteria to achieve PK equivalence were for geometric mean (GM) ratio and its 90% confidence interval (CI) to be within the range of 0.80 to 1.25.

Secondary endpoints included maximum observed serum concentration (Cmax), safety, and immunogenicity.

Results: A total of 148 subjects received study treatment (ABP 710: n = 49; infliximab EU: n = 49; infliximab US: n = 50). After a single dose, the adjusted least squares (LS) GM of AUC₀→∞ and Cmax were as follows: ABP 710, 335.59 µg/mL and 123 µg/mL; infliximab EU, 337.06 µg/mL and 121 µg/mL; infliximab US, 375.22 µg/mL and 127 µg/mL. The ratios of adjusted LS GM (90% CI) for AUC₀→∞ and Cmax between ABP 710 and infliximab EU were 0.996 (0.9042, 1.0963) and 1.021 (0.9624, 1.0827) and that between ABP 710 and infliximab US were 0.894 (0.8122, 0.9848) and 0.972 (0.9167, 1.0301). The ratios of adjusted LS GM (90% CIs) of AUC₀→∞ and Cmax between infliximab US and infliximab EU were 1.113 (1.0115, 1.2252) and 1.05 (0.9066, 1.1338). The 90% CIs of these ratios were fully contained within the 0.80 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab, as well as between infliximab EU and infliximab US. There were no deaths, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study; 1 subject in the infliximab EU group developed polymyalgia that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.7%; infliximab US: 86.0%) and the majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of study (Day 57), 40% subjects on ABP 710, 27% on infliximab EU, and 32% on infliximab US were positive for binding ADAs; 13% on ABP 710, 19% on infliximab EU and 10% on infliximab US were positive for neutralising ADAs.

Conclusion: Results of this study demonstrate PK similarity between ABP 710 and infliximab sourced from the EU and the US, as well as between infliximab EU and infliximab US following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profiles were comparable among treatment groups.

Contact E-mail Address: hari.patel@takeda.com

Introduction: Complex perianal fistulas (CPF) are common among Crohn’s disease (CD) patients and are associated with substantial morbidity. The burden and management of CPF are poorly studied.

Aims & Methods: To systematically review the literature on epidemiology, global disease burden, and treatment outcomes for CPF in CD patients. PubMed, Embase, and Cochrane were searched for relevant articles published from 2000...
forward; congress abstracts were searched from 2011 forward. CPFs were defined as fistulas with interphincteric, transphincteric, suprphincteric, extrahepatic, or horseshoe tracts.

Results: 353 records were reviewed by 2 independent researchers, and 63 relevant articles and abstracts were selected for inclusion (including 3 epidemiology and 3 burden; the rest were treatment guidelines/patients' treatment outcome studies). The estimated cumulative incidence of CPF in CD, based mostly on studies conducted in referral centres, ranges from 12%–14% (2 studies). CPF can result in significant morbidity and greatly diminished quality of life; up to 59% of patients (1 study) are at risk of fecal incontinence. Treatment options include a combination of medical and surgical interventions. However, across all options identified, a high proportion of patients experience treatment failure (lack of or inadequate response) and relapse (Table). Only 4 identified studies were conducted specifically in patients refractory to anti-tumor necrosis factor (TNF) agents—a population with high unmet needs (one study of perifistular injections of infliximab, and three studies of surgical interventions). Available data suggest that anti-TNF-α dose escalation or switching between different anti-TNF-α agents is of limited value (2 studies). Table—Rates of treatment failure and relapse or reoccurrence among patients with complex perianal fistula.

Conclusion: CPFs in CD pose substantial clinical burden. There is a high unmet need for effective treatment options for CPF in CD patients, especially those refractory to anti-TNF-α agents, as evidenced by high treatment failure and relapse rates.

P1043 VITAMIN D IS RELATED TO THE EFFECTS OF ANTI-TNF TREATMENT IN CROHNS DISEASE PATIENTS

M. Batistof, M. B.G. Costa1, K. T.P.E. Silva2, J. P.V. Costa3, C. C.S.O. Reviglio1, E.C. Oliveira1, J. R. Filho1
1Gastroenterology, Federal University of Goiás, Goiânia/Brazil
2Surgery, Organización Panamericana de Gastroenterología (OPGE), Goiânia/Brazil

Contact E-mail Address: maurobatistow@yahoo.com.br

Introduction: Vitamin D deficiency is common in patients with Crohn's disease (CD). It is believed that this deficiency is related to the CD activity. Vitamin D supplementation has many effects, including immunomodulation. However, the role of Vitamin D (VD) in severe CD patients using Anti-TNF is still unclear.

Aims & Methods: To evaluate the results of the VD replacement at different doses; check possible immunomodulatory action of vitamin D in CD patients with Anti-TNF. We conducted a double-blind, randomized, prospective study. 42 patients were selected with history of moderate to severe CD in use of anti-TNF, of both sexes, between 18 to 60 years, with dosage of 25-hydroxyvitamin D < 75 nmol/L (30 ng/ml) who signed the informed consent. Were excluded patients with less than 18 or over 70 years, pregnant women, chronic kidney or liver diseases, sarcoidosis, tuberculosis, hyper- or hypoparathyroidism, neoplasias, use of anticonvulsants; and patients who received calcium supplements or VD in the last 6 months. 30 patients were randomized. Patients were submitted to a questionnaire of sun exposure, quality of life (IBDQ), clinical examination, VD dosage, C-reactive protein (CRP), fecal calprotectin (FC) and were divided into three groups: 1 Group (G1): 10 patients receiving 2,000 U/VD, VO/week for 8 weeks, 2 Group (G2): 10 patients receiving 10,000 U/VD, VO/week for 8 weeks; 3 Group (G3): 10 patients receiving 2,000 U/VD, VO/week for 8 weeks. At the end of 8 weeks the patients answered IBDQ and were submitted to VD, FC and CRP dosage. All patients were followed for 52 weeks and checked for disease activity recurrence (CDAI > 150, FC > 300, CT scan). CRP, FC and VD levels.

Results: IBDQ improvement was observed in all groups with statistically significant results in G2 (p = 0.04) and G3 (p = 0.01). Increased VD were observed in all groups, and VD (mean ± SD) x 1000 IU/VD week: G1 - (19.5 ± 5.1) x 26 ± 6.7) p = 0.07; G2 - (19.1 ± 4.1) x 26 ± 5.8) p = 0.04; G3 -19.5 ± 6.4 x 46 ± 12.7) p < 0.001. CRP dosage were reduced, although not statistically significant, at G2 and G3 (5.8 ± 4 x 3 9 ± 2.8) p = 0.18 (5.2 ± 7.3 x 2.4 ± 3.6) p = 0.2; and increased in G1 (8.1 ± 10, 3 x 13, 4 ± 19.9) p = 0.3. There was a significant decrease in FC in G3 (1014 ± 450 x 483 ± 564) p = 0.04, no significant decrease in G2 (767 ± 751 ± 823 ± 535) p = 0.2, and increase in G1 (1101 ± 744 ± 1357 ± 819) p = 0.4. 52 week follow showed that recurrent disease activity were predominant in patients with VD < 30 (p = 0.004) and statically significant results were observed in disease activity recurrence rate (p = 0.006), FC (p = 0.02) and CRP (p = 0.01) when compared patients with VD > 30 and VD < 30.

Conclusion: 50,000 U/week was the best dosage for VD replacement and is related to immunomodulation. Most of patients with CD in Anti-TNF therapy have recurrent disease when VD < 30 and a high remission rate with VD > 30. VD levels are related to the effects of Anti-TNF therapy in CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1045 CLINICAL EFFECTIVENESS OF GOLIMUMAB IN CROHN'S DISEASE – AN OBSERVATIONAL STUDY BASED ON THE SWEDISH NATIONAL QUALITY REGISTRY FOR INFLAMMATORY BOWEL DISEASE

Contact E-mail Address: sara.rundquist@regionorebro.se

Introduction: Golimumab is approved for the treatment of moderate to severe ulcerative colitis, but not Crohn's disease (CD). Therefore, its potential efficacy in CD remains largely unknown. Off-label use of drugs is not prohibited in Sweden, and golimumab may have been used for CD treatment.

Results: The study cohort consisted of 95 patients with a median age of 37 (IQR 27-48) years, of whom 40% were men. The majority of the patients (90.5%) had previously experienced treatment failure for at least one anti-TNF agent. At the start of golimumab, 41% were on a concomitant immunomodulator and 16% on corticosteroids. After a median follow-up time of 21 (IQR 10-36) months, 60 (63%) patients had stopped treatment with golimumab. Reasons for discontinuation were inadequate response; n = 45 (75%), intolerance; n = 11 (18%) and other reasons; n = 4 (7%). Estimated drug continuation rates were 73% at 12 weeks and 42% at 52 weeks. Concomitant treatment with corticosteroids at baseline seemed to be associated with a higher risk of discontinuation of golimumab (unadjusted HR: 1.97; 95% CI: 1.04-3.73; p = 0.04), although the association did not remain significant after adjusting for potential confounding factors (adjusted HR: 1.76; 95% CI: 0.84-3.67; p = 0.13).

Aims & Methods: We aimed to describe the CD population that is treated with golimumab in Sweden and to assess the long-term effectiveness, defined as drug continuation rate, as well as identify predictors of drug discontinuation. Patients with CD who received at least one injection of golimumab were identified through the Swedish national quality registry for inflammatory bowel disease (SIBWIRE). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariate and multivariate Cox proportional hazard regression models were used to identify predictors of golimumab discontinuation. The variables sex, age, duration of disease, location, perianal disease, smoking status, previous surgery, concomitant treatment with corticosteroids or immunomodulators at baseline, prior anti-TNF therapy and CRP at baseline were included in the models.

a44 studies reported treatment outcomes for CPF in CD patients. Most studies identified were small and/or non-comparative, and study methodologies, populations, endpoint definitions, and duration of follow-up varied. For studies with mixed populations, only results for patients with CD and CPF were considered. 
bDefined as lack of or inadequate response to therapy (i.e. lack of complete response). cDefined as standard of care used at each centre excluding anti-TNFs and surgery in 2 studies and as standard medical care at each centre including anti-TNF and surgery in 2 studies.
**Results:** Analysis and consisted of those patients enrolled in the study who had received at least 80% of the scheduled therapy with corticosteroids and/or immunosuppressants. Quality of life was evaluated by using the validated questionnaires EuroQol-5D (EQ-5D) and the 36 items Short-Inflammatory Bowel Disease Questionnaire (S-IBDQ).

target, little or no information is available regarding the ratios of free and TNF-bound infliximab in the intestinal tissue.

**Aims & Methods:** We aimed to assess the presence of free versus TNF-bound infliximab in the intestinal tissue of IBD patients and its possible association with clinical outcomes. Protein was extracted from frozen intestinal tissues of infliximab-treated IBD patients. TNF-bound infliximab and free infliximab were detected using ELISA and normalized to tissue protein concentration. Concurrent serum drug levels (SDL), anti-drug antibodies (ADA), and TNF-bound infliximab levels, patient’s pharmacotherapy, clinical response based on physician global assessment (PGA), and endoscopic appearance (severity determined according to mayo scor- ing in ulcerative colitis and endoscopic assessment of ulceration severity, extent of disease and affected area in Crohn’s disease) and pathological results (severity determined by observing pathologist graded as normal, mild, moderate and severe disease) at the time of colonoscopy were determined. Correlation were performed using Spearman’s rank correlation test.

**Results:** Twenty-four biopsies from 13 patients (11 Crohn’s disease and 2 ulcerative colitis patients) were tested. Non-inflamed tissue infliximab levels, but not inflammatory tissue infliximab levels, were correlated with SDL (R = 0.849, p = 0.007; FDR = 0.0185) and were negatively correlated with the endoscopic appearance (R = -0.7214, p = 0.0185) and pathological severity (R = -0.7099, p = 0.0059). TNF-bound infliximab was measured in both inflamed and non-inflamed specimens and did not show any correlation with drug levels in the serum or tissue. ADA was only detected in a single patient, precluding statistical analysis. Notably, no TNF-bound infliximab was measured in the serum.

**Conclusion:** These findings show that pharmacokinetic-pharmacodynamics interaction, as measured by SDL, better reflects drug levels in healthy mucosa rather than the inflamed one, and suggest a more complex drug/target interaction in inflamed tissue, which cannot be explained by target binding only. Future studies assessing changes during the course of mucosal healing may allow their use as surrogate markers for this purpose.

in just one of these 14 patients (1.4%) (p < 0.001). Median (IQR) TL were significantly higher in the ADA negative group compared to the ADA positive group [9.21 (7.00–12.99) vs. 3.45 (1.72–5.44) µg/mL, p < 0.001]. A significant correlation between TL and ADA levels could be found (Spearman’s rho = 0.562, p < 0.001). Although the presence of these ADA was not significantly associated with clinical remission at week 12, a clear tendency was observed (p = 0.136). During median (IQR) follow-up of 1.46 (0.32–3.48) years, 43 out of 116 patients (37.1%) needed ADM dose-escalation. Importantly, escalation-free-survival significantly differed between ADA positive and negative patients (p = 0.001). Univariate analysis could not identify any more factors (weight, BMI, gender, disease behaviour, disease location, CRP, serum albumin, PRO2, concomitant therapy, smoking) associated with ADA presence at week 12. Interestingly, 50% of the ADA positive patients had TL above 4 µg/mL would not have been dose optimized proactively according to current practice. Thus, out of these 7 patients needed dose-escalation afterwards which could have been expected based on the ADA positivity.

Conclusion: A drug-resistant assay can identify ADA to ADM before all drug has been neutralised and TL become undetectable. As these ADA at week 12 are significantly associated with need for dose-escalation and can appear before TL drops below the threshold of 4 µg/mL, they may be better to identify those patients who could benefit from dose-escalation. Moreover, the differences in TL between patients at week 12 can finally be explained by the presence of ADA measured with a drug-resistant assay.

Introduction: Compliance is a significant problem in the medication of patients with chronic diseases, especially during periods where patients are completely unaware of their disease and just take their drugs to prevent disease recurrence. (1) During the last years Shared Medication Record (SMR) was introduced in Denmark which is a national database containing information on current medication of all Danish residents. SMR include information on where, when, and how much medicine the patients buy at the pharmacies. Therefore with SMR it becomes possible for doctors to see if patients retrieve the prescribed medicine at the pharmacy. Patients with chronic inflammatory bowel diseases (IBD), ulcerative colitis (UC) or Crohns Disease (CD), have periods of flares of the disease but in many cases also long periods when the disease is in remission. The majority of patients need medication to reduce the risk of recurrence of disease. Clinical means that they need to take medicine even if they have no symptoms of disease. Previous American studies have shown that a number of patients in this situation do not take their medication and thus are at increased risk for relapse of the disease (1). There are no corresponding data for Danish patients. We wanted to find out the proportion of Danish IBD patients in remission who buy the prophylactic treatment as prescribed, and whether this proportion will change when the patients are informed about that the doctor can see if they pick up the medicine at the pharmacy.

Aims & Methods: The purpose of this study was to investigate whether Danish patients with IBD in remission buy the prophylactic treatment as prescribed, if these patients buy a larger part of their medicine when they know that the doctor can see which medicines they buy at the pharmacy. 100 consecutive patients with UC in remission and at least six months and 10 IBD, treated with a fixed dose of Mesalazine, azathioprine, or Mercaptapurine during the preceding six months were enrolled from Randers Regional Hospital Adult Gastroenterological Outpatient Clinic. Patients were randomized 1:1 either to receive information that the doctor could follow their pharmacy refills, or not to get information on this. The patients were not informed that they participated in a study. All patients had a second visit six to 12 months later. Patients who had flares in disease activity during the study period was excluded. Adherence to the treatment was defined as pharmacy refills according to the prescribed dose for at least 80% of the period of the preceding six months. Fisher’s exact test was used as test of independence between groups.

Results: 67% of the patients in the study were adherent to their medical treatment during the first study period decreasing to 48% during the second study period (P < 0.001). There was no difference in the decrease in adherence between patients informed about SMR and those who were not informed. Younger patients were less prone to adherence compared to older patients at the first study visit (Age groups: 19-39:40-59/60+: Years, adherence 48/71.6% (P < 0.05). We found no differences related to disease (UC/CD), sex, 5-ASA,antiparin, or admission route (oral/recatl).

Conclusion: Adherence to treatment fell from the first visit when the disease had been in remission for at least six months, to the second study visit when the disease had been in remission for at least 12 months. This was independent of whether the patients were aware that the physician could follow their medication refills or not. This might indicate that adherence to medical treatment of IBD decreases over time when the disease is in remission.

Treatments received by patients at discharge were Immunosuppressants (30.8%), antibiotics (21.3%), mesothoracic (19.1%), mesalazine (12.1%) and antiTNFa (0.9%). A total of 235 patients (74.8%) had a medication change throughout the follow-up period, mainly within the first year after surgery (47.1%, n=148). Median time to first medication change was 10 (IQR 4–22) months. More often therapeutic decision was the introduction or dose escalation of thiopurines or change to a more potent agent (68.1%, n=160) followed by the introduction of an antiTNFa drug or dose escalation (51.4%, n=121). Ninety-two out of 95 patients with planned endoscopy within first year after surgery had Rutgeerts scoring (RS) available, 37 (40.2%) and 55 (59.7%) showed RS<12 and <12 respectively. More patients with a RS≥12 had a medication change as compared to patients with a RS<12, but the differences didn’t reach statistical significance (45.9% vs 36.36%). Reasons for medication change were “endoscopic without clinical recurrence” (52.9% RS≥12 vs 10.0% RS<12, p=0.010), “clinical recurrence” (29.4% RS≥12 vs 25.0% RS<12) and “others” (23.5% RS≥12 vs 60.0% RS<12, p=0.045).

Results: The number of planned endoscopies carried out within the first year after surgery increased significantly from 2007 to 2010 showing a steady implementation of guidelines recommendations. Changes in medication within this period were more frequent in the setting of endoscopic recurrence. Acknowledgements: Funded by Merck Sharp & Dohme of Spain

Introduction: Etrolizumab, an anti-β7 monoclonal antibody targeting α4β7 and αEβ7 integrins, showed efficacy and safety versus placebo (PBO) during 10 weeks (wk) of induction in patients with moderate-to-severe ulcerative colitis in the Phase 2 EUCALYPTUS trial (Vermeire S. Lancet. 2014;384:309–18). Since a reduction in histologic inflammation has been linked with improved long-term clinical outcome (Bryant R et al. Gut. 2016;65:408–14), and the FDA recommends using both histologic and endoscopic assessments for efficacy evaluation, the effect of etrolizumab on histologic inflammation was evaluated in mucosal biopsies from EUCALYPTUS patients using the Roberts histopathology index (RHI; Mosb MH. Gut. 2017;66:50-8) and Nancy histological index (NHI; Marchal-Bressenot A. Gut. 2017;66:43-9).

Aims & Methods: 124 patients were randomly assigned (1:1:1) to receive subcutaneous etrolizumab (100 mg at wk 0, 4, and 8, with PBO at wk 2, or 420 mg loading dose at wk 0, followed by 300 mg at wk 2, 4, and 8) or placebo. Biopsies were taken using flexible sigmoidoscopy/full colonoscopy from the most inflamed colonic area within 10–40 cm from the anal verge at baseline (BL) and at wk 10. 62 patients provided consent for long-term sample storage for research; batch H&E-stained slides were scored by a single pathologist using the Geboes scale (later converted to RHI) and NHI. At wk 10, mean changes in RHI and NHI scores for pooled etrolizumab or PBO were calculated. Subanalyses explored histologic response (reductions of ≥ 6 or 10 points or ≤50% improvement from BL RHI) and ≥1 or 2-point reduction from BL NHI (remission (no neutrophils, RHI ≤4 and NHI = 0, ≤1 or 2) and correlation with endoscopic improvement.

Results: Analysis included 56 patients with BL data and BL NHI > 1. At wk 10, mean NHI scores decreased by a greater extent with etrolizumab compared with PBO, regardless of anti-tumor necrosis factor α (aTNF) experience (RHI −8.4 vs −1.6; P=0.032 and NHI −1.2 vs −0.2; P=0.011 for all comers). A greater proportion of etrolizumab-treated patients achieved categorical histologic improvement and remission with an endoscopic subscore (RHI ≤1 wk 10 n = 6, 100% experienced histologic response as assessed by RHI (5/5 with RHI non-missing at wk 10), and 83% (5/6) by NHI. Mean (SD) RHI changes were −19.2 (10.0) in patients with an ES ≤1 at wk 10 versus −4.4 (10.1) in patients with an ES >1. Mean (SD) NHI changes were −2.5 (1.5) in patients with an ES ≤1 at wk 10 versus −0.6 (1.3) in patients with an ES >1. Spearman’s
correlation coefficients between RHI and NHI were 0.82 at BL and 0.91 at wk 10, while both histologic scores were similarly correlated with ES (0.25-0.28 at BL and 0.38-0.40 at wk 10).

*Must have achieved ≥ 1 point improvement*
NHI 0 = no histologically significant disease
NHI 1 = chronic inflammatory infiltrate with no acute inflammatory infiltrate
NHI 2 = mildly active disease

**Conclusion:** Histologic activity assessment using RHI or NHI demonstrates improvement after wk 10 with etrolizumab treatment and was greater in aTNF-naive patients. Importantly, RHI or NHI reductions were associated with improved ES at wk 10.

**Aim:** To assess the long-term efficacy and safety of etrolizumab in patients with moderate-to-severe UC who responded to induction therapy with etrolizumab.

1. Inflammab has been shown to induce and maintain long-term clin-
2. sponding to responders (week 2: median level 7.2 g/ml vs. 13.5 g/ml, p = 0.0019, week 6: median level 2.2 g/ml vs. 9.5 g/ml, p < 0.001, respec-
3. CI 2–10.8, p = 0.0004) and at higher levels in non-responders compared to responders (week 2: median AT1 7.3 g/ml-eq vs. 3.8 g/ml-eq, p = 0.005, week 6: 10.8 g/ml-"eq vs. 4.4 g/ml-"eq, p = 0.008, respectively). Moreover, week 2 AT1 levels > 4.3 g/ml-"eq (AUC = 0.68, p = 0.002, sensitivity 77%, specificity 86%), and AT1 levels < 6.8 g/ml (with peaks 7.8%, with specificity 71%) were predictive of primary non-response. In analyses of various demo-
4. in patients towards topical products. A qualitative market research study was performed in the USA and 3 European countries (Germany, UK and Italy). The primary patient recruitment sources were online web portals, e-mail campaigns and social networking sites. Informal feedback gathered from online patient activists to identify the right sources was also used. In order to select patients with more advanced disease and/or a longer disease history current or past steroid medication was mandatory as a qualification for inclusion in the market research. A structured questionnaire covering 14 items was pre-
5. of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painful administration.

**Results:** In this survey cohort patients had been diagnosed with UC for > 5 years on average, 2/3 of patients had left-sided disease and less than a third had extensive disease. The majority of patients experienced at least 1 flare-up each year and less than 15% of patients had them only rarely. ASA and steroids were the most commonly used medications in all countries, biological treatments were reported as highest in 35% (US) to the lowest 16% (UK) as stated by the patients. The vast majority of patients stated that they had treatment experience with different products at some time during their treatment journey, ASA and IS being slightly lower number in the US (83%) compared to the EU countries (Range 89–92%). Rectal enemas were the most common formulation delivery for topical ASA products in all markets (79%) followed by suppository (25%) and foam (13%). A total of 53% of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painful administration.

**Introduction:** This study aimed to gain insight into what caregivers consider important to use topical therapy almost all patients stated to have used rectally administered products at some point during their disease journey and even patients in the USA were very familiar with these medications. Although physicians see patients as the primary driver for the resis-
6. day at our hospital, a survey regarding SM was distributed among 46 nurses. Also, 50 IBD-interested gastroenterologists were invited to respond to the same survey by email with a link to the survey. The survey contained questions regarding the caregivers’ views on ways for patients to apply SM in an outpatient setting (12 options were given). Caregivers were asked to state whether they thought these options would be valuable to patients or not, and to name their top three options. Also, caregivers were asked their views on factors that could

Introduction: Selective GMA using Adacolm® device is a non-pharmacological therapeutic option for patients affected by IBD, but its precise role among the various treatments available and its true effectiveness are still debated. In particular, steroid-dependent patients, refractory or intolerant to immunosuppressants and biologics, represent a sub-group of patients with limited options of treatment. Recently, a multicentric open-label trial [the ART trial *] showed, for the first time a clinical benefit of 61% in these problematic patients.

Aims & Methods: The aim of this study was to further evaluate, in our real-life clinical experience, the efficacy and safety of GMA in these difficult-to-treat patients. We retrospectively reviewed the clinical data of patients treated with GMA-Adacolumn® in our center between 1/1/2008 and 12/31/2015. Only steroid-dependent and/or AZA/IFX/ADA-resistant or intolerant cases were considered. GMA was performed once a week for a minimum of five consecutive weeks. Occasionally, one or two additional sessions were performed. A clinical response was defined as a ≥ 3 point reduction in the clinical activity index (CAI) for ulcerative colitis (UC) and a ≥ 100 points reduction of the Crohn disease activity index (CDAI) for Crohn disease (CD) after 12 weeks from the beginning of the treatment.

Results: The study population included a total of 30 patients (17 males, 13 females, mean age 49 years, range 21–73) affected by UC (20 patients) and CD (10 patients). Eight patients (5 UC, 3 CD) were excluded from the final analysis for a loss of data. In the remaining 22 patients, a clinical response at week 12 was observed in 15 (68%). The response was better in UC (11/15; 73%) than in CD (4/7; 57%). A steroid-sparing effect was observed in all responsive patients. GMA was generally well tolerated, as only 4 patients (13%) reported mild adverse events (headache in two, hypotension in one, vascular procedure complication in one) and no patients discontinued the apheresis due to the adverse events.

Conclusion: In our real-life single-center experience, focused to a selected group of difficult-to-treat patients affected by IBD, GMA with Adacolm® seems to be, in a short-time evaluation, a useful and safe option of treatment, supporting the recent data from the ART trial. Prospective randomized trials in larger sample of patients and with more extended follow-up are needed to confirm these results.

Reference

myrrh (Commiphora molmol E.), chamomile flower (Matricaria chamomilla L.) and coffee charcoal (Coiffa Arabica L.) is used for the treatment of gastrointestinal complaints. Clinical data suggest its use for the maintenance therapy of inflammatory bowel disease [1]. Despite clinical and chemical data, pharmacological data supporting the observed efficacy remain insufficient.

Aims & Methods: The present study aims to investigate the influence of the single and combined herbal extracts with regard to its antiinflammatory and immunomodulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine signaling of stimulated intestinal epithelial cells and activated macrophages. Myrrh and chamomile flower extract exerted spasmolytic effects by inhibiting acetylcholine-induced contractions in rat small intestinal preparations (IC50: myrrh ¼ 25 μg/mL; chamomile flower ¼ 383 μg/mL). In combination, chamomile flower and myrrh interacted additively (IC50(myrrh) ¼ 74 μg/mL; chamomile flower ¼ 196 μg/mL) resulting in a DRI of 1.9. All three plant components inhibited CCL13 release from LPS-stimulated human macrophages (IC50: myrrh ¼ 10 μg/mL; chamomile flower ¼ 82 μg/mL; coffee charcoal ¼ 25 μg/mL). Synergistic effects exerted by the herbal combination in inhibiting CCL13 release significantly reduced IC50 values (IC50(myrrh) ¼ 5 μg/mL; chamomile flower ¼ 22 μg/mL; coffee charcoal ¼ 29 μg/mL) resulting in a DRI of 3.7. Combined CCL13 induced CCL10 release from Caco2 cells was reduced by all herbal components (IC50(myrrh) ¼ 41 μg/mL; chamomile flower ¼ 364 μg/mL; coffee charcoal ¼ 447 μg/mL) with comparably high IC50 values. However, application of the herbal combination, significantly reduced the IC50 of the plant extracts (myrrh-IC50 ¼ 25 μg/mL; DRI ¼ 1.7; chamomile flower-IC50 ¼ 124 μg/mL; DRI ¼ 2.9; coffee charcoal-IC50 ¼ 124 μg/mL; DRI ¼ 3.6). IL8 release from cytokine-challenged Caco2 cells was inhibited after myrrh (IC50 ¼ 3 μg/mL; 28% max inhib.) and coffee charcoal (IC50 ¼ 218 μg/mL; 75% max inhib.) but increased after chamomile flower treatment (IC50 ¼ 39 μg/mL; 29% max stimul.). Treatment with all three plant extracts resulted in a moderate IL8 inhibition with an inverted U-shape concentration-response curve (IC50(myrrh) ¼ 56 μg/mL; coffee charcoal ¼ 281 μg/mL; 77% max inhib.).

Conclusion: The herbal components myrrh, chamomile flower and coffee charcoal influenced chemokine signalling of stimulated intestinal epithelial cells and activated macrophages. Myrrh and chamomile flower additionally exerted anti-inflammatory effects. Synergistic and additive effects between the plant extracts justifies the composition of the traditional herbal medicinal product (Myrrhinil-Intest®) and its application for the treatment of inflammatory intestinal disorders.

P1065 ARE TROUBLE LEVELS OF ANTI-TNF DRUGS RELATED WITH TREATMENT FAILURE AND TREATMENT ORGANIZATIONAL ISSUES?
1J. Genzþ, 2S. Vieujean1, 3M. Barrientos-Aceña3, 4A. Llach4, 5J. E. Dominguez-Manubarreiro1, 6J. E. Muñoz5, 7J. M. Giráldez-Montero7, 8R. Ferreiro Iglesias8, 9M. Jayas-Diaz9

Contact E-mail Address: manubarreiro@hotmail.com

Introduction: Therapeutic drug monitoring of infliximab (IFX) and adalimumab (ADA) is required because treatment failure is commonly used if patients show loss of response, but there are scarce data about the influence of trough levels on prognosis.

Aims & Methods: The aim of the study was to evaluate the relationship between drug concentration and anti-TNF and treatment failure and duration of treatment in a real life environment. METHODS A prospective observational study was performed in a cohort of patients with inflammatory bowel disease. Patients were included consecutively through visits to the hospital to receive IFX or ADA. Inclusion criteria were all age >18 year patients, being treated with one of the study drugs at standard dose as maintenance therapy and giving consent to participate in the study. In the first visit, blood samples were extracted for drug concentration determination. Patients were followed-up for the next 2 years. Trough drug concentrations and drug antibodies were measured by an ELISA technique (Promonitor). Patients with IFX levels <3 mcg/mL and ADA <5 mcg/mL were considered under lower limit of therapeutic range (LLTR). Moreover, the number of patients that discontinued treatment (complete success) or discontinued (failures) the treatment were analyzed. Any change in dosage (intensification) or in the type of drug was considered as discontinuation of the treatment. Chi square test was used to analyze the dependence between the categorical variables and t-student for continuous variables with normal distribution.

Results: 134 patients were consecutively included, 53 male (40%), 92 (68%) patients with Crohn’s disease (CD) and 42 (32%) with ulcerative colitis (UC). 52 (39%) patients were treated with IFX and 55 (39%) with ADA. Mean age was 43 [19–71] years. After finishing the follow-up, 107 (79%) patients continued the same treatment regimen (success). A total of 59% of this group of patients were with drug concentrations above LLTR. The remaining 27 patients changed their treatment (failures). In the failure group, only 41% of the patients were above LLTR, 18.2% less with respect to success treatment group. These results did not reach statistical significance (p = 0.09), but are in agreement with current evidence. When type of inflammatory disease was analyzed, a greater percentage of patients below the LLTR were found in the UC group (41.3% vs 52.4%, CD and UC respectively), but the difference did not reach statistical significance. Regarding the duration of the treatments, the duration was similar in the group of patients with lower concentrations compared to the group with high drug concentrations (46.6 vs 42.6 months). However, when the duration of treatment was analyzed in patients who discontinued, significant differences were observed (43.8 vs 20.2 months in the < LLTR and > LLTR groups respectively).

Conclusion: The percentage of patients who continue treatment was higher when drug concentrations were above LLTR. However, these high levels did not prevent the early relapse of some of them.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1066 IMMUNOSUPPRESSIVE CO-TREATMENT WITH INFlixIMAB AND ADALIMUMAB IS NOT SUPERIOR TO ANTI-TNF MONOTHERAPY TO PREVENT TREATMENT FAILURE AND TREATMENT DISCONTINUATION IN ULCERATIVE COLITIS
1S. Vieujean1, 2E. Louis2, 3C. Reenaers3
1Gastroenterology, CHU Liège, Liège, Belgium
2University Hospital CHU de Liége, Liège, Belgium
Contact E-mail Address: catherine.reenaers@chu.ulg.ac.be

Introduction: In Crohn’s disease there is clear benefit from combination therapy with infliximab (IFX) and immunosuppressive drugs (IS), while the benefit seems more limited for adalimumab (ADA). Although some studies suggest a benefit of combination therapy with IFX in ulcerative colitis (UC) few data are available concerning combination therapy with ADA.

Aims & Methods: Our aim was to compare real life efficacy of anti-TNF mono- therapy (IFX and ADA) and anti-TNF+IS for UC maintenance. This was a retrospective study of patients with UC treated with IFX or ADA in 2 Belgian academic and regional Hospitals from 2004 to 2014, divided in treatment periods of at least 3 months, a failure semester as anti-TNF withdrawal for secondary loss of response, intolerance or surgery, treatment optimization of IFX or ADA dose escalation or steroids start. Semesters with and without failure and with or without optimisation were compared through univariate and multivariate analysis.

Results: 478 patients in 60 patients with IFX and 175 semesters in 33 patients with ADA were included. The mean IFX and ADA treatment duration were respectively 49 (±33) months and 38 (±19) months. Within patients treated with IFX, 32 patients received IFX + IS during the first semester. IFX was administrated as monotherapy in 361/478 semesters (76%). Respectively 218/478 (46%) and 78/478 (16%) with IFX required dose escalation and corticosteroids course. IFX + IS was associated with more semesters with failure (5% vs 3%, p = 0.02) and numerically more semesters with dose escalation (64% vs 28%, p = 0.06). There was no difference in corticosteroids use (p = 0.63). IS during the first semester was not associated with lower risk of IFX failure (p = 0.41) nor with a longer survival without IFX withdrawal (p = 0.20). Continuing the IS treatment beyond the first semester was not associated with fewer semesters with failure (p = 0.18). Within patients treated with ADA, 19/33 patients received IFX + IS during the first semester. ADA was administrated as monotherapy in 93/175 semesters (53%). Respectively 54/175 (48%) and 42/175 (24%) semesters were treated with IFX + IS. No significant differences were noted between patients that continued IFX + IS dose escalation or steroids without and with withdrawal of IFX + IS. IS during the first semester was not associated with fewer semesters with failure (p = 0.20).

Conclusion: In this real-life experience, combination therapy of IFX or ADA with IS during the first semester or prolonged after the first semester was not associated with less dose escalations, steroids courses or treatment failures.
RESULTS: mucosal healing (MH) at week 52. Secondary outcomes were: the rate of continuous clinical response and remission, was the rate of corticosteroid (CS) free remission (PUCAI Aims & Methods: The objective of the present study was to evaluate the effectiveness and safety of adalimumab (ADA) in children with ulcerative colitis (UC) who received previous IFX therapy (43% intolerant, 50% not-responders, 7% positive anti-IFX antibodies). Fifty-two weeks after ADA initiation 13 patients (35.3%), median HBI values significantly decreased during the study, in the whole population and in group A, whereas no change was recorded in group B (respectively, P = 0.3, P = 0.3, and P = 0.8, respectively). Moreover, despite not statistically significant difference in quality of life in both groups at T0, in group A quality of life improved after the diet compared to group B (respectively, P = 0.06, P = 0.05 and P = 1).

Conclusion: We demonstrated that a low FODMAP diet, for a limited period of 6 weeks, is able to improve both disease activity, at least for CD, and quality of life in IBD patients. Further, larger multicentre studies are needed to confirm these preliminary data.

P1069 SUBCUTANEOUS USTEKINUMAB PROVIDED CLINICAL AND BIOLOGICAL BENEFIT FOR 9/12 REFRACTORY PEDIATRIC CROHN’S DISEASE

C. Martinez-Vinson. J. Hugot, M. Belliuiche, J. Viala
Gastroentérologie Pédiatique, Hôpital Robert Debré, Paris/ France

Contact E-mail Address: christine.martinez-vinson@aphp.fr

Introduction: Ustekinumab has shown a good safety profile and efficacy to induce and maintain remission in adult patients with refractory Crohn’s Disease (CD). Data are lacking in children.

Aims & Methods: All CD patients under 18 years who received ustekinumab were included in this retrospective observational study performed in a single tertiary paediatric centre.

Results: See table.

Conclusion: Subcutaneous ustekinumab is effective to induce and maintain remission in severe pediatric CD refractory to anti-TNF antibody.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: We analyzed 107 patients with CD, with a total of 428 visits until W14. The principal reason to start infliximab was failure of immunosuppressive therapy (60%). Infliximab proved to be an effective treatment in our cohort since 75.7% (n=81) patients were responders to infliximab and 40% (n=42) were in clinical remission whereas 24.3% (n=26) were non respondents at W14. At week 14, 107 patients were divided in three groups related to the clinical activity of their disease: lack of clinical response, partial clinical response, clinical remission. It concerns respectively 26, 39 and 42 patients. Major baseline characteristics were not associated with clinical remission: sex, age at diagnosis, disease location, time between diagnosis and induction, age at induction. Drugs associated with infliximab at W0, W2, W6 or W14, whether it was immunosuppressive agents or corticoids, were not associated with remission. Patients with low albumin levels had a worse response at induction Activity score at induction was also statistically associated with clinical remission: each decreasing of 10 points of activity score at induction increase of 0.48 times the risk to obtain clinical remission. Trough residual of infliximab > 8.5 µg/ml at W6 increase of 11.3 times the risk to obtain clinical remission at W14. Lack of growth retardation at induction increased of 3.98 times the risk to obtain clinical remission at W14.

Conclusion: Infliximab measurement in combination with evaluation of clinical severity (low body weight, growth retardation, hypoalbuminemia, severe disease) appears to be a reasonable strategy for predicting both short- and long-term treatment outcomes with IFX in the initial stage of treatment. Early detection of response to IFX is critical for the management of CD, especially in acute severe patients: it seems that the infliximab trough level at week 6 (> 8.5 µg/ml) is predictive of a remission at week 14. Second, some patients, especially patients with low body weight, growth retardation, hypoalbuminemia and severe disease may require higher doses than standard doses.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** In adult Inflammatory bowel disease (IBD), skin adverse reactions have a prevalence of 1.6 to 22%. This side effect occurs more frequently in patients treated with infliximab (IFX) for IBD. Datas in the pediatric population are lacking so far.

**Aims & Methods:** All patients aged 2 to 18 years, with Crohn’s disease (CD) or Ulcerative colitis (UC) and treated for the first time by IFX between January 2002 and March 2014, were considered for inclusion in this monocentric retrospective study.

**Results:** Basline Patients: 115 patients were treated with IFX for CD and 23 for UC. IFX treatment was initiated at the age of 14, about 2 years after diagnosis. The indication for treatment was in 61.6% (n = 85) resistance to conventional therapy, in 26.8% (n = 37) a perianal fistulizing disease and in 11.6% (n = 16) a severe colitis. At the first injection, the median PCDAI was 35 (25; 45) for CD and the median PUCAI 35 (25; 45) for UC. The duration of treatment with IFX ranged from 45 days to 8 years and median was 23.9 months (11.6; 36.5). Psoriasis: 20 patients (14% of the cohort) had an IFX-induced psoriasis. 70% of them (n = 14) of patients were in remission when the psoriasis was diagnosed. Psoriasis was diagnosed at the 8th injection (6; 15), though 355 (239; 532) days after the start of biotherapy. 20% of patients had a combo therapy: 50% of them were treated by 6-mercaptopurine, 25% by azathioprine and 25% by methotrexate. The median IFX trough levels (TRI) when psoriasis occurred was 4.7 mcg/mL (1.8; 9.6) and 4.1 mcg/mL (2.1; 8.8) at the previous visit. Median Antibodies to IFX (ATI) rate was 0%. All were supported by local treatments. No patients discontinued biotherapy following the psoriasis. Personal or family history of psoriasis, and the smoking status have not been collected. We compared the psoriasis occurrence with psoriasis (n = 20) and without psoriasis (n = 127) with an univariate model. All children in the psoriasis group were followed for a CD. There was more perineal location of CD in psoriasis group with a significant difference (p = 0.003).

**Conclusion:** 14% of our IBD patients treated with IFX developed psoriasis during follow-up. All were CD, more frequently it occurred for CD with perineal lesions, at the 8th injection in median, with no ATI.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1072 PLATELET ABNORMALITIES AND ANEMIA IN PAEDIATRIC IBD: ARE THEY LINKED?**
M. Votto 1, F. Viviano 2, F. Viola 3
1Pediatría, IRCSS Policlinico San Matteo, PAVIA/Italy
2Pediatría E Neuropsichiatria Infantile, Università La Sapienza, Roma/Italy
Contact E-mail Address: marinarvotto@gmail.com

**Introduction:** Crohn’s Disease (CD) and Ulcerative Colitis (UC) are two major forms of Inflammatory Bowel Disease (IBD). In children with IBD anemia is common and is a combination of iron deficiency and anemia of chronic disease (ACD). IBD are associated with several alterations of platelets, including count, number, shape, and function.1 In clinical practice, the most common platelet alteration is thrombocytosis. In IBD, thrombocytosis is associated with iron deficiency anemia and chronic inflammation2. The importance of platelet function is not yet substantially increased incidence of thromboembolic phenom- ena in IBD3.

**Aims & Methods:** The aim of the study is to demonstrate the link between anemia, thrombocytosis and platelet aggregation in pediatric IBD patients. This study includes 51 children and adolescents recruited from the Pediatric Gastroenterology Unit of Policlinico Umberto I in Rome. Patients younger 6 years, with inherited platelet defects, hemoglobinopathies, and receiving ther- apies that alter platelet function, are excluded. We collect disease activity scores (Pediatric Crohn’s Disease Activity Index [PCDAI], Pediatric Ulcerative Colitis Activity Index [PUCAI]). The laboratory investigations include: complete blood count, mean corpuscular volume (MCV), mean platelet volume (MPV), mean corpuscular haemoglobin concentration (MCHC), levels of hemoglobin (Hb) and iron, transferrin, iron saturation, ferritin and plasma anti-TNF alpha. Diagnostic criteria for anemia are based on ECOO guidelines. Platelet aggregation is evaluated on platelet-rich plasma in an AggRAM aggregometer with Born’s Method. The results were reported as the maximal percentage of aggregation observed after 4 min stimula- tion in response to collagen (1 pg/mL) and adenosine diphosphate (ADP 0.8 pM and ADP 2 pM).

**Results:** The study include 51 children and adolescents, 24 with UC and 27 with CD. Median age is 15.3 years (±3.5). Iron deficiency anemia combined to ACD is the most common type (58.3% in UC and 50% in CD). Hemoglobin levels are significantly lower in patients with UC compared to CD patients (p = 0.0202). No significant differences are observed between mean values of red cells, MCV, MCHC, RDW, iron, transferrin and serum ferritin both in CD and UC. Thrombocytosis prevails in UC compared to CD patients, but no significant correlation was found. No differences are observed between mean values of PDW and MPV in both groups.In patients with UC, a negative correlation was found between mean values of hemoglobin and platelet count (p = 0.0314). Moreover in patients with CD, disease activity was positively correlated with platelet count (p = 0.0040). Platelet aggregation results higher in anemic patients. In anemic children, mean baseline platelet aggregations - induced by ADP 0.8 pM and collagen 1 pg/mL - are significantly higher in UC compared to CD (p = 0.001 and p = 0.030 respectively). Another significant correlation is observed between platelet aggregation - induced by ADP 0.8 pM and ADP 2 pM - in anemic UC patients compared to non-anemic UC patients (p = 0.002 and p = 0.040 respectively). Platelet aggregation - induced by ADP 0.8 pM is sig- nificantly higher in anemic UC patients with active disease (PUCAI > 20) com- pared to same patients whose disease is in remission (p = 0.042) and compared to patients with active CD (p = 0.054).

**Conclusion:** In our cohort, mixed anemia (iron deficiency anemia combined to anemia of chronic disease) is the most common type of anemia. Thrombocytosis is a condition more frequent in anemic IBD patients, specially in UC. In UC, anemia and disease activity are significant correlated with platelet hyperaggrega- tion. Future studies are required to identify the mechanisms of action that could account for paradoxical adverse events in anemia and platelet dysfunction in IBD patients. Thrombocytosis and anemia could represent major risk of thrombosis, independently from acquired or inherited hemostasis defects.

P1073 RELATIONSHIP BETWEEN CLINICAL COURSE OF ULCERATIVE COLITIS (UC) DURING PREGNANCY AND OUTCOMES OF PREGNANCY: A RETROSPECTIVE EVALUATION STUDY

A. Ito, O. Teppeli, T. Katutishi
Dept. Medicine, Inst. Gastroenterology, Tokyo Womens Medical University, Tokyo/Japan

Contact E-mail Address: itoouami@ige.twmu.ac.jp

Introduction: Ulcerative colitis (UC) is a chronic, intractable disease with a long clinical course. UC has a marked influence on the lifestyle of patients, and its effects on pregnancy and childbirth especially can become a problem for women in their child-bearing years. Various studies have suggested that it is desirable for pregnant women with UC to give birth while remaining in a state of remission.

Aims & Methods: The present study evaluated pregnant women with UC attending our hospital who became pregnant during remission, in order to examine the factors that contributed to recurrence of UC during pregnancy. We investigated 40 pregnant patients in remission (44 cases) attending our hospital between January 2008 and July 2016 who had remained in remission for one year prior to pregnancy. After becoming pregnant while in remission, patients who stayed remission until delivery were classified into the ongoing remission group (35 cases) and patients with recurrence during pregnancy were classified into the recurrence group (9 cases). Remission was defined as a Lichtiger clinical activity index (CAI) of less than 4. Relapse was defined as a CAI ≥ 5 with the need for initiation or dose escalation of steroids or administration of biological agents during pregnancy, items examined: Clinical characteristics (age at onset, disease duration, age of becoming pregnant, disease type, and treatment), the CAI in the first, second, and third trimesters, and whether or not patients continued treatment during pregnancy were examined and compared between the two groups.

Results: There were significant differences between the two groups with respect to the age of becoming pregnant (32.9±4.4 years in the ongoing remission group vs. 28.3±7.0 years in the recurrence group), the CAI in the second trimester (2.9±4.6 vs. 3.5±1.6), the CAI in the third trimester (2.9±0.7 vs. 5.4±2.0), and whether oral treatment was continued (continuation of treatment [yes/no]; 30:5 in the ongoing remission group vs. 5:4 in the recurrence group). Regarding the discontinuation of oral treatment, two patients in the ongoing remission group and one patient in the recurrence group discontinued it on their own judgment, while two patients in the recurrence group discontinued it due to hyperemesis. Discussion: The present study revealed that factors influencing the recurrence of UC during pregnancy were the age of becoming pregnant, and the continuation of oral treatment. Our results showed that younger women were more susceptible to recurrence. As expected, discontinuing oral treatment was a factor that contributed to recurrence. However, the reasons for discontinuing treatment during pregnancy differed from those for non-pregnant women. Some patients discontinued treatment on their own judgment because they were concerned about adverse effects on the fetus, while others had difficulty with continuing treatment due to hyperemesis. With regard to the effects of medications on the fetus, medical staff should provide an explanation about the safety of treatment and should be aware that patients may have various concerns about drug therapy. If patients have difficulty continuing oral treatment due to severe hyperemesis, administration of local therapy should be considered.

Conclusion: During pregnancy, it is important to continue treatment for UC so that patients can give birth while remaining in remission. Accordingly, intervention by medical staff is particularly necessary in order to provide pregnant women with information and explanations regarding treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1074 USE OF STEROIDS IN ADULTS AND ADOLESCENTS WITH UC DURING PREGNANCY AND LIMITATIONS TO PREGNANCY: A NATIONAL AUDIT

Introduction: Corticosteroids have been effectively used for decades for the rapid induction of clinical remission in patients with Inflammatory Bowel Disease (IBD). However, their adverse event profile is well-known, particularly with long-term use and in younger populations, and they have no role in maintenance of remission. Steroid-sparing agents and more recently biological therapy have reduced systemic steroid use, but the incidence of steroid prescriptions especially in the outpatient setting is not known.

Aims & Methods: The aim of this study was to capture real-life steroid use in both adult and adolescent populations older than 13 years old who attend a dedicated IBD clinic in a tertiary referral centre. We tried to identify risk factors associated with appropriate or excessive steroid use in the whole cohort and in the two subgroups separately. All consecutive IBD patients who were followed up for at least one year in the adult and adolescent clinic in UCLH and attended their IBD appointment during February and March 2017 were included in the study.

A steroid assessment questionnaire was completed by the clinician during the visit for eligible patients. Use and type of steroids prescribed during the past year was recorded, as well as appropriate bone protection and disease activity based on the physician global assessment.

Results: 60 adolescents and 59 adults were included in the study. Two thirds of adolescents had Crohn’s disease while in the adult population Crohn’s and ulcerative colitis (UC) were equally distributed. 57 (95%) adolescents had been exposed to thiopurines and 47 (78%) to anti-TNFs as opposed to 69% (p = 0.002) and 39% (p < 0.001) of adults respectively. Vedolizumab exposure was similar in adults and adolescents. The percentage of patients with moderate to severe disease at last visit was comparable between two groups (80, 30%).

Conclusion: The present study revealed that factors influencing the recurrence of UC during pregnancy were the age of becoming pregnant, and the continuation of oral treatment. Our results showed that younger women were more susceptible to recurrence. As expected, discontinuing oral treatment was a factor that contributed to recurrence. However, the reasons for discontinuing treatment during pregnancy differed from those for non-pregnant women. Some patients discontinued treatment on their own judgment because they were concerned about adverse effects on the fetus, while others had difficulty with continuing treatment due to hyperemesis. With regard to the effects of medications on the fetus, medical staff should provide an explanation about the safety of treatment and should be aware that patients may have various concerns about drug therapy. If patients have difficulty continuing oral treatment due to severe hyperemesis, administration of local therapy should be considered.

Conclusion: During pregnancy, it is important to continue treatment for UC so that patients can give birth while remaining in remission. Accordingly, intervention by medical staff is particularly necessary in order to provide pregnant women with information and explanations regarding treatment.

Introduction: In patients with active ulcerative colitis (UC), myeloid lineage leucocytes are known to be elevated with activation behaviour, including the CD14+ CD16+ DR++ monocyte phenotype, which is a major source of tumour necrosis factor-α. Therefore, selective depletion of myeloid leucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adacolumn is expected to promote remission, or enhance drug efficacy. Potentially, GMA should be a relevant treatment option in patients in whom drug therapy has limitations.

Aims & Methods: Our major objective was to apply GMA as remission induction therapy in paediatrics and adolescents with UC when first-line 5-aminosulphosalazine or mesalazine had failed. Thirty consecutive patients with active ulcerative colitis (UC), age 11–19 years, body weight 33–55.5 kg were given mesalazine (n = 23) or sulphosalazine (n = 7) as the first-line medication. Twenty patients relapsed while remaining in the first-line medication. Two patients relapsed while remaining in the first-line medication. Two patients were not responders to first-line medication and received GMA with the Adacolumn, at 2 sessions in the first week, then weekly, up to 11 sessions.

Results: Patients who achieved ≥5 decrease in the clinical activity index (CAI) after 5

Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest: aminosalicylates should respond well to GMA and avoid pharmacologicals. Clinical remission and mucosal healing, while in non-responders to GMA mono-therapy, majority with mucosal healing. 3 months in those who received. Therefore, at week 12, all 30 patients were in remission, majority with mucosal healing. Additionally, GMA has a good safety profile, which is a very favourable feature in growing patients.

Disclosure of Interest: A.R. Saniabadi: Dr. Saniabadi has a non-regular employment position at JIMRO. All other authors have declared no conflicts of interest.

References

Aims & Methods: The aim of this study was to review the investigations and outcomes of IB and AILD in children with a primary diagnosis of AILD and to identify possible risk factors for development of IB in children with AILD. Children with AILD were identified from electronic case notes between 2007 and 2010 and those with a diagnosis of IB prior to AILD excluded. AILD was diagnosed and treated as per centre protocol. Diagnostic endoscopy for IB was performed, based on GI symptoms and/or elevated FC (>60μg/g). Data were described at time of liver diagnosis; endoscopy and last liver follow up. Patients were classified as AILD-IBD or AILD. Mann Whitney and Chi squared test were used to analyse data where appropriate, significance p < 0.05.

Results: Of 37 (12 male) children, diagnosed with AILD (ASC 11), 23 underwent diagnostic endoscopy after a median time from diagnosis of 27.6 [20.1 to 53.9] weeks. 20/23 reported GI symptoms and FC was elevated in 13/18 tested.

Conclusion: In our cohort 35% of children presenting with AILD were subsequently diagnosed with IB. Possible risk factors for development of IB in AILD are low haemoglobin, being leaner and younger at diagnosis. An elevated FC and the presence of GI symptoms are useful to assess the need for diagnostic endoscopy when considering diagnosis of IB in the context of AILD. As current immunosuppression may mask mild features and signs of IB a lower threshold for endoscopy should be considered in these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Comparison of clinical and laboratory findings in AILD and AILD-IBD groups.
Results: Twenty-one patients with chronic refractory angiodysplasia bleeding were recruited in this study, included 10 women, aged between 40–85;11 cases of male, aged between 31–70. One patient with colic vascular malformation died of massive hemorrhage due to self-withdrawal. Among the remaining 20 patients who were given thalidomide regularly for 6 months. (1). Eight patients come across constipation, sleepiness and dry mouth. There were no skin rashes, peripheral neuropathy and any other adverse reactions during the treatment. All side-effects resolved when thalidomide was discontinued. (2). The red blood cell after treatment was increased compared with the total procedure time (P = 0.05). The ALT after treatment (32.9 ± 18.5U/L) compared with before treatment (36.3 ± 4.3 g/L) with time (P = 0.05). (4). Prothrombin time (PT) after treatment (12.1 ± 1.3s) compared with before (11.8 ± 1.4s); APTT after treatment (30.2 ± 3.7 s), compared with before (31.0 ± 2.6s); the difference was statistically significant (P > 0.05). (5). 6 cases of colonic capillary malformation review colonoscopy, and the vascular malformation improved significantly after treatment. Conclusion: Thalidomide, with its antiangiogenic mechanism of action, seems to be a promising drug in bleeding angiodysplasia as a treatment option for patients unable to benefit from other available modalities of treatment. the study drug was well tolerated.

Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. We have reported the preliminary safety results of endoscopic detachable snare ligation (EDSL), a new method for diverticular hemorrhage.1 The bleeding diverticulum was ligated with a detachable snare. Unlike the endoscopic band ligation, removal of the scope to attach a liglation device and reinsertion for treatment are not needed in this method. We performed a clinical trial to evaluate the efficacy and safety of EDSL.

Aims & Methods: This multicenter single arm phase II study was conducted in 12 Japanese institutions. Patients suspected of diverticular bleeding were enrolled from June 2015 to March 2017. Patients with serious heart, renal, or liver failure, sepsis, disseminated intravascular coagulation, and high-dose steroid use (prednisolone dosage > 10 mg/day) were excluded. The primary endpoint was the early (within 1 month) rebleeding rate in patients who were treated with EDSL.

Results: Of 123 patients with diverticular hemorrhage, 101 were treated with EDSL and the early rebleeding rate was 5% (5/101). The rebleeding rate in ITT population was 9% (11/123). Success rate of EDSL was 78% (96/123).

Conclusion: EDSL is an effective, safe, and convenient treatment method for colonic diverticular hemorrhage.

P1080 RISK FACTORS FOR EARLY AND LATE RE-BLEEDING IN PATIENTS WITH COLONIC DIVERTICULAR BLEEDING

Gastroenterology And Hepatology, St. Marianna Medical University, Kawasaki, Japan

Contact E-mail Address: ysatou@ marianna-u.ac.jp

Introduction: Incidence of colonic diverticular bleeding has increased in recent years. Colonic diverticular bleeding is problematic because of the following reasons: the low detection rate of the bleeding source by endoscopy and frequent re-bleeding. At our hospital, we have a policy of performing emergency lower gastrointestinal endoscopy for all patients with colonic diverticular bleeding within 24 h of their admission. We have reported that the following factors can contribute to the unsuccessful identification of the bleeding source: extravasation revealed by abdominal contrast computed tomography (CT), and mounting of a hood to the tip of an endoscope during lower gastrointestinal endoscopy. However, risk factors for re-bleeding in patients with colonic diverticular bleeding were still unknown.

Aims & Methods: In this study, we examined the risk factors for early and late re-bleeding in patients with colonic diverticular bleeding. From January 2004 to April 2016, we admitted 432 patients (285 men and 147 women, mean age: 71 ± 13 years) to our hospital for treatment following a diagnosis of colonic diverticular bleeding based on abdominal CT and endoscopy findings. Early and late re-bleeding was defined as macroscopically bloody stools as a result of colonic diverticular bleeding during hospitalization and after discharge, respectively. Risk factors for early and late re-bleeding were retrospectively examined using univariate and multivariate analysis.

Results: Early re-bleeding occurred in 112 patients (26%; 86 men and 26 women, mean age: 71 ± 12 years). The mean duration until re-bleeding was 3.9 ± 2.4 days, and the average, early re-bleeding occurred 1.7 ± 1.2 times. On average, lower gastrointestinal endoscopy was performed 2.7 ± 1.2 times and endoscopic hemostatic treatment was performed 1.0 ± 1.0 times. In the univariate analysis, significant differences were seen in males (P = 0.005), in the use of oral antplatelet agents (P = 0.012), and in patients not undergoing endoscopic hemostasis (P = 0.004). In the multivariate analysis, male gender (P = 0.006; odds ratio 2.06, 95%CI 1.23–3.44), the use of oral antplatelet agents (P = 0.008; odds ratio 1.85, 95%CI 1.17–2.93), and patients not undergoing endoscopic hemostasis (P = 0.005; odds ratio 1.5, 95%CI 0.31–0.81) were independent risk factors for early re-bleeding. Late re-bleeding was seen in 72 of 345 patients who were able to follow up (21%; 46 men and 26 women, mean age: 73 ± 12 years). The mean duration until late re-bleeding was 41 ± 40 months, and on average, late re-bleeding recurred 1.5 ± 1.2 times. Only the use of oral antplatelet agents (P = 0.05; odds ratio 1.72, 95%CI 0.98–2.98) was identified as an independent risk factor for late re-bleeding in the univariate and multivariate analysis.

Conclusion: Not undergoing endoscopic hemostasis and male gender were identified as risk factors for early re-bleeding, indicating the importance of choosing measures and hemostatic treatments to improve the detection rate of bleeding sources during endoscopy. The use of oral antplatelet agents was a risk factor for both early and late re-bleeding, suggesting the need for patient management through multi-departmental cooperation.

P1081 ACUTE LOWER GASTROINTESTINAL BLEEDING–IS NOBLADS THE ANSWER?

S. Xavier1, J. Magalhães2, J. Cotter3

1Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga/Portugal
2Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Guimarães/Portugal
3Pt Government Associate Laboratory, 4 ICVS/3B’s, Braga/Guimarães/Portugal

Contact E-mail Address: smaxavier@gmail.com

Introduction: Acute lower gastrointestinal bleeding (ALGIB) constitutes an important gastroenterological emergency. A new score (NOBLADS) that intends to determine the risk of severe ALGIB was recently developed. We aimed to assess the validity of this score in a cohort of patients with ALGIB.

Aims & Methods: Retrospective study. Emergency consecutive admissions for ALGIB were reviewed. Severe ALGIB was defined as transfusion of ≥2 units of packed red blood cells (PRBC) and/or hematocrit decrease of ≥20% within the first 24 h and/or recurrent bleeding after 24 h of stability. NOBLADS score was calculated and its discriminative capacity for severe ALGIB as well as for overall outcomes was assessed.

Results: Included 118 patients with a mean age of 73±14.4 years and 52.5% males. Most frequent etiologies for ALGIB were diverticular bleeding (23.7%) and post-polypectomy (21.2%). ALGIB was severe in 38.1% of patients. NOBLADS score showed a weak discriminative capacity to determine severe ALGIB (AUC = 0.68, p < 0.01). However, when comparing patients with NOBLADS <4 and ≥4, patients with higher scores were significantly older (69.2±15.7 years vs 78.6±10.0 years, p < 0.01), had lower hemoglobin levels as admission (11.8±2.5 g/dL vs 10.2±2.5 g/dL, p < 0.01), were transfused with more units of PRBCs during the first 24 h and during hospital in-stay (0.4±0.9 vs 1.1±1.3, p < 0.01 and 1.0±2.2 vs 3.0±3.3, p < 0.01, respectively) and were more frequently admitted to intermediate care units (35.2% vs 59.6%, p < 0.01). No differences were found between the two groups regarding in-stay length, rebleeding rate, need for surgery or death.

Conclusion: NOBLADS score showed a weak discriminative capacity to determine severe ALGIB however, patients with NOBLADS ≥4 had greater PRBCs transfusion need and were more frequently admitted to intermediate care units. New or improved scores that can predict severe ALGIB are needed to determine more precisely appropriate care and to allow for a standardized approach.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In Japan, CRC screening was launched as a national policy for all ages over 40 years ago. It is demanded that CRC screening have been performed with the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer with cut-off value of 20 µg Hb/g stool. Between 2011 and 2014, 957 CRCs and 12,290 polyps were detected. 957 CRCs were detected with 3,421 cases from the screening (2000–2014) with 2-day FIT. The concentration of FIT was grouped in 20–80, 80–140, 140–200 and over 200 µg Hb/g stool. Screening have been performed with the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer. CRCs were analyzed with age group (40–49, 50–59, 60–69, over 70 year-old), size (1–24, 25–49, over 50 mm), location (proximal, distal), Dukes’ classification (Dukes A, D, invasive, B, C, D) depending on the concentration. The chi-squared test was used to compare of each group.

Results: There was no difference in gender and age group for concentration. The concentration of CRCs in the distal colon was significantly higher in the proximal colon [distal 39% (861/2,200) and proximal 32% (337/1,053) with over 200 µg Hb/g stool]. The concentration of CRCs with larger size was significantly higher than smaller size [1–24 mm 27% (533/1,961), 25–49 mm 54% (439/819) and over 50 mm 64% (169/263) with over 200 µg Hb/g stool]. The concentration of invasive CRCs was significantly higher than in-tramural CRCs [intra-mucosal 23% (370/1,617) and invasive 50% (888/1,793) with over 200 µg Hb/g stool]. The concentration of Dukes B, C and D were significantly higher than Dukes A except for intra-mucosal. There was no difference between Dukes B and D [Dukes A except for intra-mucosal 36% (325/910), B 68% (247/363), C 60% (232/385) and D 69% (61/89) with over 200 µg Hb/g stool].

Table 1: Fecal Hb concentration and progress of colorectal cancer

</table>

Conclusion: In 20–80 µg Hb/g stool, there were CRCs with smaller size, no invasion, in the proximal colon, Dukes A except for intra mucosal CRCs and so on. When the cut off value is raised over 80 µg Hb/g stool, the detection of early stage CRCs and proximal CRCs may be lost. There were many advanced CRCs with concentration over 200 µg Hb/g stool. Therefore, when the participants, who are positive with high concentration of FIT, need to take a further examination as soon as possible. Why concentration of CRCs can be lost in the proximal colon? It may be related to the fact that the number of detectable CRCs in the distal colon are more than in the distal colon. We will go on researching mechanism about this.

P1084 COLONOSCOPY SURVEILLANCE DETECTS A HIGH PREVALENCE OF ADVANCED COLORECTAL NEOPLASIA AND SERRATED POLYPOSIS SYNDROME IN HODGKIN LYMPHOMA SURVIVORS

L. S. Rigter1, M.C.W. Spaander2, B. M. Aleman3, T.M. Bissingel4

1Gastroenterology & Hepatology, Eramus Medical Center Rotterdam, Rotterdam/Netherlands
2Radiation Oncology, Netherlands Cancer Institute, Amsterdam/Netherlands
3Dept. Of Gastroenterology & Hepatology, Radboud University Medical Centre, Nijmegen/Netherlands
4Gastroenterology And Hepatology, University Medical Center Utrecht, Utrecht/Netherlands

Introduction: A colonoscopy was performed in 101 HL survivors, who were signifi-
cantly younger than the general population cohort that underwent a pri-
mary colonoscopy among HL survivors treated with abdominal radiotherapy
and/or alkylating chemotherapy have an increased risk of colorectal
neoplasia was detected per HL survivor (standard deviation 4.9) vs. 1.1
in the Dutch general population cohort that underwent a prede-
finite interim analysis. Results: A colonoscopy was performed in 101 HL survivors, who were signifi-
cantly younger than general population controls (median 51 years (interquartile range 45–57) vs. 60 years (interquartile range 55–65), p< 0.001). A mean of 3.5 neoplastic lesions was detected per HL survivor (standard deviation 4.9) vs. 1.1 per control (standard deviation 1.8, p < 0.001). Despite their young age, the
prevalence of advanced neoplasia was higher in HL survivors than in controls
(25% (95% confidence interval 16–33%) vs. 12% (10–14%), p < 0.001). Advanced adenomatous polyps were detected in 14% (8–21%) of HL survivors and 9% of controls (7–17%, p = 0.001). The prevalence of advanced hormone
dependent prostate cancer was higher in HL survivors than in controls (12% (6–18%) vs. 4% (3–5%), p < 0.001). Serrated polyposis syndrome was present in 6% (2–11%) of HL survivors and 2% (0–7%) of controls (p < 0.001).

Conclusion: HL survivors treated with abdominal radiotherapy and/or procarba-
zine have a high prevalence of advanced colorectal neoplasia. Colonoscopy sur-
veillance should therefore be implemented as standard of care.

Aims & Methods: We aim to investigate the incidence of prostate cancer as a
second primary malignancy among patients with prior primary colorectal cancer
(CRC) using a nationwide population-based dataset. This study is a nationwide
population-based retrospective cohort study. We followed up with patients
registered in the Republic of Korea National Health Insurance Corporation
who were diagnosed with colorectal cancer between 2007 and 2014 and investigated
the incidence of prostate cancer (one year lag period). The incidence of prostate
cancer was also evaluated in age and gender-matched controls using a cohort of
patients diagnosed with colorectal cancer during the same period. The incidence
rate for prostate cancer was defined as the number of newly diagnosed prostate cancer patients
to 1000 person-years. To assess the role of detection bias-related to the follow-
up of CRC, follow-up started at the date of CRC diagnosis and continued until
the earliest date of prostate cancer diagnosis, death, loss to follow-up, or the 2015
year-end. We used Cox proportional hazards models to identify prostate
occurrences among CRC patients. We also performed the multivariable analysis.
Multivariable models included the variables of age, sex, body mass index, hyper-
tension, diabetes mellitus, dyslipidemia, and income.

Results: We analyzed a total of 85,462 primary CRC survivors. During the
follow-up period of 494,222 person-years, 2005 (2.3%) developed prostate cancer
(incidence rate 4.06/1,000 person-years). The median duration of follow-up was
5.78 years. Compared with the general population, CRC patients had a significantly
increased risk of primary prostate cancer (HR = 2.30, 95% CI = 1.82–2.426; P < 0.001).

Conclusion: Men who develop colorectal cancer are at an increased risk of pros-
tate cancer, with the greatest risk in men under the age of 55. This data suggests
that CRC patients under 55 years old require regular screening for prostate cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1086 SITE AND STAGE DISTRIBUTION OF SCREEN DETECTED AND CLINICALLY DETECTED COLORECTAL CANCERS IN THE NETHERLANDS

E. Toes-Zoutendijk1, A. Kooyker1, M. A. Elferink2, V. Lemmens2, M. E. Van Leerdam3, I. Lansdorp-Vogelaar4

1University Medical Center Rotterdam, Rotterdam/Netherlands
2Netherlands Comprehensive Cancer Organization, Utrecht/Netherlands
3Dept. Of Gastroenterology, Netherlands Cancer Institute, Amsterdam/Netherlands
4Department Of Public Health, Erasmus University Medical Center, Rotterdam/Netherlands

Disclosure of Interest: e.toes-zoutendijk@erasmusmc.nl

Introduction: To reduce the burden of colorectal cancer (CRC) mortality, screen-
ing has been introduced. Screening can be beneficial if cancers are detected in an
earlier stage or in a pre-malignant stage, as survival rates of these patients will
improve.

Aims & Methods: In this study stage distribution of screen detected CRCs were
compared with clinically detected CRCs in the Netherlands. All CRCs detected
in men and women aged 55 to 75 years in the Netherlands in 2015 were included
in the analysis. Data were gathered from the Dutch Cancer Registry. The current
analysis is based on 70% of these cancers that had staging information
available at initial data retrieval. Data will be updated in May 2017.

Results: A total of 6,517 CRCs in 2015 with staging information were
available for the preliminary analysis. Of those, 2,591 (39.8%) were diagnosed as a result of
CRC screening (screen detected), 3,463 (53.1%) presented with symptoms
and were detected clinically (clinically detected), 118 (1.8%) were detected during surveill-
colonoscopy (203 (3.1%) as coincidental finding and of 143 (2.2%) the method of detection
was unknown. Screen detected cancers were more often diagnosed in an earlier stage (stage I and II) compared with clinically detected cancers, 1,687 (66.5%) and
1,115 (95.8%) respectively (p < 0.001). Screen detected cancers were more often
diagnosed in the left side of the colon compared with clinically detected cancers,
46.2% vs 31.5% (p < 0.001). Comparison of stage by location distribution showed that left sided cancers were most often diagnosed in an early disease stage
to 59.0% of the CRCs in stage I or II, followed by the right sided cancers
with 52.8% of the CRCs in stage I or II. The CRCs of the rectum were most
often diagnosed in a late disease stage, only 39.4% in stage I or II. Table 1 shows the
comparison of stage by location distribution by location and method of detection.
With screening detected cancers, 68.8% of the right sided cancers, 71.0% of the left sided cancers,
and 56.5% of the rectum CRCs were diagnosed in an early disease stage (stage I and II) which was all higher than clinically detected cancers (p < 0.001).

2Pathology, Université Félix Houphouet-Boigny, Abidjan/Côte d’Ivoire

Contact E-mail Address: lucie.bienfait@erasme.ulb.ac.be

Introduction: According to European and American series,1,2 up to 20% of colorectal cancers are characterised by instability at microsatellite sites and have deleterious mutations in mismatch repair (MMR) genes (MLH1, MSH2, MSH6 and PMS2) or hypermethylation of the MLH1 promoter gene. MMR deficient colorectal cancers are predominantly found in the right colon. Although an increasing rate of colorectal cancer has been observed in many low- and middle-income countries including in West Africa,3 data on epidemiology and biology of colorectal cancer in native Africans from this region are scarce.

Aims & Methods: We aimed to study the incidence of MMR deficiency in Ivory Coast and to compare the data with those from a tertiary center in Belgium. Immunohistochemistry for MLH1, MSH2, MSH6 and PMS2 was performed on paraffin-embedded tissue samples from 83 colorectal cancers (54% males) operated in Abidjan and from 343 colorectal cancers (48% males) from Erasme University Hospital in Brussels. Immunohistochemical staining was interpreted as normal or loss of expression.

Results: Colorectal cancer is occurring at a younger age in Ivory Coast compared to Belgium (median age: 53 vs. 66). In both populations, MMR deficiency was detected in 13% of cases (11 and 43 cases, respectively). Whereas MMR deficient cancers in Brussels were mainly found in women (26:43 i.e. 61%) and with loss of the predominant location of MMR deficient tumours was different between both series: in the Brussels patients group, MMR deficient tumours were mainly located in the right colon (33:43 i.e. 77%) whereas in the Abidjan group they were predominant (10:11 i.e. 91%) in the left colon. With regard to the involved proteins, 6:11 (55%) of the MMR deficient cases from Ivory Coast were characterised by loss of expression of MSH2 and MSH6 whereas this immunohistochemical staining pattern was observed in only 9:43 (20%) cases from Belgium.

Conclusion: Our pilot study reveals marked differences in presentation of MMR deficient colorectal cancer between the two geographic regions. In contrast to Europe, MMR deficient colorectal cancer in Ivory Coast is mainly found in male patients and in the left colon. Moreover, there are differences with regard to the involved mismatch repair proteins. Together with the younger age at presentation, these data suggest differences in epidemiology and biology of colorectal cancer in native Africans from West Africa compared to the European population.

P1088 ROUTINE MOLECULAR ANALYSIS FOR LYNCH SYNDROME IN PATIENTS WITH ADVANCED ADENOMA OR COLORECTAL CANCER WITHIN A NATIONAL SCREENING PROGRAM FOR COLORECTAL CANCER

A. Goverde1, W. Nm Djineng2, M.J. Brun1, R.M.W. Hofstra1, M. Doukas2, M. M. Van Der Weiden1, H.J. Dubbink1, A. Wagner1, M.C.W. Spaander1

Contact E-mail Address: a.goverde.1@erasmusmc.nl

Introduction: Lynch syndrome (LS) is the most common hereditary cause of colorectal cancer (CRC). Identifying LS carriers and their affected family members is of great importance for prevention of CRC. Routine screening for LS by immunohistochemical staining (IHC) in CRC patients ≤70 years of age is recommended. LS screening in adenoma patients could yield more benefit, since CRC can still be prevented in these patients. A small number of participants of the national CRC screening program is expected to have LS. We aimed to assess the diagnostic yield of IHC for LS in patients with advanced and multiple adenomas or CRC within the Dutch national fecal immunochromic test (FIT)-based CRC screening program.

Aims & Methods: We included participants of the national CRC screening program, referred to our center after a positive FIT from December 2013 to December 2016. IHC for MLH1, MSH2, MSH6 and PMS2 protein was performed on advanced adenomas and CRCs found at colonoscopy. Adenomas were considered advanced if they had a villous component, high-grade dysplasia or were ≥10 mm in size. Also, in cases with ≥2 non-advanced adenomas, IHC was performed on the largest adenoma. MLH1 hypermethylation analysis was performed in cases with concurrent LS gene mutation for germline mutation analysis. If no pathogenic mutation was found, we performed somatic mutation analysis.

Results: A total of 1006 patients (54% male; mean age of 67 years (±6 years)) with positive FIT were included in the study. At colonoscopy, 355 (35%) patients (63% male; mean age of 67 years (±6 years)) had a CRC and/or adenoma eligible for IHC. A total of 322 adenoma patients were analyzed. None had aberrant IHC. Seven cases with IHC for LS were referred for genetic counselling. Both patients had no family history suspect for LS. In both cases no germline MLH1 mutation was found and somatic mutation analysis showed that both had a likely sporadic tumour.

Conclusion: Our results indicate that routine LS screening by IHC and MLH1 hypermethylation in patients with advanced and multiple adenoma within a national FIT-based screening CRC program is not an effective strategy. The diagnostic yield of LS screening in younger adenoma patients should be assessed.

Introduction: Colorectal cancer (CRC) is a leading cause of cancer mortality in the Veneto Region (North-eastern part of Italy). Population screening of adults between 50 and 75 for CRC was begun in 2002, and it became standard practice in all the local health units (LHU) of the region in 2008. LHU provided also follow-up colonoscopies and 7 LHU no. The current retrospective cohort study was carried out to evaluate the impact of CRC screening on the rate of surgical oncology procedures to treat colon and rectal cancer.

Aims & Methods: Data from hospital discharge records (HDR) regarding CRC patients hospitalized between 2000 and 2015 were collected. All CRC patients whose principal diagnosis was colon and/or rectal cancer were included in the study. The number of patients studied rose approximately 18% reaching 1,547,097 for the last year (2015). The Standardized Hospitalization Ratio (SHR) using five-year age groupings was calculated and expressed per 10,000 population.

Results: During the study period, 30,399 surgical procedures for colorectal cancer were performed (colon 63%, rectum 36%, secondary malignant neoplasm 1%) with a SHR of 139.1; the number was higher in males (1.69 vs. 1.02; OR: 1.66; CI 95%: 1.62–1.7; p < 0.05). An analysis of the annual SHR distribution uncovered two distinct phases: during the first phase there was a rising tendency that reached its maximum value in 2007 (166.9; X2 trend: 46.73; p < 0.05) and during the second there was a falling tendency that reached its minimum value in 2015 (102.3; X2 trend: 429.791; p < 0.05). An analysis of the annual SHR distribution uncovered two distinct phases: during the first phase there was a rising tendency that reached its maximum value in 2007 (166.9; X2 trend: 46.73; p < 0.05) and during the second there was a falling tendency that reached its minimum value in 2015 (102.3; X2 trend: 429.791; p < 0.05). When the cancer sites were analysed, it was seen that despite the peak in 2007, the rate of surgical procedures of the proximal colon during the last year was the same as the 2000 value (41.3); there was, instead, a relevant decrease in the rate of procedures on the distal colon and rectum which fell from 94.2 to 59.2 (–37.5%). The study also shows that there was no significant difference in the reduction in surgical procedures for CRC in LHU in which the screening program included a follow-up colonoscopy (SHR 2015: 139.8; –29% with respect to those centers where it was not forseen (SHR 2015: 138.5; –28%).

P1090 ETHNIC VARIATION IN ADENOMA DETECTION IN THE UK FLEXIBLE SIGMOIDOSCOPY BOWEL CANCER SCREENING PROGRAMME

D. N.F. Lim, S. Mellor, S. Szrervas-Jones, D. Boots, H. Whitney, B. Miri, A. Maptye, P. Wurm, R. J. Robinson
Digestive Diseases Centre, University Hospital of Leicester NHS Trust, Leicester/United Kingdom

Contact E-mail Address: dennis.lim@uhl.nhs.uk

Introduction: The NHS bowel scope screening programme was introduced in 2013 with all adults aged 55 invited for a ‘one-off’ flexible sigmoidoscopy over a period of 2 years. Sigmoidoscopy is followed by colonoscopy if significant adenomas are found in order to reduce the risk of colorectal cancer (CRC). The Cancer Research United Kingdom database was cross referenced with the endoscopic and histology findings from 4287 patients undergoing flexible sigmoidoscopy over the period of the study. The aims of the study was to evaluate the polyp detection rate (PDR), adenoma detection rate (ADR) and cancer detection rate (CDR) in British Asian Indians compared with British Whites.

Methods: A total of 4287 patients underwent sigmoidoscopy over the 2-year period. 1169 individuals had polyps (50%).

Results: 4287 patients underwent sigmoidoscopy over the 2-year period. 1169 individuals had polyps (50%). The highest PDR was 30.8%, 20.1% for SSA/P, and 11.7% for HLS. The highest ADR was 12.0%, 8.6% for SSA/P, and 4.7% for HLS. The highest CDR was 0.9%, 0.3% for SSA/P, and 1.5% for HLS.

Conclusion: This study found no cancers and significantly lower PDR and ADR in British Asian Indians compared with British Whites. The study suggested that sigmoidoscopy screening in Asian Indians may be lower than in White population and hence may need to be targeted towards the Asian Indian community.

P1091 DEAD BOX POLYPEPTIDE 27 PROMOTES TUMORIGENICITY IN COLORECTAL CANCER THROUGH ACTIVATING NUCLEAR FACTOR KAPPA B PATHWAY AND ITS EXPRESSION IS ASSOCIATED WITH POOR SURVIVAL IN PATIENTS

H. Chen1, J. Tang2, C.C. Wong1, J. Fang3, J.J.Y. Sung1, J. Yu7
1Institute Of Digestive Disease And Department Of Medicine And Therapeutics, State Key Laboratory Of Digestive Disease, The Chinese University of Hong Kong, Hong Kong/Hong Kong Pre; 2Division Of Gastroenterology And Hepatology, Shanghai Institute Of Digestive Disease, Ren Ji Hospital, Shanghai Jiao Tong University, Shanghai/China

Introduction: We identified for the first time that DDX27 (DEAD box polypeptide 27) gene was amplified in colorectal cancer (CRC) by whole genome sequencing. Amplification of DDX27 was detected in 47% (47/100) of primary CRC tumors and positively correlated with its mRNA overexpression. DDX27 plays a pivotal oncogenic role in colorectal carcinogenesis by promoting cell proliferation and inhibiting apoptosis. In this study, we investigated its function, mechanism and biological implication in CRC.

Aims & Methods: Downstream effectors and pathways of DDX27 were identified by promoter luciferase reporter assay, RT-Profiler PCR array and western blot. The interacting partners of DDX27 were screened by BioID method and further validated using immunoprecipitation assay and immunofluorescence staining method. Clinical implication of DDX27 was assessed in two human CRC cohorts by quantitative PCR method and immunohistochemical staining of tissue microarrays.

Results: Promoter luciferase reporter assays revealed that DDX27 mainly activated nuclear factor kappa B (NF-kB) pathway in CRC cell lines (HTC116 and SW480). Ectopic expression of DDX27 promoted transcription of NF-kB signal- ing targets including BCL2A1, BIRC3, CCL20, CXCL13, NFKBIA, TNF and TNAFIP3. Conversely, silencing of DDX27 showed an opposite effect on NF-kB signaling. Treatment of NF-kB inhibitors CAPE and JSH-23 abolished the pro- moting effect of DDX27 on CRC cells growth. We revealed that DDX27 enhanced and prolonged NF-kB signaling via reducing the accumulation of nuclear IκBα, which negatively regulates transcriptional activities of NF-kB and transport NF-kB proteins back to the cytoplasm. DDX27 overexpression markedly increased the recruitment of NF-kB p65 inside nucleus and promoted NF-kB activity in CRC cells under TNF-α stimulation. NPM1 was identified as a potential binding partner of DDX27 by BioID method to screen for protein-protein interactions. The interaction of NPM1 and DDX27 inside nucleus was further validated by endogenous immunoprecipitation assay and immunofluorescence staining. Knockdown of NPM1 abrogated DDX27-activating NF-kB signaling, as well as its tumor-promoting function. Kaplan-Meier curves showed that higher DDX27 expression was significantly associated with shortened survival in patients with CRC of two independent cohorts (N = 199 for Beijing cohort using quantitative PCR method, and N = 275 for Shanghai cohort using immunohistochemical staining of tissue microarrays; both P < 0.05).

Conclusion: DDX27 plays an important oncogenic role in promoting CRC tumorigenicity via activation of NF-kB pathway. Higher expression of DDX27 is correlated with poor prognosis in CRC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
significant differences between serrated lesions, SSA/Ps and HPs were positive for MUC5AC in comparison with TSAs. We performed immunohistochemistry on intestines from APCfl/fl mice, and expression correlates with resistance against carcinogenesis. The azoxymethane (AOM) induced colon carcinogenesis mouse model was used. Colonic mucosal samples were collected from wild type (WT) C57bl/6 mice and C57BL/6 mice that either underwent colonic biopsies or irradiation of the intestine. In TLR4KO mice sacrificed at 8 months, 1.4 polyps/mouse were significantly different from WT (p = 0.002, p = 0.001, respectively). Similarly, at 8 months the rate of epithelial cells expressing CD80 or MHC-I or MHC-II were significantly lower in TLR4KO than in WT mice (p = 0.001, p = 0.01, respectively). Moreover, at 8 months, 5/7 TLR4KO mice compared to 0/7 WT ones had at least a colonic adenocarcinoma (p = 0.02). At this time point, CD4+CD25−, CD4+CD25+FoxP3+, CD8+CD28+, CD8+CD38+ cells rate was significantly lower in TLR4KO mice than in WT ones (p < 0.001, p = 0.01, respectively). Similarly, at 8 months the rate of epithelial cells expressing MHC-I and MHC-II were significantly lower in TLR4KO than in WT mice (p = 0.01, p < 0.001, respectively).

Conclusion: TLR4 deficiency significantly accelerate the progression of colonic carcinogenesis through a progressive decline of antigen presentation and lack of co-stimulation at later stages. These impairments are associated to a decline of T cell response in all its form (Treg, T helper and cytotoxic). All these findings are coherent with a pivotal role of TLR4 in the immune surveillance mechanism.

Introduction: Less than a hundred polyps defines attenuated familial adenomatous polyposis (AFAP). APC or MUTYH involvement has been described in 60% of the cases. The natural history of AFAP without identified genetic defects is not enough evaluated. In our study we compare clinical and endoscopic features of polyposis in patients carrying APC or MUTYH mutation and wild type patients.

Aims & Method: 102 cases (35 F, 67 M; mean age 51; range 28–79) of AFAPs were registered at our Institution between 1996 and 2014. They had no family history and presented more than 10 adenomas at index colonoscopy. Genetic testing for APC and MUTYH genes was performed. Patients were put in a program, after having cleaned the colon, consisting in colonoscopy after one year and then the colonoscopic interval was based on the number of polyps from 1 to 3 years. Odds Ratio test was used to compare APC or MUTYH mutated and wild-type patients.

Results: Out of 102 patients with AFAP we identified a genetic defect in 36 patients (35.3%; 12 with APC and 24 MUTYH) and 66 (64.7%) were wild-type. The mean endoscopic follow up was 10 years (2–31) in the mutated group and 6 years (2–23) in the wild-type group. Table 1 describes endoscopic and clinical features between the two groups. We observed some statistically differences between groups: the mutated group was younger than 50 years of age and a higher number of polyps, right colon was mainly involved and endoscopic follow-up was mostly every year. Patients of wild-type group never underwent to colectomy during follow-up and they displayed few adenoma recurrences in 24% of cases. On the other hand 14% of mutated patients underwent colectomy for dense polyposis and 28% had more polyps than at index colonoscopy and 11% no polyps at all. These 11% displayed mutation in MUTYH.

Regarding extra-colonic manifestations we observed duodenal adenomas in 5 (13.8%) patients and desmoids tumor in one patient of mutated group. Two gastric cancers and one melanoma were diagnosed in the wild type group. We observed a different behavior between mutated and wild-type patients. Patients with genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutional genetic background could be suspected in wild-type patients when a continuous development of new polyps has observed and further genetic investigation should be offered by multi-gene testing.

Conclusion: We observed a different behavior between mutated and wild-type patients. Patients with genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutional genetic background could be suspected in wild-type patients when a continuous development of new polyps has observed and further genetic investigation should be offered by multi-gene testing.

Extracellular miRNAs are stable and its expression is less characterized in plasma. Altogether, overlapped miRNA profiles between tissue and plasma are less explored.

**Aims & Methods:** The present study was designed to characterize the tissue and circulating miRNA profile through colorectal adenoma-carcinoma sequence in human adenoma in mice peripheral blood samples. Furthermore, purpose of our study was to determine the origin of detected miRNAs in tumor-adenent C33/C57BL/6 and non-adenent CBAJ mice tumor models. To achieve that goal, human peripheral blood and biopsy of normal (N), tubular (AT), tubulovillous (TV) and colorectal adenoma (CRC) volunteered and plasma were also collected two times a week over 45 days from C33BL/6-C38, CBAJ mice. MiRNAs were isolated and Affymetrix GeneChip miRNA array analysis performed for screening of the altered miRNA profile. RT-qPCR methodology was performed for the identification of target genes.

**Results:** In the case of human samples out of 1733 detectable miRNAs, 306 miRNAs were expressed in normal, 334 in adenoma and 321 in CRC. Characteristic miRNA expression alteration was observed in the comparison of A550 CRC, VS A550 healthy samples. Whether miR-126 can regulate the process of EMT in CRC is still unclear. Ras family members include Ras, RhoA, Cdc42, and Rac1. These were first identified as oncogenes that promote tumor growth and invasion. RhoA, as molecular switch, cycles between an active state (GTP bound) and an inactive state (GDP bound) and its activity levels are influenced by numerous cellular events. Considering the above mentioned facts we wrote the RhoA activity and RhoA signaling pathway play an important role in miR-126 regulating EMT process, cell proliferation, migration and invasion of CRC cells.

**Conclusion:** RhoA signaling pathway was the key signaling pathway of miR-126 in suppressing the EMT, proliferation, migration and invasion of CRC cells. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal carcinoma is one of the leading causes of cancer-related mortality worldwide. Tumor associated macrophages (TAMs) are critical stromal components intimately involved with the progression, invasion, and metastasis of cancer cells. Recently, increasing studies have demonstrated that microRNA-126 (miR-126) had an important role in colorectal cancer. The expression of miR-126 decreased significantly in colorectal cancer, particularly in highly metastatic cell lines, indicating that miR-126 may inhibit tumor development and metastasis. However, the mechanism underlying miR126 inhibiting cancer is uncertain, and its function in cross-talk between colorectal cancer cells and TAMs are still in its infancy.

Aims & Methods: In this study, we investigate the cross-talk between cancer cells and TAMs in colorectal cancer microenvironment, and find out what role the miR=126=CXCX12=IL6 axis plays in it. Methods: (1)The effect of miR-126 on CXCX12 expression was assessed in the CRC cell line Caco2 transferred with a miR-126 mimic or inhibitor to increase or decrease miR-126 expression; (2) We build a co-culture system of TAMs and transferred cancer cells, and use AMD3100(100 ng/ml) to block CXCX12/CXCR4 axis, then detect the recruitment and inflammation factors secretion of TAMs: (3) Furthermore, the TAMs co-cultured before were taken away from the previous system and put into a new co-culture system with untreated colorectal cancer cells, and IL6 neutralizing antibody was added in. We detect the expression of EMT associated factors and STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as P < 0.05 (two-tailed).

Results: (1)miR-126 negatively regulate CXCX12 expression in post-transcript level; (2)Inhibiting miR-126 of colorectal cancer cells could promote TAMs recruitment and up-regulate inflammation factors IL1β and IL6 expression. However, blocking CXCX12/CXCR4 axis by AMD3100 could reverse this effect, vice versa;(3)Inhibiting miR-126 of colorectal cancer cells could recruiting TAMs, therefore down-regulate E-cadherin protein, up-regulate slug protein, and activate STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as P < 0.05 (two-tailed).

Conclusion: Our results reveal a novel mechanism by that miR-126 repress recruitment and inflammatory factor secretion of TAMs through controlling secretion and paracrine signaling of CXCX12 to inhibit colorectal cancer growth and metastasis.

Introduction: Narrow Band Imaging (NBI) enable detection for vascular-rich small, flat lesion and recognition of mucosal surface compared with normal colonic mucosa and vascular pattern in colonoscopy. However, recent studies revealed no significant difference in overall adenoma detection rate with the use of NBI compared with white light imaging (WLI). Blue Laser Imaging (BIL) is next-generation of image enhanced endoscopy technique using LASER light source that were realized with lighting and image processing suitable for visualization of microvessels and structures in the superficial portion of the mucous membrane.

Aims & Methods: Our aim was to determine whether the use of BIL enhances the adenoma detection rate (ADR) and miss rate compared with WLI. A total of 130 patients were enrolled screening or surveillance colonoscopy in Saga University Hospital were included. Three patients were excluded because of poor bowel preparation. One hundred and twenty-seven patients were randomized to tandem colonoscopy with BIL followed by WLI (BIL-WLI group) or WLI following BIL (WLI-BIL group). Polyp (adenoma) detection rates, miss rates, and the number of polyps (adenoma) detected person per mean adenoma detection rate) were examined between the two groups.

Results: The BIL-WL group and WL-WL group comprised 64 and 63 patients, respectively. The proportion of patients with polyps (adenoma) was 62.5% in BIL-WL group compared with 63.5% in WL-WL group. There was no significant difference between two groups regarding ADR. The number of adenomas detected per person (ADR) of BIL-WL group and WL-WL group were 2.84 and 3.01.

Conclusion: There were no significant difference in the overall polyp (adenoma) detection rate with BIL-WLI group or WL-WL group. However, miss rate was higher in WL-WL group compared with BIL-WL group (10.0% vs 1.6%, P = 0.0014). Further, BIL detected more polyps per patient compared with WL group (2.84 vs 1.90). BIL may improve polyp miss rate and the number of polyps per subject (mean adenoma detection rate) in the colonoscopy.

Conclusion: Patients with adenomas/carcinomas are older and those with proximal adenomas/carcinomas have more polyps but are smaller in size. One in three adenocarcinomas picked up during colonoscopy would be out of reach of a flexible sigmoidoscopy. Furthermore, over one third of the proximal cancers would not have distal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancers have two development theories. One of the development theories is “adenoma-adenocarcinoma sequence” developing from protruded-types “polyps” we know generally. The other is considered to emerge directly from normal epithelium, not through the adenomatous stage. Recently, it is revealed most of this type are depressed-type carcinomas. This theory is called “de novo” pathway. We studied clinicopathological characteristics and long-term prognosis mainly on depressed-type colorectal carcinomas. Aim: We analyzed the pathological characteristics of depressed-type colorectal carcinomas compared with flat- and protruded-type. A total of 2930 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to December 2011 and in total 112 cases were diagnosed as T1 carcinomas. Among these, 71 specimens were large sized 477 colorectal tumors were analyzed in this study. Morphological development classification, 244 lesions (21.7%) were depressed-type, 385 lesions (34.2%) were flat-type and 498 lesions (44.1%) were protruded-type. We analyzed the pathological features of these lesions.

Results: The rate of distant metastasis or recurrence was 0.9% (10/1127). Among these 10 cases, 5 cases were developed from depressed-type lesions and one showed a para-aortic lymph node metastasis and four showed a lung metastasis. The rate of submucosal invasion in all the lesions was 72.4% in depressed-type, 3.2% in flat-type and 2.9% in protruded-type. Within less than 5 mm in diameter, that was 10.6%, 0% and 0% respectively. Among T1 carcinomas, the rate of vessel invasion was 64.3% in depressed-type, 34.3% in flat-type and 38.4% in protruded-type. Most of poorly differentiated or mucinous adenocarcinoma was 17.2%, 10.4% and 13.5%, that of massively submucosal invasion was 94.7%, 71.7% and 67.9%, and that of tumor budding was 36.5%, 16.1% and 17.3%, respectively. The rates of these pathological factors were significantly higher in depressed-type lesions. On the other hand, the rate of adenomatous component was 4.9%, 52.2% and 50.8%, respectively. It was significantly lower in depressed-type lesions, suggesting that they emerge directly from normal epithelium, not through the adenomatous stage.

Conclusion: Depressed-type colorectal carcinomas invade massively even when they are small. They had higher risks of vascular invasion, poorly differentiated or mucinous adenocarcinomas, massive invasion and tumor budding than flat- or protruded-type. For their rapid growth and malignant potential, whether the lesion is depressed-type or not is very important in the diagnosis of colorectal carcinomas.

Introduction: Hypoxia signaling has been found to enhance cancer cell survival, chemoresistance, motility, tumour angiogenesis as well as self-renewal capacity and proliferation of putative cancer stem cells. One of the key player in hypoxia is carbonic anhydrase IX (CAIX) which is a hypoxia-inducible enzyme. CAIX is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH in hypoxia. There is also evidence that extracellular vesicle (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells and we have previously demonstrated, that CAIX positive EVs secretion is increased in response to hypoxia in colorectal cancer cells.

Aims & Methods: Within this study, we explored a possibility to use CAIX for the isolation of hypoxic EVs from colorectal cancer (CRC) patients’ plasma. EVs were isolated from plasma samples of 27 CRC patients and 25 healthy donors (HD) by using sequential centrifugation, filtration and size-exclusion chromatography steps. EVs where quantified by Nanoparticle tracking analysis (NTA) and CAIX positive EVs where determined by ApoeeaA50.

Results: Statistically significant increase in the amount and size of EVs was observed between CRC and HD cohorts based on NTA data. ApoeeaA50 data revealed that there is a tendency for the percentage of CAIX-positive EVs to increase with the stage of CRC and is higher in stage III-IV CRC patients than in HD. In addition, it is higher in patients with metastases than without distant metastases.

Conclusion: There is an increased total EV number, EV size and CAIX positive EV amount in CRC patient plasma compared to HD plasma, that might have diagnostic and prognostic value. (Financed by Latvian Council of Science and University of Helsinki.

Introduction: Recent cancer genome analyses identified extensive genetic intratumoral heterogeneity (ITH), suggesting a Big Bang model in which tumors grow in a Darwinian fashion. ITH may be a key mechanism to maintain tumorigenicity in the presence of genetic/epigenetic stress. ITH of KRAS mutations was frequently observed in colorectal cancers (CRCs), suggesting that these were founder mutations.

Aims and Methods: We aimed to clarify the association between ITH of driver mutations and clinicopathological characteristic in colorectal tumors. A total of 711 specimens from 477 colorectal tumors were analyzed in this study. The specimens were obtained from respective portions. BRAF, KRAS and TP53 mutations were analyzed by pyrosequencing and direct sequencing. Hot spot mutations of 50 cancer related genes were analyzed using the Ion PGM sequencer.

Results: ITH of KRAS and TP53 mutations was frequently observed in colorectal tumors with multiple subclones. Heterogeneity of KRAS or TP53 mutations between early and advanced subcomponents (e.g., KRAS G12D in early portion and KRAS G13D in advanced portion) progressively increased during the progression of colorectal cancer. Genetic analysis with endoscopic, clinical and histopathological data was carried out for 207 patients and 148 CRCs. 52 CRCs (35%) were considered ITH of KRAS or TP53. Up to 6 representative polyp biopsy specimens were collected and stored in a formalin-free medium and finally embedded in paraffin-blocks, followed by histopathological assessment. Targeted Next Generation Sequencing (TNGS) was performed with the extracted DNA from the paraffin-embedded tissue blocks. Up to 10000 reads were generated for each sample. Our studies revealed the existence of subclones in CRCs, and the potential of detecting them using less invasive endoscopy.

Conclusion: Our results demonstrate that the detection of ITH of KRAS/TP53 mutations is critical for the prognosis of colorectal carcinomas. Intratumoral heterogeneity in the microstructure of CRCs may represent molecular subclones in early colorectal lesions and may be predictive of the malignant progression.

Introduction: Colorectal cancer (CRC) is an important contributor to cancer mortality and morbidity worldwide. 80% of CRCs arise via the adenoma-carcinoma sequence, 10-20% CRCs by sessile serrated adenomas (SAs). Hyperplastic polyps are regarded harmless. Current surveillance strategies for CRC following polypectomy are determined by endoscopic and histopathological factors. Such a distinction has also been challenged.

Aims & Methods: The study was aimed for molecular characterization of colonic polyps in patients who underwent screening colonoscopy. Correlation of the genetic analysis with endoscopic, clinical and histopathological data was attempted to potentially better define relevant risk marker or sub-groups at risk for prediction of surveillance intervals. 100 Patients were enrolled in this study. Usually no risk patient (TNCT2552) were classified as high grade adenomas (78%; 80% of clusters). Up to 6 representative polyp biopsy specimens were collected and stored in a formalin-free medium and finally embedded in paraffin-blocks, followed by histopathological assessment. Targeted Next Generation Sequencing (TNGS) was performed with the extracted DNA from the paraffin-embedded tissue blocks. Up to 10000 reads were generated for each sample. Our studies revealed the existence of subclones in CRCs, and the potential of detecting them using less invasive endoscopy.

Results: In 100 patients, 234 polyps were removed. 121 polyps (54.0%) were sized <10 mm, 71 (31.7%) were ≥10 mm. For 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.6%) were adenomas and 110 polyps (49.1%) non-adenomatous lesions. No data were available
P1108 QUANTITY, FRAGMENT LENGTH AND GLOBAL DNA METHYLATION LEVEL ALTERATIONS OF CIRCULATING CELL-FREE DNA IN COLORECTAL ADENOMA, CANCER AND INFLAMMATORY BOWEL DISEASES

E. Marék1, A. Kalmár1, O. Galamb2, K. Szegéti2, B.K. Barták1, Z.B. Nagy1, B. Wichmann2, Z. Tulassay2, P. Igaz1, B. Molnar1

Introduction: Cell-free DNA (cfDNA) is circulating in human plasma and its amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cfDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cfDNA level can be measured in cancer patients during physical exercise.

Aims & Methods: We aimed to analyze cfDNA changes (quantity, fragment length, global DNA methylation level) in physiological conditions (during physical exercise) and in neoplastic and inflammatory colorectal diseases. Plasma was separated from 64 patients (16 colorectal carcinomas (CRC), 13 colorectal adenomas (AD), 19 inflammatory bowel disease (IBD), and 16 normal (N) donors without evidence of disease). Plasma samples were also collected from 6 healthy athletes before, during and after physical training. cfDNA amount was quantified with Qubit fluorometry (Invitrogen). CfDNA fragment length distribution was assessed by Bioanalyzer 2100 using High Sensitivity DNA assay (Agilent). Global DNA methylation was analysed by bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) (Qiagen).

Results: High cfDNA amounts were observed in plasma samples of patients with colorectal adenoma (20.61 ± 10.70 ng/ml), colorectal cancer (24.13 ± 20.02 ng/ml) and IBD (22.27 ± 14.60 ng/ml) compared to healthy subjects (10.33 ± 3.22 ng/ml). Highly elevated cfDNA amounts were found in plasma samples of patients during physical exercise (66.17 ± 29.00 ng/ml), while the cfDNA amount decreased after physical activity (51.87 ± 39.80 ng/ml).

Conclusion: cfDNA amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cfDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cfDNA level can be measured in cancer patients during physical exercise.

Introduction: A dynamic portrait of the metabolic status of living systems, has demonstrated its great potential for use in the diagnosis of various cancers by applying advanced analytic techniques and bioinformatics tools. Recently, very few metabolic markers in CRC have been consistently discovered, but metabolic profiling of patients with CRC including precancerous lesion in colorectum remains poorly understood and warrants investigation due to its non-invasive sampling method.

In this study, we investigate the differences in urine metabolic profiles between patients with colorectal neoplasia (CRN) including CRC and precancerous lesion, and healthy volunteers using a NMR-based urine metabolic study. Moreover, we evaluate applicability as diagnostic tool of urine metabolomics for early detection of precancerous colorectal lesion with high sensitivity and specificity. Urine metabolic profiles of patients with colorectal neoplasia were analyzed by NMR spectroscopy, which has several advantages including reliable degree of reproducibility, easy-to-identify metabolites, high throughput output, and non-destructive sample treatment, has not been applied to urine samples.

Aims & Methods: In this study, we investigate the differences in urine metabolic profiles between patients with colorectal neoplasia (CRN) including CRC and precancerous lesion, and healthy volunteers using a NMR-based urine metabolic study. In addition, we evaluate applicability as diagnostic tool of urine metabolomics for early detection of precancerous colorectal lesion with high sensitivity and specificity. Urine metabolic profiles of patients with colorectal neoplasia were analyzed by NMR spectroscopy, which has several advantages including reliable degree of reproducibility, easy-to-identify metabolites, high throughput output, and non-destructive sample treatment, has not been applied to urine samples.

Results: After patients underwent endoscopic resection or surgical resection for CRC, advanced adenoma has been diagnosed in 36 patients, stage O CRC in 24 patients, stage I CRC in 8 patients, stage II CRC in 7 patients, stage III CRC in 13 patients and stage IV CRC in 4 patients. CEÁ and CA 19-9 levels for patient with stage I to IV CRC and healthy control were also assessed. Among patients with CRC stage I to IV CRC, CA 19-9 were increased in 19/24 (80%) patients and healthy individuals with 9/10 (90%) respectively. The sensitivity and specificity of CA and CA 19-9 were 6.2% and 99.3%.

Conclusion: The OPLS-DA model was validated by cross-validation and the predictions model indicated statistically significant difference between pre-invasive CRC as well as advanced CRC and normal with a Q2 value of 0.71. Furthermore, the prediction validation study, the sensitivity and specificity for diagnosing pre-invasive CRC was 96.2% and 95%, respectively. The grades predicted by the PLS-DA model showed that area under the curve was 0.823 for taurine, 0.783 for alanine and 0.842 for 3-aminoisobutyrate. In multiple receiver operating characteristics curves analyses, taurine, alanine, and 3-aminoisobutyrate were good discriminator for CRC patients.

Disclosure of Interest: NMR-based urine metabolic profiles significantly and accurately discriminate between patients with pre-invasive CRC as well as CRC.
advanced CRC, and healthy control with high accuracy. It demonstrates an applicability of urinary SMRT metabolomics as screening tool for accurate diagnosis of pre-invasive CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Symptoms alone are poor predictors of underlying colorectal pathology. Only 14% of patients referred for colonoscopy from primary care have significant bowel disease (SBD), colorectal cancer (CRC), high risk adenoma (HRA, defined as ≥3 or any ≥1 cm) and inflammatory bowel disease (IBD). We have reported that undetectable faecal haemoglobin (f-Hb), measured by a faecal immunochromatographic test (FIT) is a good rule-out test for SBD.1,2 Since December 2015, GPs in Tayside have been encouraged to use FIT test as an adjunct to history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Aims & Methods: Patients in primary care with new bowel symptoms were encouraged to complete a FIT in addition to blood count and renal function check. We prospectively recorded FIT tests received, referrals to secondary care and colonoscopy findings over 1 year from December 2015 to December 2016. FIT tests were analysed by HMJACKarc (Kyowa Medex Co. Ltd., Japan) with an analytic range of <10 to >400µg Hb/g faeces. Referral rates with FIT were examined along with clinical findings at colonoscopy.

Results: 5,655 FIT tests were received. 76.2% had undetectable f-Hb, and 152 (2.7%) were untestable. 4,108 patients were referred of whom 2,338 (57%) returned a FIT. In 1,378 patients with a FIT result vetted to colonoscopy, 284 had SBD (20.6%); 86 CRC, 124 HRA and 74 IBD. 44% of patients examined along with clinical findings at colonoscopy. We prospectively recorded FIT tests received, referrals to secondary care and colonoscopy findings over 1 year from December 2015 to December 2016. FIT tests were analysed by HMJACKarc (Kyowa Medex Co. Ltd., Japan) with an analytic range of <10 to >400µg Hb/g faeces. Referral rates with FIT were examined along with clinical findings at colonoscopy.

Conclusion: A FIT test is an essential adjunct to the history, examination and blood tests in the assessment of bowel symptoms. Undetectable f-Hb is reassuring Primary Care that SBD is unlikely and referrals to secondary care have reduced. At colonoscopy, yield of SBD has increased and is high in those with detectable f-Hb. Excluding patients with co-existing anaemia or diarrhoea, an undetectable f-Hb is a good rule-out test and will miss only 5% of all SBD. Furthermore, f-Hb concentration could aid triage irrespective of symptoms.

3Department Of Pathology, Jikei University School of Medicine, Tokyo/Japan

Contact E-mail Address: ichimotanny14@yahoo.co.jp

Introduction: Most T1 colorectal cancers (CRCs) undergo surgical colectomy in western countries with established clinical guidelines despite the low incidence (approximately 10%) of lymph node metastasis (LNM). Therefore, many patients without LNM undergo unnecessary surgeries.

Aims & Methods: To reduce unnecessary surgeries, we aimed to predict the risk of LNM in T1 CRCs by using artificial intelligence (AI). Data on 690 consecutive patients with T1 CRCs who had undergone colectomy between April 2001 and March 2016 were retrospectively analyzed. Data of a randomly selected 590 patients were used for machine learning for the AI model, which analyzed five clinicopathological factors: tumor location, lymphatic invasion, vascular invasion, tumor budding and histological invasion. The remaining 100 patients served as a test set for validating the AI model and output the predicted LNM as positive or negative. To validate the AI model, sensitivity, specificity and
accuracy and calculated and compared with American, European and Japanese guidelines (1–5).

**Results:** Sensitivity was 100% (95% CI, 56%–100%) in all models. Specificity and accuracy of the AI model, American, European and Japanese guidelines were 68% (58%–78%) vs. 45% (35%–56%) vs. 12% (6%–21%) vs. 8% (3%–13%) and 71% (61%–80%) vs. 50% (40%–60%) vs. 20% (13%–29%) vs. 16% (9%–25%), respectively. The rate of unnecessary surgeries of the AI model was calculated as 29% in comparison with American 50% (P = 0.004, odds ratio [OR] 2), European 80% (P = 0.001, OR 10), and Japanese 84% (P = 0.001, OR 13).

Conclusively removing unnecessary surgeries compared with current guidelines while providing high sensitivity. AI will help in making decisions as to whether additional surgery is indicated after endoscopic resection of T1 CRCs. Grant support: Grants-in-Aid for Scientific Research (Number 17K1972) from the Japan Society for the Promotion of Science.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

3.65% were superficial submucosal carcinomas (<1000μm). During UEMR, two cases (both using AUTOCUT mode) of spurting bleeding were observed (4.45%). Hemostasis was easily achieved in both cases by dipping. No patient required blood transfusion. One patient had abdominal pain on the day after resection without signs of pneumatoperitoneum on CT scan. There was no perforation or delayed bleeding.

Conclusion: This study supports the existing data indicating acceptable rates of technical success and low incidence of adverse events with UEMR. The results of this study without cup were similar with the previous ones using cup. Further comparative studies with and without cup, using different settings and especially between UEMR and traditional EMR are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1117 ADENOMA DETECTION RATE INFLUENCES RISK PREDICTION OF METACHRONOUS ADVANCED COLORECTAL NEOPLASIA IN LOW-RISK PATIENTS

Contact E-mail Address: ileanaelona@hanmail.net

Introduction: Current guidelines recommend surveillance colonoscopy after 10 years or surveillance in 5-10 years in individuals with no or 1-2 non-advanced adenomas.

Aims & Methods: We hypothesized that risk of metachronous advanced colorectal neoplasia varies based on clinical characteristics and colonoscopy quality. We identified 7,171 participants with no or non-advanced adenomas at first-time screening colonoscopy. The risk of metachronous AN at surveillance colonoscopy 3-5 years later was investigated according to clinical characteristics and endoscopist adenoma detection rate (ADR).

Results: In multivariate analyses, strong associations between increasing age, male sex, current smoking, family history of colorectal cancer, follow-up interval, increasing number of adenoma, and low ADR and risk of any metachronous colorectal neoplasia were observed. For metachronous AN, increasing age, male sex, increasing number of adenoma, and low ADR were independent risk factors. Among patients with 1-2 small adenomas, women with age ≥60 years or men comprised a hidden-risk group, which had 5.3% risk of metachronous AN at surveillance. Women <60 years old with 1-2 low-risk adenomas had very low risk (1.2%) of metachronous AN as individuals with no adenoma. Furthermore, incidence of metachronous AN was significantly higher in individuals who were considered cured after endoscopic ADRE (<32%) than in those screened by endoscopists with a higher ADR (≥32%) (3.2% vs. 0.6%, respectively; P=0.001).

Conclusion: According to patient and adenoma characteristics, and ADR of the endoscopist, the risk of metachronous AN varies among low-risk patients. In recommending surveillance colonoscopy, these factors should be taken into consideration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1118 EXPERIENCE OF PER ANAL ENDOSCOPIC MYECTOMY (PAEM)

Contact E-mail Address: toyonaga@med.kobe-u.ac.jp

Introduction: The technique of endoscopic submucosal dissection has recently been improved, and large and complexed lesions such as those invading ileocecal valve and appendix orifice can be resected en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle retraction (MR) sign are often difficult to be resected completely. We devised a new method called ‘Per Anal Endoscopic Myectomy’ for such lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer.

Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM. PAEM cases performed in our hospital and an affiliated hospital were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrotic area with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases.

Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, 4 cases with submucosal invasion, and 1 case with deep submucosal invasion were resected en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgery or adjuvant chemoradiation. In surgical cases, they could permit anus-preservation.

Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable complete ganglion en bloc resection and make accurate pathological diagnosis. No complications were recorded in our experiences. Further investigation into the significance of PAEM would be needed.

P1119 LOCAL RECURRENCE AFTER ENDOSCOPIC MUCOSAL RESECTION FOR HIGH-RISK LESIONS: MAY WE BETTER PLAN THE ENDOSCOPIC FOLLOW-UP ACCORDING TO PROCEDURAL, TECHNICAL AND HISTOPATHOLOGICAL CHARACTERISTICS?
C. Quondamatari, C. Lucidi, R. Lupenta

Gastroenterology, Regina Elena Cancer Institute, Rome/Italy

Contact E-mail Address: qcinzia@ymail.com

Introduction: Endoscopic mucosal resection (EMR) is an increasingly used technique for the removal of large sessile and flat-laterally-spreading colorectal lesions. At present, surveillance colonoscopies are ever performed to ensure detection and adequate treatment of residual or recurrent adenoma (RA), which, occurring in 10–40% of non-pedunculated lesions, currently represents the main limitation of this technique. Fortunately, endoscopic detection of RAs in the post EMR scar is currently highly accurate using HD-WL (high definition-white light) and NBI (narrow band imaging). Anyway, indications for follow-up
colonicoscopy and optimal time intervals are currently unclear. An adequate United European Gastroenterology Journal 5(5S) A557

P1020 TREATMENT STRATEGY FOR LOCAL RECURRENCES AFTER ENDOSCOPIC RESSECTION OF COLORECTAL NEOPLASMS

Contact E-mail Address: saito@scchr.jp

Introduction: Local recurrences after endoscopic resection (ER) frequently occur, and recently, the efficacy of EMR appears lower than that of ESD, especially for lesions of low or high grade dysplasia. We conducted a series of five retrospective studies encompassing 400 patients treated with EMR or ESD. In this study, we present the findings from a single center, prospective, randomized, un-blinded, non-comparative study to determine the optimal treatment strategy for local colorectal neoplasms.

Aims & Methods: The study was designed to compare the efficacy of EMR and ESD for local recurrences of colorectal neoplasms. The primary endpoints were complete response rate (CRR) and local recurrence-free survival (LRFS) at 1 year.

Results: 60 patients were enrolled (30 EMR, 30 ESD). The median age was 69 years (range: 33-85) and the median tumor size was 22 mm (range: 5-70). The median follow-up time was 13 months (range: 1-36). The local recurrence rate was 7% in the EMR group and 13% in the ESD group. The CRR at 1 year was 93% in the EMR group and 87% in the ESD group. The LRFS at 1 year was 100% in the EMR group and 94% in the ESD group.

Conclusion: EMR is an effective and safe treatment for local recurrences of colorectal neoplasms. However, ESD may be necessary for lesions with higher risk of recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic stent placement in acute large-bowel obstruction due to colorectal cancer has been established as a palliative therapy or bridge to surgery with good outcomes in Japan. While, efficacy of chemotherapy after endoscopic colon stenting has not been evaluated. This study is a prospective, multicenter study evaluating the efficacy of chemotherapy after endoscopic colon stenting for local recurrences.

Aims & Methods: The aim of this study was to evaluate efficacy of chemotherapy after endoscopic colon stenting by comparing with that after surgery. Sixty five patients with colorectal cancer of stage IV presenting obstructive symptom visit our hospital from January 2012 to December 2016 were classified into SC group who have underwent chemotherapy after endoscopic colon stenting (32 patients) and OC group who have undergone chemotheraphy after surgery (25 patients). The patients’ background, adverse effects of chemotherapy and 3 months survival were compared between groups.

Results: There have not been any significant differences in patient age (65.5 ± 9.3 in SC vs. 61.5 ± 14.1 in OC, p = 0.21), male to female ratio (25:7 in SC vs. 14:9 in OC, p = 0.16) and performance status (0.6 ± 0.7 in SC vs. 0.7 ± 0.8 in OC, p = 0.66). The average colorectal obstruction scoring system (0, requiring continuous decompressive procedure; 1, No oral intake; 2, Liquid or enteral nutrition; 3, Soft solids, low-residue, and full diet with symptoms of strictures; 4, Soft solids, low-residue, and full diet without symptoms of strictures) score was significantly severe in OC (1.7 ± 1.1) than in SC (0.7 ± 0.9, p = 0.01). Adverse effects included perforation (1), stent slippage (6), re-obstruction by tumor progression (3) in SC, and ileus (1), abdominal abscess (1), renal insufficiency (1) in OC. The frequency of combined use of molecular target drugs (Beverazumab/Pantitumab/ Cetuximab) at first chemotherapy has significantly differed (p < 0.01) between SC (0.11/9) and OC (12/40). The median survival day was not significantly different between SC (595) and OC (459, p = 0.93). In SC, survival was found significantly longer with additional surgery (913, n = 13) than without (325, n = 19, p < 0.01). In OC, survival did not significantly differ between with resection of the primary tumor (666, n = 16) and without (595, n = 7, p = 0.93).

Conclusion: This study has demonstrated that the survival of SC was identical to that of OC, and additional surgery was found to significantly improve the prognosis in SC. Chemotherapy after endoscopic colon stenting was considered tolerable as a palliative therapy or bridge to surgery for obstructive colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

delivery system passage (e.g. Niti-S Colon Stent, Taewoong-Medical, Seoul, South Korea) or when a guidewire was unable to be passed through the stricture because of limited maneuverability of the endoscope, procedures below were followed. (1) A thinner scope, PCF-PQ260L, with a 2.9 mm tip and a 2.8 mm channel (Olympus Medical Systems, Tokyo, Japan) is inserted and advanced to the stricture, facilitated by its “passive bending” feature. An ultrathin endoscope (for transnasal use) or a gastroscope are alternatives. (2) A guidewire (GW, 0.035 inch Jagwire) is traversed through the stricture by coordinating manipulation of an ERCP-catheter (Article-No.0130211; MTW Endoskopie, Wesel, Germany). (3) Fluoroscent examination through the catheter to delineate the lesion. (4) For colonoscopy replacement, withdraw the scope and the catheter, leaving only GW. (5) Before reinserstion of the SCC, insert the catheter from the channel until it sticks out of the scope tip. (6) Pass GW backward into the catheter tip. Then move the catheter over GW and advance it further to connect with another catheter tip. (7) Gently move the SCC ("over the catheter") into the rectum and advance it in the more straightened (less winding) intestine. (8) After the colonoscope is advanced only as proximally as possible, shift to a standard TTS maneuver (withdraw only the catheter, leaving GW and insert the SEMS delivery along GW past the stricture where it is deployed). Results: See table. Conclusion: AOver-the-catheter9 colonoscope replacement (OTC-CR) technique can be a Salvage maneuver which facilitates a successful SEMS placement in MRO cases with peritoneal disseminations that preclude a conventional TTS procedure. Readiness of thin endoscopes and appropriate rigidity and force transmissibility of an ERCP-catheter that enable advancement of an SCC with maximum safety are thought to be linked to reduced chances of technical failures. Disclosure of Interest: All authors have declared no conflicts of interest. References 1. Japanese Colon Stent Safe Procedure Research Group (http://colon-stent.- com/001_mainpage_en.html) 266, F Sigmoid colon Sigmoid colon Intrinsic PCF-PQ260L Close Success/Success 2 66, F Sigmoid colon Sigmoid colon Intrinsinc PCF-PQ260L Close Success/Success 3 76, M Pancrease Sigmoid colon Extrinsic PCF-PQ260L Away SCJ Close Success/Success 4 41, F Transverse colon (resected) Sigmoid colon Sigmoid colon Extrinsic GIF-Q260J Close Success/Success 5 55, F Ovary Sigmoid colon Extrinsic EG-580NW Away Success/Success 6 49, F Stomach Transvers colon Extrinsic PCF-PQ260L Close Success/Success 0 – 3 3 CROSS, ColorOlo Obstruction Scoring System (Reference 1) Among 63 pulliative MCO cases, initial attempt to place a 22 mm SEMS by TTS procedure was unsuccessful in 6 cases (Table), all of whom had peritoneal dissemination. The reasons for technical failures were; impossible insertion of an SCC to the stricture due to carcinomatous adhesions or narrowing in 5 cases and failure in passing GW through the stenosis due to a limited viewing angle to the stricture in one case. With OTC-CR, approach to the main stenosis with a thinner (alternative) scope, GW traverse, "over-the-catheter" replacement to the SCC, and a 22 mm SEMS placement were successful in all of the 6 cases with adequate clinical improvements (CROSS score change). Notably, ultimate TTS procedures were possible from reinserted SCC distant from the stricture in 3 cases. No adverse events occurred during the procedures.

P1123 RESULT OF THE FIRST ROUND OF THE COLORECTAL CANCER SCREENING PROGRAMME IN THE BALEARIC ISLANDS (SPAIN) M. Florido1, M. Novellsa2, M. Heredía2, E. Miro3, C. Sanchez-Contador4, J. Gelabert1, S.P. Ortega1, J. Reyes1, P. Garcia-Cortes3, J.A. Lucero2, Z. Salman2, C. Rodrigueza2, A. Rua2, M.J. Garcia2 1Gastroenterology, Hospital Comarcal de Inca, Inca/Spain 2Gastroenterology, Hospital Can Misses, Ibiza/Spain 3Gastroenterology, Hospital Mateu Orfila, Mahon/Spain 4Dirección General De Salud Publica I Participación, Conselleria de Sanitat, Palma/Spain Contact Email Address: monica.florido@hcm.es Introduction: Colorectal cancer (CRC) is the most common cause of cancer in western countries. In Balearic Islands 700 new cases per year are diagnosed. The cost-effectiveness of CRC screening programmes are clearly demonstrated in the studies and the important public health problem of CRC justifies the development of control strategies. The aim of this study is to present the results and impact during the first round of the program in Balearic Islands. Aims & Methods: The first round includes the period from January 2015 through December 2016. The program has been developed in the areas of Menorca, Ibiza, Formentera and Tramuntana (Majorca), including 50% of the Balearic Islands population. The target population (people who reside in these areas aged between 50 and 69 years old) was 75,757 individuals. Exclusion criteria. Colonscopy performed in the previous 5 years, previous diagnosis of CRC, follow-up colorectal cancers because colon disease and severe illness-contraindication for the participation. People received the invitation by letter. Quantitative immunochromatographic occult fecal blood testing (i-FOBT/OC-Sensor) was the screening method. The kit was delivered at pharmacies joined the program. The samples were deposited in urns placed in health centres. Participants who tested positive (≥100 ng/ml) were referred to pre-endoscopy evaluation and follow-up colonscopy. The colonoscopies were performed according to the quality criteria of guidelines. Results: Overall participation rate (number of people who provide their i-FOBT sample) was 36.5% (n = 21,555). Positive rate of i-FOBT was 7% (1438) and 94.3% of those positive tests underwent a colonoscopy (5.7% of exclusions in pre-endoscopy evaluation). 996 colonoscopies were performed. 47 adenomas with high grade dysplasia, 24 carcinomas in situ and 6 adenocarcinomas were found. Only 19% of these adenocarcinomas were T3 or T4 lesions while the rest presented earlier stages. 26% of colonoscopies were classified as high risk (≥5 adenomas or at least one ≥20mm). They have been reported 2 cases of colon perforations, both resolved by endoscopic treatment. Conclusion: We observed an acceptable participation rate in the first round of the colorectal cancer screening programme of the Balearic Islands. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area. Disclosure of Interest: All authors have declared no conflicts of interest. Gastroenterology. 2017 Apr 17. pii: S0016–5085(17)35441–0. doi: 10.1053/j.gastro.2017.04.006.
Aims & Methods: Thirty Thai IBS patients, and age and sex matched 20 Thai controls were included. Four biopsy samples were taken from each of the sigmoid colon and the rectum during a standard colonoscopy. Sections from these biopsy samples were immunostained for serotonin, peptide YY, oxyntomodulin (enteroglucagon), pancreatic polypeptide, somatostatin, Msi 1, and neurogh 3. The densities of immunoreactive cells were determined with computerized image analysis (1).

Results: In both the colon and rectum, the density of serotonin cells was lower in IBS patients than controls. Whereas the density of PYY cells was increased in both the colon and rectum of IBS-D, it was reduced in IBS-M and IBS-C. The density of oxyntomodulin cells was reduced in both the colon and rectum of all IBS subtypes. While the density of PP cells was unaffected in the colon, it was reduced in the rectum. Somatostatin cell density was unaffected in both the colon and rectum. The densities of Msi 1 and neurogh 3 were unchanged in both the colon and rectum.

Conclusion: The present findings of abnormal densities of the large-intestine enteroendocrine cells in Thai patients combined with previously reported changes in Western IBS patients (2) support the notion that intestinal enteroendocrine cells are involved in the pathophysiology of IBS. However, the changes in the enteroendocrine cells differed from those in Western patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

Introduction: Opioid-induced constipation (OIC) is a common side effect of opioid therapy that significantly affects multiple aspects of a patient’s life. Naldeemedine (NAL) is a peripherally-acting mu-opioid receptor antagonist developed for the treatment of OIC. In Phase 3 studies, NAL improved the frequency of spontaneous bowel movements, straining, consistency of stools, and patient assessment of constipation symptoms (PAC-QOL) and quality of life (PAC-QOL), measures of patient’s quality of life, compared with placebo (PBO). The aim of this analysis is to assess the impact of NAL on overall satisfaction and to show if a simple score can assess the impact of treatment of OIC with NAL 0.2 mg once daily on patient’s satisfaction with constipation and abdominal symptoms at the last study visit. The number and proportion of subjects in each grade were calculated and the overall difference between groups was assessed by Wilcoxon rank sum test. The mean subject global satisfaction score (SGSS) was also compared between groups. For SGSS scores, from 1 to 7 were replaced with scores from 1 to 7.

P-value between groups* 0.0005 < 0.0001 < 0.0001

*Wilcoxon rank sum test

Conclusion: Treatment of OIC with NAL 0.2 mg once daily for 12 or 52 weeks led to greater satisfaction with constipation and abdominal symptoms compared with PBO, consistent with previously-reported improvements of PAC-SYM and PAC-QOL with NAL compared with PBO. The proposed SGSS appears to be a simple way to assess the impact on quality of life of OIC treatment.

P1127 IBEROGAST PREVENTS CHANGES IN INTESTINAL PERMEABILITY INDUCED BY PSYCHOLOGICAL STRESS IN MICE

Introduction: The herbal preparation STW 5 has been reported to increase intestinal chloride secretion. However, the ability of STW 5 to modulate paracellular and transcellular permeability remains currently unknown. Therefore, we aimed to...
to study the ability of STW 5 to modulate intestinal permeability under basal and regional stress conditions.

Aims & Methods: C57 bl6 mice were gavaged for 14 days with STW 5 (3 mL/kg). After 10 days of treatment, mice were subjected to water avoidance stress (WAS) for 4 consecutive days. In vivo permeability to FITC–Sulfonic Acid (FSA, 400 Da) and Horse Radish Peroxydase (HRP, 44KDa), total transit time and colonic transit (fecal pellet output - FPO) were assessed at Day 0 (D0), D10 and D14 of IB treatment. Ex vivo permeability to FSA and HRP was assessed on jejunum, ileum, proximal colon and distal colon at D14 using Ussing chambers. Corticosterone blood level was measured at D10 and D14.

Results: In vivo permeability to FSA and HRP as well as total transit time were not modified by STW 5 in basal and WAS conditions. However, STW 5 prevented the increase in permeability to HRP induced by WAS in the jejunal and proximal colon. Furthermore, while STW 5 tended to increase colonic transit as compared to control in basal conditions, it prevented the increase in transit induced by WAS. Finally, STW 5 did not modify the corticosterone induced by WAS.

Conclusion: Our study suggest that STW 5 can prevent WAS induced changes in paracellular and transcellular permeability in specific regions of the gastrointestinal tract. Such effects could contribute to the therapeutic effects of STW 5 in irritable bowel syndrome and support novel therapeutic indications for pathologies in which barrier functions are altered.

P1129 ALTERING SPHINGOSINE-1-PHOSPHATE WITH AGING INDUCES MOTILITY DYSFUNCTION OF COLON SMOOTH MUSCLE BY BKCA UPRREGULATION IN RATS

S. Xiaoau
The First Affiliated Hospital Of Nanjing Medical University, Nanjing Medical University, Nanjing/China

Contact E-mail Address: shenxiaoxue006@163.com

Introduction: Large conductance Ca2+-activated K+ channel (BKCa channel) was shown to play critical roles in regulating smooth muscle contractility by modulating membrane potential, at the same time, age-associated changes in BKCa expression may contribute to the development of motility disorders of the gastrointestinal tract. Sphingosine-1-Phosphate (SIP), component of Sphingolipids in the cell membranes, may affect BKCa expression. Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM) in rats.

Aims & Methods: Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM)in rats. Forty Sprague-Dawley rats at the same age were randomly divided into five groups. After different times of administration, finally they were divided into different-age group: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. Colon motility function and contractility of circular muscle strips were measured. The expression of BKCa and phosphorylated myosin light chain (P-MLC) level were tested in colon tissues of rats with varying ages by immunohistochemical, RT-PCR and western blot. SIP levels in colon tissues were tested by LC-MS/MS analysis. Primary cultured colon smooth muscle cells (SMCs) from normal adult rats were used in complementary in vitro studies. In the absence and presence of SIP with different concentrations, the expression of BKCa, P-MLC level, single-channel activity, intracellular Ca2+ mobilization were tested. At the same time, in the presence and absence of SIP, SMCs were transfected with anti-SIP antibody. BKCa siRNA transfection was used to investigate whether P-MLC expression and intracellular Ca2+ mobilization were affected by BKCa expression in SMCs. The expression and phosphorylation of Akt, JNK, ERK, NFKb, and PKC were examined by western blot analysis to investigate the effect between SIP and BKCa.

Results: Aged rats showed prolonged colonic transit time and weakness of circular muscle contraction compared with the young (10 weeks old) SD rats. LC-MS/MS analysis exhibited that the levels of SIP were significantly higher in the CSM from aged rats, demonstrating that SIP varies depending on age. BKCa (α-subunit and β-subunit) levels in CSM were shown to increase in an age-dependent manner from 10- to 80-week-old rats by mRNA, protein and immunohistochemical, but P-MLC expression decreased. In colon SMCs by BKCa siRNA transfection, we found P-MLC levels increased. Exogenously added SIP upregulated BKCa in colon SMCs in a concentration-dependent manner. Circular muscle Ca2+ mobilization through inhibiting SIP and induced the decline of P-MLC. Our results also proved that SIP upregulated BKCa through the Akt/ERK/JNK pathways. The expression of BKCa decreased by treatment with inhibitor of Akt/ERK/JNK pathways or siRNA.

Conclusion: The results of our study show that altered SIP due to aging upregulates BKCa via the Akt/ERK/JNK mediated pathway in CSM. BKCa upregulation inhibits Ca2+ influx and MLC phosphorylation and thereby reduces the contractile force characterized by the contractile force. These findings represent the first evidence for the mechanism of the contractile dysfunction of CSM observed in older individuals, which may be implicated in age-associated gastrointestinal motility disorders.

P1130 DIABETES-RELATED ALTERATIONS IN THE EXPRESSION OF THE INFLAMMATORY CYTOKINES, TUMOR NECROSIS FACTOR ALPHA AND INTERLEUKIN 6 IN THE MYENTERIC GANGLIA AND ITS MICROENVIRONMENT OF DIFFERENT INTESTINAL SEGMENTS

L. Chandrakumar, D. Mezei, B. P. Barta, Z. Szalai, N. Bödi, M. Bagyanszki

Introduction: Growing amount of evidence has indicated that increase of the hyperglycaemia-induced oxidative stress and decreased effectiveness of the endogenous antioxidant protection play the major role in the initiation of diabetes-related neuronal damage. Using a streptozotocin-induced diabetic rat model we recently demonstrated that nitricergic neuronal, which are key regulators of peristalsis, display different susceptibilities to diabetic damage and also to treatments in the distal part of the gastrointestinal tract. On these results we suggested the importance of the molecular differences in the microenvironment in the pathogenesis of diabetic nitricergic neuropathy.

Aims & Methods: Aim to reveal the quantitative differences in the expression of the pro-inflammatory cytokines like tumor necrosis factor alpha (TNFα) and interleukin 6 (IL6) in the myenteric ganglia and its microenvironment of the different intestinal segments, quantitative immunogold electron microscopy was used. Ten weeks after the onset of diabetes, segments from the duodenum, ileum and colon of diabetic and control rats were processed for post-embedding immunohistochemistry.

Results: The density of TNFα- and IL6-labeling gold particles was strictly region-dependent, with increasing to the distal part of the gastrointestinal tract of diabetic rats, the number of TNFα gold particles was significantly increased in the duodenal, decreased in the colonic myenteric ganglia, while did not show any significant differences in the ileal ganglia. The number of IL6 gold particles was not affected by diabetes in the myenteric ganglia of different gut regions. The diabetes-related alterations of TNFα- and IL6 expression were not protected by the immediate insulin replacement in any of the investigated intestinal segments. The differences in TNFα- and IL6 density were not significant in the capillary endothelium under different experimental conditions.

Conclusion: Based on these findings we presume that regionally alterations in the TNFα and IL6 expression are correlated with the diabetes-related region-specific nitricergic myenteric neuropathy.

P1131 ROLE OF SEMAPHORIN 3A IN THE POSTNATAL DEVELOPMENT OF THE ENTERIC NERVOUS SYSTEM

J. Gonzales, C. Le Berre, E. Dikkongue, M. Neunlist, H. Boudin
TENS INSERM U1235, Nantes/France

Contact E-mail Address: jacques.gonzales@univ-nantes.fr

Introduction: Critical developmental stages of the enteric nervous system (ENS) occur during the postnatal period leading to the formation of a mature neuronal network characterized by the assembly of enteric neurons into ganglia and the formation of a highly organized pattern of neuronal connectivity. However, the mechanisms underlying these maturation processes are poorly understood. Semaphorin 3A (SEMA3A) is a secreted protein playing key roles in the neuronal microenvironment of the central nervous system. Here, we studied the expres sion, the cellular distribution and the role of SEMA3A and its receptor neuroglian 1 (NRPI) in the maturation of enteric neurons.
Aims & Methods: Gene and protein expression of SEMA3A and its receptor NRP1 were analyzed in distal colon tissue by immunohistochemistry on day 1 (PN1) and day 3 (PN3) using specific antibodies. The impact of SEMA3A on neuronal outgrowth was assessed in cultures of enteric nerve cells cocultured with SEMA3A-transfected COS-7 cells.

Results: A peak of mRNA expression for SEMA3A and NRP1 was observed in neurons cocultured with SEMA3A-transfected COS-7 cells. The impact of SEMA3A on neuronal outgrowth was assessed in cultures of enteric nerve cells cocultured with SEMA3A-transfected COS-7 cells.

Conclusion: This study shows the expression of SEMA3A and its receptor NRP1 in the ENS during early postnatal period. Immunohistochemistry of colon tissue indicated that SEMA3A immunoreactivity was not associated with any specific cellular profile, but was distributed in small clusters disseminated throughout the tissue, a pattern consistent for a secreted protein. NRP1 was found in neurons, mainly associated with axonal processes, and was not detected in glial or muscle cells. Enteric neurons cultured in the presence of SEMA3A-expressing COS cells showed a strong reduction in axon length and complexity, while the ganglion size was unaffected.

P1135 TRANS-ABDOMINAL INTERFERENTIAL ELECTRICAL STIMULATION IS EFFECTIVE IN MANAGING REFRACTORY LOWER GASTROINTESTINAL DYSMOTILITY DISORDERS

J. Moore, P.R. Gibson, R.E. Burgeill
Gastroenterology, Monash University, Melbourne/Australia/1/FIC

Introduction: There is emerging interest in non-pharmacological management of gastrointestinal dysmotility via neuromodulatory techniques. A new method of non-invasive neuromodulation - transabdominal interferential electrical stimulation - has apparent efficacy in a paediatric population with difficult constipation.

Aims & Methods: We report our experience of its use in adult patients with functional megacolon who are refractory to conventional management. This is a descriptive case series of consecutive adult patients presenting to a tertiary referral functional gastrointestinal disorders clinic with refractory constipation that were taught and used home-based interferential stimulation for a three-month period. An experienced functional gut nurse specialist between October 2015 and Feb 2017. The validated PAC-SYM and PAC-QOL questionnaires were given at commencement of stimulation and after three months of use. Overall symptom severity was assessed by 10 cm VAS. An intention to treat analysis was conducted for any patients who commenced stimulation.

Results: Seven patients with refractory constipation (3 with slow-transit and 4 with idiopathic constipation) responding inadequately to pharmacological and non-pharmacological therapies underwent stimulation. Mean (range) age was 47 (26–73) and 2 were male. All 7 patients completed the stimulation period. There was a reduction in PAC-SYM in all patients (median IQR 24 [18–36] vs 14 [8–20]; p = 0.005). PAC-QOL was assessed in 4 patients and fell from 75 [69–85] to 39 [18–52]. Four were able to cease previously heavy daily laxative use and 2 were able to half their use, one currently weaning off prucalopride. One remained on daily laxative use despite soft, formed stool. All reported satisfaction with stool type. Ongoing benefit remains in 2 after 4 and 12 months since ceasing its use, where the rest tend to use the stimulator intermittently.

Conclusion: Interferential electrical stimulation improved symptoms in patients with functional constipation. Randomized placebo controlled trials are justified.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Neuro-gastroenterology, National Hospital for Neurology and Neurosurgery, London/United Kingdom

Introduction: YH12852 is a novel 5-HT4 receptor agonist currently under clinical development for the treatment for gastrointestinal motility disorders (GIMDs).

Aims & Methods: The study aimed to evaluate the safety, tolerability, pharmacokinetic and pharmacodynamic profiles for YH12852 in healthy volunteers with ≥3 spontaneous bowel movements per week (SBMs/week) and patients with functional constipation (FC). A randomized, double-blind, placebo- and active-controlled, parallel-group study was performed in healthy subjects and FC patients, who were administered YH12852 (0.3, 0.5, 1, 2 or 3 mg), prucalopride 2mg or placebo once daily after breakfast for 2 weeks. Subjects recorded bowel habits throughout the study period. Intensive pharmacokinetic blood samples were also collected (ClinicalTrials.gov identifier NCT02338367).

Results: Twenty-nine healthy subjects and 27 FC patients were enrolled. Treatment-emergent adverse events (TEAEs) were mostly mild and no serious adverse event was reported. The most frequently reported AE in the YH12852 and prucalopride group was headache. TEAEs in the YH12852 groups were similar to the placebo group. The change from baseline in weekly SBM frequencies averaged over the 2-week treatment period were 3.5, 3.8, 6.3, 4.6 and 3.9 for YH12852 0.3, 0.5, 1, 2 and 3 mg, respectively, 4.0 prucalopride and 2.6 placebo. The proportion of responders (defined as those with a ≥1 increase from baseline) was 100%, 100%, 100%, 100% and 75% in the YH12852 treatment groups (87.5%, 100%, 100%, 100% and 0.3, 0.5, 1 and 2 mg, respectively), with the exception of the 3 mg group (80.0%), compared with that in the prucalopride (83.3%) and placebo groups (28.6%). The mean stool count assessed by the Bowel Frequency Form Scale were comparable between the YH12852 and prucalopride groups. The time to reach the peak concentration of YH12852 was 4 hours. Steady state was achieved approximately 5 days after the first administration of YH12852 with a half-life of 23–28 hours. YH12852 showed a linear pharmacokinetic profile over 0.3–3 mg.

Conclusion: YH12852 was well tolerated and its safety profile was comparable to that of prucalopride. YH12852 appeared to increase bowel movement greater than prucalopride, particularly at 0.5–2 mg. YH12852 may have a significant potential for the treatment of GIMDs.

P1137 HEALTHCARE PROFESSIONALS FAIL TO PROVIDE ADEQUATE CANCER PATIENTS WITHOUT OPIOID-INDUCED CONSTIPATION TO STRONG-OPIOID UNASSISTED TREATMENT OPTIONS

V. Andrensen1, V. Banerji2, G. Hall1, A. Lass3, A. V. Emmanuel1
1Gastroenterology, Iraediclitic Hospital, Hamburg/Germany
2InsightDojo, London/United Kingdom
3Medical, Shinomori Limited, London/United Kingdom

Introduction: Constipation is a common side effect of opioid use. Available laxative therapies for opioid-induced constipation (OIC) leave the patient with significant residual symptoms, which may lead them to adjust or stop their opioid intake in order to have a bowel movement, unless effectively counselled.

Aims & Methods: This subgroup analysis of an international survey investigated counselling resources, information-seeking, and sources of support in subjects with constipation caused by the use of strong opioids (e.g. buprenorphine, fentanyl). This was a quantitative, questionnaire-based, online survey conducted in France, Germany, Italy, Spain and the UK among respondents aged ≥40 years with largely non-cancer-related chronic pain, treated long-term with strong opioids and having constipation (N = 2016). The survey assessed past medical history, opioid use, treatment of constipation, symptoms, burden of disease, and effects on quality of life of constipation.

Results: In general, responders find it difficult to combine pain management relief and constipation and do not have enough knowledge to balance them (36%). Approximately one-fifth (22%) of respondents were very or somewhat dissatisfied with the effectiveness of their current constipation treatment and only 43% strictly adhered to prescribed treatment regimens, with 32% researching other treatment options. A significant number of responders (44%) admitted that their constipation becomes so bothersome that they have to combine different methods to relieve it, and 40% often cut down their opioid medication or even skip it entirely (9%) to relieve constipation. To manage their constipation, respondents regularly used a variety of approaches, including dietary measures (48%), exercise (23%) and single (32%) or multiple (15%) laxative treatments. Only 45% of respondents reported that their healthcare professionals (HCPs) had warned them about constipation as a potential side effect of opioid use. Almost two-thirds of respondents (63%) reported that their HCP was the main information source on opioid-induced constipation. Although 58% of respondents stated that they would have liked their HCP to provide more information about OIC, 48% preferred to deal with constipation on their own, rather than discuss it with their HCP. Other common sources of information were online search engines (44%) and online health forums (29%). Less than half of respondents (43%) strictly adhered to prescribed treatment regimens, with 32% researching other treatments.

Conclusion: A proportion of patients are not satisfied with their current constipation treatment and they sometimes find balancing the need for adequate pain relief with constipation side effects challenging; consequently, many fail to adhere to their prescribed treatment regimens, or resort to using suboptimal strategies, such as increasing their opioid intake, to relieve constipation. Despite this dissatisfaction, many HCPs are not counselling patients adequately about constipation as a common potential side effect of opioid use. While most patients would like to have more support from their HCP, nearly half prefer to deal with constipation on their own, perhaps due to embarrassment or resignation.

P1138 THREE-DIMENSIONAL HIGH-RESOLUTION ANORECTAL MANOMETRY IN CHILDREN AFTER SURGERY FOR ANORECTAL DISORDERS
M. Banasik1, A. Banaszkiewicz2, M. Dziekić2, A. Kaminski3, P. Albrechti1

Introduction: Three-dimensional high-resolution anorectal manometry (3DHRAM) is the most precise tool to assess function of the anal canal and may be useful in evaluation of children after surgery on lower gastrointestinal tract that may present wide spectrum of symptoms from gastrointestinal tract. Our aim was to evaluate children after surgery for anorectal disorders using 3DHRAM.

Aims & Methods: We performed a prospective study of 43 children (30 male, mean age, 7 years) after surgery for anorectal disorders at the Departments of Pediatric Gastroenterology and Nutrition, Medical University of Warsaw, Poland. The group consisted of 24 children after surgery for Hirschsprung’s disease (HD), 12 children after surgery for anal atresia (AA) and 7 children after proctocolectomy for other reasons (PC). In all children conventional manometry was performed to compare the data obtained previously. Pressures of the anal canal were divided into 8 segments and the resting and squeeze pressures of puborectalis muscle (PRM) were recorded in segments covering its anatomical localization. These data were compared to raw data obtained in our laboratory from healthy children published previously (HC group). To assess correlation between manometry and symptoms, all children (after surgery and HC group) were divided into groups with respect to symptoms, as follows: asymptomatic (A), non-constitutive fecal incontinence (NRFI) and constitutive fecal incontinence (RFI).

Results: The lowest values of resting, squeeze and the pressure of PRM were observed in AA (55.6 mmHg, 121.7 mmHg and 44.17 mmHg, respectively). As compared to asymptomatic children, the lowest mean and maximum resting pressures were observed in NRFI (69.6 mmHg and 61.3 mmHg, respectively; p < 0.000). Significantly lower maximum squeeze pressure was recorded in both, NRFI and RFI (168.1 mmHg and 103.8 mmHg, respectively; p = 0.03). ROC cut-off value for mean resting pressure between asymptomatic children and patients with fecal incontinence was 68.5 mmHg. Significantly lower PRM squeeze pressure were observed in NRFI group and lower PRM squeeze pressure in RFI (45.6 mmHg and 63.6 mmHg, respectively). Threshold of urge were significantly higher in group C as compared to A group (87.5 cmHg and 30 cmHg respectively; P = 0.03).

Conclusion: Our study demonstrated lower pressure parameters in children after surgery with the lowest values in patients suffering from anal atresia, which was correlated with incontinence. 3DHRAM may be useful tool for assessing the function of the anorectum of children after surgery.

P1139 UK CLINICAL EXPERIENCE AT 52 WEEKS WITH LINACLIDATE: FOR IRRIITABLE BOWEL SYNDROME WITH CONSTIPATION
A. V. Emmanel1, J. McLaughlin1, Y. Yianakou2, S. Mcclain-Smith3,4
1Salford Royal, Salford/United Kingdom
2Salford University, Salford/United Kingdom
3NHS Foundation Trust, County Durham and Darlington, Durham/United Kingdom
4*pH Associates Ltd, Marlboro/United Kingdom

Introduction: Linacotide, a guanylate cyclase C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific real-world data to support this.

Aims & Methods: A multi-centre, observational prospective 52-week study was conducted in eight specialist hospitals in England and Scotland. The primary objective was to describe the change in IBS-Symptom Severity Scale (IBS-SSS) score from baseline at 12 weeks after linacotide initiation. Consenting patients with irritable bowel syndrome with constipation (IBS-C) were recruited for the study. Data on patient demographic and clinical characteristics, concomitant medications, patient-reported outcomes, including IBS-SSS score, and adverse events were collected. Results at 12 weeks (primary endpoint) have been presented previously; here we report analysis of real-world clinical experience 52 weeks post-linacotide initiation.

Results: 202 patients were recruited; 185 (92%) were female. At baseline, median age was 44.9 (range 18–77 years); 84 (42%) reported concomitant laxative use. Mean baseline IBS-SSS score was 339 (standard deviation [SD] ± n = 193); 129 (67%) patients had IBS-C classified as severe (score ≥ 300); 54 (28%) moderate (175–300), nine (5%) mild (75–175) and one (0.5%) normal (≤ 75). At 52 weeks, mean IBS-SSS score was 256 (SD ± 116; n = 78); 31 (40%) patients had severe, 27 (35%) moderate, 14 (18%) mild and six (8%) normal. IBS-SSS scores improved significantly between baseline and 52 weeks, with a mean decrease of 71 (SD ± 106) points overall (t-test p < 0.001; n = 76 with paired data) and 94 (SD ± 102) points on the patients remaining on linacotide (t < 0.001; n = 34). Of the 76 patients with paired data, 41 (54%) reported no change to treatment (ie reduction in IBS-SSS score of ≥50 points, or score fell below 150 if baseline score >150) [Table]. At 52 weeks, 41 (29%; n = 202) patients remained on linacotide; 87 (43%) had stopped (≤4 doses in past week, most commonly due to side effects (n = 51) or lack of efficacy (n = 18), and 74 (37%) were lost to follow-up/not known. Overall, 174 adverse events possibly related to linacotide were reported in 77 (38%) patients, most commonly diarrhoea (25%; n = 51), abdominal pain (9%; n = 18) and abdominal distension (6%; n = 13).

Table: Change in IBS-SSS score at 52 weeks from start of linacotide

<table>

<th>Patients, n</th>
<th>Patients, %</th>
</tr>
</thead>
<tbody>
<tr>
<td>≥50</td>
<td>76</td>
<td>100</td>
</tr>
</tbody>
</table>

Conclusion: Linacotide was associated with a significant improvement in IBS-SSS score at 52 weeks and was reasonably well tolerated. These results provide valuable insights into the longer-term outcomes of linacotide treatment in patients with IBS-C in real-world clinical practice.

Introduction: Irritable bowel syndrome (IBS) may be associated with disturbances of gut microbiota composition and functions, such as altered bacterial fermentation.

Aims & Methods: The aim was to study the effect of faecal microbiota transplantation (FMT) on gut bacterial fermentation products: short-chain fatty acids (SCFAs). Patients diagnosed with IBS according to Rome III criteria (n = 113) were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscope. Faecal samples were collected from the donors and the patients before FMT and from the patients after FMT until week 20/28 after FMT as follows: nausea (P < 0.001), vomiting, abdominal pain, diarrhea, constipation and anorexia.

Results: Before FMT, concentrations of several SCFAs were significantly lower in IBS patients compared to donors (Table 1). After FMT, concentrations of SCFAs increased within the first 3 weeks, and the increment lasted up to 28 weeks (Table 1). Acetate, propionate and iso-butyric acids and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and iso-capric acids) were analysed by vacuum distillation followed by gas chromatography. The patients completed IBS symptom questionnaire (IBS-SQ) before and after FMT at weeks 1, 3, 12, and 20/28. All the samples were stored at −80°C until analysis. Faecal concentrations of major SCFAs (acetic, propionic and n-butyric acids) and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and iso-capric acids) were assessed by HPLC-MS improved from before FMT until week 20/28 after FMT as follows: nausea (p = 0.0013), bloating (P < 0.0001), abdominal pain (P < 0.0005), diarrhea (P < 0.001), constipation (P = 0.03), and anorexia (P = 0.09). Correlations were found between abdominal pain and both acetic acid (r = 0.69, P < 0.04) and total SCFAs (r = 0.69, P = 0.044) in IBS patients before FMT. Inverse correlations were found 3 weeks after FMT between nausea and iso-valeric acid (r = −0.65, P < 0.014), and between constipation and propionic acid (r = −0.74, P < 0.0001), iso-butyric acid (r = −0.79, P < 0.0001) and n-valeric acids (r = −0.79, P < 0.0001) and iso-valeric acid (r = −0.72, P < 0.0001).

Disclosure of Interest: All authors have declared no conflicts of interest.

Data are presented as mean ± SEM. Comparison: Kruskal-Wallis multiple comparisons test with Dunn’s post test. *Donors at the beginning of the study vs. patients 1 week after FMT. **Donors at the beginning of the study vs. patients 3 weeks after FMT. ***Donors at the beginning of the study vs. patients 12 weeks after FMT, ****Donors at the beginning of the study vs. patients 20/28 weeks after FMT. FMT: faecal microbiota transplantation. SCFAs: short-chain fatty acids

Conclusion: Our results reveal differences in faecal fermentation products between patients with IBS and healthy donors, and suggest that FMT may act to normalise such alterations of gut microbial functions.

P1141 HEALTHCARE RESOURCE USE IN PATIENTS WITH IRRITABLE BOWEL SYNDROME WITH DIARRHOEA BASED ON A SURVEY OF PHYSICIANS IN THE UNITED KINGDOM

A. Marciniak1, D. Collomb2, S. Baker3, R. Goosey4

1Allergan plc. Marlow/United Kingdom
2Kantar Health, Epsom/United Kingdom

Contact E-mail Address: Anne.Marciniak@Allergan.com

Introduction: Irritable bowel syndrome with diarrhoea (IBS-D) is a chronic gastrointestinal disorder associated with significantly increased healthcare resource use (HCRU) and a substantial economic burden. In clinical practice, adequate relief (AR) of symptoms is an important measure of treatment effectiveness.1 However, the difference in HCRU related to IBS-D between patients with AR and those with inadequate relief (IR) has not yet been assessed.

Aims & Methods: This objective of this study was to quantify the HCRU in patients with AR of IBS-D symptoms compared to patients with IR. An online survey assessing HCRU was distributed to general practitioners (GPs) recruited from market research panels in the UK in August 2016. GPs opted-in to complete the survey via an email link and were screened before being invited to complete the main survey. Screening criteria included having seen patients with a chronic gastrointestinal condition in the past three months, having seen patients with IBS-D in the past 3 months and having decided on what treatments were prescribed for patients with IBS. The survey was a 15-minute web-based survey, including 12 questions collecting information on the use of medical services and procedures amongst patients with IBS-D for the first year following diagnosis and for subsequent years. Respondents were required to answer the survey considering patients who had AR of IBS-D symptoms and those who did not (IR), based on the respondents’ own assessments. Statistical analyses included t-tests for two independent samples comparing mean scores for those with IR vs those with AR during the first year after diagnosis at a 5% risk level, with p < 0.05 denoting significance.

Results: The online survey was completed by 50 GPs, with responses from 46 GPs included in this analysis (four responses were excluded due to data quality reasons). The reported total number of medical visits was significantly higher for patients with IR vs patients with AR during the first year after diagnosis (mean 10.11 vs 5.20; p < 0.001), with similar results seen for subsequent years (mean 8.20 vs 4.38). Significantly higher numbers of GP office visits, outpatient visits and emergency room visits were reported for patients with IR, with the greatest difference seen for GP office visits (2.37 more visits/year on average; incremental 4-week increase of 0.182; p = 0.003) [Table]. Similarly, the total reported mean number of procedures was significantly higher for patients with IR vs patients with AR (8.11 vs 4.52; p = 0.046), with number of colonoscopies having the greatest difference between the two groups (2.17 vs 0.91; 1.26 more procedures/year on average; incremental 4-week increase of 0.097; p = 0.008). Similar results were seen for the subsequent years after diagnosis, with patients with IR having more medical procedures compared to patients with AR (4.08 vs 2.56).

# p < 0.05 compared to patients with adequate relief

Conclusion: GPs reported that patients with IBS-D considered as having IR of symptoms had increased HCRU, including more GP office visits and more colonoscopies, compared to patients with AR. These results highlight that IR is potentially an important driver of increased HCRU in patients with IBS-D, emphasising that effective treatments that provide AR may reduce HCRU and the associated economic burden.

Introduction: Selective Serotonin Reuptake Inhibitors (SSRIs) have shown efficacy in reducing symptoms but less so on pain in irritable bowel syndrome (IBS). Comorbid anxiety frequently occurs in IBS. We hypothesized that SSRIs will particularly be effective in reducing abdominal pain in IBS patients with pronounced comorbid anxiety. As methods for symptom evaluation were used 1) gastrointestinal symptom rating scale (GSRS) as primary parameter and 2) a new method called the Experience Sampling Method (ESM). With ESM digital assessments are completed randomly and repeatedly during daily life, therewith capturing fluctuating symptom patterns more accurately than retrospective questionnaire methods.  

Aims & Methods: IBS patients with comorbid panic disorder were included in a randomized controlled trial on escitalopram versus placebo. Measurements were completed at baseline (t=0) and after 3 (t=3) and 6 months (t=6). At each time point, the gastrointestinal symptom rating scale (GSRS) and a 7-day ESM period were completed. Subjects completed ESM assessments on a palmtop computer at 10 random moments each day during 7 consecutive days. ESM periods were analysed when at least 1/3 (i.e. 23) of the assessments were completed. Mixed linear models were applied with the GSRS (primary endpoint) as the dependent and treatment group as the independent variable, as well as with ESM - abdominal pain scores as the dependent and treatment group and ESM - anxiety scores as the independent variables.  

Results: In total 15 (15 escitalopram and 14 placebo; 21 female; 37 ± 14.8 years; equal abdominal pain and anxiety scores at baseline) were included. Average GSRS-AP scores were not significantly different between escitalopram and placebo at t=3 (B: 0.265, SE: 0.451, p=0.557) or t=6 (B: 0.229, SE: 0.539, p=0.670). For the ESM analyses, at t=6, average abdominal pain scores were significantly lower (B: 1.30, SE: 0.623, p=0.037) (on a 1−7 scale) in the escitalopram group compared to placebo. With increasing anxiety levels (scores 2, 3 and 4) this difference further increased to 1.57, 1.84 and 2.11, respectively. A sensitivity analysis on subjects that completed all 3 valid ESM periods (i.e. at least 1/3 of total number of assessments at t=0, t=3 and t=6) showed similar results.  

Conclusion: Using GSRS as primary outcome, no significant effect of escitalopram over placebo on abdominal pain was found over a 6-month period. However, using ESM, a significant improvement in abdominal pain was observed, related to anxiety scores. These data 1) challenge the value of traditional retrospective methods with end-of-period symptom recording and 2) are in favour of novel more accurate momentary symptom registrations such as the Experience Sampling Method.

Introduction: Linaclootide, a guanylate cyclase-C agonist, stimulates intestinal fluid secretion and decreases visceral hypersensitivity and is licensed for use in irritable bowel syndrome with constipation (IBS-C). There is a relative paucity of data concerning its effect on gastrointestinal (GI) motility.  

Aims & Methods: We aimed to compare the effect of linaclootide on segmental and pan-enteric motility in IBS-C. 14 patients with Rome III defined IBS-C (3 male, mean age 37 years, range 20-64) underwent a wireless motility capsule (WMC) using a standardized protocol. Segmental transit was derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires assessing GI (verbal descriptor anchored visual analog scale (VDVAS) assessing sensory intensity (VDVAS-I) and unpleasantness (VDVAS-U)) and somatic symptoms (Personal Health Questionnaire (PHQ) as well as quality of life (EQ-5D) were administered. The WMC and questionnaires were repeated after 28 days of linaclootide 290mcg per od.  

Results: Changes in GI motility are shown in Table 1. Linaclootide improved VDVAS-I and VDVAS-U (130.7 ± 20.8 vs. 106.5 ± 33, p=0.03 and 113 ± 22 vs. 85.8 ± 33, p=0.01) and quality of life (58.4 ± 21.2 vs. 68 ± 17.6, p=0.02). Linaclootide reduced somatic symptoms (8.3 ± 2.2 vs. 5.9 ± 1.4, p=0.007). Change in pH across the ileocaecal junction correlated with improvement in VDVAS-I and U (r=0.6, p=0.03 and r=0.64, p=0.02).  

Table 1: Changes in GI physiology following linaclootide.  

Baseline (mean and standard deviation)  Post treatment (mean and standard deviation)  P  Value  
Gastric emptying time (minutes) 154 ± 64 177 ± 57 0.4  
Small bowel transit time (minutes) 353 ± 152 299 ± 139 0.3  
Colonic transit time (minutes) 3017 ± 1305 1983 ± 1216 0.04  
Whole gut transit time (minutes) 3517 ± 1375 2432 ± 1180 0.04  
Ileal contractility (AUC) 262 ± 142.2 221 ± 113.5 0.5  
Colonic contractility (AUC) 90.9 ± 78.3 134.6 ± 93 0.006  
Change in pH across the ileocaecal junction -2.4 ± 0.2 -2.1 ± 0.4 0.03  

Linaclootide improved VDVAS-I and VDVAS-U (130.7 ± 20.8 vs. 106.5 ± 33, p=0.03 and 113 ± 22 vs. 85.8 ± 33, p=0.01) and quality of life (58.4 ± 21.2 vs. 68 ± 17.6, p=0.02). Linaclootide reduced somatic symptoms (8.3 ± 2.2 vs. 5.9 ± 1.4, p=0.007). Change in pH across the ileocaecal junction correlated with improvement in VDVAS-I and U (r=0.6, p=0.03 and r=0.64, p=0.02).  

Conclusion: Linaclootide reduced colonic transit and enhances contractility. These changes in GI motility are accompanied by improvements in symptoms and quality of life and are associated with a reduction in extra-gastrointestinal symptoms. Change in pH across the ileocaecal junction has been proposed as a surrogate marker of caecal fermentation. Thus the beneficial effect of linacloptide on symptoms may therefore be related to a reduction in fermentation. This potential biomarker warrants further exploration.

P1144  RELATIONSHIP BETWEEN RIFAXIMIN THERAPY AND SEHCAT TEST IN PATIENTS WITH DIARRHEA-PREDOMINANT IRITABLE BOWEL SYNDROME OR FUNCTIONAL DIARRHEA  

Contact E-mail Address: alexandrurazucerulla@gmail.com  

Introduction: Bile acids (BAs) and gut microbiota have been involved in IBS pathophysiology. BA diarrhea (IBD) is often found in patients with irritable bowel syndrome with diarrhea (IBS-D) or functional diarrhea (FD). Bile acids and rifaximin have both been shown to improve symptoms in these patients. It is unknown whether a SeHCAT test may help to predict response to rifaximin or whether rifaximin treatment affects SeHCAT test result.  

Aims & Methods: a) To determine if a SeHCAT test may be used to predict response to rifaximin in patients with IBS-D or FD; b) To assess if rifaximin modifies SeHCAT result.  
Consecutive patients diagnosed with IBS-D or FD were prospectively included in the study. All patients received rifaximin 400mg TID for 2w. A SeHCAT test was performed to evaluate presence of BAD before and 1 month after rifaximin treatment. BAD was defined as SeHCAT retention <10%. Number of daily stools, number of daily watery stools, Bristol stool scale, abdominal pain, distension and presence of urgency were recorded before and after treatment. IBS severity score (IBS-SS) was also calculated.  

Results: Forty-one patients were included. BAD was present in 23 patients (56%). No clinical differences were found between BAD or non-BAD patients at study entry. Rifaximin resulted in a significant improvement in the number of daily stools (Δ −1.5; P<0.01), daily watery stools (Δ −2.1; P<0.01), Bristol scale (Δ −1.1; P<0.01), abdominal pain (Δ −0.5; P<0.01), distension (Δ −0.3; P<0.01), urgency (Δ −0.7; P<0.01) and in the IBS-SS (Δ −7.8; P<0.01). No differences were found between BAD and non-BAD patients in the improvement of any item. Rifaximin treatment did not modify SeHCAT value (9.5% before treatment and 10.7% after treatment; P=0.4).  

Conclusion: Half of the patients diagnosed with IBS-D or FD present BAD according the SeHCAT test. Rifaximin treatment confers significant clinical improvement irrespective of the presence of BAD. Rifaximin treatment does not affect SeHCAT test.  

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: To evaluate IR in patients treated with ELX in a post hoc analysis from two randomised, double-blind, placebo (PBO)-controlled Phase 3 trials (IBS-3001, IBS-3002). Patients meeting Rome III criteria for IBS-D were randomised 1:1:1 to twice-daily (BID) ELX (75 or 100 mg) or PBO. Efficacy was evaluated through Week 26. For evaluation of AR, patients were asked “In the last 7 days, have you had inadequate [satisfactory] relief of your IBS symptoms?” (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for ≥50% of the total weeks during the target time interval were considered AR responders.2,5 Patients answering “No” were considered to have incomplete relief, while patients with ≥5 consecutive weeks that patients reported IR over Weeks 1-12 and 13-24 of treatment. Patients without AR analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

Results: Overall, 2428 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p < 0.001] and 56.3% [p < 0.001] vs 46.4%, respectively) and at 26 weeks (51.5% [p < 0.001] and 49.0% [p < 0.004] vs 41.8%, respectively).2 Over the first 12 weeks of treatment, a greater proportion of patients reported no IR of IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1-5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p < 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13-24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

Table: Consecutive weeks of inadequate relief

<table>
<thead>
<tr>
<th>Weeks 1-12</th>
<th>Weeks 13-24</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELX 75 mg BID</td>
<td>ELX 100 mg BID</td>
</tr>
<tr>
<td>ELX 100 mg BID</td>
<td>PBO</td>
</tr>
</tbody>
</table>

Inadequate relief rate, %

Number of consecutive weeks with inadequate relief

0 | Inadequate relief rate, %

1-5 | 14.4 | 23.6 | 24.8 | 26.8 | 39.5 | 37.1

5-8 | 46.7 | 50.2 | 49.2 | 35.9 | 33.8 | 37.6

>8 | 5.3 | 3.8 | 2.9 | 4.7 | 3.9 | 3.7

Conclusion: In this post hoc analysis of the pooled ELX Phase 3 studies, ELX-treated patients experienced fewer consecutive weeks of IR compared to those receiving PBO, within both Weeks 1-12 and 13-24 of treatment. As IR is thought to increase healthcare resource use and subsequent healthcare costs associated with IBS, further prospective study of the impact of ELX on AR and any subsequent reduction in healthcare costs is required, including the relationship between the number of consecutive weeks of IR and patients' behaviour towards healthcare resource use.

P1145 FECAL MICROBIOTA TRANSPLANTATION FOR PATIENTS WITH POST-INFECTIONOUS OR ANTIBIOTIC-INDUCED IRRITABLE BOWEL SYNDROME: RESULTS FROM A PROSPECTIVE PILOT STUDY

1Gastroenterology And Hepatology, VU university medical center, Amsterdam/ Amsterdam/Netherlands
2Medical Microbiology And Infection Control, VU University Medical Center, Amsterdam/Netherlands
3Medical Microbiology, Leiden University Medical Center, Leiden/Netherlands
4Gastroenterology And Hepatology, Haaglanden Medical Centre, The Hague/ Netherlands

Aims & Methods: We performed an open label pilot study in the VU University medical center in Amsterdam from August 2016 through January 2017, to evaluate the effect of FMT in patients with post-infectious IBS (n = 5) and patients with antibiotic-induced IBS (n = 5). Participants with clinical symptoms lasting over six months, an IBS-symptom severity score (IBS-SSS) of at least 175 points, and a negative screening for gastrointestinal pathology were eligible. Donor feces (198 ml) was provided by the Netherlands Donor Feces Bank (NDFB) and administered via a duodenal tube. Participants did not receive pre-treatment or bowel cleaning. Participants were followed for eight weeks via two validated questionnaires: IBS-SSS (range 100-500), and IBS-Quality of Life score (IBS-QOL; range 0-100%). Fecal samples were obtained before and after FMT for microbiota analysis. Following the recommendation of the European Agency Medicines, FMT was considered clinically effective if participants reported an IBS-SSS improvement of at least 30% compared to baseline, eight weeks after FMT.

Results: The mean IBS-SSS of all patients had improved significantly from 137 (±74) points at baseline to 245 (±117) at eight weeks after FMT (p = 0.008); the median IBS-SSS improved with 40% from 340 (range 230-480) to 205 (range 80-470). Also, a significant improvement was seen in bowel pain (p = 0.039), satisfaction about bowel habit (p = 0.018), and influence of IBS symptoms on daily life (p = 0.011). There was no difference in bloating, or number of days with abdominal pain. The mean IBS-QOL improved from 51% to 66% (p = 0.008). FMT was considered effective in three patients with antibiotics and one patient with post-infectious IBS (≥30% improvement). In general, fecal microbiota analysis showed that the microbiota composition of responders shifted to that of their corresponding donors. Non-responders initially also did (which was associated with IBS-SSS improvement), however, eight weeks after FMT, the microbiota composition had shifted back towards baseline.

Conclusion: Treatment with FMT appears promising for antibiotic-induced and post-infectious IBS. Based on these results, a randomized placebo controlled trial is warranted.

3Allergan plc, Jersey/City/United States of America/NJ

Contact E-mail Address: gwen.wiseman@allergan.com

Introduction: Adequate relief (AR) of irritable bowel syndrome (IBS) symptoms is a commonly used global outcome measure to assess treatment benefit in both clinical trials and real-life clinical practice. Conversely, inadequate relief (IR) is considered an important driver for patients to use healthcare resources such as general practitioner or gastroenterologist consultations. Eluxadoline (ELX) is a mixed µ-opioid receptor (OR) and κ-OR agonist and δ-OR antagonist approved for the treatment of IBS with diarrhoea (IBS-D) in the US and Europe.
receptor antagonists, is approved for the treatment of IBS-D in adults, based on two large, 3 phase clinical trials where eluxadoline met the primary composite response endpoint of simultaneous improvement in abdominal pain and stool consistency over 26 weeks.

**Aims & Methods:** These post hoc analyses of two double-blind, placebo-controlled, Phase 3 clinical trials of eluxadoline (IBS-3001 and IBS-3002) aimed to assess responder and non-responder rates over 4-week intervals for eluxadoline vs placebo, and the proportion of responders/non-responders who continued or discontinued treatment. Patients meeting Rome III criteria for IBS-D were randomly assigned to twice-daily treatment with eluxadoline (75 or 100 mg) or placebo. Patients rated IBS symptoms daily, including worst abdominal pain (WAP; 0–10 scale, with 0 = placebo). Patients rated IBS symptoms daily, including worst abdominal pain (WAP; 0–10 scale, with 0 = placebo). Patients rated IBS symptoms daily, including worst abdominal pain (WAP; 0–10 scale, with 0 = placebo).

**Results:** Of the 2423 patients in the pooled Phase 3 ITT population, 249 were classified as having severe IBS-D. Over Weeks 1–4, 26.8% and 30.3% of patients with severe IBS-D were responders with eluxadoline 75 and 100 mg, respectively, vs 8.1% of patients on placebo (Table). Higher proportions of patients were responders with eluxadoline vs placebo over each subsequent 4-week interval, with response rates observed at Weeks 1–4 consistently maintained across all subsequent 4-week time intervals. With both eluxadoline and placebo, proportions of responders discontinuing were <2% across each 4-week interval, and discontinuation rates in non-responders were higher than in responders (Table). Similar findings were observed in the ITT analysis set: over Weeks 1–4, 22.7% and 24.6% of patients were responders with eluxadoline 75 and 100mg, respectively, vs 12.3% of patients on placebo. Discontinuation rates among responders with both eluxadoline and placebo remained <1% across all 4-week time intervals.

**Conclusion:** Proportions of responders with eluxadoline 75 and 100 mg were consistently higher vs placebo across all 4-week intervals in the treatment period in patients defined as having severe IBS-D. Furthermore, discontinuation rates among patients showing a treatment response remained consistently low compared to non-responders. However, as these analyses were conducted in a clinical trial setting, the relatively high continuation rates in non-responders may not reflect the real-world situation. These findings suggest that eluxadoline has sustained efficacy in treating the diarrhoea and abdominal pain associated with IBS-D, including in patients with severe and inadequately managed symptoms.

**Introduction:** Diets reducing the content of fermentable short chain carbohydrates (fermentable oligo-, di-, mono-saccharides, and polyols (FODMAPs)) as well as the National Institute of Health Care Excellence (NICE) diet have been reported to be effective in the treatment of patients with irritable bowel syndrome (IBS) (1,2). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota (3). Change in pH around the ileocecal junction is considered to be a surrogate biomarker of caecal fermentation (4,5).

**Aims & Methods:** We aimed to compare the effect of a low FODMAP diet vs the NICE diet on change in ileocaecal pH. We performed a single centre, randomized controlled trial of adult patients with Rome III defined IBS-mixed bowel habit (IBS-M) comparing the two dietary interventions. At baseline, patients ingested a wireless motility capsule (WMC) using a standardized protocol. Segmental transit times were derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires evaluating GI (verbal descriptor scale), symptom distress (VDSAS), and quality of life (EQ-SD) were administered. The WMC and questionnaires were repeated after 26 days of dietary interventions. The primary endpoint was change in ileocaecal pH after the intervention. Secondary outcomes included changes in transit times, contractility and symptom scores.

**Results:** After screening, 32 patients (23 female, median age 37 years, range 18-65) were randomized. Baseline symptom severity and demographics were similar between the two groups. Relative to baseline, there was a reduction in the change in ileocaecal pH with the low FODMAP diet group compared to the m-NICE group (3.37 ± 0.3 vs 0.0035 ± 0.4, p = 0.047) suggesting reduced fermentation. Changes in GI motility are shown in Table 1.

**Conclusion:** The low FODMAP diet reduces caecal fermentation in comparison to the NICE diet as indexed by a reduction in the change in pH across the ileocaecal junction. Both diets improved GI and extra-GI symptoms as well as quality of life. Neither diet has a demonstrable differential effect on ileal/colonic contractility or segmental/whole gut transit times. It is therefore plausible that the efficacy of the low FODMAP diet in IBS-M is via mediated by alterations in the microbiota.

P1151 PREVALENCE OF ANAL SQUAMOUS INTRAEPITHELIAL LESIONS IN LIVER TRANSPLANTED PATIENTS

Gastroenterology Department, Hospital São João, Gastroenterology Department, Porto/Portugal

Background: There are few studies in liver transplant recipients, but no information exists regarding prevalence in liver transplantation.

Objective: To evaluate the prevalence of anal squamous intraepithelial lesions in liver transplant recipients compared with healthy subjects.

Methods: A retrospective case-control study involving liver transplant recipients that were compared with a healthy control group. All patients were submitted to anal cytology. Those with abnormal cytological results, namely high-grade squamous intraepithelial lesions (HSIL), atypical squamous cells which cannot exclude high-grade squamous intraepithelial lesions (ASC-H), low-grade squamous intraepithelial lesions (LSIL) and atypical squamous cells of undetermined significance (ASC-US), were submitted to high-resolution anoscopy with biopsies of any suspicious lesion.

Results: A total of 59 liver transplant recipients and 57 controls underwent anal cytology. In the liver transplant group, 37 (63%) were men, with a mean age of 54 ± 10 years. The most common indication for transplantation was alcoholic cirrhosis in 26 patients (44%), the majority of the patients were only on tacrolimus (n = 29, 51%), and had been transplanted a mean of 8 ± 5 years ago. In the healthy control group, 36 (63%) were men, with a mean age 59 ± 11 years.

Conclusion: Liver transplant patients have a higher risk of anal squamous intraepithelial lesions and screening should be considered especially in smokers.

P1150 A SYSTEMATIC REVIEW AND META-ANALYSIS TO DETERMINE WHETHER BALLOON EXPULSION TESTING MIGHT BE AN APPROPRIATE INITIAL OFFICE-BASED TEST FOR DYSSYNERGIC DEFECATION

E. D. Shah, J. Farzad, W. D. Chey

Introduction: Balloon expulsion testing (BET) is a recommended means of identifying dyssynergic defecation (DD) in patients with chronic constipation (CC) and is recommended for use in the diagnosis of DD in patients with constipation symptoms and chronic constipation. However, it may not be related to reduced gas and distention, and should be used as a tool to diagnose DD in the setting of altered bowel habit. The aim of this study was to assess the clinical utility of BET as an initial test for DD and to determine appropriate testing parameters.

Methods: We conducted a literature search (PubMed, Embase, conference abstracts from 1950–2016) to identify (1) case-control studies of DD or unselected CC subjects and healthy controls and (2) cohort studies of unselected subjects with CC. Eligible studies reported BET test parameters and results as well as presence of DD defined by constipation symptoms and a positive reference test (anorectal manometry [ARM], defecography, or electromyography[EMG]). Study quality was assessed using QUADAS criteria. We extracted age, sex, enrollment criteria, BET test parameters (subject position, stool consistency, allowed expulsion time), and DD diagnostic criteria. Data were independently extracted by two authors. Meta-analysis was performed using a bivariate mixed-effects regression model. Meta-regression was performed to evaluate effects of individual test parameters. Between-study heterogeneity was evaluated using an I² statistic. Publication bias was assessed using Deeks funnel plot summary test.

Results: We identified 15 eligible studies comprising 2,090 individual assessments of balloon expulsion, of which 14 studies of 1,760 subjects were eligible for cohort analysis, and 1,968 subjects were eligible for case-control analysis. Among cohort studies, the AUC was 0.80 (95% CI 0.61–0.91) with 70% sensitivity (95% CI 52%–83%) and 77% specificity (95% CI 70%–82%). Among pooled cohort and case-control studies, the AUC was 0.84 (95% CI 0.68–0.93) with 80% sensitivity (95% CI 53%–82%) and 81% specificity (95% CI 75%–86%). Further test performance characteristics stratified by subject position are reported in Table 1. Subject positioning (seated vs. left lateral decubitus) did not significantly affect AUC in cohort (p = 0.32) or case-control (p = 0.43) analysis. Pooled sensitivity (p = 0.50) and specificity (p = 0.66) were similar between seated and left lateral BET in analysis of unselected CC cohort studies, though specificity was higher with left lateral BET in pooled analysis of all studies (p = 0.03). The allowable time for balloon expulsion did not significantly affect summary sensitivity (p = 0.92) or specificity (p = 0.96) in meta-regression within the evaluated range of 1 and 5 minutes. There were enough studies to warrant meta-analysis of balloon distension characteristics, 13 of 17 studies reported 50–60 mL of water. When pooling cohort and case-control studies, both age (p = 0.01) and gender (p = 0.01) appeared to influence test performance. AUC and specificity did not significantly affect test performance (ARM p = 0.35, defecography p = 0.43, or EMG p = 0.08). Continent of origin (p = 0.34) and year of study (p = 0.29) did not differ to significantly influence test performance. There was no evidence of publication bias (p > 0.5).

Conclusion: The performance characteristics of balloon expulsion could support the use of this test to screen for dysynergic defecation in chronically constipated subjects.

Gastrointestinal mediated food allergy (GMA) is a common disorder rising in recent years. The scientific research on this disease has increased, however its diagnosis still remains difficult to date. Diamine oxidase (DAO) is an enzyme that deactivates histamine, the main mediator in allergic reactions, through oxidative deamination. It has been shown that the enzymatic activity of DAO is diminished in the colonic mucosa of patients with GMA. Up to now no studies concerning the expression of DAO in the upper gastrointestinal tract (GIT) of patients with GMA have been published. Therefore, the objective of this study was to analyse the immunohistochemical staining of DAO and its localisation in the upper GIT of patients with or without GMA.

Aims & Methods: The study was retrospective. The GMA group consisted of 21 patients with diagnosed food allergy. The control group (CG) included 17 patients with neither food allergy nor food intolerance. Tissue samples from esophagus, cardia (subdivided in esophageal and gastric region), corpus, antrum and duodenum already obtained during endoscopy were immunohistochemically stained for DAO. The expression of DAO was semi-quantitatively analysed with the following scale based on the staining intensity of DAO (SI-DAO): 0 (none), 1 = low, 2 = medium, 3 = high intensity. The localisation of DAO was also examined vertically from the epithelium to the submucosa in all tissues.

Results: Immunohistochemical analysis found DAO in all segments of the upper GIT. The control group (CG) included 17 patients with neither food allergy nor food intolerance. Tissue samples from esophagus, cardia (subdivided in esophageal and gastric region), corpus, antrum and duodenum already obtained during endoscopy were immunohistochemically stained for DAO and its localisation in the upper GIT of patients with or without GMA. With the use of the staining intensity of DAO (SI-DAO) in the upper GIT, a median SI-DAO of 1.1 was observed in both groups, but this difference was not statistically significant. The SI-DAO was also examined vertically from the epithelium to the submucosa in all tissues. The analysis was performed twice by the same examiner in two separate points of time. Furthermore, the tissue samples were immunohistochemically stained for MBP and CD117 in order to count the number of eosinophils and mast cells respectively. Two measurements were performed inside an area of 100 mm² in the lamina propria (LP); one in the subepithelial superficial lamina propria (SLP) and one in the deeper lamina propria (DLP). The average of these two measurements constituted the number of these cells for each tissue.

Conclusions: The above mentioned findings indicate that DAO is present in low amounts in all segments of the upper GIT. But only in the duodenum a significant difference was found between GMA and CG, thus indicating that histamine-mediated symptoms most likely arise in duodenum. Therefore, regarding the upper GIT, the immunohistochemical staining of DAO only in duodenum could serve as an additional diagnostic parameter for detecting patients with GMA and possibly other histamine-mediated diseases. The above mentioned distribution pattern of DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the transepithelially absorbed exogenous histamine as well as of the endogenous histamine, as its highest staining intensity is found at the SLP throughout the upper GIT.

Disclosure of Interest: All authors have declared no conflicts of interest.
L-cysteine has been proposed as adjuvant therapy in CAG; the amino acid binds covalently to acetaldehyde (a Group I human carcinogen), removing it from the stomach. The aim of present study was to use L-cysteine to improve the symptoms in patients with diagnosis of CAG.

Aims & Methods: One hundred fourteen consecutive patients (M = 43, mean age 49.9 years) with CAG (based on endoscopic diagnosis of CAG) and means of both gastric histology (moderate to severe chronic, atrophic, body gastritis according to the OLGA staging system) and serology (pepsinogen 1 < 25 μg/l, gastrin-17 > 14 pmol/l) el GastroPanel®, Bioht, Oy, Finland) entered the study. Forty-one patients (11 M, mean age 49.8 yr, range 27–71 years) were treated with L-cysteine (100 mg 3 times daily, with meals) for 24 months (Group 1). As a control group we enrolled 73 CAG patients (M = 32, mean age 55.5 yr, range 32–77 yrs) followed up for 24 months without any related therapy (Group 2). The diagnostic fullness, nausea, bloating) were recorded at baseline and after 3, 6, 12, 24 months, according to severity score (0–3 for each symptom, min. 0 = no symptoms; max. 12 = full symptom).

Results: The typical symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.93; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 (p < 0.01). Subdividing the CAG patients according to the etiology (autoimmune gastritis or Helicobacter pylori infection) no differences were found in improving symptoms. No relevant side effects were observed during the study.

Conclusion: The administration of L-cysteine to subjects affected by moderate–severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up.

Introduction: Despite undergoing potentially curative resection a significant proportion of patients develop cancer recurrence. Several cellular and humoral components of systemic inflammatory response have been reported and associated with poor outcome. To date, no study has comprehensively examined the relationship between readily available markers of inflammation and survival in gastric cancer.

Aims & Methods: Patients undergoing surgery for stage I-II gastric cancer between 2004-2016 at a regional unit were identified. Measurements of various systemic inflammation markers were recorded pre-operatively. Pathological factors were recorded from reports issued at the time of resection. The modified Glasgow Prognostic Score (based on CRP and Albumin), Neutrophil-Lymphocyte Ratio, Platelet-Lymphocyte Ratio and Neutrophil-Platelet score were calculated. Pathological variables including TNM stage, differentiation and vascular invasion were also recorded. Survival endpoints of overall survival (OS) and disease-free survival (DFS) were used.

Results: 331 patients were identified and 291 patients underwent potentially curative resection for gastric cancer. On unvariable DFS analysis, female gender, proximal location, T-stage, N-stage, TNM, vascular invasion, poor differentiation, R1 status, platelet count and mGPS were significantly associated with poor survival. On multivariable DFS analysis, mGPS (Hazard Ratio (HR) 2.51 95% Confidence Interval (CI) (1.35–4.65); p = 0.001) was an independent predictor of survival and was also observed in OS with mGPS (HR 2.75 (95%CI 1.65–4.59); p < 0.001). The mGPS was associated with advanced T-stage (p = 0.013), TNM stage (p = 0.013) and poor differentiation (p = 0.030).

Conclusion: The mGPS was the only inflammatory based marker to independently predict poor DFS and OS and may represent the optimum method for systemic inflammatory response quantification.

Introduction: Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments. In-hospital mortality from UGIB has decreased throughout the past 2 decades in-hospital and delayed 6-months mortality, rebleeding and delayed 6-months bleeding and cardiovascular events. Final results: 507 patients were included (339 males; aged 62 ± 16.4). The incidence of rebleeding was 17.3% (n = 88). In the univariate analysis, factors related with rebleeding were creatinine levels (1.52 vs. 1.15; p < 0.001), tachycardia (96.28 vs. 88.24; p < 0.001), low levels of albumin (2.80 vs. 3.28; < 0.001) and low blood pressure (103 vs. 115; p < 0.001). In a multivariate analysis tachycardia and high creatinine were independent risk factors for rebleeding, and albumin showed as an independent protective factor (Table 1). Rebleeding was associated with in-hospital mortality (p < 0.0001); by contrast, it was not related to delayed 6-months mortality and with both hemorrhagic and hemorrhagic events. The UGIB risk scores AIMS 65 and Rockall showed poor predictive ability for acute mortality in the rebleeding patients’ group and was similar for Blatchford score (based on AURC).

Conclusion: Rebleeding in UGIB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameters. AIMS65, Rockall and Blatchford were the best predictive indicators for in-hospital mortality but worked poorly in the patients who suffered rebleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1157 A CASE-CONTROL STUDY ON THE RISK OF UPPER GASTROINTESTINAL MUCOSAL INJURIES IN SUBJECTS PRESCRIBED NSAIDS AND ANTI-THROMBOTIC DRUGS USING THE LARGE ORGANIZED DATABASE OF CLAIMS IN JAPAN

N. Sugisaki1, R. Ikawati2, K. Fujimoto3

Introduction: Upper gastrointestinal (GI) adverse effects induced by NSAIDs and anti-thrombotic drugs are increasing along with progressive aging of society. Recently it is essential to perform pharmaco-epidemiological studies to identify adverse effects in the real-world setting using a large-scale medical database. We conducted a case-control study to assess the risk for upper GI mucosal injuries in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

Aims & Methods: The medical claims database developed by Japanese Medical Data Center (JMDC) Co., Ltd. was selected as data source in the present retrospective observational study. The JMDC claims database comprised of integrated medical and pharmacy claims, and includes both hospital and outpatient care from over 90 payers (approximately 3.7 million of population on an accumulated basis). Eligible subjects were aged 20 to 74 and registered for at least 3 months in the database from January 2009 to December 2014. The evaluated upper GI mucosal injuries were peptic ulcers (143,271 cases), upper GI bleeding (10,545 cases) and gastroesophageal reflux disease (GERD: 154,755 cases) with diagnosis by ICD-10 codes and implementation of the upper GI endoscopy. For the each test-case, ten controls which matched age, sex and diagnosis month were identified from the database. Multivariate logistic regression analysis was used to calculate odds ratios of occurrence of each upper GI mucosal injuries caused by NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antiplatelet drugs (except low-dose aspirin) and antiocoagulants.

Results: The odds ratios of peptic ulcers were 1.45, 1.31, 1.50, 1.53 and 1.62 for NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antiplatelet drugs, and antiocoagulants, respectively. The odds with time decreased with the occurrence of peptic ulcers (p < 0.0001 in each). The odds ratios of upper GI bleeding were 1.76, 1.62, 1.96, 1.82 and 2.38, and those of GERD were 1.54, 1.41, 1.89, 1.67 and 1.91, and these odds ratios were statistically significant in each medicine with GI bleeding and GERD (p < 0.0001 in each). The odds ratios of all the upper GI mucosal injuries were the highest in the patients with antiocoagulants, and the ratios were relatively low in those with NSAIDs and COX-2 selective inhibitors. The odds ratios tended to increase with the number of prescribed
medicines (1 agent < 2 agents < 3 agents, peptic ulcer: 1.38 ± 2.49 ± 4.52, upper GI bleeding: 1.74 ± 3.95 ± 7.77, GERD: 1.61 ± 2.96 ± 5.85, respectively). The upper GI mucosal injuries were exacerbated in complication of lifestyle-related diseases, including hyperlipemia and diabetes mellitus.

Conclusion: Prescribing NSAIDs and anti-thrombotic medicines was associated with increased risks of developing upper GI injury. The present large-scale, cross-sectional study utilizing the large organized database of claims in Japan provided precise clinical evidence for safety management of medical drugs in the clinical settings in Japan.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Cardiology Department, Erasme Hospital, Universite Libre de Bruxelles, Brussels/Belgium
4Gastroenterology, Hepatopancreatology And Digestive Oncology, Erasme Hospital, Universite libre de Bruxelles ULB, Brussels/Belgium

Contact E-mail Address: alia.hadeafi@gmail.com

Introduction: Percutaneous left atrial appendage occlusion (LAAO) is increasingly recognized as valid alternative therapy to reduce thromboembolic risk in patients with non valvular atrial fibrillation (AF) and contraindications for long term oral anticoagulation (OAC) therapy. Patients at high thromboembolic risk with previous gastrointestinal bleeding (GIB) might be at risk of bleeding recurrence in case of resuming anticoagulation. They could be selected for alternative therapies like LAAO. Up to now, there is no scientific consensus for patient selection for LAAO based on recurrent GIB risk.

Aims & Methods: We aimed to review the literature on gastrointestinal (GI) bleeding under anticoagulation to propose a method to define the reversibility profile of each lesion in an organ by organ and lesion by lesion approach to stratify the risk of bleeding individually. We systematically collected data from both prospective and retrospective studies from pubmed in order to extract rebleeding risk by ephology. The reversibility profile was defined by type of treatment needed to cure the lesion. Low reversibility (LR) profile was defined as a need for heavy treatment (surgery, radiotherapy, embolisation) to cure the lesion or as diffuse lesions.

Results: The most frequent reported causes of bleeding are peptic gastroduodenal ulcer (60%) for upper GI, diverticulosis (40%), colitis (20%) and anorectal diseases (20%) for lower GI and angiodysplasia (23%) for the midgut, these latter being responsible for 5% of all GI bleeding causes. The rate of rebleeding under OAC therapy is 5-7%. The incidence of VKA is higher than in patients with aspirin use. The rate of recurrent bleeding for upper GIB, lower GIB and obscure GIB are respectively 30%, 44% and 45%.

In the upper GI tract, lesions at high risk of bleeding recurrence are Dieulafoy lesions and angiodysplasia with reported rates up to 40% in some series. In the lower GI tract, lesions at highest risk are diverticular disease, angiodysplasia, colitis and radiation rectitis with bleeding recurrence rates reaching 60%, 20%, 40% and 20% respectively. For the midgut, angiodysplasia (20%) and bleeding of unknown origin (20%) are associated to the highest risk of recurrent bleeding.

LR profile lesions with high rebleeding risk are present for diffuse angiodysplasia, systemic diverticulosis and Dieulafoy lesions.

Conclusion: In conclusion, GI lesions at high risk of recurrent bleeding with low reversibility profile are infrequent and include in particular: diffuse angiodysplasia, colonic diverticulosis and Dieulafoy lesions. Patients with AF having those lesions undergoing GIB under anticoagulation might be the best candidates for alternative therapies like LAAO. Larger studies are needed to assess the long term outcome of patients treated by LAAO for GIB under current oral anticoagulant therapies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1161 COMPARISON OF RISK-SCORING SYSTEMS IN PREDICTING NEEDS OF INTERVENTION AND CLINICAL OUTCOMES OF UPPER GASTROINTESTINAL BLEEDING

M. Ooi, W. Low, R. Bryant, N. Q. Nguyen 
Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieeoi ali@yahoo.com

Introduction: There are several risk-scoring systems that are available to assist the management of upper gastrointestinal bleeding (UGIB). The aim of this study is to compare the performance of pre-endoscopy (pre-RE), post-endoscopy Rockall score (post-RE) and GBS and AIMS65 scores in predicting the need for intervention in patients admitted to hospital for UGIB.

Aims and Methods: Data related to the three scoring systems were collected prospectively and scores were calculated in consecutive patients who were admitted with acute UGIB to the Royal Adelaide Hospital over 24 months. The performance of these scoring systems was evaluated by constructing receiver operating characteristics (ROC) curves, in predicting the following outcomes was assessed: the need for endotherapy, rebleeding risk, transfusion requirement, surgical intervention and death. All patients received high dose acetylsalicylic acid prophylaxis.

Results: Of 895 (66.4 ± 0.66yrs) patients who presented with UGIB, 622 (402M; 65.7 ± 0.60yrs) underwent endoscopy with 123 (38%) required endoscopic therapy, 42 (13%) repeated endo-therapy and 12 (3.7%) surgery for haemostasis. 

The scoring systems performed equally well in predicting the need for surgery (GBS vs. Rockall vs. AIMS65 AUC: 0.72 vs. 0.67 vs. 0.71) and death (AUC: 0.75 and 0.72 vs. 0.69).

Conclusion: The AIMS65 is an independent risk factor for rebleeding of HDU after endoscopic hemostasis, with a dose-response relation (P = 0.015).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1162 STEROID ADMINISTRATION IS AN INDEPENDENT RISK FACTOR FOR REBLEEDING IN HEMORRHAGIC DUODENAL ULCER WITH A DOSE-RESPONSE RELATION

Division Of Gastroenterology, Tohoku University Graduate School of Medicine, Sendai/Japan

Contact E-mail Address: waku-style@festa.ocn.ne.jp

Introduction: Hemorrhagic gastroduodenal ulcer is commonly seen in routine clinical practice, and there have been many studies investigating risk factors for rebleeding. However, few studies have evaluated hemorrhagic gastric ulcers (HGU) and hemorrhagic duodenal ulcer (HDU) separately. Furthermore, the relation between steroid administration and rebleeding in hemorrhagic gastro- intestinal ulcer remains unclear.

Aims and Methods: The aim of this study was to clarify the difference of rebleeding between HGU and HDU, and associated factors for rebleeding of HGU and HDU. Between March 2005 and September 2016, 176 consecutive patients with hemorrhagic gastroduodenal ulcer (106 with HGU and 70 with HDU), who underwent endoscopic hemostasis, were enrolled in this study. Regular dose proton pump inhibitor was administrated to all patients after the diagnosis of hemorrhagic gastroduodenal ulcers. Rebleeding was defined as hematoma or melena with ulcers confirmed by endoscopy or a decrease in the hemoglobin level > 2 g/dl in the presence of endoscopically proven ulcers. First, we compared the rebleeding rate between HGU and HDU. Subsequently, associated factors for rebleeding of HGU and HDU were calculated by logistic regression analysis individually. The estimated factors were age (< 65 vs. >65yrs), gender, location of ulcer (upper third/middle or lower third in HGU and 2nd portion/bulbs in HDU), underlying comorbidities (ischemic heart disease, liver cirrhosis, hypertension, diabetes mellitus, and hyperlipidemia), number of ulcers (multiple/single), hemostasis method (pure ethanol injection therapy/other therapies), anti-platelet therapy, anti-inflammatory therapy, steroid administration, anticoagulant administration, antacid administration, initial ulcer bleeding, hypoalbuminemia (serum albumin level ≤ 2.5 g/dl), and hemodilution. We further investigated the detailed association between steroid administration and rebleeding in HDU, including dose-response relation.

Results: The rebleeding rate of HGU and HDU were 5.7% and 22.9%, respectively, which was statistically significant (P = 0.001). There was no missing data in the estimated factors. Although no factor was associated with rebleeding in HDU, multivariate logistic regression analysis revealed that the independent factors for rebleeding in HDU were multiple ulcers [odds ratio (95% confidence interval) = 24.2 (2.76–213), P = 0.004], steroid administration [1.40 (1.73–113), P = 0.015], and hemodilution [0.53 (1.00–90.7), P = 0.049]. Regarding the detail of steroid administration, multivariate analysis showed that middle or high steroid administration (> 20 mg in prednisolone) (52.7 [3.19–871], P = 0.006) was a significant factor for rebleeding of HDU, with a dose-response relation (P = 0.003).

Conclusion: HDU developed significantly higher rebleeding after endoscopic hemostasis, compared with HGU. In addition to multiple ulcers and hemodil- lysis, we firstly demonstrated by multivariate analysis that steroid administration is an independent risk factor for rebleeding of HDU after endoscopic hemostasis, with a dose-response relation.

P1163 EFFICACY AND SAFETY OF BIO-INSERT MINERAL SMECTITE IN CONTROLLING GASTROINTESTINAL HEMORRHAGE: AN ANIMAL STUDY PILOT

J. Wang¹, L. Zhao², M. Wang³, L. Liu², Z. Fan², X. Wang² 
¹The First Affiliated Hospital with Nanjing Medical University, Nanjing/China 
²Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kiri978@sina.com

Introduction: Granular smectite is bioinert mineral and efficient for curing diarrhea. Inspired by its dehydration and tissue-covering effect, this pilot study was to investigate its efficacy and safety for controlling hemorrhage in rats.

Aims and Methods: 32 rats were divided into four equal groups. For hemorrhage model, a horizontal 10-mm incision was made on the lower part of the left hepatic lobe. Commercial hemostatic powder, smectite, starch and normal saline were respectively applied. Bleeding duration and blood loss were recorded. 1 week later, rats were sacrificed and liver tissue was collected for histopathology.

Results: Smectite demonstrated the best hemostasis effect, and its mean coagula- tion time was 1.45 ± 0.026 min. Commercial hemorrhagic chitosan stypic powder need 2.5 ± 0.04 min for complete clotting, while Starch group was 4.25 ± 0.06 min and normal saline group was 5.04 ± 0.08 min. Similarly, smectite led to less loss of blood (0.6188 ± 0.034 g, while rats lost 2.3288 ± 0.123 g blood (p < 0.05) under normal saline treatment. For starch and commercial chitosan, the blood loss was respectively 2.0862 ± 0.061 g and 1.925 ± 0.028 g. Histopathological results confirmed that smectite was biocompat- ible to tissue.

Conclusion: The mineral smectite powder was the superior candidate for hemorrhage treatment in vivo. Compared with common polysaccharide agents, smectite could induce faster coagulation and reduce blood loss. More importantly, bios- nert smectite was biocompatible and even promoted the wound healing. For gastrointestinal application, smectite powder could be delivered through endo- scalar probe, while its inspiring efficacy required more endoluminal hemorrhage tests.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1164 PREDICTORS OF LIFE THREATENING MUCOSAL ULCERATION AFTER VASCULAR SCLEROTHERAPY

A. S. Hanafy 
Internal Medicine, Zagazig University, Zagazig/Egypt

Contact E-mail Address: dr_amr_hanafy@yahoo.com

Introduction: Life-threatening bleeding could occur early after vascular sclerotherapy in cirrhotic patients.

Aims and Methods: We aimed to determine simple predictive factors of this complication in cirrhotic patients. Among 750 patients treated with vascular sclero- therapy (esophageal varices: 605, 87.3%) and (gastric varices: 95, 12.7%) Zagazig University hospital-endoscopy unit- Internal medicine department, in the period from October 2014 till July 2016. 150 patients (20%, mean age 46.2 ± 4.9 years) (EV = 129, GV = 21) developed bleeding due to scler- otherapy induced ulcers confirmed by endoscopy 6.4.2 ± 1.3 days after the proce- dure. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and cryptogenic in (1%). A case-control study was performed comparing these
patients with 150 patients who underwent endoscopic variceal sclerotherapy without the development of bleeding due sclerant ulceration. Results: Bleeding occurred 6.4 ± 2.1 days (2–10) following sclerotherapy. Twenty-three patients died following the bleeding (15.3%). Using a multivariate analysis; pre-procedural factors as serum albumin ≥2 g/dl [OR 1.3], total bilirubin ≥1.6 mg/dl [OR 1.3], platelet ratio index (APRI) > 1 [OR 1.2], low prothrombin concentration <50% [OR 1.5]. Intra-procedural factors as amount of ethanolamine >15.5 ml [OR 2.6], ammonia ≥3.5 ml [OR 2.9]. Post-procedural factors within 24 hours after endoscopy; leukocytosis ≥>12,000 cell/ml [OR 1.9], drop of hemoglobin ≥10% of the pre-endoscopic value [OR 3.2], prolonged INR ≥1.55 [OR 1.2]. Conclusion: Bleeding related to sclerant ulcers is not uncommon, but may be life threatening. The proposed predictive factors should be watched and minimized before and during variceal sclerotherapy.

Introduction: Few studies were reported on the association between sleep disorders and Rome III-based functional dyspepsia (FD).

Aims & Methods: The aim of this study is to investigate the prevalence of sleep disorders in FD patients and the risk factors associated with sleep disorders. This multicenter, cross-sectional study had been conducted from August 2014 to December 2016 at 6 hospitals in Korea. Inclusion criteria were FD patients (>18years) met the Rome III criteria among the patients visited the gastroenterology department for dyspepsia. Exclusion criteria were prior surgery to the gastroduodenal area and no abnormal finding on endoscopy. Exclusion criteria were prior surgery to the gastroduodenal area and no abnormal finding on endoscopy. Exclusion criteria were prior surgery to the gastroduodenal area and no abnormal finding on endoscopy.

Results: This multicenter study included 160 FD patients and 223 healthy control groups. The total Pittsburgh Sleep Quality Index score was higher in FD patients than health controls (7.8 ± 4.3 vs 5.6 ± 3.1, p = 0.000). The prevalence of sleep disorder was significantly higher in FD patients than healthy control (41.2% vs 18%, p = 0.000). In univariate analysis, FD was significant risk factor for sleep disorder (OR 3.12, p = 0.001). The independent risk factors for sleep disorder in multivariate analysis were OR 1.80, p = 0.026, female (OR 1.78, p = 0.028) and depression (OR 2.91, p = 0.000).

Conclusion: FD significantly impacted on sleep disorder. FD was independent risk factor in sleep disorder.

Introduction: Dyspepsia and gastro-oesophageal reflux are highly prevalent in the general population, but the two conditions are felt to be separate entities. However, there are numerous mechanisms implicated in the pathogenesis of functional dyspepsia, some of which are common to gastro-oesophageal reflux symptoms (GORD), including visceral hypersensitivity and delayed gastric emptying. To inform future research on potential shared pathophysiological mechanisms, it is important to estimate the strength of association between the two conditions, and whether this association remains stable depending on the criteria used to define these conditions, as well as geographic location.

Aims & Methods: We conducted a systematic review and meta-analysis to estimate the prevalence of dyspepsia in individuals with gastro-oesophageal reflux symptoms, and to quantify the overlap between the two disorders. MEDLINE, EMBASE, and EMBASE Classic were searched (up until September 2016) to identify population-based studies reporting the prevalence of dyspepsia and GORD (OR 1.5). Kaplan-Meier survival analysis (≥15 years), defined using specific symptom-based criteria or a questionnaire. The prevalence of dyspepsia and weekly GORD were extracted for all studies. Pooled prevalence, according to study location and criteria used to define weekly GORD or dyspepsia, as well as odds ratios (OR), with 95% confidence intervals (CIs) were calculated. The degree of overlap between the two was examined.

Results: Of 14,132 papers evaluated, 79 reported prevalence of weekly GORD. Nineteen of these study populations, containing 111,459 participants, also reported the proportion of individuals with dyspepsia. The prevalence of dyspepsia in those with weekly GORD was 43.9% (95% CI, 35.1–52.9%). The pooled OR for dyspepsia in individuals with weekly GORD, compared with those without, was 6.94 (95% CI 4.33 to 11.12). The OR for dyspepsia in weekly GORD significantly higher than for any geographical region of the world, indicating a significantly higher diagnostic criteria used. The pooled degree of overlap between the two conditions was 25.9% (95% CI, 19.9–32.4%), varying from 22% when the Bowel Disease Questionnaire was used to define weekly GORD, to 42.6% with the Mayo Reflux Questionnaire.

Conclusion: The OR of dyspepsia in individuals with weekly GORD was seven-fold that of individuals without GORD, and that there is overlap between the two conditions in up to one-quarter of individuals. Reasons for this remain speculative, but may include shared pathophysiological mechanisms or residual confounding.

Introduction: In the recent years, there has been an increasing recognition of the presence of gastrointestinal (GI) dysfunction in patients with neurologic diseases. There are no studies examining a relationship between achalasia and neurodegenerative/demyelinating diseases of central nervous system, although these diseases might have common features. For example, a number of genetic variations have been shown to increase the risk of both conditions (e.g. HLA-DQB1-insertion on chromosome 6 may be strongly associated with both achalasia and multiple sclerosis suggesting that autoimmune processes are involved in their etiopathogenesis). Several other findings (e.g. inflammatory infiltrates, Lewy’s bodies, geospatial gradient etc.) are also present in both patients with achalasia and with neurodegenerative/demyelinating diseases.

Aims & Methods: The aim of our prospective study is to examine a prevalence of neurodegenerative/demyelinating diseases in a cohort of consecutive patients with confirmed esophageal achalasia. Achalasia was diagnosed by high-resolution manometry, endoscopy and esophagogram. A total of 140 consecutive patients with esophageal achalasia have been questioned about the occurrence of neurological diseases and symptoms in their personal and family history. Those with a suspicion of a neurological disease were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGID.s. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGID.s. Achalasia was diagnosed by high-resolution manometry, endoscopy and esophagogram. A total of 140 consecutive patients with confirmed esophageal achalasia (dysphagia, regurgitation, chest pain). Among patients with a presence of neurological symptoms, 5 patients (3.6%) had definitely been diagnosed with a neurodegenerative/demyelinating disease: multiple sclerosis - 2 patients, Lebert’s optic neuritis - 1 patient, Parkinson’s disease - 1 patient and Allgrove syndrome - 1 patient). Furthermore, 7 patients with a positive questionnaire had been diagnosed with other neurological diseases (tetrany n=1, carpal tunnel syndrome n=1, episcleritis n=1, subdural hematoma n=1, idiopathic intracranial hypertension n=1) and 4 patients had a positive questionnaire had been diagnosed with other neurological diseases (tetrany n=1, carpal tunnel syndrome n=1, episcleritis n=1, subdural hematoma n=1, idiopathic intracranial hypertension n=1). For those with neurological symptoms (vs. 0 out of 89 patients without neurological symptoms) had a positive family history of a neurodegenerative or a demyelinating disease. Among 106 patients with a neurodegenerative/demyelinating disease, 30 of them (27.8%) described dysphagia as a part of their personal history. These patients will be examined by esophageal manometry.

Conclusion: Our results imply an increased prevalence of neurodegenerative/demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

Introduction: Visceral pain is a complex percept influenced by numerous factors. Of these, differences in the autonomic nervous system (ANS)–in particular, parasympathetic cardiac vagal tone (CVT)–has been suggested to have a physiological role in the regulation and modulation of painful sensory signalling, to the extent of vagal nerve stimulation (to raise subject CVT) being tested as a possible anti-nociceptive.

Methods: To date, no studies have explored the brain functional connectivity or network properties of CVT in relation to a painful stimulus, and thus this was our aim. In 21 healthy participants (10 male; mean age 30 years (range 21–53 years), we quantified resting CVT using a Neuroscope. For all subjects, functional MRI data were acquired using a 3T MRI scanner during painful oesophageal balloon distension as described elsewhere(1). The effect of resting CVT on brain networks during acute oesophageal pain were determined by means of network based statistics(2). Both groups had prior to any pain both an autonomic visceral pain literature and included the following: bilateral neck, upper thorax, upper ribcage, upper abdomen, lower abdominal, lower thorax, both shoulders, labia (28%) described dysphagia as a part of their personal history. These patients will be examined by esophageal manometry.

Results: We identified a unique subcortical brain connectivity network in the high resting CVT individuals when exposed to acute oesophageal pain. This complex symmetrical network comprised all 11 nodes with a total of 18 edges (significant

When considered jointly with other predictors, psychological attribution of symptoms was significantly positively related to both bowel symptom severity (non-FGID: OR = 0.31, SE = 0.13; Full: OR = 0.74, SE = 0.11) and epigastric symptom severity (FGID: OR = 0.63, SE = 0.09; Full: OR = 0.63, SE = 0.11). The same was the case for worry (Bowel: Full: OR = 1.40, SE = 0.21; Epigastric: OR = 1.58, SE = 0.27; Full: OR = 1.54, SE = 0.23). For bowel symptoms, problem-focused coping (OR = 2.30, SE = 0.98) was an additional independent positive (notably, not negative) predictor among participants without FGIDs. 
functional connections). These interconnections included the following: thalamo-amygдala, thalamus-hypothalamus, hypothalamus-NAc, amygdala-puinеn amygdala-NAc and insula-patumеn. No significant network was identified for the low CVT group.

Conclusion: During acute oesophageal pain, resting cardiac vagal tone yields a unique combination comprising numerous complex subcortical brain regions, many of which have been previously associated with either visceral pain or modulation of baseline autonomics either at the physiological or neuroanatomical level (3). Previous research has suggested that a high resting CVT may be protective of nociceptive signalling, and furthermore studies investigating vagal nerve stimulation have included and reported that of anti-nociception (4). Given the well-established role of these subcortical regions in pain processing, we suggest that this network identified may be of significance as to the neurophysiological process of parasympathetic modulation of painful sensory signalling. Lastly, to date, no studies have undertaken real-time assessment of the ANS (including CVT) during functional brain imaging and acute visceral pain. Future studies should investigate for this.

P1170 RAPID DRINK CHALLENGE (RDC) TEST DURING OESOPHAGO-GASTRIC JUNCTION OUTFLOW OBSTRUCTION D. Biasutto, F. Mion, A. Garros, S. Roman Digestive Physiology, Lyon 1 University and Hospices Civils de Lyon, Lyon;France

Contact E-mail Address: d.biasutto@unicampus.it

Introduction: Oesophageo-gastric junction outflow obstruction (OGJOO) is of unclear significance. It may be secondary to an incomplete form of achalasia, a mechanical obstruction or be idiopathic. Rapid drink challenge (RDC) test is easy to perform during oesophageal HRM.

Aims & Methods: We aimed to assess the yield of RDC in patients with OGJOO. From a database of 3222 consecutive oesophageal HRM performed from 01/2012 to 03/2017, we extracted patients with OGJOO according to the Chicago Classification v3.0. HRM protocol consisted of 10 5-ml water swallows in supine position and RDC test (200-ml free drinking) in sitting position. Distal contractile integral (DCI) integrated relaxation pressure (IRP), distal and pan-oesophageal presurization (POP; homogenous oesophageal presurization >30 mmHg) were reported for 5-ml swallows. POP and oesophageal shortening (OS) were analysed during RDC. Symptom severity was assessed with Eckardt score. Causes of OGJOO were determined by reviewing patients’ chart for previous surgical process of parasympathetic modulation of painful sensory signalling. While RDC test cannot be used to determine EGJOO cause, patients with POP or OS during RDC had more severe dysphagia than those without. In patients with POP, the highest DCI might be secondary to obstruction. Further prospective studies should determine if RDC test could help to select patients who might benefit from treatment.

P1171 THE NORMATIVE VALUES OF A NEW 36 CHANNELS WATER PERFUSION ESOPHAGEAL MOTILITY CATHETER S. Bor, S. Kipcak Gastroenterology Sec., Ege Reflex Study Group, Ege University, izmir;Turkey

Contact E-mail Address: kipcaksegzi@gmail.com

Introduction: High resolution manometry (HRM) is performed with solid-state catheters (SS) in many centers. However according to Chicago classification, very limited data from healthy volunteers are available for some catheters and starting from IRP, numerical values are crucial for the diagnosis. Because of the cost of the SS-HRM catheters many centers especially from developing countries use water perfusion HRM (W-HRM) catheters up to 24 channels and normal values are even more limited.

Aims & Methods: We evaluated a prototype 36 channels W-HRM reused catheter allowing to measure 3-D pressure volume analysis of lower esophageal sphincter in healthy volunteers and compared to 36 channels SS-HRM catheters (Laborie-MMS Canada). We included 43 healthy volunteers without any upper gastrointestinal complaint. Upper gastrointestinal endoscopy and 24h impedance-pH monitoring performed in all subjects. Four subjects were excluded because of silent GERD. 39 subjects were analysed (25 males, W-HRM (n = 39), SS-HRM (n = 33)). Thirty-three patients underwent two esophageal manometry studies within two consecutive days with a random order. Procedures were performed in supine position with receiving ten times 5 ml water, five times solid food and multiple water swallow with 200 ml of water. 36 channel water-perfused 3-D HRM catheter and 36 channel solid state HRM catheter were used (Laborie-MMS Canada).

Results: There was significant differences between two catheters in terms of Integrated Relaxation Pressure (IRP), Distal Contractile Integral (DCI) and DCI expanded, LES resting pressure, % of ineffective peristalsis, and esophageal length both with water and solid food swallows (Table). No difference has been shown with distal latency (DL), LES length, breaks size (Table).

Conclusion: Water perfusion HRM catheter exhibits significantly lower values especially for IRP, DCI, LES resting pressure. Centers which are working with water perfusion catheters should not accept universal normal established with solid state catheters and need to work on their normative values. The ineffective peristalsis pattern is common with water perfusion catheters.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table (continued)
Introduction: The Chicago Classification (CC V3.0) defined the presence of esophageal outflow obstruction (EGJ-OO) when the value of integrated releasing pressure (IRP) is higher than 15 mmHg during high-resolution manometry (HRM). Both low-volume (10 ml) multiple rapid swallow (MRS) and high-volume (200 ml) rapid drinking test (RDT) were never evaluated to detect the inhibition of esophageal body in patients with EGJ-OO.

Aims & Methods: The aim of this study was to compare the efficacy of MRS and RDT in evaluating the esophageal body inhibition during repetitive swallow in patients with EGJ-OO and in patients with functional heartburn (FH) considered as control group. From a larger group of patients evaluated for dysphagia with negative upper endoscopy, we enrolled consecutive patients with EGJ-OO, and as control group, patients with functional heartburn (FH) defined according to the Rome IV criteria. EGJ-OO was defined according to CC V3.0. HRM performed according to the Italian guidelines. All patients underwent 3 MRS (10 ml of water in 5 swallow in less than 10s) and 1 RDT (200 ml of water freely drunk). The mean DCI of MRS and the DCI of RDT were compared with DCI of 10 single swallows (SS). The MRS/SS and RDT/SS ratio were calculated.

Results: We evaluated 30 patients with EGJ-OO (18 males; mean age 49.5 ± 12.4 yrs) and 30 patients with FH (17 females; mean age 41.2 ± 13.6). Impedance and pH 24-h analysis was performed to select patients with FH (normal AET and number of reflux and lack of reflux-symptom correlation). During HRM the mean DCI resulted similar in patients with EGJ-OO compared to FH (p = 0.039). One-hundred and eighty MRS and 60 RDT were evaluated. The lack of body inhibition was found in 11% (20/180) during MRS and in 53% (15/30) of FH (p < 0.05). The MRS/RDT ratio resulted >1 in both groups. All results are reported in Table 1.

Conclusion: Patients with EGJ-OO showed less peristaltic reserve during MRS and RDT. The RDT evidenced more frequently lack of body inhibition in patients with EGJ-OO.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: MRS is a more reliable test to detect peristaltic esophageal reserve when compared to RDT both in patients with IEM or those with normal esophageal peristalsis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introducción: El objetivo de este estudio consistía en comparar la eficacia de la MRS y el RDT en la evaluación de la inhibición de la masa esofágica durante el acto de deglución repetitiva en pacientes con EGJ-OO y en pacientes con bocio funcional (FH) considerado como grupo control. De un grupo mayor de pacientes evaluados por disfagia con endoscopia negativa, se incluyeron consecutivos con EGJ-OO, y como grupo control, pacientes con bocio funcional (FH) definido de acuerdo al criterio de la IV Romeo. EGJ-OO se definió de acuerdo al CC V3.0. HRM según las guías italianas. Todos los pacientes realizaron 3 MRS (10 ml de agua en 5 tragos en menos de 10s) y 1 RDT (200 ml de agua bebiendo libremente). El DCI medio de MRS y el DCI de RDT se comparó con el DCI de 10 tragos singulares (SS). La relación MRS/SS y RDT/SS se calculó.

Resultados: Se evaluaron 30 pacientes con EGJ-OO (18 varones; edad media 49.5 ± 12.4 años) y 30 pacientes con FH (17 mujeres; edad media 41.2 ± 13.6). Impedancia y pH 24-h se analizaron para seleccionar pacientes con FH (normal AET y número de reflus y falta de correlación síntoma-síntoma). Durante HRM, la media de DCI se resultó similar en pacientes con EGJ-OO comparado con FH (p = 0.039). Ciento y ochenta MRS y 60 RDT fueron evaluados. La falta de inhibición de masa fue encontrada en 11% (20/180) durante la MRS y en el 53% (15/30) de FH (p < 0.05). La relación MRS/RDT resultó >1 en ambos grupos. Todos los resultados se reportan en el Table 1.

Conclusion: Los pacientes con EGJ-OO mostraron menos reserva peristáltica durante MRS y RDT. El RDT evidenció más frecuentemente la falta de inhibición de masa en pacientes con EGJ-OO.

Disclosure of Interest: Todos los autores han declarado no tener conflicto de interés.
Distension to F. Wuestenberghs PATIENTS WITH OESOPHAGEAL DIVERTICULA compared to controls). Trans-EGJ bolus flow metrics were similarly abnormal assessing esophageal bolus presence (NI) and clearance (IR) were consistently abnormal of esophageal bolus transit and esophageal emptying in conjunction with lower proximal smooth muscle contractile function with all bolus consistencies in GERD patients compared to controls. Metrics assessing esophageal bolus presence (NI) and clearance (IR) were consistently abnormal in GERD patients (Table, p = 0.001 for all bolus consistencies for each comparison to controls). Trans-EGJ bolus flow metrics were similarly abnormal in GERD (BFT, p < 0.001 for all bolus consistencies compared to controls). IBP metrics were highest with solid swallows, especially in GERD patients compared to controls (Table). Within GERD, a gradient of increasing dysfunction in bolus presence and bolus clearance was noted, with least abnormalities with water swallows and the worst metrics with bread swallows (p < 0.02 across groups for each bolus comparison). IBP-EF (p < 0.05) and trans-EGJ BFT (p = 0.004) were higher during water and viscous swallows with atypical symptoms compared to typical symptoms. NI was consistently lower in patients reporting ≤75% symptom improvement following AFS with all bolus consistencies (p ≤ 0.046).

Conclusion: Automated pressure flow analysis of HRM studies demonstrates abnormalities of esophageal bolus transit and esophageal emptying in conjunction with lower proximal smooth muscle contractile function with all bolus consistencies in GERD patients compared to controls. Metrics assessing esophageal bolus presence may have prognostic value in GERD patients undergoing AFS. Disclosure of Interest: N. Rommel: Holder of patent on AIM technology with Taher Omari T. Carlson DA, et al. Neurogastroenterol Motil. 2017
Results: We enrolled 35 achalasia patients (14 Type I, 16 Type II and 5 Type III). Ten patients underwent PD, 11 LHMD, 8 LHMD-T and 6 LHMD-NR. At baseline, no significant difference (p = 0.766, 0.434, 0.782) was observed in sex, age, smoking status or Eckardt score, GERDQ score, integral relaxation pressure (IRP) and Eckardt-CI were recorded. All Type III subjects underwent LHMD-D (3) and LHMD-T (2). After all the procedures, in all the patients there was a significant decrease in Eckardt score, IRP and EGJ-CI (p < 0.001, < 0.001 and < 0.05, respectively). PD and LHMD-NR showed higher Eckardt-CI (20.9 ± 23.5 ± 11.1 mmHg, respectively) and IRP (12.2 ± 3.4 and 13 ± 4.5, respectively) than LHMD-D and LHMD-T (18.4 ± 5.9, p < 0.05 and 9.3 ± 4.1 p < 0.05 mmHg/cm, respectively for EGJ-CI; 5.2 ± 2.5, p < 0.05 and 2.3 ± 3.7 p < 0.001 mmHg/cm, respectively for IRP). Post-operative Eckardt score was lower in LHMD-D and LHMD-T (2.1 ± 0.5 and 2.0 ± 0.6, respectively) than PD and LHMD-NR (4.2 ± 1.0, p < 0.01 and 3.7 ± 1.5, p < 0.05). Post-operative GERDQ score was significant higher in LHMD-T (3.0 ± 1.7 vs. 8.2 ± 3.9, p < 0.05). Low post-operative Eckardt-CI values correlated with an increased risk of high post-operative GERDQ score (p < 0.05, odds ratio 4.223, 95% CI 0.964–2.123).

Conclusion: All procedures performed to treat achalasia produced an adequate relief of dysphagia. LHMD-D and LHMT seem to result in a stronger alteration of the EGJ with LHMT resulting in an increased risk of post-operative reflux.

P1179  EFFECTIVENESS OF CAP-ASSISTED DEVICE IN THE ENDOSCOPIC MANAGEMENT OF FOOD BOLUS OBSTRUCTION IN THE UPPER ESOPHAGUS

M. Ooi, E. J. Young, N. Q. Nguyen
Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieoo_ail@yahoo.com

Introduction: Although cap-assisted technique has been shown to be effective in removing food bolus from the upper gastrointestinal tract, there is no data on food bolus obstruction (FBO). This study aimed to assess the performance of cap-assisted technique in the management of esophageal FBO, as compared to conventional endoscopic methods.

Aims & Methods: Outcomes of all patients who present with FBO requiring emergency endoscopic management between 2011 and 2016 were prospectively collected. The main measured outcomes were procedural success, procedural time, complications and length of hospital stay.

Results: In total, 113 patients (214M:102F; 58.3±18.3 years) were enrolled with FBO. Of FBO, 267 (84.7%) had evidence of food bolus in the esophagus on endoscopy and 48 (15.2%) patients had spontaneous passage of food bolus. Out of the 199 patients who had impacted FBO, 93 had cap-assisted technique and 106 had conventional approach, with no differences in the type of location of FB. The success rate of cap-assisted technique (100%) was comparable to that of conventional techniques (97.2%, P=0.10). Patients who had failed extraction by conventional techniques (n=3) were successfully treated when switched to cap-assisted approach. Cap-assisted approach was associated with a shorter total procedural time (34.8±22 min, P=0.006), a shorter length of hospital stay (0.95±0.36 and 1.38±1.36 days, P=0.0017) and more en-block removal (95% vs 22%, P<0.0001). There were more complications in the conventional than the cap-assisted group (7/106 vs. 0/93; P=0.01).

Conclusion: Cap-assisted technique is 100% effective in the management of impacted FBO in the esophagus, with a significantly shorter procedural time and lower complication rate than conventional methods. Although the findings suggest that cap-assisted technique should be the first line technique in the management esophageal FBO, further evaluation with a randomized multicenter trial is warranted.

Introduction: Functional dyspepsia (FD) is defined in that there is no evidence of organic disease which is likely to explain the symptoms. However, there was no obvious definition about “organic disease”. Therefore, during the endoscopic examination, we have to consider such findings as the “organic disease” or not. If these findings have no obvious definition about “organic disease”. Therefore, during the endoscopic examination, we have to consider such findings as the “organic disease” or not. If these findings have no evidence of obvious mucosal change which may cause dyspepsia, the patient should be considered as non-erosive reflux disease in the Kyoto classification. This classification, endoscopic findings are defined precisely. However, it is not discussed whether we can consider such findings as the “organic disease” or not. Interestingly, AUC5 and AUC15 values (24.85 /1.31 and 56.11±2.51, respectively) in EPS patients with pancreatic enzyme abnormalities were significantly higher than the ratio of EPS patients without it. There were more complications in the conventional than the cap-assisted group (7/106 vs. 0/93; P=0.01). Overall, 64% of EPS patients with pancreatic enzyme abnormalities were diagnosed by endoscopy as having concomitant early chronic pancreatitis post-GRAF results.

Conclusion: Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There was not available data about the overlap between functional dyspepsia (FD) and pancreatic diseases.

Aims & Methods: We aimed to determine whether epigastric pain syndrome (EPS) accompanying with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS using endosonography. We enrolled 99 consecutive patients presenting with typical symptoms of FD, including patients with postprandial distress syndrome (EPS) and EPS with pancreatic enzyme abnormalities (n=41) and EPS without pancreatic enzyme abnormalities (n=42) based on Rome III criteria. Gastric motility was evaluated using the 13C-acetate breath test. Early chronic pancreatitis was detected by endosonography and graded from 0 to 7.

Results: The ratio of female patients among EPS patients (34/41) with pancreatic enzyme abnormalities was significantly (p=0.0018) higher than the ratio of female EPS patients (20/42) without it. Postprandial abdominal distention and physical component summary (PCS) scores in EPS patients with pancreatic enzyme abnormalities were significantly disturbed compared to those in EPS patients without it. Interestingly, AUC1, AUC5, and AUC15 values (24.85±1.31 and 56.11±2.51, respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly (p=0.002 and p=0.001, respectively) increased compared to those (19.75±1.01 and 47.02±1.99, respectively) in EPS patients without it.

Conclusion: Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

Introduction: Caustic esophageal injury is corrosive burns of esophagus and mostly caused by ingestion of chemical caustic substances such as strong acid or alkali. The caustic esophageal stricture is refractory and patients suffered from multiple dilation. Clinical ESD results revealed that benign stricture would be the first line technique in the management esophageal FBO, further evaluation with a randomized multicenter trial is warranted.

 Disclosure of Interest: All authors have declared no conflicts of interest.
Results: The endoscopic follow-up was planned every month. After 1 months, 18.23 cm esophageal region had to be normal. Within 6 months, the stricture process was existingly delayed as expected. The patient stated his symptom was remarkably improved. Gastroscopy revealed the esophageal implanted lesion was covered with an epithelium and the luminal surface was flat, without ulceration.

Conclusion: Autologous esophageal mucosa transplantation might facilitate tissue re-epithelialization, reduce pathological fibrosis, and be helpful for managing or preventing esophageal strictures. More clinical controlled trials are required to provide evidenced-based recommendation and promote its clinical application.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to compare the prevalence of FD in patients with OSA and healthy volunteers. A total of 60 consecutive OSA patients (defined as Epsworth sleepiness scale > = 10, and apnea-hypopnea index > 10/hour during polysomnography; mean age: 47.6 years, male: 83.3%) and 60 healthy age-and-sex-matched volunteers were recruited in a prospective case-control study. Questionnaires were applied for the diagnosis of functional gastrointestinal disorders (FGIDs) according to Rome III criteria.

Introduction: The assessment of acid secretion is important in order to prescribe H2 blockers or proton pump inhibitors (PPIs) for treating gastroesophageal reflux disease (GERD). However, it is not currently used in clinical practice. Serum pepsinogen I (PGI) has been proposed as a non-invasive surrogate. Aim of this study was to compare in a group of patients with different acid related diseases serum levels of PGI and M.A.O.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: The mean M.A.O. value in group 1 was 2.15 mEq/l, in Group 2 52.49 mEq/L, in Group 3 17.48 mEq/L. A statistically significant difference was found between the 3 groups (Group 1 vs. Group 2 p < 0.00001; Group 1 vs. Group 2 p < 0.001; Group 2 vs. Group 3 p < 0.0001). The PGI mean values in Group 1 was 11.39 μg/l, in Group 2 107.72 μg/l in Group 3 84.28 μg/l (Group 1 vs Group 2: p = 0.00001; Group 2 vs Group 3 p < 0.05). The relationship between M.A.O. and PGI showed a Pearson R = 0.683 (p = 0.001). No statistically significant difference was found comparing M.A.O. and PGI in the single groups (p = ns).
In the 118 subjects of the control group (63 women), the mean age was 28.3 years (range: 18–72 years), BMI 23.2, (M 24.2; F 22.3, P

The mean age of patients with MO was 43.1 years (range 19–68) with no

Aims & Methods: We conducted a cross-sectional study of 32,762 asymptomatic adults who underwent routine health check-ups including screening endoscopy from August 2006 to December 2011. Sarcopenia was defined as appendicular skeletal muscle mass (ASM)/body weight (%) value beyond two standard deviations below the mean for healthy young adults. Participants were categorized into four groups according to obese and sarcopenic status: normal, obese, sarcopenic, and obese sarcopenic.

Results: In a multivariate model adjusted for age, sex, smoking status, alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was higher in obese [adjusted odds ratio(OR), 1.38; 95% confidence interval (CI), 1.18–1.64] compared to the non-obese group. Moreover, VAT, ratio of VAT to SAT, and TAT were significantly higher in LC

Contact E-mail Address: ayllonsonia@hotmail.com

Introduction: Obese patients with MO were considered one of the 21st century plagues in the Western world. Although its etiology is multifactorial, eating habits represent an important factor in its development. (1). The caloric load, the proportion of its components and its patterns have been the object of multiple studies (1–5). One of the most controversial aspects is the relationship between the frequency of meals and body weight.

Aims & Methods: The aim of the study was to determine the food rhythm (frequency and time spent in eating) in patients with morbid obesity (MO), based on diary records during the 24-H esophageal ph-monitoring studies. This was a retrospective study, including 100 patients (77 women), with MO in whom bariatric surgery was indicated and 118 non-obese subjects from the control group of the Spanish Digestive Motility Group. All were submitted to esophageal manometry and 24-H esophageal pH-monitoring according to the usual technique. During pHmetry it was recommended that the diet be similar as usual. The relationship of demographic aspects with the number of meals and the time invested in them, based on data from the pH meter was analyzed.

Statistical analysis was performed with the STATGRAPHICS Centurion program. The limit of statistical significance was set at p < 0.05. The study was approved by the ethics committee of our hospital. The informed consent of the participants was obtained for the performance of the tests.

Results: The mean age of patients with MO was 43.1 years (range 19–68) with no difference between men and women. The mean BMI was 41.55 (M 43.3; F 41.0, P = 0.05). Age and BMI differ-

Conclusion: Our findings suggest that sarcopenia, regardless of obesity, is more harmful condition for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1187 FOOD RATE (FREQUENCY AND TIME SPENT IN EATING) IN PATIENTS WITH MORBID OBESITY: DIFFERENCES AND SIMILARITIES BETWEEN MEN AND WOMEN

P1188 ONE DRINK CAN INCREASE A RISK FOR ESOPHAGEAL, STOMACH AND COLORECTAL CANCER IN A COHORT OF 23,323,730 KOREAN ADULTS

Y.J. Choi, D.H. Lee

Internal Medicine, Seoul National University Bundang Hospital, Seongnam/Korea, Republic of

Contact E-mail Address: olivi606e@naver.com

Introduction: Epidemiologic findings of low-volume alcohol consumption in relation to gastrointestinal cancers including gastric cancer are inconsistent.

Aims & Methods: The association between alcohol intake and esophageal, gastric and colorectal cancer risk in a population-based prospective cohort of 23,323,730 adults in Korea who had undergone a biennial evaluation provided by the National Health Insurance Corporation between the years 2009 and 2012.

Results: After median 3.4 years of follow-up, 9171 esophageal, 135,382 gastric and 154,970 colorectal cancer cases were identified. Cox proportional hazards regression models were used to estimate hazard ratios (HR) and corresponding 95% confidence intervals (95% CI). Light drinking as well as moderate to heavy alcohol consumption significantly increased the risks of the three gastrointestinal cancers (HR 1.51; 95% CI, 1.43–1.60; HR 1.08; 95% CI, 1.06–1.09; HR 1.12; 95% CI, 1.11–1.14) compared with non-drinkers after adjusting for age, sex, smoking, exercise, income, body mass index, and diabetes. For esophageal cancer, there was a dose-dependent linear relationship. However, no association was observed between prediagnostic alcohol consumption and all cause mortality.

Conclusion: Light drinking including even one alcoholic drink a day is associated with increased risks of esophageal, gastric and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1189 THE INFLUENCES OF VISCERAL FAT AREA ON THE SITES OF ESOPHAGEAL MUCOSAL BREAKS AND SYMPTOM SEVERITIES IN SUBJECTS WITH GASTROESOPHAGEAL REFLUX DISEASES

E. Cho, J.H. Kim

Internal Medicine, Dongguk University College of Medicine, Goyang/Korea, Republic of

Contact E-mail Address: kimjaehak@duc.or.kr

Introduction: Some studies have suggested the central obesity as a risk factor for gastroesophageal reflux diseases (GERD). However, the associations between visceral adipose tissue (VAT) and the sites of esophageal erosions or the symptom severities of GERD have not been studied yet.

Aims & Methods: The aim of this study was to evaluate the influences of visceral adipose tissue and the locations of erosions and symptoms of GERD. The subjects who underwent abdomen computerized tomography and esophagogastroduodenoscopy for routine checkup at the same day were collected from January 2007 to October 2016. 177 subjects who had erosive esophagitis (LA class A to D) were enrolled. Questionnaires including gastrointestinal symptoms were written before examinations. The abdominal obesity was evaluated by measuring visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), ratio of VAT to SAT, total adipose tissue (TAT), body mass index (BMI) and waist circumference (WC).

Results: Lesser curvature (LC) side of esophagogastric junction (EGJ) was the most frequent site of mucosal breaks (103 cases, 58.2%) followed by posterior wall side (71 cases, 40.1%), anterior wall side (25 cases, 14.1%) and fundus side (4 cases, 9.9%). Mucosal breaks in 24-H pH monitors were found in study subjects (61.3% vs. 36.4%, p = 0.04). BMI (25.6 ± 4.5 vs. 24.2 ± 3.1, p = 0.01) and WC (89.0 ± 11.8 vs.85.0 ± 9.1, p = 0.01) were significantly higher in LC group. Moreover, VAT, ratio of VAT to SAT, and TAT were significantly higher in LC group. In the multivariate analysis, a higher VAT area (odds ratio (OR) 3.47, 95% confidence interval 1.38 to 8.73, 1st quartile vs. 4th quartile, p < 0.01) and ratio of VAT to SAT (OR 2.99, 95% CI 1.15 to 6.70, 1st quartile vs. 4th quartile, p = 0.02) were strongly associated with the mucosal breaks in LC.
P1190 A LESS COMPETENT OESOPHAGO-GASTRIC JUNCTION IS ASSOCIATED WITH OESOPHAGEAL ACID HYPERSENSITIVITY EVEN IN HEALTHY CONTROLS

C. Lottrup1, A. L. Krarup1, P. Ejstrud2, B. P. Mcmahon1, A. M. Drews1 1Mech-sense, Department Of Gastroenterology And Hepatology, Aalborg University Hospital, Aalborg/Denmark 2Surgery A, Aalborg University Hospital, Aalborg/Denmark 3TAGG Research Centre, Tallaght Hospital and Trinity College, Dublin/Ireland

Contact E-mail Address: chlo@rm.dk

Introduction: In normal subjects, the oesophago-gastric junction (OGJ) sphincter complex maintains a tight barrier between the oesophagus and stomach acid. However, gastro-oesophageal reflux disease (GERD) caused by acid reflux has a prevalence of up to 26% [1]. One major factor determining whether gastro-oesophageal reflux occurs and eventually generates symptoms is the competency of the OGJ, which can be studied using distensibility testing. This way, we have previously shown in patients with Barrett’s oesophagus and healthy controls that an incompetent sphincter function was associated with more frequent reflux symptoms [2]. In the same patient groups, we also found greater oesophageal acid exposure and lower mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [1]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Aims & Methods: We aimed to characterize oesophageal acid sensitivity in relation to OGJ competence, hypothesizing that sensitivity increases with impaired sphincter function. Twenty-three patients with Barrett’s oesophagus (mean age: 64.2 ± 7.7 years) and 12 healthy controls (mean age: 54.9 ± 10.8 years) were examined. A standard upper endoscopy to locate the OGJ was followed by distensibility testing of the OGJ using the EndoFLIP probe. At a later visit, experimental oesophageal sensitivity was assessed using a multimodal stimulation probe. After placement in the oesophagus just above the OGJ, the probe allows the filling and emptying of an attached polyurethane bag with water, stimulation with electrical current, and infusion of acid. Using this probe, mechanical disturbance of the bag, thermal stimulation at increasing temperature, electrical stimulation, and acid perfusion with 0.1 M hydrochloric acid (a Bernstein test) were performed. All stimulations were stopped when the subject felt moderate pain, equal to seven on a 0–10 visual analogue scale validated for visceral pain. Data were analyzed using multi-level, mixed-effects regression analysis in Stata 12.

Results: Oesophageal acid sensitivity increased with a more incompetent sphincter function. A lower tolerated acid volume was associated with greater distensibility index (P = 0.03) and with lower pressure (P = 0.03) in the OGJ in all subjects examined together and separately in healthy controls (P = 0.006 and 0.03, respectively). Performing separate analyses in patients with BO, these associations were not present (all P > 0.7). Sphincter function was associated with neither oesophageal sensitivity to mechanical, heat, nor electrical stimulation (all P > 0.13).

Conclusion: Oesophageal acid sensitivity increased with a more incompetent OGJ. Based on this and previous findings, we suggest that even in some healthy controls, a modest degree of OGJ incompetence allows gastric acid to reflux. This may again lead to low-grade oesophageal inflammation and mucosal damage, thereby evoking acid hypersensitivity. The latter mechanism probably constitutes a reflux protective mechanism towards acid reflux. Disclosure of Interest: B.P. McMahon: Barry P McMahon holds a minor share in Crospon Inc., Galway, Ireland who manufactures the EndoFLIP probe. All other authors have declared no conflicts of interest.

P1191 THE MUCOSAL INTEGRITY IN PHENOTYPES OF GASTROESOPHAGEAL REFLUX DISEASE SUBGROUPS AND FUNCTIONAL HEARTBURN

P. Ergun1, S. Kipcak1, S. Bor2 1Gastroenterology Sec., Ege Reflux Study Group, Ege University, Izmir/Turkey 2Gastroenterology Service, Ege Reflux Study Group, Ege University, Izmir/Turkey

Contact E-mail Address: pelinergun@yahoo.com

Introduction: Three different phenotypes of gastroesophageal reflux disease (GERD) such as erosive reflux (ERD), nonerosive reflux (NERD), esophageal hypersensitivity (EH) and functional heartburn (FH) might have different pathophysiologic changes within the esophageal epithelium and the data is limited.

Aims & Methods: We aim to investigate the electrophysiological differences and diffusion characteristics as a reflection of tissue integrity using Ussing chamber technique. Distal esophageal mucosal biopsies from 14 healthy controls (5 men, 40.6 ± 11.2 years) and 62 patients with GERD (40 men, 42.9 ± 12.3 years, n = 26 LA grade A/B, n = 8 LA grade C/D, n = 22 NERD, n = 6 EH) and 11 patients with FH were studied from November 2015 until March 2017. GERD and quality of life questionnaires, high-resolution esophageal manometry, 24-hr impedance-pH monitoring, upper gastrointestinal endoscopy with esophageal biopsies were performed in all patients. Biopsies were put into the chambers to measure the transepithelial resistance (TER), potential difference (PD) and tissue permeability via fluorescein diffusion within two hours as well as evaluation of dilated intercellular spaces with light microscopy.

Results: Esophageal biopsies of healthy volunteers (163.5 ± 41.1 ohms) had significantly higher TER when compared to total GERD patients (132.5 ± 38.7 ohms). Although the TER results of whole GERD subtypes decreased compared to healthy controls, only ERD groups were significantly lower (123.3 ± 29.8 ohms) (Table 1). There was also no significant difference in any (FH, EH, NERD) groups between NERD, FH and EH groups. The mucosal permeability of GERD subtypes was significantly higher than the healthy controls. The PPI-unresponsive subjects (n = 10, 94.8 ± 36.5 pmols) were much more permeable to fluorescein compared to PPI-responsive subjects (n = 52, 56.0 ± 32.4 pmols) in all GERD patients (p = 0.009).

Conclusion: The TER and permeability results imply that ERD and NERD groups showed a barrier disruption. However, epithelial permeability was not different in EH and FH groups. The dilatation of intercellular spaces may contribute to increased mucosal permeability in true-NERD and ERD patients. EH and FH patients might have different pathophysiologic pathways than others.

P1192 PEPINS AND PH LEVELS OF HUMAN GASTRIC JUICES IN GASTROESOPHAGEAL REFLUX DISEASE SUBGROUPS AND FUNCTIONAL HEARTBURN

P. Ergun1, S. Kipcak1, P. Dettmar2, A. Woodcock2, S. Bor3 1Gastroenterology Sec., Ege Reflux Study Group, Ege University, Izmir/Turkey 2Gastroenterology Service, Ege Reflux Study Group, Ege University, Izmir/Turkey 3Biomed Limited, Hall/United Kingdom

Introduction: The major noxious agents of gastroesophageal reflux disease (GERD) on the esophageal epithelium are gastric acid and pepsin. Nevertheless, there is no precise information about pepsin concentrations in gastric juice.

Aims & Methods: We aimed to address the pepsin values and pH results among subtypes of GERD and functional heartburn. 46 patients with GERD (23 erosive reflux disease LA grade A/B (ERD-A/B), 5 ERD-C/D, 14 nonerosive reflux disease-NERD, 4 esophageal hypersensitivity-EH), 8 functional heartburn (FH) and 17 healthy controls (HC) were included into the study. Upper gastrointestinal endoscopies were performed off PPI. Patients were instructed not to aspirate the local anaesthetic solution and biopsy channel of the endoscope was dried before the suction. The gastric juices from the subjects were aspirated during endoscopy into a special beaker and their pH values were measured immediately. The specimens were analysed using the Peptest lateral flow device (RD Biomed Ltd UK), a colorimetric assay containing two unique human monoclonal antibodies that capture and detect pepsin protein.

Results: There were no significance between pepsin levels in any GERD phenotypes, FH and healthy controls (Table 1). The pH results of patients with ERD (1.8 ± 0.6) were significantly lower versus HC (2.6 ± 1.5). The pH levels of the
esophageal hypersensitivity (1.5 ± 0.2) were significantly decreased when compared to HC (2.6 ± 1.6) and also true NERD (4.0 ± 2.0).

Conclusion: Pepsin may be considered a damaging factor in pathophysiology of GERD, but we could not find any difference between GERD phenotypes and unaffected controls. NERD group had less gastric acid versus other groups but this finding needs more studies to confirm.

3Oncological Gastroenterology, Centro di Riferimento Oncologico di Aviano S.O.C. di Gastroenterologia, Aviano/Italy

Introduction: The diagnosis of Hp-related non-atrophic gastritis was made by means of values: PGI: 30–120 mU/L. The diagnosis of Hp-related non-atrophic gastritis was made by means of values: PGI: 30–120 mU/L; the diagnosis of gastroesophageal reflux disease (GERD) was diagnosed according to FSSG scale (Frequency score for the symptoms of gastroesophageal reflux disease) and 50 BMI < 30 non-obese, non-obese and not (GERD) diagnosed according to FSSG cases have been included. The cases included in the study concerned have been surveyed by means of the questionnaire including the demographic data and the extra esophageal reflux symptom. Serum biochemistry analyses (fasting glucose, insulin, lipid panel, uric acid, TSH, ALT) have been checked. Waist circumference has been measured. Body compositions and anthropometric measurements have been assessed through the biomechical impedance method (TANITA).

Results: In this study a statistically significant difference (p < 0.05) has been found when GERD-diagnosis group is compared with normal health control group in regard to waist circumference, BMI; LDL, Fat, Fat Mass, Total Body Water(TBW), obesity level, reflux score, acid reflux score and total score measurements. Fat free mass (FFM), muscle mass, bone mass, bone mineral density (BMD) measurements in between the both groups have not been found statistically significant difference (p > 0.05). Considering the extra esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, apnea, teeth grinding and GORH and the extra esophageal reflux symptoms has been found. Finally the patients group a positive correlation between acid reflux score and BMI (r = 0.298) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = -0.273) (p < 0.003) has been determined.

Mann Whitney U Test (Monte Carlo) - Min.:Minimum - Max.:Maximum

Conclusion: The frequency and severity of gastroesophageal reflux symptoms in the non-obese is closely related with body fat composition as those in the obese. Increase in abdominal and visceral fat composition may cause high risk of gastroesophageal reflux disease in individuals irrespective of their obesity.

Introduction: Esophageal baseline impedance (BI) levels have been recently proposed as a marker of mucosal integrity. Indeed, patients with non-erosive reflux disease (NERD) showed lower distal esophageal BI levels compared to healthy controls (HCs) due to the presence of abnormal esophageal acid exposure time (AET). On the other hand, no differences were found between NERD and HCs at proximal esophagus due to the limited proximal migration of the refluxate. Systemic sclerosis (SSc) is a systemic disease characterized by the deposition of collagen and matrix proteins in the connective tissue of the skin and visceral organs, such as the gastrointestinal tract. This event could potentially affect the conductivity of the esophageal wall and consequently reduce BI levels, also at proximal level, but data in this regard are limited.

Aims & Methods: We aimed to prospectively compare BI levels between a group of NERD patients and two groups of SSc patients, one with a clear manometric picture of scleroderma esophagus (i.e. hypotensive esophageal-gastric junction pressure and absent peristalsis) and one without esophageal involvement. Consecutive patients with heartburn and those with a definite diagnosis of SSc underwent upper endoscopy in order to assess the presence of esophageal mucosal lesions. Further, a group of healthy subjects was used as controls (HCs). Thereafter, all esophageal-negative and SSc patients underwent high-resolution manometry and impedance-pH testing off-therapy. Impedance-pH tracings were blindly and manually reviewed, and we measured distal AET and BI values at 3, 5, 7, 9, 11, 13, 15 and 17 cm above the lower esophageal sphincter, during the overnight rest, for at least 30 minutes after excluding swallows and reflux induced changes. NERD was diagnosed in case of reflux symptoms and abnormal AET.

Results: Fifty patients [38F; mean age 51.5 years] with NERD, 50 SSc patients [44F; mean age 49.5 years] with esophageal involvement, 30 SSc patients [28F; mean age 49.5 years] without esophageal involvement and 50 HCs [37F; mean age 49.5 years] were enrolled. All 50/50 (100%) NERD patients [median 7.2] and 44/50 (88%) SSc patients without esophageal involvement [3.1] and 0/50 (0%) patients with esophageal involvement [8.3] showed an abnormal AET compared to proximal median BI levels, whereas they were much lower in NERD patients with esophageal involvement (p < 0.05).

Conclusion: Proximal esophageal BI levels are able to segregate between scleroderma patients with and without esophageal involvement. The advent of novel and poorly invasive methods for the assessment of esophageal mucosal integrity will allow us to perform this measurement without the need of prolonged probe insertion.

Introduction: Gastroesophageal reflux disease (GERD), is characterized by frequent relapses after withdrawal of therapy and no prognostic markers of relapse are available to predict the outcome of the patients. Gastrin-17 (G-17) has been proposed as a non-invasive marker of reflux disease as well as a good marker of response to the therapy. Pepsinogen I (PG I) and Gastrin-17 (G-17) are claimed to increase in a statistically significant manner after proton pump inhibitors (PPIs) therapy. Aim of the study was to assess the prognostic value of G-17 and PG I levels for the prediction of early GERD relapse in a prospective open study.

Aims & Methods: We prospectively enrolled 221 consecutive GERD patients (F 113, mean age 52.5 years; range 28-74 years) with endoscopically proved diagnosis of esophagitis, according to the L.A. classification, all symptomatic (heartburn and/or regurgitation). All patients were treated with rabeprazole 20 mg once a day for 6-8 weeks, assessing at the end of the therapy the symptoms’ modifications by means of a questionnaire. In the group of asymptomatic patients, we performed a one-year follow-up, recording the GERD relapse episodes; only on-demand antacids were permitted. All patients underwent at baseline a blood sample and after the acute course of PPI therapy.

Results: One hundred eighty five patients were asymptomatic after the 6-8 weeks of PPI therapy and entered in the prospective evaluation for 12 months. 19 subjects were lost lasting the follow-up and finally 166 patients were available for the study analysis. 72 patients experienced at least one GERD relapse episode (first group) against 94 ones free of symptoms for one year (second group). The mean values of both PG I and G-17 after the 6-8 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 96 μg/L, G-17 2.6 pmol/L; after therapy: PG I 164 μg/L, G-17 19 pmol/L; p: <0.001; second group: baseline PG I 98 μg/L, G-17 2.9 pmol/L; after therapy: PG I 116 μg/L, G-17 6.3 pmol/L; p: ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

Conclusion: Gastrin-17 and pepsinogen I increase after full-dose of PPI in GERD acute phase seems to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1197 THE DIAGNOSTIC VALUE OF ESOPHAGEAL MUCOSAL AND BASELINE IMPEDANCE MEASUREMENTS IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE

Introduction: Various biomarkers have been studied to evaluate the integrity of esophageal epithelium in distinguishing phenotypes of gastroesophageal reflux disease (GERD). Baseline impedance (BI) measurement is likely to be one of these and can be measured during the 24-hour ambulatory intra-esophageal impedance-pH study. Mucosal impedance (MI) measurement is a technique that was introduced in recent years and is a practical method that can be applied during endoscopy, but the validation studies are insufficient. BI & MI measured with the same regular impedance catheter and data from 118 patients with different reflux phenotypes and controls were evaluated.

Aims & Methods: Patients were divided into five groups: mild (ERD A-B, n = 31), severe erosive esophagitis (ERD C-D, n = 11), non-erosive reflux disease (NERD, n = 26), functional heartburn-esophageal hypersensitivity (FH-EH, n = 17), healthy controls. High resolution manometry, 24-h MII-pH, upper gastrointestinal endoscopy were performed. BI values were taken at the sleeping time period at night when reflux and swallowing did not occur. MI measured during endoscopy, a regular impedance-pH catheter passed through the biopsy

References
channel of the scope. Distal two rings were contacted to the distal and proximal part of the esophagus approximately 20–25 cm, using a supervised Greenfield 5 mm, 1 pH impedance catheter were used.

**Results:** MI can differentiate ERD from non-erosive groups but do not have a diagnostic value to discriminate NERD from FH-EH or controls. However, BI might be a better tool to discriminate NERD from healthy controls. Since regular catheters are failed, new balloon-shaped catheters should be validated. BI might be a better tool to discriminate NERD from controls. This implicates that the esophageal epithelial resistance is impaired in this particular group compared to controls.

**Conclusion:** All authors have declared no conflicts of interest.
Currently, there are no real-world data assessing the efficacy of short-term empiric treatment with PPIs in GERD patients in China.

**Aims & Methods:** This was a multicenter, prospective, observational study carried out in a real-world setting. The primary objective was to determine the overall responder rate in patients with typical GERD symptoms after 4 weeks of empiric treatment with PPIs. Responders were defined as having heartburn/regurgitation on ≤1 day during the prior 7 days, assessed by the Gerd-Q questionnaire. Outpatients aged between 18 and 65 years with a Gerd-Q score ≥8 were enrolled if they were prescribed standard-dose PPIs as empirical treatment and were not planned to have an endoscopy within 4 weeks of enrollment. The PPI regimen prescribed was decided completely at the physicians’ discretion. Patient demographics, diagnosis, prescribed PPI regimens, Gerd-Q score and symptom frequency were recorded. Data were collected at baseline, 2 weeks and 4 weeks after initiating PPI treatment. Results from the full analysis set (FAS) are presented.

**Results:** A total of 1,000 patients from 10 centers were screened for this study, of which 987 met the inclusion criteria and were included in the FAS. The mean age was 45.2 ± 11.6 years, the mean body mass index was 23.4 ± 3.3 kg/m², and 50.3% of the patients were male. The mean duration of GERD was 0.8 ± 2.1 years, with a mean baseline Gerd-Q score for the week before screening of 10.5 ± 1.9. During the 4 weeks’ treatment, the proportion of patients receiving at least one dose of PPI was 98.5%. Esomeprazole was the most frequently received PPI (57.1% of patients). Other PPIs (rabeprazole, lansoprazole, pantoprazole and omeprazole) were received by 50.1% of patients and 7.2% of the patients sequentially received ≥2 PPIs in the duration of the study. A total of 787 (79.7%) patients either completed the 4-week PPI treatment or withdrew after response, of which the responder rate was 74.0% [95% CI, 70.75–77.05%] (Table 1). Among the 818 patients who completed 2 weeks’ treatment, the responder rate was 57.0% [95% CI, 53.5%–60.4%, p < 0.001]. The overall median time to response (±IQR) was 9 days [5–15]. The responder rate of the GERD-Q score demonstrated a decreasing trend. The proportion of patients with a Gerd-Q score ≥8 reduced from 100% at baseline to 29.5% and 17.4% at 2 and 4 weeks, respectively.

**Table 1: Responder rate and median time to response for different PPIs**

**Contact E-mail Address:** tarig007@yahoo.com

**Introduction:** Laparoscopic Anti-Reflux Surgery (LARS) is an established alternative treatment to pharmacological therapy for patients with Gastro Esophageal Reflux Disease (GERD), yet its safety and efficacy in obese patients is controversial. A systematic review and meta-analysis was performed to compare LARS related to obesity.

**Aims & Methods:** The primary outcome measure was the relative incidence of recurrent reflux related to BMI. Secondary outcome measures were relative re-intervention rates in the form of endoscopic dilation or surgery, conversion to open surgery, and early return to theatre. MEDLINE and the Cochrane Library (January 1970 to November 2016) were searched for studies reporting clinical outcomes of LARS in patient cohorts stratified by Body Mass Index (BMI). Data was grouped according to BMI, ≤30 kg/m² (non-obese) and >30 kg/m² (obese). Results were pooled in meta-analyses as Odds Ratios (OR).

**Results:** Eleven eligible observational studies comparing LARS in non-obese (n=2) and obese (n=16) patients were included. The relative incidence of reflux was significantly lower in the non-obese cohort (OR 0.34, 95% CI 0.19 to 0.60, p = 0.001), however no significant differences were observed in rates of operative morbidity (OR 0.87, 0.65 to 1.18, p = 0.38), redo surgery (OR 1.18, 0.68 to 1.27, p = 0.73), endoscopic dilation (OR 1.06, 0.49 to 2.33, p = 0.88), conversion to open surgery (OR 1.17, 0.55 to 2.48, p = 0.68), or early return to theatre (OR 0.77, 0.44 to 1.37, p = 0.38).

**Conclusion:** LARS can be performed safely in obese patients, but risks higher morbidities in comparison to non-obese patients. Clinicians should be aware that obesity may adversely affect LARS outcome and careful consideration be given in the consent process inherent within the optimal management of GORD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1203 GASTROESOPHAGEAL REFLUX DISEASE REFRACTORY TO PROTON PUMP INHIBITOR THERAPY. INCOMPLETE ACID INHIBITION OR DIAGNOSTIC ERROR?**

Gastroenterology, Hospital Clinico San Carlos, Madrid/Spain

**Contact E-mail Address:** jperezserna@gmail.com

**Introduction:** The use of PPIs represents the main treatment in gastroesophageal reflux disease (GERD), having demonstrated its effectiveness both in the control of inflammation and symptomatology. However, between 10–20% of patients present persistent symptoms or lesions despite the treatment.

**Aims & Methods:** The aim of the study was to assess the presence of acid reflux in patients submitted to our department with the diagnosis of refractory GERD, due to low or no response to PPIs. This was a retrospective study including 190 patients (55 men, 135 women) referred to our service with the diagnosis of GERD from January 2008 to December 2015. Based on the diagnostic criteria, two groups were made. Group 1: included 63 patients (33.2%) diagnosed of GERD due to typical symptomatic reflux and at least one positive complementary test (pHmetry, LUS or LES pH recording). All of them underwent a 24-H pHmetry study in a single channel, esophageal and gastric, off-PPI treatment. In 17 patients the pHmetry study was performed with multichannel intraluminal impedance (15 cases) or Bilitec (2 cases). Group 2: included 127 patients (66.8%) who had been diagnosed of GERD only on the basis of typical symptoms; all of them underwent esophageal double channel 24-H pH-metry off-PPI. All of the studies (24-hour pHmonitoring or multichannel intraluminal impedance-pH studies) (MARK III, Delta and Digtigrph pH-Z, Synectics, Gyven, Medtronic) were performed according to standard technique.

**Results:** Pathological pHmetry was present in 91 patients (47.9%), 24 from group 1 and 67 from group 2. Pathological acid reflux was therefore ruled out as a cause of symptoms in 52.1% of all cases studied: 60 patients (47.2%) from group 2, and 33 patients (51.9%) from group 1. In addition, out of the 24 patients with pathological reflux in pHmetry in group 1 (true refractory patients), 9 had an incomplete response, with a percentage of time with pH < 4 less than 7.5% (mild reflux), which probably was not the cause of the symptomatology.

**Conclusion:** Proton pump inhibitors (PPIs) are the drugs of choice in the treatment of GERD. However, its efficacy may be compromised for a variety of reasons including: non-compliance, bioavailability, episodes of nocturnal acid break-through, poor gastric emptying, etc. In most of the patients referred for implementation or stimulation-related adverse effects were reported in the two-month follow-ups.

**Conclusion:** Electric stimulation represents a prospective approach for treating GERD in clinics. This novel wireless LES stimulation system was also safe and effective for treating GERD rabbits. After implantation, its passive medical appliance benefit patients and keep the long-term efficacy for clinical GERD management.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1204 LOW-FODMAP DIET RESULTED EFFECTIVE IN REDUCING SYMPTOM PERCEPTION IN PATIENTS WITH FUNCTIONAL HEARTBURN

I. Martinucci1, E. Savarino2, G. Guidi1, K. Nardi1, S. Tolone1, M. Frazzoni4, L. Fuccio1, L. Frazzoni1, M. Bellini1, V. Savarino6, S. Marchi1, N. De Bortoli1

Introduction: Recently, low-FODMAP diet has been proposed as potential treatment in patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional symptoms. The aim of this study was to evaluate the efficacy of low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux (GERD) compared to patients with non-erosive reflux disease (NERD). As secondary aim we investigated the reduction of lower gastrointestinal symptoms in both groups. We enrolled patients with heartburn and negative upper endoscopy who were scheduled for upper gastrointestinal endoscopy (erosalophgeal manometry and pH monitoring, MII-pH) at Gastroenterology Unit in University of Pisa. We excluded patients older than 75 and younger than 18, those with primary esophageal motor disorders and with previous abdominal surgery. Medical history, volup-tuary habits and response to proton pump inhibitor (PPI) treatment were recorded. By means of MII-pH we splitted patients in two populations: NERD group (abnormal esophageal acid exposure or number of refluxes) and FH group (correlation and no heartburn relief during PPI treatment). All enrolled patients were evaluated with validated questionnaires (Likert and VAS) to evaluate heartburn occurrence pre- and post a nutritional approach with low-FODMAP diet for 6 weeks.

Results: We included 31 patients (20 female; mean age 49.1 yrs; mean BMI 24.4) into the study. NERD group was composed of 13 patients (6 female; mean age 48.7 yrs; mean BMI 25.7). FH group was composed by 18 patients (11 female; mean age 50.9 yrs; mean BMI 23.9). All patients showed symptom improvement regarding bloating, abdominal pain and stools composition (p < 0.001) after low-FODMAP diet (see Table 1). Moreover, we observed a very important reduction of heartburn in the FH group (from 8.4±2.5 to 2.3±1.1; p < 0.001 on VAS scale) compared to the NERD group (7.2±2.2 a 6.9±1.9; p=0.624 on VAS).

Conclusion: This pilot study showed that a low-FODMAP diet was able to reduce heartburn perception in patients with FH and who did not obtain any symptom relief after PPI treatment. Larger prospective randomized controlled trial is mandatory to further explore these findings.

Introduction: Because of a higher prevalence of BE in males, recommendations in current guidelines are mainly based on male BE patients and make no difference in surveillance according to gender. Nevertheless, it is unknown whether BE patients have the same neoplastic progression and acceleration rate as male patients.

Aims & Methods: The aims of this study were (1) to evaluate the difference between males and females in probability of and (2) time to neoplastic progression, as well as (3) gender differences in stage distribution of neoplastic progression in surveilled BE patients. In this multicenter prospective cohort study we included 729 patients with BE who met the inclusion criteria of a segment of ≥2cm and confirmed intestinal metaplasia. Endoscopic surveillance was performed according to the American College of Gastroenterology guidelines.

Conclusion: The risk of HGD and overall neoplastic progression and acceleration rate of HGD development is higher in male BE patients compared to females. On the other hand descriptive statistics show proportionally more EAC in females as well as an advanced stage of EAC at diagnosis. Further research into the differential aspects of neoplastic progression in BE between men and women, may have future consequences for gender specific guideline recommendations, including the timing of follow-up.

Disclosure of Interest: Given its proven safety and efficacy, RadioFrequency Ablation (RFA) is the preferred ablation modality for dysplastic Barrett’s Esophagus (BE). However, RFA is associated with significant drawbacks, such as the need for large controller units, multiple deployment steps and capital investment. The Focal CryoBalloon Ablation system (FCBA; C2 Therapeutics, Redmond City, CA, USA) is another ablation method based on the application of extreme cold - that has recently been developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. FCBA comprises a handheld, through-the-scope system with a conformable balloon that is simultaneously inflated and cooled using nitrous oxide, resulting in ice patches of approximately 2cm³ on the targeted mucosa. Previous studies applying FCBA to limited areas of BE (1 to 2 small BE islands per patient) have shown promising results. Data on
efficacy and safety of FCBA in the treatment of larger BE segments, however, are lacking. Therefore we aimed to assess the safety and efficacy of a single treatment with FCBA for dysplastic BE.

Aims & Methods: Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. Patients with a BE >6 cm in length and with a confirmed diagnosis of low-grade (LGD) or high-grade dysplasia (HGD) or after endoscopic resection for visible lesions, were included. Exclusion criteria included previous focal ablation therapy and strictures. At baseline, all visible BE was treated with side by side ablations of 10 seconds, including the circumferential treatment of the gastroesophageal junction (GEJ). Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of endoscopic stricture or other adverse events.

Results: We enrolled 20 patients with dysplastic BE (>85% male, mean age 66 (±8) years), with a median BE length of 0 cm (IQR 0–0; 1–3) and with a baseline diagnosis of LGD (10; 50%), HGD (1; 5%), or mucosal adenocarcinoma (9; 45%). Ten (50%) had undergone endoscopic resection of a visible lesion before cryoballoon and 8 (40%) had undergone previous curvilinear RF A. During a median ablation time of 16 minutes (IQR 11–19), all BE, including circumferential ablation of GEJ was successfully ablated in all patients. No adverse events occurred, and median pain directly post-treatment was 4 out of 10 (IQR 0–5), whereas this was 1 (IQR 0–2) and 0 (IQR 0–1) at days 2 and 7. At the 3-month follow-up endoscopy, median endoscopic regression of initial BE was found to be 95% (IQR 93–98), this included 13 patients (65%) with a complete 100% regression. All biopsies confirmed squamous regeneration with endoscopic remission. No significant endoscopic strictures or other complications were noted.

Conclusion: Our multicenter, prospective trial shows that a single treatment with CryoFocal balloon ablation therapy is safe, well-tolerated and effective for eradication of dysplastic BE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Radiofrequency ablation (RFA) is safe and effective for eradication of dysplastic Barrett’s Esophagus (BE), but may be associated with significant post-procedural pain. As an alternative, cryobalization using the Focal CryoFocalablation Ablation system (FCBA) has recently been developed, which ablates BE by freezing it using nitrous oxide. Early uncontrolled studies suggest comparable safety and efficacy of FCBA and RFA in eradicating dysplastic BE. Therefore we compared pain endpoints like pain might play a determining role in selecting the best treatment modality. In contrast to heat-based ablation, FCBA preserves the extracellular matrix which might be associated with less pain while maintaining sufficient depth of ablation.

Methods: We aimed to compare post-procedural pain between focal RFA and FCBA.

Aims & Methods: Between January 2016 and March 2017 all patients undergoing focal ablation therapy of BE, either with RFA or FCBA performed in two tertiary referral centers in the Netherlands, were approached to complete a digital diary. A short questionnaire was daily sent to patients for 14 days post-treatment, to assess (1) odynophagia, (2) chest pain (both assessed using VAS range from 0 to 10), and (4) dysphagia (assessed using a score ranging from 0 to 10) and (4) use of analgesics. Primary outcome included maximum VAS score (maximum score for either item 1 or 2), secondary outcomes included area under the curves (AUCs) for all items assessed, maximum reported VAS score at score (maximum score for either item 1 or 2), and use of analgesics. Primary outcome included maximum VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p <0.01). For odynophagia, the maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p <0.01). For chest pain in rest (78 vs 20.5, p <0.01), for use of analgesics (9 vs 3.1, p <0.01), and for dysphagia (2.6 vs 8.2, p <0.01). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p <0.01). For odynophagia, the maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p <0.01). For chest pain in rest (78 vs 20.5, p <0.01), for use of analgesics (9 vs 3.1, p <0.01), and for dysphagia (2.6 vs 8.2, p <0.01). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p <0.01).

Conclusion: In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared to RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

Introduction: Radiofrequency ablation (RFA) with endoscopic mucosal resection is recommended for Barrett’s Oesophagus (BO) related neoplasia. In this study, we evaluated RFA treatment outcomes for BO stratified according to baseline histology, i.e. low-grade dysplasia (LGD), high-grade dysplasia (HGD) and intramucosal carcinoma (IMC). We retrospectively reviewed the treatment outcomes of patients with dysplastic BO between January 2007-2017. Patients received 3-monthly RFA until endoscopic and histologic remissions were achieved. Outcomes measured were: 1) complete remission of dysplasia (CRD) and intestinal metaplasia (CRIM), 2) stricture rate, and (3) durability of CRD and CRIM. Patients on active treatment protocol were excluded.

Results: We identified 113 patients who completed RFA treatment (21 LGD, 46 HGD and 46 IMC). There were no significant difference between the groups in the age, gender, circumferential and maximum length of BO, and stricture rate. CRD and CRIM were achieved in 94.7% and 78.8% of patients, respectively. When stratified according to baseline histology, there was no significant difference in CRD rate among LGD (95.2%), HGD (95.7%) and IMC (93.5%) (p =0.89). Similarly, there was no significant difference in CR IM rate among LGD (71.4%), HGD (76.1%) and IMC (84.8%) (p =0.31). CRD durability at 12 and 36 months (n =107) was 99.0% and 97.0%, respectively. CRIM durability (n =89) at 12 and 36 months were 98.5% and 92.7%, respectively. When stratified according to baseline histology, CRD durability at 12 and 36 months for LGD and IMC were 100% at both time points, and 97.7% and 93.6% for HGD, respectively (log rank p =0.31). CRIM durability at 12 and 36 months for LGD, HGD and IMC were 100%, 96.4%, 100%, and 100%, 88.5%, 95.5%, respectively (log rank p =0.60).

Conclusion: The treatment outcomes for BO were similar in patients with different baseline histology. Our results showed that once CRD and CRIM were achieved, these were durable over time.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Endoscopic mucosal resection (EMR) is currently the first-line treatment for high-grade dysplasia (HGD) in BarRET’s esophagus (BE). Despite improvements in the characterization of dysplasia, the management depend on the pathological analysis of biopsies previously performed. However, the level of concordance between cytologists in such situation remains discussed. The aim of this study was to evaluate the discordance between biopsy sample (BS) and EMR concordance between cytologists in such situation remains discussed. The aim of this study was to evaluate the discordance between biopsy sample (BS) and EMR specimen in case of HGD, as well as cytologists’ inter and intra-observatory variability.

Aims & Methods: This was a retrospective study including a prospective histological relecture (BS and specimen) in two expert centers. The inclusion criteria were: BE with HGD on pre-operative biopsies resected by EMR. The initial biopsies from other centers were collected and re-examined by our cytologists. The BS discordant with EMR specimens were recorded in a numeric file (Teleslide) and a second lecture was carried out by 2 experts and 2 fellows (1 of each per center). Five diagnoses were considered: no metaplasia (no BE), metaplasia without dysplasia, LGD, HGD, Adenocarcinoma. Concordance statistical tests were performed to assess the variability between BS and EMR specimen and among the cytologists.

Results: Between January 2005 and December 2015, 87 patients have undergone EMR for HGD on biopsies, in both centers. Among them, 41 (47%) had a discordant result between biopsies and resection specimen. The histological diagnosis on BS (16.4%), metaplasia, adenocarcinoma in 4 cases (4.6%) and one patient had no metaplasia. Finally, 33 patients could be analyzed, 29 men and 4 women, with a mean age of 63 years old. The mean length of BE according to Paris classification was C3-M5, with relief adenocarcinoma in 9 cases. A mean number of 1.4 endoscopic sessions was performed, with a mean of 2.7 resected pieces per EMR, which was macroscopically complete in 63.6% of the cases. The mean follow-up was 38 months. After histological relecture, the Kappa coefficient for the diagnosis of HGD was low on the initial BS, and ranged between 0 and 0.6 for the EMR specimen. The inter-observatory concordance was 0.2 (for both BS and EMR specimen) for the diagnosis of HGD. For other diagnoses, it was ranged between 0 and 0.5 for biopsies and between 0 and 0.6 for EMR specimen. The kappa coefficient regarding the presence of HGD was 0.5 for biopsies and 0.4 for the EMR. There was 0.4 and 0.5 for the fellows, respectively. The intra-observatory (between BS and EMR specimen) after relecture was ranged between 0.6.

Conclusion: The discordance rate between initial diagnosis of HGD on BS and final diagnosis on EMR specimen is high. This could have a direct impact on the management of BE.

analyzed by cell counting kit-8 assay. Cell cycle and apoptosis were evaluated by flow cytometric analysis. Protein levels of p53 were determined by western blot analysis. Differences between groups were tested for significance using Student’s-t test (two-tailed).

Results: ESCC tissues examined in this study showed an obvious increment in TRPM2-AS expression when compared to normal tissues. Meanwhile, TRPM2-AS expression was positively related to lymph node metastasis, TNM stage and clinical stage. And upregulated TRPM2-AS expression was turned to be remarkably correlated with the shorter survival of ESCC patients which could act as an independent predictor for both overall survival time and disease-free survival. In addition, overexpression of TRPM2-AS could promote the proliferation and inhibit the apoptosis of ESCC cells, while knockdown of TRPM2-AS had a reverse function. Furthermore, downregulation of TRPM2-AS enhanced the expression of p53 in ESCC cells.

Conclusion: This study suggested that long non-coding RNA TRPM2-AS could be a potential oncogene of ESCC. TRPM2-AS expression might be served as another potential therapeutic target and prognostic biomarker. In addition, our study suggests that the inactivation of TRPM2-AS could contribute to the aggressiveness of ESCC by regulating the expressions of p53 in vitro, which may be a potential oncogene and therapeutic target for ESCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1213 ROLE OF CD80 EXPRESSION IN INFLAMMATORY-RELATED ESOPHAGEAL CARCINOMA

Introduction: Esophageal adenocarcinoma (EAC) is an increasingly common cancer with a poor prognosis. EAC is the final step of a pathway starting with esophageal reflux disease, intestinal metaplasia, and dysplasia. The expression of cytokine expression by esophageal cancer cells is significantly lower than in the normal mucosa of healthy patients. This may be one of the mechanisms of immune escape of cancer cells in the esophageal cancer. Aims & Methods: The aim of this study was to investigate the role of CD80 in the inflammatory esophageal carcinogenesis and to characterize the immune environment of EAC. Mucosa samples from cancer and from healthy esophagus were obtained during esophagectomy from patients affected by EAC. Fresh biopsies were obtained from patients who underwent endoscopy for screening or follow-up. Immunohistochemistry for CD80 was performed. Fresh biopsies were analyzed by flow cytometry to quantify the expression of CD80, its receptor CD28 and the lymphocytes activation marker CD38 on esophageal epithelial cells and CD8 infiltrating lymphocytes, respectively. A model of reflux induced esophageal inflammation was created with a sysylyctin-oil-micro-jejunostomy. C57Bl/6 mice were randomized to receive or not intraperitoneal injections of anti-CD80 antibody. The esophageal-gastric specimens were collected 32 ± 2 weeks after the immunization and analyzed in a blinded fashion. Non-parametric statistics was used.

Results: Flow cytometric analysis of esophageal biopsies from healthy controls, Barrett esophagus, dysplastic esophagus and esophageal adenocarcinoma reveals that the expression of the costimulatory molecule CD80 by epithelial cells peaks during metaplasia in the inflammatory esophageal carcinogenesis. In the mice that received antiCD80 antibodies the rate of dysplasia in the fore stomach was significantly higher (5/7) compared to that observed in vehicle treated wild type mice (1/6).

Conclusion: The human and the in vivo data that we obtained suggest that in inflammation-driven esophageal carcinogenesis there is evidence of an active immune surveillance process mediated by the overexpression of CD80 costimulatory molecule. The human and the in vivo data that we obtained suggest that in inflammation-driven esophageal carcinogenesis there is evidence of an active immune surveillance process mediated by the overexpression of CD80 costimulatory molecule. The human and the in vivo data that we obtained suggest that in inflammation-driven esophageal carcinogenesis there is evidence of an active immune surveillance process mediated by the overexpression of CD80 costimulatory molecule.

Introduction: Altered glucose metabolism has become a recognised feature of tumor cells, which is characterized by an increased glucose uptake and preferential dependence on glycolysis for energy production. As a consequence, cancer cells produce large amounts of lactate, which is pumped out the cytosol by monocarboxylate transporters (MCTs), mainly MCT 1 and 4. MCT inhibition has not been investigated in esophageal adenocarcinoma (EAC) yet. The aim of this study was to evaluate the effect of the interplay between dysregulation of monocarboxylic oncoprotein genes and oncosuppressor genes within the tumor cells, and immunoviroenvironment and its effect on patients’ prognosis is still largely unknown.

P1216 AIRWAYS MICROENVIRONMENT IN ESOPHAGEAL ADENOCARCINOMA (EAC): THE ROLE OF THE NUCLEAR P53 EXPRESSION IS ASSOCIATED TO WORSE DISEASE-FREE SURVIVAL

Introduction: Esophageal adenocarcinoma (EAC) microenvironment is characterized by the presence of abnormal proliferation and oncoprotein genes within the tumor cells, by lack of cytokines with anti-cancer effect and by high expression of immuno-suppressive factors. The interplay between oncogenes’ disregulation and immune microenvironment and its effect on patients’ prognosis is still largely unknown.

Aims & Methods: The aim of this study was to evaluate the effect of the interplay between dysregulation of oncogenes and oncoppressor genes within the tumor cells and immune microenvironment on EAC prognosis. Mucosa samples from EAC tissue were obtained during esophagectomy from 169 consecutive patients operated. Immunohistochemistry for MLH1, MSH2, MSH6, PM2, CMYC, p16, HER2 and nuclear p53 expression was performed. CD8 infiltration, CD8 and NK cells cytolytic activity (CD107) of tumor infiltrating lymphocytes and antigen-presenting cells across the time course of the tumor (EOC and AZD3965) with immunohistochemistry. Mutational analysis for BRAF was performed. Cox proportional hazard models were created to investigate the role of each marker adjusted for cancer stage. The association between each marker and the presence of nodal metastasis was assessed with exact tests.

Results: In our EAC patients’ series, one patients had BRAF mutation (V600E) and 5 of them had microsatellite instability. CD107 overexpression within the cancer was associated to the presence of nodal metastasis (p = 0.029). In patients with both nuclear p53 overexpression revealed to be an independent predictor of early recurrence with [HR = 2.995 (95% CI = 1.124–7.9896) p = 0.029] as well as cancer stage [HR = 2.693 (95% CI = 1.6693 to 5.6666) p < 0.001]. On the other hand, nuclear p53 overexpression also tended to be an independent predictor of overall survival [HR = 2.9339 (95% CI = 0.9613 to 8.9663) p = 0.06] while cancer stage confirmed to be the main survival predictor [HR = 1.8689 (95% CI = 1.8108 to 3.2314) p = 0.025].

Conclusion: In EAC, CD8 and NK cell cytolytic activity within the tumor was associated to nodal metastasis and CD107 expression might be used as a marker of it. Moreover, nuclear p53 overexpression within the tumor might be used as a marker of early recurrence after esophagectomy and then used to plan follow up strategies. No apparent relation between progression or mismatch repair gene or BRAF mutation was observed.

Disclosure of Interest: All authors have declared no conflicts of interest.
increased apoptosis of OACM5.1C cells whereas did not affect apoptosis of OE3.3 cells.

Conclusion: Metastatic and non-metastatic esophageal adenocarcinoma cells exhibit different glycolytic metabolism and response to pharmacological inhibition of MCT1, which increases apoptosis in metastatic cells. Further preclinical studies are needed to determine the potential of blocking lactate transporters on the treatment of metastatic EAC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1216 THE PREDICTIVE FACTOR FOR PERFORATION IN ESOPHAGEAL ESD

Introduction: Although endoscopic submucosal dissection (ESD) is accepted as a standard treatment for early stage esophageal neoplasia, esophageal perforation is sometimes experienced as main adverse event. Esophageal perforation causes mediastinal emphysema, mediastinitis, and pneumothorax, those sometimes require emergency surgery.

Aims & Methods: We evaluated the predictive factors for esophageal perforation in patients who received esophageal ESD. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients with 927 lesions were resected with ESD. Among these 93 patients, the MM in 16, the SM1 in 18, and the SM2 in 15 in the follow-up group were cases with lacking data. The primary outcome was determination of the predictive factors for esophageal perforation in patients who received esophageal ESD. The secondary outcome was clinical outcomes. Perforation was defined as a hole in the muscularis mucosae wall exposing the mediastinal cavity. Logistic regression multivariate regression analysis with generalized estimating equations was used to analyze repeated measured data.

Results: A total of 549 cases with 927 lesions were evaluated. Of those, perforation occurred in 15 cases (2.7%) with 15 lesions (1.6%). A lesion diameter (Odds ratio; OR = 1.05, 95% confidence intervals; CI: 1.02–1.07, p < 0.001) and the proximity of the tumor to a previous ESD scar (OR = 6.66, 95% CI: 1.80–24.6, p = 0.004) were both associated with perforation using crude logistic regression analysis. Multivariate logistic regression analysis also showed that a lesion diameter (OR = 1.05, 95% CI: 1.03–1.07, p < 0.001) and the proximity of the tumor to a previous ESD scar (OR = 13.0, 95% CI: 2.48–67.9, p = 0.002) were independent predictive factors for perforation.

Conclusion: Larger lesion and the proximity of the tumor to a previous ESD scar increased the likelihood of perforation in patients who received esophageal ESD. The tumor invades the MM in 9 patients, the SM1 in 3, and the submucosa to a depth more than 200um (SM2) in 29 in the CRT group and the LPM in 3 patients, the MM in 16, the SM1 in 18, and the SM2 in 15 in the follow-up group (p = 0.91). Lympathic invasion was positive in 21 patients in the CRT group and 12 in the follow-up group (p < 0.01). Vascular invasion was positive in 27 patients in the CRT group and 29 in the follow-up group (p = 0.32). Lymph node metastases of the submucosa and submucosal vertical margin was found in 7 patients in the CRT group and 9 in the follow-up group (p = 0.097). CRT-related grade 3 or 4 early adverse events were leukopenia 24.3% (10 patients), neutropenia 29.3% (12), febrile neutropenia 4.9% (2), diarrhea 2.4% (1), anorexia 17.9% (7). In the CRT group, 38 of 40 patients received chemotherapy as scheduled. Treatment was discontinued in the second course in 2 patients, and 7 required dose reduction. Lymph-node metastasis were found in 2 patients in the CRT group and 7 in the follow-up group (p = 0.15). In 15 cases with recurrence in the CRT group, lymph-node metastasis were seen in the irradiated field 46 and 49 months after treatment, respectively. 1 patient in the CRT group and 3 in the follow-up group died of esophageal cancer (p = 0.43). The overall survival (OS) rate at 2 years was 97.2% in the CRT group and 93.8% in the follow-up group (p = 0.002). The relapse-free survival (RFS) rate at 2 years was 97.1% in the CRT group and 83.4% in the follow-up group (p = 0.02).

Conclusion: Additional CRT after endoscopic resection in patients with esophageal squamous-cell carcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preservation strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1218 SAFETY, EFFICACY AND OUTCOME OF ENDOSCOPIC SUBMUCOUS DISSECTION FOR THE TREATMENT OF EARLY BARRETT’S NEOPLASIA
M. Onaka, M. Konradsson, P. Elbe, M. Nilsson, M. Lindblad, I. Rouvelas, F. Bälldque-Silva
Gastrocenterium, Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: masami.ngo@icr.or.jp

Introduction: Endoscopic submucosal dissection (ESD) was developed in Japan for en bloc resection of large gastrointestinal neoplasias and has progressively been adopted in the West. Currently, early Barrett’s neoplasia is mainly treated with endoscopic mucosal resection (EMR) and/or radiofrequency ablation, being the role of ESD in this context not well-established yet. Our aim is to evaluate the safety, efficacy and outcome of ESD for the treatment of early Barrett’s neoplasia.

Aims & Methods: Fifty consecutive ESD cases of early Barrett neoplasia were performed in 42 patients in our center between 2011 and 2016. All ESDs were performed under full narcosis after multidisciplinary team conference discussion and patient’s consent. The primary endpoint was the rate of en bloc resection. Secondary endpoints included rate of R0 and curative resection, a comparison of pre- and post- ESD histology, procedure time, procedure-related adverse events, and rate of remission at follow-up. This study was approved by the Stockholm Regional Ethical Committee.

Results: Mean age was 67 years (range 46–84), being 74% male and 72% long segment BE. The mean specimen size was 52 mm (range 16–159 mm). ESD resections included <25%, 25–50%, 50–75% and 75–100% of the lumen circumference in 4/31/12/3 of cases, respectively. En bloc, R0 and curative resection were obtained in 96% (48/50), 80% (40/50) and 70% (35/50) of cases, respectively. The primary ESD histology corresponded to low-grade dysplasia in 57% of the neoplasia (n = 30) and adenocarcinoma (n = 15). One case of LGD was upstaged to intramucosal AC, 10/30 cases of HGD were upstaged to adenocarcinoma. In 8/ 15 cases of AC, there was submucosal invasion on the ESD specimen. In 14/50 of the resected specimens there was multifocal neoplasia. The mean procedure time was 120 minutes. There were 2 perforations (4%) treated endoscopically and 2 (4.0%) postoperative bleedings treated conservatively. Six patients (12%) developed esophageal strictures that were managed endoscopically. The 30 days mortality rate for the 42 patients was 0. The 15 non-curative resections were referred to further ESD, 1 received chemoradiotherapy and 2 patients are under surveillance. In the 10 esophagectomy cases, 4 patients had AC in the remnant Barrett’s esophagus and 2 patients had lymph node metastasis. Complete remission was
found in 100% (35/35) of patients with curative resection at median follow-up of 25 months (range, 4–64 months).

Conclusion: In the proper setting, ESD is safe and effective for the treatment of early Barrett’s neoplasia with high en bloc and complete resection rates and good curative rate. ESD enables full pathological assessment in lesions not suitable for en bloc resection with EMR. There were no recurrences in the cutaneous cases, which increases the role of ESD for the management of early Barrett’s neoplasia.

Introduction: Recently, it has been reported that proton beam therapy (PBT) is the effective treatment for patients with esophageal squamous cell carcinoma (ESCC). However, there are few reports regarding the endoscopic evaluation of efficacy after PBT at the primary site. Aims & Methods: The aim of this study is to clarify the adequate endoscopic evaluation of eradication of ESCC after PBT, and the clinical results of salvage endoscopic treatment for local recurrence. Patients with clinical T1 ESCC, and who had been treated with PBT between April 2013 and June 2016 at the National Cancer Center Hospital East were investigated. The total dose of PBT was 60 Gray- Equivalent (GyE). The efficacy of PBT at the primary site was evaluated with endoscopy, and the definition of complete response (CR) was used according to the same criteria as that of conventional chemoradiotherapy (CRT) as follows; disappearance of tumor lesion and ulcer, and absence of cancer cells with biopsy was verified. The endoscopic evaluation was performed within 2 months after the completion of PBT, and we repeatedly evaluated every month if the lesion did not achieve CR. The treatment for local recurrence after PBT was chosen based on the depth of the tumor as follows; endoscopic resection (ER) for CT1a, esophagomyotomy or photodynamic therapy (PDT) for CTb or deeper depending on patient’s condition.

Results: Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and those with stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. All patients underwent concurrent systemic chemotherapy. 43 patients (98%) underwent endoscopy for sizing, a handle, and a small disposable cryogen cartridge. The balloon is Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA). Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Early studies for FCBA of Barrett’s esophagus have shown promising results, however, limited data are available for FCBA of ESCN. In this study we aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1219 ENDOSCOPIC CRYOBALOON ABLATION IS SAFE, WELL-TOLERATED AND HIGHLY EFFECTIVE IN THE ERADICATION OF ESOPHAGEAL SQUAMOUS CELL NEOPLASIA

Introduction: Globally, 80% of all esophageal cancer cases are esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasia (ESCN). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCN, curative endoscopic treatment can be performed. ESCN mainly occurs in developing countries, often with limited endoscopic expertise and resources, like Central and Eastern Asia and Eastern and Southern Africa. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA) is a new endoscopic ablation therapy that comprises a balloon catheter with a conformable balloon that obviates the need for sizing, a handle, and a small disposable cryogen cartridge. The balloon is simultaneously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2cm2. FCBA is easy to use and requires no capital equipment. Early studies for FCBA of Barrett’s esophagus have shown promising results, however, limited data are available for FCBA of ESCN. In this study we aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN.

The circumference of the resection ≥75% was significantly associated with post-operative stenosis (OR = 3.5; P < 0.05). The average number of endoscopic dilatations for resolution of stenosis was 9.16 (±7.62). No procedure-related mortality occurred. Follow-up data median was 11 months.

Conclusion: Endoscopic surveillance of HSNNC is very important for SENs after resection. ESCN and ESD of these lesions are feasible and safe with acceptable complications risks despite the high rates of stenosis in resections >75% of the circumference.

Disclosure of Interest: All authors have declared no conflicts of interest.
enrolled. At baseline, side-by-side ablations of 10 seconds were performed on United European Gastroenterology Journal 5(5S) A593

Results: for pain), complete response (CR) rates (absence of MGIN or worse in biopsies), 63 MGIn, 17 HGIn with a median lesion of 2 (IQR 2–3) cm in length. Of these, 79 patients (99%) were successfully treated; 3 developed superficial, self-limited mucosal lacerations upon balloon inflation and 2 of them were successfully re-ablated 3 months later. A median of 5 (IQR 3–7) treatments were performed per patient, in median ablation time of 8 (IQR 5–10) minutes. As of April 2017, 77/79 (97%) patients completed a 3-month follow-up endoscopy and 69/77 patients (89%) exhibited endoscopic and histologic CR. Eight patients had residual USL and were again treated, a median of 5 months later and median ablation time of 10 (IQR 9–12) minutes. To date, 4 patients have undergone a 12 month endoscopy and all continue to exhibit endoscopic and histologic CR. No significant strictures have been noted on follow-up. Three patients developed fever shortly after treatment which was treated with aspirin. Post-procedure median VAS was 1 (IQR 0–2) at day 2, and 0 (IQR 0–0) at days 7 and 30. Conclusion: Preliminary results of our multicenter open prospective cohort study suggest that FCBA of ESC is safe, well-tolerated, and highly effective in inducing endoscopic and histologic remission. Longer term (12 month) follow-up data is pending.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1222 THE ENDOSCOPIC TREATMENT STRATEGY FOR SUPERFICIAL ESOPHAGEAL CANCER Y. Nagamuchi Department Of Gastroenterology And Hepatology, Nagasaki University Hospital, Nagasaki/Japan Contact E-mail Address: naoyuki3435@nagasaki-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) allows en bloc removal of superficial esophageal squamous cell carcinoma (SCC). However, esophageal stricture often occurs after ESD when the lesion involves more than three-fourth of the circumference of the lumen. Frequent balloon dilation via endoscopy is required in such situation, thus causing health economic problem. In this study, we investigated the clinical outcomes, and prevention of post-ESD stenosis.

Aims & Methods: A total of 652 cases in 516 consecutive patients were treated by ESD in our department from April 2006 to December 2016. We investigated the following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroids administration, the local steroids injection, endoscopic transplantation of tissue-engineered autologous oral mucosal epithelial cell sheets, or steroid oral + local injection combination therapy for the prevention of post-ESD stenosis.

Results: 1. Clinical outcomes: En bloc resection rate was 99.8% and en bloc curative resection rate was 90.0%. The rate of perforation, post-ESD bleeding, and post-ESD stenosis was 0.2%, 0.8% and 6.1%, respectively. 2. Prevention of post-ESD stenosis: (1) Oral steroid vs Steroid injection vs Cell sheet transplantation: In oral steroid group, the stenosis rate was 14.9%, and the ulcer healing period was 59.5 days. In steroid injection group, the stenosis rate was 12.9%, and the ulcer healing period was 66.0 days. In cell sheet transplantation group, the stenosis rate was 40.0% and the ulcer healing period was 36.0 days. There was no significant difference between these 3 therapies, and these therapies prevent post-ESD stenosis to significant extent. However, ulcer healing period of the cell sheet transplantation was significantly shorter compared with the other 2 therapies. (2) The usefulness of SH oral + local injection combination therapy. We investigated limitations of steroid administration, and cell sheet transplantation in order to prevent post-ESD stenosis. The following 4 factors (more than 9/10 of circumferential resection, more than 5 cm of longitudinal resection, cervical esophagus, post history of chemoradiation therapy or endoscopic resection) were the stenosis prevention treatment-resistance factors. Therefore, we examined the stenosis rate according to the number of these 4 factors. The stenosis rate of the cases which have 0 or 1 factor, the case which has more than 2 factors in semicircular cases, and the complete circular cases is 4.9%, 30.3%, and 44.8%, respectively. The stenosis rate of the cases which have more than 2 factors and complete circular cases are significantly higher, compared to the cases which have 0 or 1 factor. As a result, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. In contrast, in SH oral + local injection combination therapy, the stenosis rate of the cases which have more than 2 factors and the complete circular cases is 12.5% and 14.3%, respectively. Taken together, the stenosis rate of SH oral + local injection combination therapy is significantly lower, compared to the other 3 therapies.

Conclusion: Esophageal ESD achieved high en bloc resection rate and curability with low rates of complications. Oral steroid, steroid injection therapy and cell sheet transplantation may be effective treatment strategy for reducing post-ESD stenosis. However, the above-mentioned 4 factors are the stenosis prevention treatment-resistant factors in these 3 therapy cases. Furthermore, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. SH oral + local injection combination therapy is very useful for prevention of post-ESD stenosis and has a potential as the treatment-resistant cases.

P1223 DIAGNOSIS OF TUMORS IN THE CERVICAL AND UPPER THORACIC ESOPHAGUS: EFFICACY OF ENDOSCOPIC ULTRASONOGRAPHY USING A JELLY-FILLING METHOD WITH WATER-SOLUBLE LUBRICATING JELLY N. Matsuura1, N. Hanoka2, R. Ishihara3, S. Yamamoto1, T. Akasaka1, Y. Takeuchi1, K. Higashino2, N. Uedo3, H. Iishi3

1Gastrointestinal Oncology, Osaka international Cancer Institute, Osaka/Japan Contact E-mail Address: ibutar9@yahoo.co.jp

Introduction: Endoscopic ultrasound (EUS) is the standard modality for qualitative diagnosis of submucosal tumors (SMTs) and determining the depth of invasion of esophageal cancer. Standard EUS, however, comprises a continuous water-filling or water-filled balloon method, which creates some problems for patients (feeling of filling the water in the stomach, and pain caused by inflation of balloon compression). Aspiration of water is especially problematic during the diagnosis of lesions in the cervical or upper thoracic esophagus. To resolve such disadvantages, we recently reported a method that includes probe EUS with a jelly-filling technique (EUS-J) for evaluating superficial esophageal squamous cell carcinoma (SCC). The procedure is characterized by filling the esophageal lumen with a water-soluble lubricating jelly (K-Y lubricating jelly; Johnson & Johnson, Tokyo, Japan) that is used for routine endoscopy and is harmless to humans. In the current study, we retrospectively evaluated the usefulness of EUS-J with water-soluble lubricating jelly for lesions located in the cervical and upper thoracic esophagus.

Aims & Methods: Patients with an esophageal SCC or SMT in the cervical or upper thoracic esophagus were included. EUS-J with water-soluble lubricating jelly was performed using a high-resolution probe. Before examination, several 5 mL syringes containing the Water Soluble Lubricating Jelly were prepared. When a patient under sedation was intubated with midazolam, an endoscope (GF-2T260Q; Olympus, Tokyo, Japan) was inserted into the targeted area in the esophagus. A 30- or 20-MHz miniature probe was then inserted through the left channel of the endoscope, and 40 mL of jelly was instilled through the working channel until the esophageal lumen was filled.

Results: From December 2010 to March 2017, we used EUS-J to evaluate 61 patients with esophageal SCCs and 10 with SMTs in the cervical or upper thoracic esophagus. There were 10 lesions in the cervical esophagus and 61 in the upper thoracic esophagus. Thus, 61 SCCs, 13 MGINs, and 9 SMTs were included in our study. The other 48 SCCs did not undergo chemoradiotherapy. Of these 61 patients with esophageal SCC, 60 lesions (98.3%) could be detected with EUS-J. 44 lesions treated either by endophagocytosis (n = 7) or endoscopic resection (n = 37). Histologic diagnosis was T1a in 27 lesions, T1b in 17 lesions. The overall accuracy of diagnosing invasion depth was 70.5% (31/44 lesions) by EUS-J. Among the 10 SMTs, we diagnosed seven leiomyomas derived from muscularis mucosa and one lesion due to vertebral body compression. The remaining two lesions were, respectively, a diminutive SMT (<3 mm) and a small lesion in the cervical esophagus adjacent to the hypopharynx. Neither was detectable using EUS-J because of their small size and difficulty with instrumental maneuvering. There were no adverse events during EUS-J, including aspiration pneumonia.

Conclusion: EUS-J with water-soluble lubricating jelly is useful and safe for diagnosing lesions in the cervical or upper thoracic esophagus. To our knowledge, this is the first report of using EUS with lubricating jelly for lesions located in this anatomic region.

Introduction: The patients with early gastric cancer (EGC) who have undergone non-curative endoscopic resection (ER) need additional surgery. Our previous study reported short-term data about 29 days were optimal time when consider- ing non-curative endoscopic resection and curative surgical outcome. (Ann Surg Oncol. 2014 Jan;21(1):1232–9.) This study is a long-term follow-up study to evaluate the impact of previously proposed optimal time interval from ER to additive surgery by on the surgical and oncological outcomes.

Aims & Methods: A total of 2850 patients who were diagnosed with EGC underwent ER at the Severance and Gangnam Severance Hospitals, Seoul, Korea, between January 2007 and December 2014. We analyzed totally 302 (10.6%) patients who underwent additive gastrectomy after non-curative ER. The patients were divided into 2 groups according to the time interval point, as the earlier operation group (group A) and the later operation group (group B). The time interval point, at which operative time and estimated intraoperative blood loss (EIBL) of the earlier operation group and the later operation group

Disclosure of Interest: All authors have declared no conflicts of interest.
shown the greatest disparities, was evaluated. We retrospectively evaluated long-term follow-up study for oncological outcomes about follow-up duration, locoregional recurrence, distant recurrence.

Results: The median follow-up duration is 40.36 ± 20.74 months in all patients. Based on the previous our study, we divided patients two groups who underwent operations after 29 cases. Of the 302 patients, 133 were in Group A (>29days) and 169 in Group B (>29days). There were more differences between two groups about ASA score, ER Specimen size, intra-op. transfusion, PODI Hendom- discharge, Maximal postoperative CRP in the clinicopathological characteristics. Like previous our study the operative time, EBL, tumor size was significantly longer and more in group A compared with group B. There were totally 7 patients locoregional and distance recurrence during follow-up period. There were no differences in oncological outcomes between two groups.

Oncological recurrence for Each Group

<table>
<thead>
<tr>
<th>Characteristics</th>
<th>n = 133</th>
<th>n = 169</th>
<th>p-value</th>
</tr>
</thead>

</tbody>
</table>

Conclusion: Based on long-term follow-up data, surgery time after ER in EGC does not affect oncological outcome. These long-term follow-up results suggest that additional surgery at about 1 month after ER is optimal for better surgical outcomes without affecting the oncological outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1225 THE POINT TO DISTINGUISH EARLY GASTRIC CANCER FROM DEPRESSION TYPE OF GASTRIC INTESTINAL METAPLASIA

T. Wakatsuki, S. Furutachi, H. Yamashita
Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan

Contact E-mail Address: t_wakatsuki0530@yahoo.co.jp

Introduction: This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful Helicobacter pylori eradication, we often observe multiple reddish depressed lesions and “patchy redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crease (LBC) has been a highly accurate sign of the IM. There are, now, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intraepithelial microinvadion (IEMI),” and 2) “Over flow”, Over flow is that the endoscopic finding that the structure of depressed lesions spreads to the outside of the depression.

Aims & Methods: The aim of this study is to clarify the usefulness of two endoscopic findings in order to detect the EGC in the group thought to be an IM. This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful Helicobacter pylori eradication, we often observe multiple reddish depressed lesions and “patchy redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crease (LBC) has been a highly accurate sign of the IM. There are, now, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intraepithelial microinvadion (IEMI),” and 2) “Over flow”, Over flow is that the endoscopic finding that the structure of depressed lesions spreads to the outside of the depression.

Results: The ratio of LBC was 75% in IM group, which was significantly higher than eradication group (7.7%), and small EGC group (9.4%). The ratio of irregular microsurface pattern was 33% in IM group, which was significantly lower than eradication group (92%), and small EGC groups (84%). The ratio of irregular microvascular pattern was 0% in IM group, which was significantly lower than eradication group (92%), and small EGC group (81%). The ratios of IEMI and Over flow lead to the diagnosis of EGC in addition to other endoscopic findings.

Conclusion: EIM and Over flow leads to the diagnosis of EGC in addition to other endoscopic findings.

P1226 IRON DEFICIENCY ANEMIA—ARE THERE ANY PREDICTORS OF GASTROINTESTINAL MALIGNANCY?

S. Xavier, 1 J. Magalhães, 2 J. Cotta, 3

1Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga/Portugal
2Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Portugal
3Pt Government Associate Laboratory, 4 ICVS/38’s, Braga/Guimaraes/Portugal

Introduction: Iron deficiency anemia (IDA) may be the only sign of gastrointestinal (GI) malignancy. The identification of predictive factors of GI malignancy in patients with IDA could help the physician to establish patients’ priority to endoscopic assessment, contributing to an earlier diagnosis.

Aims & Methods: retrospective study of 344 patients submitted to endoscopic assessment for IDA. Included adult patients with IDA and excluded patients with GI or extra-GI bleeding, total gastrectomy, exclusively vegetarian diet or iron intake from medical records.

Results: Included 121 patients with mean age of 68.5±17.0 years and 54.5% females. GI malignancy was identified in 14.9% of patients (gastric in 12, colonic in 6 patients). A statistically significant association was found between the presence of IDA and age (72.2% vs 40.8%, p = 0.01), GI symptoms (61.1% vs 11.7%, p < 0.01), weight loss (61.1% vs 5.8%, p = 0.01), need for hospitalization (88.9% vs 49.5%, p < 0.01), iron serum levels and transferrin saturation (19.7 ± 10.1 mL/L vs 30.4 ± 18.9 mL/L, p = 0.01). At logistic regression analysis only weight loss (p = 0.01), GI symptoms (p < 0.01), transferrin saturation (p < 0.01) and need for hospitalization (p < 0.01) showed a significant association with the diagnosis of GI malignancy. Transferrin saturation showed a weak discriminative capacity (AUC=0.67, p = 0.01) however, values of transferrin saturation ≤11% had a sensitivity of 94.4% and a negative predictive value of 97.1% for GI malignancy (CI 95%: 93.3-98.7).

Conclusion: In patients with IDA the diagnosis of GI malignancy is established in a significant percentage of patients and patients with GI symptoms, weight loss or with need for hospitalization should be given priority in the performance of endoscopic examinations. Transferrin saturation may help the physician in establishing the urgency of endoscopic assessment, since patients with values over 11% have a very low probability to have GI malignancy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Detection of gastric cancer in its early stage is pertinent in reducing disease-specific mortality. However, early detection has not been achieved in many countries where the incidence of gastric cancer is high. In order to overcome this problem, we developed an e-learning system for international endoscopists to improve endoscopic diagnosis of early gastric cancer. However, it has not been investigated whether such learning system is useful in clinical practice.

Aims & Methods: The objective of this trial is to investigate whether the intensive on-site TTT course is useful for increasing early detection rate of gastric cancer in Chinese high-volume endoscopy center. Five Chinese doctors (the TTT group) who were invited to the TTT course and the other five age and experience-matched Chinese doctors (the non-TTT group) in the same facility who did not attend the TTT course were included in this trial. Endoscopists of the TTT group attended 2-day learning course 4 times from March 20, 2015 to March 25, 2016. Endoscopists of the non-TTT group did not attend any learning program during the same period. Lectures of the TTT course included the detection of early gastric cancer by screening endoscopy using white-light endoscopy alone and the feature of the detected subtle gastric mucosal lesion using white-light endoscopy or magnifying endoscopy with narrow-band imaging. Contents used in the lecture had been reported to be useful by an e-learning trial [1, 2]. All the instructions were given by an experienced Japanese endoscopist (K. Yao) who constructed the e-learning system [1, 2]. Endoscopists also received on-site hands-on endoscopic training in order to make sure they obtained enough knowledge and technique. Furthermore, we held case conferences in order to share common experiences. During the period, the number of both newly detected early gastric cancers and screening gastroscopy procedures was recorded. The primary end-point was to compare the early detection rate between the TTT and the non-TTT group. (Early detection rate = the number of newly detected early gastric cancers / the number of screening gastroscopy procedures)

Results: The data obtained from the 275 consecutive cases of screening gastroscopy procedures by the TTT group endoscopists and from the 323 consecutive cases of screening endoscopy procedures by the non-TTT group endoscopists were analyzed. In the TTT group, four cases with early gastric cancers were detected and no early gastric cancer was detected. The early detection rates of
the TTT and the non-TTT group were 1.5% and 0%, respectively. There was a significant difference in early detection rate between the TTT and the non-TTT group (Fisher’s exact test, P = 0.046).

Conclusion: This clinical trial clearly showed that the systematic intensive TTT course is useful for improving early detection rate of gastric cancer in clinical practice at Jikei University endoscopy center. (NCTD20358578)

P1228 COMPARISON OF ENDOSCOPIC SUBMUCOSAL DISSECTION AND SURGERY FOR THE TREATMENT OF EARLY GASTRIC CANCER: SINGLE-CENTER LONG-TERM OUTCOME STUDY

1Department Of Internal Medicine, Keimyung University School of Medicine, Daegu/Korea, Republic of
2Department Of Surgery, Keimyung University School of Medicine, Daegu/Korea, Republic of
3Department Of Gastroenterology And Hepatology, The Jikei University, Tokyo/China

Introduction: Endoscopic submucosal dissection (ESD) is believed to be a possible modality for early gastric cancer. But there is little report about long-term outcomes of the ESD directly compare with the surgery. The purpose of this study is the comparison between the two treatment modalities outcomes about the outcome. Aims & Methods: We performed a retrospective analysis of 1243 patients with stage I early gastric cancer without lymph node involvement. 551 patients were treated with ESD, and 692 patients were treated with subtotal or total gastrectomy. Long-term overall and disease-specific survival rates, development of new lesions, and complications were analyzed.

Results: The mean age was higher in the ESD group (64.9 ± 9.5 vs. 58.5 ± 11.7, P = 0.001) and female distribution was higher in surgery group (30.5% vs. 38.9%, P < 0.001). In ESD group, diabetes was more frequent (12.9% vs. 7.1%, P < 0.001). The overall survival rate was similar (96.2% vs. 96.7%, P = 0.136), but disease-specific survival rate was significantly higher in ESD group (99.8% vs. 98.7%, P = 0.037, log-rank test). During 10 year follow up period, new lesions were observed in 3.6% of ESD group and in 5.3% of surgery group (P < 0.001). ESD group showed less complications (4.5% vs. 16.3%, P < 0.001) and shorter hospital day than surgery group (5.27 days vs. 12.09 days, P < 0.001).

Conclusion: Although the development of new lesions were more frequent than surgery, ESD has similar overall survival rate and even higher disease-specific survival rate than surgery. Also, ESD has less complications and shorter hospital day than surgery. Therefore, ESD is an effective therapeutic method in early gastric cancer as well as surgery.

Contact E-mail Address: hdiwhi@naver.com

Introduction: Gastric cancer is the most common cancer worldwide and the third leading cause of cancer-related death globally [1]. With the widespread eradication of H. pylori and early detection, the incidence and mortality of gastric cancer have been declined rapidly in the past few decades [2-3]. However, the prognosis of patients with metastatic diseases was still dismal and most cases survived less than one year [4]. Current primary and standard therapies for metastatic gastric cancer mainly included chemotherapy, consisting of fluoropyrimidine/cisplatin-based combination regimens[5]. Although radical gastrectomy was the first-line treatment for early gastric cancer[6], the value of gastrectomy in stage IV was still a great controversy.

Aims & Methods: We aimed to investigate the impact of primary tumor resection on survival outcomes among patients with metastatic cancer. We identified an eligible cohort of the population with stage IV gastric cancer from the Surveillance, Epidemiology and End Results (SEER) database between 2004 to 2012. The overall prognosis of advanced patients with or without gastrectomy was assessed by Kaplan–Meier and log-rank analysis. Multivariate Cox proportional hazards regression models was performed to analyze the effect of primary tumor resection on overall and cancer-specific mortality. To further reduce potential baseline bias in patient selection between two groups, we adopted 1:1 propensity score matching to re-examine the effect of resection.

Results: We finally identified 12984 eligible patients with metastatic GC between 2004 and 2012, including 1977 patients with gastrectomy and 11007 without resection. The median survival time for patients with or without surgery were 9.0, 4.0 months respectively. Patients who received surgery had a significantly survival advantage of gastrectomy in patients with stage IV gastric cancer. In the propensity score matched model analysis, gastrectomy was associated with increased overall (HR,0.54, 95% CI, 0.51–0.58) and cancer-specific survival (HR,0.50, 95% CI, 0.50–0.55).

Conclusion: Based on population-based studies, we demonstrated that there was a survival advantage of gastrectomy in patients with stage IV gastric cancer. Further prospective studies are needed to verify our findings.

Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is an uncommon variant of gastric adenocarcinoma which has a distinct clinicopathological, immunohistochemical, and endoscopic features (1-3). However, the molecular biological features of GAFG have not been well elucidated.

Aims & Methods: We evaluated clinical and molecular characteristics of GAFG in comparison with conventional gastric adenocarcinoma. Among 831 patients with gastric adenocarcinoma who underwent surgery or endoscopic resection in Juntendo University Hospital between January 2010 and December 2016, we enrolled 13 cases of GAFG, defined as an extremely well differentiated adenocarcinoma with expression of pepsinogen-I and/or H/K-ATPPase 1. To clarify current mutations of GAFG, next generation sequencing (NGS) was performed for all cases of the tumor and normal tissue formalin-fixed paraffin-embedded samples, using Ion PGM™ system with the Hotspot Cancer Panel v2 targeting 50 genes (Thermo Fisher Scientific). We also carried out immunohistochemical staining including MUC1/C, MUC3/C, MUC6, and CD10, and analyzed association among genetic alterations and mucin phenotype.

Results: Clinicopathologically, all patients [62(9) y (range 43–80), 8 male, 5 female] had submucosal invasive adenocarcinomas with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) μm. Neither local recurrence nor metastasis were detected at a median of 6.7 months (4–17) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had mutations of GNAS. The frequency of mutations was significantly higher (38.5% vs. 6.2%, p < 0.001) in GAFG. Furthermore, the frequency of TP53 mutation was significantly lower (7.7% vs. 47.8%, p < 0.05) in GAFG. However, there were no significant differences in the frequencies of KRAS and STK11 mutations. In addition, all lesions showed gastric phenotype (i.e. immunopositive for MUC5AC and/or MUC6). There were no significant differences between genetic alterations and mucin phenotype.

Conclusion: The present clinical and comprehensive genetic analysis identified the frequent presence of GNAS mutation and low-grade malignancy of GAFG.

Introduction: Runx-related transcription factor 3 (Runx3) is a transcription factor playing an inhibitory role in the malignant behavior of gastric cancer. Long non-coding RNAs (LncRNAs) exert their functions mainly by binding with corre- sponding transcription factors, among which Runx3 is the most common ones. However, the LncRNAs that could bind with and affect the expression or activity of Runx3 are still unclear.

Aims & Methods: Potential Runx3-binding LncRNAs were screened by an online program (RNA22) software and validated by RNA immunoprecipitation (RIP). Specific HOTAIR binding site with Runx3 was confirmed further by RNA Pull down. The E3 ubiquitin ligases involved in the ubiquitin-proteasome degradation of Runx3 were recognized through co-immunoprecipitation assay.

Conclusions: HOTAIR induces the ubiquitin-proteasome degradation of Runx3 by enhancing its interaction with a E3 ubiquitin ligase Me3C3 in gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Promoter hypermethylation plays a vital role in cancer development through transcriptional silencing of tumour suppressor genes. Using Infinium Human Methylation 450 BeadChip (450K) array, we first identified calcium binding protein 39-like (CAB39L) to be preferentially methylated in gastric cancer (GC) and it may function as a potential tumour suppressor gene.

Aims & Methods: In this study, we aim to investigate the biological function, molecular mechanism and clinical implications of CAB39L in GC. Clinical relevance was validated by bisulfite genomic sequencing (BGS), western blot and immunohistochemistry (IHC). In vitro functional assays were carried out by cell viability, colony formation, apoptosis, cell cycle, cell invasion and migration assays in GC cell lines. In vivo tumorigenesis was evaluated in an orthopic nude mice model. Pathway analysis was performed using RNAseq and Phospho-kinase Antibody Array. The interaction CAB39L with its protein partners was determined by co-immunoprecipitation assay.

Results: CAB39L mRNA was down-regulated in 13 out of 14 GC cell lines. Silencing of CAB39L was associated with promoter hypermethylation, and demethylatyion 5′- treatment using Azademethycine (5-Aza) restored the expression of CAB39L. In human GC, CAB39L mRNA and protein level (p < 0.0001)
were significantly decreased in GC tissues comparing to adjacent normal tissues both in Chinese cohort (n=48 pairs) and TCGA cohort (n=450). CAB39L hypermethylation was correlated with poor overall survival in Chinese cohort (n=87, p < 0.005) and validated in TCGA cohort (n=354, p < 0.005), which suggesting that CAB39L might function as a tumour suppressor. The functional importance of CAB39L was therefore investigated. Ectopic expression of CAB39L in three GC cell lines (AGS, BGC823, MKN55) suppressed cell proliferation in MTT (p < 0.01) and colony formation assays (p < 0.0001). CAB39L induced apoptosis and G1 cell cycle arrest in GC cells, concomitant with the enhanced expression of cleaved caspase-8, caspase-3, p21 and decreased cyclin D3 expression. Cell migration and invasion abilities were inhibited by CAB39L in wound healing and gel invasion assays, respectively. Conversely, CAB39L knockdown in MKN28 demonstrated opposite effects. Orthotopic mouse model also showed inhibited tumorigenicity with CAB39L-overexpressing BGC823 cells. Mechanistically, RNAseq and gene set enrichment analysis (GSEA) revealed that AMPK and ERBB2/ERBB4 signaling were involved in the tumour suppressive role of CAB39L in GC. Consistent with our RNAseq data, AKT inhibitor killed AMPK as the key activated kinase; whilst ERK1/2 was the most strongly down-regulated in CAB39L overexpressing GC cells, suggesting that CAB39L up-regulates AMPK concomitant with down-regulation of ERBB2/4/ERK signaling. Moreover, co-immunoprecipitation between CAB39L and LKB1, a bona-fide tumour suppressor that functions to activate AMPK to suppress tumorigenesis. Western blot confirmed activation of LKB1-AMPK/β cascade in GC cells expressing CAB39L, which opposite effect was observed in CAB39L silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that AMPK activation by CAB39L contributes to tumour suppression. Consistent with novel tumour suppressor functions, down-regulation of CAB39L in GC cells led to increased tumorigenesis in xenograft model, while knocking-down of CAB39L inhibited tumorigenicity in orthotopic mice model, while knocking-down of CAB39L inhibited gastric tumor growth. cDNA microarray showed that HoxC10 regulates multiple downstream genes including tumor suppressors, growth inhibitors and cell cycle arrest, concomitantly with increased expression of apoptosis markers cleaved caspase-9, -7, -3 and PARP and cell cycle inhibitors p53, p21 and p27. PKNOX2 also attenuated cell migration, cell invasion and cell cycle arrest, concomitant with increased expression of apoptosis markers cleaved caspase-9, -7, -3 and PARP and cell cycle inhibitors p53, p21 and p27. PKNOX2 also attenuated cell migration and invasion by inhibiting epithelial-mesenchymal transition. PKNOX2 in HGC27 cells was confirmed in mouse xenograft model. Tumorigenicity assay in nude mice showed that stable PKNOX2 expression significantly suppressed tumor growth in vivo. To probe the mechanism of action of PKNOX2 in GC, we performed Cancer pathway PCR array, which unveiled a profile of cell proliferation (> 6-fold) of insulin like Growth Factor Binding Protein 5 (IGFBP5) in PKNOX2-overexpressing GC cells. IGFBP5 knockdown abolished the growth inhibitory effect of PKNOX2 in GC cells, indicating that IGFBP5 mediated the tumor suppressive function of PKNOX2. Chromatin immunoprecipitation (ChIP) assay showed that PKNOX2 bind directly to IGFBP5 promoter to mediate transcription. Consistent with our data, PKNOX2 expression was positively correlated with IGFBP5 expression in the TCGA GC dataset. IGFBP5 mediated the tumor suppressive effect of PKNOX2 via activating p53 signaling pathway, as determined by western blot analysis. Consistently, p53 transfection significantly up-regulated PKNOX2 expression in GC cells, leading to tumor suppression.

Conclusion: PKNOX2 functions as a novel tumor suppressor silenced in GC by promoter methylation. Its tumor suppressive effect is mediated via IGFBP5 and the activation of p53 signaling pathway. Promoter methylation of PKNOX2 may be a useful biomarker for predicting patient prognosis.

Introduction: Gastric cancer is one of the most common malignancies worldwide. A multitude of factors contribute to the progression of gastric cancer, including activation of oncogenes and inactivation of tumor suppressors. To find the key molecules and their mutual relations in gastric carcinogenesis is of great significance for the diagnosis and treatment of gastric cancer. The homeobox (Hox) genes encode transcription factors and usually regulate the expression of target genes at transcription level. Dysregulation of Hox genes will cause the abnormality in individual development and tissue formation, and may also lead to malignant transformation. Our group have previously screened by gastric cancer tissue microarray and found that the expression of HoXC10 was remarkably upregulated in gastric cancer. At the present time, the function and molecular mechanisms of HoxC10 in gastric cancer remains poorly understood.

Aims & Methods: To investigate the expression of HoxC10 in gastric cancer, tissue samples from two clinical cohorts were used. We analyzed HoxC10 expresion in gastric cancer tissues and the corresponding adjacent non-tumor tissues, as well as its correlation with clinical pathological parameters. In addition, we also verified the results by utilizing bioinformatics analysis. We studied the effects of HoxC10 on gastric cancer cell cycle control and proliferation through combination of in vitro cell function tests and in vivo nude mouse model. Then, we screened HoxC10 potential downstream targets by using cDNA microarray and verified the results by RT-qPCR. We studied the effects of HoxC10 on p21 expression and its downstream cell cycle-related proteins and validated the correlation of HoxC10 and p21 expression in vitro and in vivo. By application of dual-luciferase reporter assay and chromatin immunoprecipitation, we explored the role of HoxC10 in p21 transcription repression.

Results: HoxC10 mRNA expression were significantly higher in fresh frozen gastric cancer tissues than in matching adjacent non-tumor tissues (91.43%, 64/70, P < 0.01). The expression of HoxC10 was related to the depth of tumor invasion, lymph node metastasis and tumor stage (P < 0.01). Using tissue microarray, HoxC10 protein expression was also found upregulated in gastric cancer tissues (91.3%, 137/150, P < 0.01) and was closely correlated with patient survival (HR = 2.8; 95% CI 2.0–7.2). Besides, in TCGA database of gastric cancer, HoXC10 was upregulated by 122 times (n=33, P < 0.01), and in Kato-III, HoxC10 overexpression was associated with poor prognosis of patients with gastric cancer (HR = 1.8; 95% CI 1.5–2.16). HoxC10-overexpressing gastric cancer cells showed accelerated G1-S phase transformation and proliferation, whereas HoxC10 knocking-down induced cell cycle arrest in G1 phase and repressed cell proliferation. Moreover, over-expression of HoxC10 accelerated gastric tumor growth in a mouse xenograft model, while knocking-down of HoxC10 inhibited gastric tumor growth. cDNA microarray showed that HoxC10 regulates multiple downstream genes including p21, a potent cell cycle regulator. A significantly negative correlation between HoxC10 and p21 were detected in gastric cancer cells and tissues. Knockdown of HoxC10 also altered the expression of some p21 downstream cell cycle regulatory proteins, such as CDK4, p27 and p21. Furthermore, we found that HoxC10 binds to the p21 promoter directly and could inhibit p21 transcription.

Conclusion: Taken together, our results suggest that HoxC10 functions as a tumor promoting gene in gastric cancer and may be an important regulator of the cell cycle of gastric cancer cells. The role of HoxC10 in cell cycle is of clinical significance for the diagnosis and treatment of gastric cancer.

Introduction: The relationship between Helicobacter pylori (H.p.) eradication and atrophic changes is debated. Although some studies report a partial restoration of serum pepsinogen I (PGI) levels after eradication, it is not clear whether this finding reflects gastric mucosal healing. L-cysteine, reducing acetaldelyde production after food intake, has been proposed for prevention of gastric carcinogenesis in patients with chronic atrophic gastritis (CAG). To assess modifications in gastric function after L-cysteine administration in CAG by means of PGI and gastrin 17 (G17) serum levels

Aims & Methods: 62 patients (18 men, mean age 47.2 yrs), with histological diagnosis of moderate to severe chronic, atrophic, body gastritis (according to 0.9) had an abnormal biopsy, were treated with L-cysteine (100 mg three times daily), up to now 24 out of 62 reached 36 months-treatment. Serum PGI and G-17 were measured at baseline and after 3, 6, 12, 24, 36 months after starting therapy.

Results: The PGI serum increased level after the starting of L-cysteine administration, as it follows: PGI mean value at baseline was 8.42 mg/l, but after 3 months therapy was 10.58, after 6 months 11.65, after 12 months 12.19, after 24 months G-17 mean value was 25.1, and after 36 months serum levels increased significantly, as a patient may have an OG cancer was not demonstrated unless exclusion of OG cancer. In this pilot no additional utility of opening direct access OGD for GP concerned a patient may have in the pilot group at 16.8 days [95%CI 16.9, 18.9].

Disclosure of Interest: All authors have declared no conflicts of interest.

P1243 FLYING OFF COURSE WITH A 2WW DIRECT ACCESS TO TEST PILOT: NOTTINGHAM'S EXPERIENCE OF THE SUSPECTED UPPER GASTRO-INTESTINAL CANCER PATHWAY CHANGE WITH GP VETTING AND OGD BOOKING
N. R. Lewis, J. Catton, E. James
Trent Oesophago-gastric Unit, Nottingham University Hospitals NHS Trust, Nottingham/United Kingdom

Introduction: Timely progress through diagnostic pathways is a leading quality measure for NHS cancer services. A hypothesis of sooner diagnosis being achievable with direct access to hospital tests from primary care is a core part of CRUK ACE program (1), and in the context of UGI cancer pathway, there is known wide variation of direct access (DA) OGD (2). This pilot evaluates the efficacy and utility of DA OGD or clinic (DA OPD) for GP concerns a patient may have OG cancer. Comparison was made with standard 2WW pathway, where allocation to OGD or OPD first was determined by GP consultant. We hypothesised that opening direct access OGD for GP concerned a patient may have OG cancer and would not be detected on OGD alone.

Aims & Methods: Pilot and UGI standard 2WW referrals 01/01/16-01/08/16 were identified from Cancer Centre records.

Results: 192 patients were in the pilot pathway, 430 via the standard 2WW. GP were more likely to allocate a patient to DA OGD (52%) compared with 32% having DTT OGD allocated by the hospital. Despite under-utilisation of protected slots for DA OGD, time to DA OGD compared to DTT did not differ (11.0 days [95%CI 10.5,11.2] versus 12.4 days [95%CI 11.0,13.9]). The same was true for time to OPD. The time on pathway was not different in the pilot group at 16.8 days [95%CI 16.9,18.9].

Conclusion: OGD as a sole investigation for symptoms has its utility in excluding or detecting OG cancer. A high proportion of cancers detected via 2WW criteria for OGD are away from the pathway, and may not be detected by OGD. A high proportion of cancers detected via 2WW criteria for OGD are away from the pathway, and may not be detected by OGD. The subgroup of patients allocated to the pilot did have a quicker exit from the pathway, at 12.4 days [95%CI 12.9,16.6] on the DTT OGD group. The pilot overall detected 8 cancers (4.2%). The standard 2WW path 55 detected 55 (12.8%). OG cancers were in 4 of the DA OGD (4%) and 14 of the DTT OGD (10.2%). A further 10 non-OG cancers were detected in the DTT group after clinic requests further investigations for the cause of their symptoms. Those patients allocated to OPD first by either GP or hospital were as likely to have cancer as those having OGD, with 4.3% of those in the pilot having cancer detected this way, but none OG cancer, and 10.3% found to have cancers in the standard 2WW group following investigation directed after clinic visit. Of these 65% were cancers other than OG cancers and would not be detected on OGD alone.

P1244 WHAT IS THE YIELD OF ROUTINE D2 BIOPSIES IN THOSE PRESENTING WITH WEIGHT LOSS AT GASTROSCOPY?
M. Yalchin, S. Zoonoozi, M. Hussein, N. Jayasooriya, K. Besherdas
Gastroenterology, Barnet Hospital, D/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Coeliac disease is a common cause of malabsorption in Western countries. The gold standard method of diagnosing coeliac disease is by investigation of duodenal biopsy. Weight loss is a symptom of malabsorption. Patients referred for upper gastrointestinal endoscopy with symptoms of a weight loss commonly undergo duodenal biopsy to assess for presence of coeliac disease. We hypothesise that those patients with weight loss and who routinely have duodenal biopsies very rarely have coeliac disease unless there are other pointers towards malabsorption.

Aims & Methods: A single-centre, retrospective analysis of consecutive patients undergoing upper gastrointestinal endoscopy for the sole indication of weight loss was undertaken within a large associate teaching hospital within North London from 2005–2016. Of these patients, we reviewed those that had duodenal (D2) biopsies and the results. If they proved abnormal, we looked back for additional markers of malabsorption, clinically and biochemically.

Results: 142 consecutive patients, 65 were Male, 77 were female, underwent OGD for weight loss. Out of this cohort, 62% (n = 88) had a duodenal biopsy. 89% (n = 78) of these had a normal biopsy. 11% (n = 10) had an abnormal biopsy,
and 6 of these patients had coeliac, whilst 4 had other pathology such as granulomatosis or duodenitis. For all the patients who had abnormals D2 biopsies, they had other clinical markers of malabsorption, such as abdominal pain and diarrhoea, or biochemical indices such as anaemia or elevated TTG antibodies.

**Conclusion:** We conclude that the yield of routine duodenal biopsies in patients endoscoped for the sole indication of weight loss is poor. In patients with weight loss in whom coeliac disease is identified on biopsy is always associated with additional symptoms or abnormalities in blood indices. We conclude that there is no need to take biopsies of the duodenum on a routine basis for weight loss alone unless there are other signs of malabsorption. This will save time (both from taking the biopsy and sampling in the lab), lower the cost (forces and pot) and improve the safety (potential perforation and bleeding risk) of the procedure.

**P1245** FUNDING DISPARITIES IN DIGESTIVE CANCER RESEARCH IN THE UNITED STATES

P. S. Liang1, K. O’Connell2, M. Du2

1Medicine, New York University, New York/United States of America

2Memorial Sloan Kettering Cancer Center, New York/United States of America

**Contact E-mail Address:** peterliang@gmail.com

**Introduction:** In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 14% of all cancer deaths. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

**Aims & Methods:** We obtained the total annual funding for cancer (including the five digestive cancers) from 2008 to 2015 using a public database of research funded by US federal agencies. We calculated funding in 2015 constant USD using the Consumer Price Index. Case and deaths estimated by the American Cancer Society were used to calculate funding per death or case for each cancer. For comparison, we also extracted data for the three most common cancers (breast, lung, prostate) and all cancers combined. As funding for research in the United States was boosted by the American Recovery & Reinvestment Act in 2009, and had lower proportional death than proportional funding (ratio of digestive cancers accounted for 23–24% of all cancer deaths from 2010–2015, but only 15% of all cancer funding in 2015), we can infer if the recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

**Results:** In 2015, 8 billion USD in federal funding was issued to all cancer research and 658 million USD to the five common digestive cancers. The five digestive cancers accounted for 23–24% of all cancer deaths from 2010–2015, but only 15% of all cancer funding in 2015. The ratio of the proportion of all cancer death to the proportion of all cancer funding, a marker of funding disparity, was 2.9. In comparison, breast cancer accounted for 7% of cancer deaths in all years, 11% of funding in both 2010 and 2015, and had lower proportional death than proportional funding (ratio = 0.8). Prostate cancer likewise had lower proportional death than funding (ratio = 0.8). Funding disparity, measured by proportional death and funding, was highest for esophageal and gastric cancer among digestive cancers and for lung cancer overall. The ratio of proportional death and funding was 12.6 for esophageal cancer but increased for the other digestive cancers during the study period. Funding per death among digestive cancers in 2015 was highest for liver cancer and lowest for esophageal cancer. Funding per death for breast cancer was more than 3-fold the funding per death for colorectal cancer. From 2010 to 2015, funding per death for digestive cancers decreased by 20% for esophageal cancer, 24% for colorectal and gastric cancer, and 28% for liver cancer; funding per death for pancreatic cancer increased. Statistically significant trends were observed for colorectal and liver cancer (p < 0.05 for both). Over the same period, funding per incident case decreased by 15% for esophageal cancer, 21% for colorectal cancer, 34% for gastric cancer, and 37% for liver cancer; funding increased for pancreatic cancer by 6%. Statistically significant trends were observed for liver (p < 0.01), colorectal, and gastric (p < 0.05) cancer. Despite the larger relative funding decrease for liver cancer, it remained the best-funded digestive cancer relative to both incident case and death. Liver cancer received more than 2.5-fold funding per incident case than colorectal and gastric cancer in 2015. Gastric cancer was the only digestive cancer to measure in the bottom two for both funding per death and per incident case.

**Conclusion:** From 2010 to 2015 in the US, federal research funding relative to the burden of disease demonstrated that digestive cancers are underfunded. Although a similar trend was observed for all cancer research, there appears to be a funding disparity for digestive cancers—especially gastric cancer—compared to breast cancer and all cancers combined. Greater investment and more equitable funding allocation may improve digestive cancer outcomes.

**Introduction:** Helicobacter pylori infection induces aberrant DNA methylation in gastric mucosa. This effect is critical for the production of promoter CpG island hypermethylation in gastric carcinogenesis.

**Aims & Methods:** H. pylori-positive patients with gastric adenoma or early gastric cancer who underwent endoscopic resection were enrolled. According to H. pylori eradication after endoscopic resection, the patients were assigned to H. Pylori eradication or non-eradication group. H. pylori-negative gastric mucosa from normal participants provided the normal control. CpG island hypermethylation of tumor-related genes (p16, CDH1, and RUNX-3) was evaluated by quantitative MethLight assay in non-tumorous gastric mucosa. The gene methylation rate and median values of hypermethylation were compared after one year by H. pylori status.

**Results:** In H. pylori-positive patients, hypermethylation of p16 was found in 80.6% of patients and 3.2% of controls, while 100% of H. pylori-negative patients showed hypermethylation (p < 0.05). The non-eradication group hypermethylation rate of p16 was 58.1% and 61.3% of the patients, and the median values of hypermethylation were significantly lower at one year compared with the non-eradication group. However, RUNX-3 hypermethylation did not differ significantly at one year after H. pylori eradication. The non-eradication group hypermethylation did not change after eradication.

**Conclusion:** H. pylori infection was associated with promoter hypermethylation of genes in gastric carcinogenesis, and H. pylori eradication might reverse p16 and CDH1 hypermethylation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** IDO promotes the effector T-cells apoptosis by catalyzing the rate-limiting first step in tryptophan (Trp) catabolism. We demonstrated that the high expression of IDO in H. pylori-infected human gastric mucosa attenuates Th1 and Th17 immune response, while decreasing inflammation and fibrosis. The efficacy of the nutraceutical compound curcumin suggest its use as an anti-H. pylori agent, but mechanisms that underlie its helpful activity are still not clear.

**Aims & Methods:** Five antral biopsies were taken from 22 patients (10 M, median age 47.5 yrs, range 20–74) who underwent gastrointestinal for dyspeptic symptoms: 1 for urease quick test (Europasol, Trieste, Italy), 2 for histology (Giemsa staining for H. pylori, and 2 for organ culture. A C-area breath test was also performed (at least two tests positive and all the three tests negative to be considered negatives). All biopsies were treated with curcumin in addition with the IDO inhibitor 1-methyl-L-Trp (1-MT, Sigma, St. Louis, MO, USA) for 20 hours and evaluated for the expression of IDO and IL-17 by Western blotting. Levels of IL-17 were also measured in culture supernatant by ELISA. Further antral biopsies from a subgroup of 14 patients were treated with curcumin in addition with the IDO inhibitor 1-methyl-L-Trp (1-MT, Sigma, St. Louis, MO, USA) and the expression of IL-17 was assessed in total RNA extracted by RNeasy Mini Kit. The ratio of IL-17 expression of C6/H. pylori-positive patients, hypermethylation of p16 was found in 80.6% of patients and 3.2% of controls, while 100% of H. pylori-negative patients showed hypermethylation (p < 0.05). The non-eradication group hypermethylation rate of p16 was 58.1% and 61.3% of the patients, and the median values of hypermethylation were significantly lower at one year compared with the non-eradication group. However, RUNX-3 hypermethylation did not differ significantly at one year after H. pylori eradication. The non-eradication group hypermethylation did not change after eradication.

**Conclusion:** H. pylori infection was associated with promoter hypermethylation of genes in gastric carcinogenesis, and H. pylori eradication might reverse p16 and CDH1 hypermethylation.

Introduction: Alterations in salivary microbiota have been linked to elevated inflammatory responses and has been reported in patients with inflammatory bowel disease and pancreatic cancer. As yet, the potential association between salivary microbiota and patients with gastrointestinal (GI) infection has not been determined.

Aims & Methods: In this study, we characterized the salivary microbiota in patients with H. pylori (HP)-associated gastritis and the potential changes of salivary microbiota after receiving HP eradication therapy. We enrolled subjects who were scheduled for diagnostic upper GI endoscopy. We obtained saliva samples from participants with peptic ulcer or cancer found on endoscopy, who have received prior HP eradication therapy. Bacterial DNA was extracted for 16s rRNA sequencing. OTU clustering was performed and found to be different from HP status by using the MiSeq Platform (Illumina). We found significant changes in the salivary microbiota of HP-negative subjects.

Results: We enrolled 16 subjects with confirmed HP gastritis and 14 HP-negative subjects. Baseline salivary samples of all subjects were found to have significantly higher bacterial diversity than corresponding gastric samples. The predominant microbial family identified in the stomach is Helicobacteraceae (55.2%) whereas Helicobacteraceae constitutes only 0.1% of salivary microbiota. In contrast, the predominant families in salivary microbiota are Prevotellaceae (23.9%) and Neisseriaceae (20.3%). When compared to HP-negative subjects, salivary microbiota in HP-positive patients showed a significant increase in the Bacteroidetes and Spirochaetaceae, and a decrease in Flavobacteriaceae families. HP eradication therapy resulted in a significant reduction in the relative abundance of families such as Bacteroidetes and Spirochaetaceae in salivary microbiota.

Conclusion: There was a significant difference in the microbial diversity and compositions between gastric and salivary microbiota in HP-infected subjects, with Helicobacteraceae dominating the gastric microbiota. HP-infected subjects had higher diversity in the salivary microbiota in the saliva which is reversed by HP eradication therapy. The significance of these microbial alterations in the saliva of HP-infected subjects and its correlation with gastric diseases deserves further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Autoimmune gastritis (AIG) results in hypo/achlorhydria due to parietal cells destruction. It is characterized by lower levels of serum pepsinogen (Pg I) and PgI/PgII ratio and increased levels of gastrin. Some Authors support an association between AIG and Helicobacter pylori (HP) infection.

Aims & Methods: The aim of our study was to assess epidemiologic, serologic and pathologic features of AIG patients with and without previous HP infection. Three hundred and eleven consecutive patients with AIG, undergoing endoscopy were included. Serum gastrin, PgI, PgII and Cromogranin A levels were determined in all patients. Multiple gastric biopsies were obtained for histology, OLGA staging and HP detection. Previous or current HP infection (HP+) was confirmed in patients by upper endoscopy and/or serologic and/or serologic data. Histology was not performed using non parametric tests.

Results: Present or previous HP infection was confirmed in 50/211 patients while 161 were negative (HP-). When we compared HP+ vs HP-, AIG, no differences were found for age and gender distribution, antral and fundic/body atrophy, OLGA staging, p, PG-I and Cromogranin A levels. Gastrin levels and Gastrin/PgI ratio, a global marker of gastric damage we previously identified, were higher in HP+ than HP- (p < 0.02). Interestingly, 15% HP+ presented antrectomy atrophy. Severity of ECL hyperplasia was higher in HP+ (p = 0.02) with a 3.5 RR of developing nodular or carcinoid lesions when compared with HP-. Serum PgI, PgII PgI/PgII and gastrin levels correlated with disease severity in HP+ (p < 0.01) but not in HP-.

Conclusion: HP+ AIG have/have had a mild infection without differences in OLGA staging when compared with HP-. HP+ are characterized by lower gastrin and gastrin/PgI levels that, considered the lack of differences in OLGA staging, suggest a greater degree of gastric AIG. AIG patients showed seroserosal digestive findings at the mean follow-up of 39.0 ± 19.1 months. Subjects with seroserosal involvement showed a higher body mass index (p = 0.033), heavier alcohol drinking (p = 0.001), more intake of nonsteroidal anti-inflammatory drug (p = 0.015), and longer follow-up period (p = 0.038). On multivariate analysis, heavy alcohol drinking (odds ratio (OR) = 6.867, 95% confidence interval (CI) = 2.089–22.577, p = 0.002) and social drinking (OR = 5.306, 95% CI = 1.410–17.913, p = 0.013) were independent risk factors for seroserosal damage.

The investigation of miR-155, miR-21, miR-146a and miR-223 expressions in Helicobacter pylori positive and negative individuals

N. Uyar Alpaslan1, E. Ucbilek2, I. O¨ . Barlas1, O. Sezgin2, S. Yara

Introduction: This study was conducted to determine the differential expression patterns of microRNAs, non-coding RNAs that control gene expression mainly through translational repression, in gastric mucosa of Helicobacter pylori (H. pylori) positive patients. Several miRNAs have been associated with promoting the inflammatory response initiated by the H. pylori infection, increasing the malignant progression of the gastric epithelium, and enhancing the invasiveness and migratory capacity of cancer cells. Using serum specimens, expression patterns of hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 were determined using Real-Time Polymerase Chain Reaction (Real-time PCR).

Aims & Methods: Patients who underwent upper gastrointestinal endoscopy, in Mersin University Faculty of Medicine, Department of Gastroenterology and diagnosed H. pylori positive and negative were recruited. H. pylori status was assessed by the rapid urease test. Serum specimens of patients, were taken for miRNA isolation. hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 expression levels were determined using comparative ΔΔCt analysis by using Real-Time PCR Systems, SDS 2.0.3 software programme. Statistical analysis of miRNAs between H. pylori positive and negative groups were compared with the Mann-Whitney U test. p < 0.05 was considered statistically significant.

Table 1

Results: H. pylori positive (n=46) and negative (n=49) were included. H. pylori was not able to the hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 expressions in serum specimens and nuclear factor-κB (NF-κB) transforming growth factor, beta (TGFβ) pathways. There was no statistically difference between H. pylori positive and negative individuals in the analysis of hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 miRNA expression levels (Table 1). In surveys, there is no statistically difference between each groups, the level of education, intake of smoking-alcohol, hypertension, diabetes, cardiovascular disease, family history of gastroduodenal disease, type of gastroduodenal disease.

Conclusion: This study may contribute to the literature in terms of preventing pro-cancerous progression in the cases of cancer resulting from H. pylori infection before the onset of cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

1252 INTERLEUKIN LEVEL IN PATIENTS INFECTED WITH CAGA(+) AND CAGA(−) STRAINS OF HELICOBACTER PYLORI

N.V. Baryshnikova1, Y.P. Uspenisky2, A. Suvorov3

1 Science Research Institute, St-Petersburg/Russian Federation
2 First Pavlov St-Petersburg State University, St-Petersburg/Russian Federation

Introduction: Change of interleukin level in patients with of chronic infections, in particular at Helicobacter pylori infection. Change of interleukin level in H. pylori infected patients is extensively studied, for example, increase in level of interleukin-8 according to a number of works is accompanied by infection with virulent strains of a microorganism. CagA gene coding synthesis of the cytokinin (CagA) of the same name capable, in addition, to exert impact on development of interleukin, in particular interleukin-8 is considered a marker of presence of pathogenicity island of H. pylori.

Aims & Methods: The aim was to define features of change of level of interleukin-8 (IL-8) and interleukin-1β at patients with the chronic gastritis associated with H. pylori infection depending on existence or lack of a gene of cagA in a microorganism genome. 40 patients with the chronic gastritis associated with H. pylori have been examined. Earlier, it was made for all patients a specification of a condition of stomach mucosa and taking biopsy from stomach antrum (2 biopastes) for the purpose of verification of H. pylori infection. Detection of a microorganism was made by rapid urease test, a histologic method and molecular-genetic research—the polymerase chain reaction (PCR) with definition of genes of urease (ureC, ureI). Besides, the PSR method presence of a cagA gene in a genome of H. pylori was detected. All patients were divided on two groups: with cagA(+) strains and with cagA(−) strains. Levels of interleukins 1β, 8, 4 were decided by immunofluorescent method (the Vektor-Best, Russia).

Results: cagA gene was detected in 30 patients (cagA(+) group) and absence in 10 patients (cagA(−) group). In cagA(+) patients mean level of interleukin-1β was 395.6 pg/ml, but in cagA(−) patients—311.2 pg/ml (p < 0.05). Level of interleukin-8 in cagA(+) patients was 2.4 pg/ml but in cagA(−) patients—0.32 pg/ml (p < 0.05).Level of interleukin-4 in cagA(+) patients was 21.6 pg/ml, but in cagA(−) patients—83.4 pg/ml (p < 0.05).

Conclusion: Presence in a genome of H. pylori cagA gene is accompanied by reliable increase in level of pro-inflammatory cytokine interleukin-8 and decrease in level anti-inflammatory interleukin-4 that can be an additional factor of development of an inflammation during H. pylori infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence and prevalence of Gastric cancer are high in Japan. The International Agency for Research of Cancer (IARC) reported that 80% of gastric cancer is caused by Helicobacter pylori (H. pylori) infection and that the incidence of gastric cancer can be reduced by 30%–40% through H. pylori eradication therapy for chronic gastritis was approved for national health insurance in February 2013 in Japan. However, the success rate of H. pylori eradication by conventional primary triple therapy has been decreased by resistance to clarithromycin. Vonoprazan, which is a potassium ion–

Introduction: Clarithromycin (CLAY)-containing quadruple therapy, i.e. concomitant therapy (CT), and bismuth-containing quadruple therapy (BQT) have been suggested as first-line therapies for eradication of H. pylori infection. Both treatments are reported to have an eradication rate higher than 90%. International guidelines recommend that choosing one regimen vs the other should be based on the regional prevalence of antimicrobial resistance, knowledge of patient’s previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. However, this therapeutic approach has never been tested systematically.

Aims & Methods: The primary endpoint of this study was to evaluate the eradication rate in H. pylori-infected subjects naïve to treatment in an area of high (CLAY 75%) CT rate based on knowledge of patients’ previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. Secondary endpoint was to assess any difference between CT and BQT in terms of efficacy, safety and compliance. Because in Italy bismuth compounds are not available, BQT was by using the new three-in-one pill (TIPG) (metronidazole 125 mg + tetracycline 125 mg + bismuth 140 mg). Patients and Methods: 1) Observational study on 144 consecutive dyspeptic patients (57 M and 87 F, median age 56 yrs). Diagnosis of H. pylori infection was through 13C Urea Breath Test (UBT), or rapid urease test and histology in patients who performed endoscopy; 3) Groups of treatment: a) 84 CT (36 M and 48 F, median age 52 yrs) and PP analyses; significance of differences by chi square test (p < 0.05).

Results: 1) Eleven of 144 patients (7.6%, 95%CI 4.3-13.5) (6/4.1%, 95%CI 3.3-15.4) in the CT group and 5/60 (8.3%, 95%CI 3.6-19.3) in the BQT group] discontinued therapy because of side effects (p = ns). Overall eradication rate was 122/133 (91.7%, 95%CI 87.2-95.6) in the PP analysis and 124/144 (84.7%, 95%CI 79-90.1) in the ITT analysis; 3) PP eradication rate was 69.87 (88.5%, 95%CI 81.6-95.8) in the CT group and 53/55 (96.4%, 95%CI 91.6-101.4) in the BQT group (p = ns); 3) ITT eradication rate was 69.84 (82.1%, 95%CI 74.3-90.8) in the CT group and 53/60 (88.3%, 95%CI 80.6-96.8) in the BQT group (p = ns); 4) Among patients who completed therapy, no significant differences between the two groups were found as to the incidence of side effects (29.4% in the CT group and 35.8% in the BQT group) or compliance to treatment.

Conclusion: 1) In an area of high CLA resistance, use of CT or BQT as first-line therapy, based on patient’s previous antimicrobial exposure, allergy to amoxicillin and patient’s wish, is a highly effective strategy with an eradication rate of 91.7% (95%CI 87.2-95.6%). CT was more effective but with more side effects compared to CT, however differences were not statistically significant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Potent acid inhibition with acid inhibitory drugs is crucial to the eradication therapy for eradication of Helicobacter pylori infection. Vonoprazan, a new PPI, non-selectively inhibits the binding of potassium ion to H+ K+-ATPase in gastric parietal cells and inhibits H+ K+-ATPase activity at 400-fold more potent than that of lansoprazole, proton pump inhibitor (PPI). Therefore, the eradication regimen with vonoprazan has been developed for increasing the eradication rate as compared with a PPI-based therapy. Although vonoprazan is mainly metabolized by CYP3A4/5, it is unclear whether its acid inhibitory effect and outcome of H. pylori eradication differ among CYP3A5 genotypes. Our aim was to clarify the impact of CYP3A5/*3 genotypes on outcomes of H. pylori eradication including vonoprazan in Japanese.

Aims & Methods: We investigated the influence of CYP3A4/5 and CYP2C19 genotypes as susceptibility to antimicrobial agents for outcome of vonoprazan-containing eradication therapy for 7 days in 105 Japanese: (1) with amoxicillin 750 mg and clarithromycin 20 mg twice daily (bid) as the first-line treatment (n = 76); (2) with amoxicillin 750 mg and metronidazole 250 mg bid as second-line treatment (n = 29). Eradication status was assessed at 8 weeks via 13C-urea breath test. CYP3A4*22, CYP3A5*3 and CYP2C19*2/*3 were genotyped for all patients.

Results: Eradication rate on intention-to-treat analysis was 82.9% (95% confidence interval: 72.5%-93.6%, 63/76) in the first-line treatment and 93.1% (95%CI 77.9%-99.9%, 27/29) in the second-line. None with CYP3A4*22 was observed. 38.3% of patients (46/120) were CYP3A5*1/*3 type and 55.0% were *3/*3 type. In naive patients, the prevalence of clarithromycin-resistant strain was 42.4% (14/33). The eradication rate in patients with CYP3A5*1/*1 and CYP3A5*1/*3 genotypes showed 77.7% (46/59) and 84.7% (33/39) in the first-line treatment. However, no significant differences of clinical outcome in the second-line therapy were seen among CYP3A5/*3 genotypes.

Conclusion: Eradication rates of vonoprazan-based eradication therapy can be achieved high compared with PPI-based therapy. However, because CYP3A5/*3 genotype may be one of determinate for outcome of eradication regimen including vonoprazan, genotyping of CYP3A5/*3 will be required to be paid attention for clinical outcome before treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Our aim was to investigate the efficacy of the VPZ-based eradication therapy. The subjects were 999 patients who were diagnosed as H. pylori infection in our institution from June 2014 to December 2016. The patients were grouped into three: VPZ group and conventional PPI (Lansoprazole or Rabeprazole) group. We evaluated the first-, second- and third-line eradication status. Each regimen of VT group was first-line eradication (VPZ 20 mg bid+ amoxicillin 750 mg bid+ CAM 200 mg bid for 7 days), second-line eradication (VPZ 20 mg bid+ amoxicillin (AMPC) 750 mg bid+ Metronidazole 250 mg bid for 7 days). Each regimen of VPZ group was first-line eradication (VPZ 20 mg bid+ AMPC 750 mg bid+ CAM 200 mg bid for 7 days), second-line eradication (VPZ bid+ amoxicillin 750 mg bid+ Metronidazole 250 mg bid for 7 days). One of the following PPI was used: Lansoprazole (LPZ) 30 mg, Rabeprazole (RPZ) 20 mg. After several months, the eradication status was examined by urea breath test, stool antigen testing and blood antibody test.

Results: The number of first-line regimen of VPZ patients was 109, and the eradication was achieved in 97 patients (87%). RPZ patients were 308, and the eradication was achieved in 288 patients (94%). The number of second-line regimen of VPZ patients was 24, and the eradication was achieved in 19 patients (79%). RPZ patients were 68, and the eradication was achieved in 60 patients (88.2%) respectively. There were statically no significant differences in second-line regimens. Adverse events
such as erosion and duodenal ulcer were reported in 6.6% (9/136) of patients in VPZ, in 3.1% (18/560) in 3-in-1 capsules containing bismuth subcitrate potassium 140 mg, metronidazole 200 mg and tetracycline 500 mg in LPZ.

Conclusion: The first-line regimen with VPZ was superior to conventional PPI regimen, and was a result not to be inferior in the safety either.

P1257 CAN TWO WEEK BISMUTH BASED QUADRUPLE THERAPY FOR RESISTANT H. PYLORI INFECTION STILL BE USED IN THE UK?

H. Logan-Ellis, L. Ben said, R. P.H. Logan
Gastroenterology, King’s College Hospital, London/United Kingdom

Contact E-mail Address: hughloganellis@kth.nhs

Introduction: Eradication of H. pylori infection cures peptic ulcer disease (PUD); however, current strategies are not ideal and many patients require repeated courses of treatment. We, and others, have recently documented that currently, within the UK, less than 30% of patients with proven PUD, are subsequently documented to have been cured by H. pylori eradication 1,2. Current therapy is not successful regarding 2nd line treatments, but the British National Formulary recommends a 2nd regimen containing bismuth subcitrate, omeprazole, tetracycline and metronidazole. However since 2016, bismuth subcitrate has not been available in the UK, but is thought to be an important in treating persistent H. pylori infection 3,4.

Aims & Methods: The aim of this observational cohort study was to evaluate the effectiveness of a 2 week bismuth based quadruple therapy in patients who had persistent H. pylori infection following previous failed eradication therapy. Patients were identified from electronic hospital records using endoscopy data set, patient administration records, and pathology data sets from Jan 2011 to Dec 2016. Initial failed H. pylori eradication was defined by either by a positive 13C-Urea Breath Test (13C-UBT) or positive HpStool Antigen test (HpSA) following H. pylori treatment in either primary or secondary care. All patients were seen, assessed and warned about the importance of compliance with treatment and of possible side effects by the specialist (RL) or the dyspepsia nurse specialist (GB). After treatment, omeprazole 20 mg bd, tetracycline 500 mg qds, metronidazole 400 mg qds and bismuth subcitrate qds for two weeks, eradication was assessed at least 4 weeks after finishing treatment by 13C-UBT (or HpSA in those patients unable to attend hospital appointment). Endoscopy was also performed in those patients whom had failed multiple previous treatments to ascertain the clinical need for further treatment by assessing any underlying ulcer diathesis and for H. pylori culture and sensitivity testing.

Results: Within the inclusion period, (and from initial failed H. pylori eradication in those patients in whom eradication of H. pylori infection is mandated by the underlying ulcer diathesis. The 2nd eradication rate is likely due to the use of bismuth high doses of antibiotics, but also by specialists ensuring patients complied with their medication. These data, together with the poor outcomes of H. pylori eradication when undertaken by general physicians, also highlight the need for H. pylori eradication to be only undertaken by specialists who have access to alternative sources of colloidal bismuth subcitrate.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aims & Methods: Methods of analysis and inclusion criteria were based on RPSMA recommendations. Relevant publications were identified by a research in PubMed, MEDLINE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been weighted ad proportions/percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odd ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software.

Results: 13 studies (both randomised clinical trials and open label pilot studies) were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated H. pylori in 50 out of 391 cases. The mean eradication rate was 14%, with a 95% CI of 2-25% (p = 0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacterium in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1–31%). Multilin strain combinations were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI 1–43%). In the comparison probiotics versus placebo, we found an OR = 9.65 in favor of probiotics, with a 95% CI of 1.97–47.36 (p = 0.005). Finally, probiotics induced a mean reduction in delta values of 8.61% (95% 3.88–11.34, p < 0.0001). No study provided data about adverse events.

Conclusion: Probiotics alone show a minimal effect on the eradication of H. pylori, thus suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate. Disclosure of Interest: All authors have declared no conflicts of interest.
P1260 COMPARISON OF CLARITHROMYCIN- AND LEVOFLOXACIN-CONTAINING TRIPLE THERAPIES FOR FIRST-LINE Helicobacter pylori ERADICATION IN IRAN

H. Fakheri1, A. Sadoghi2, S. Tirgar Fakhrei2
1 Gut And Liver Research Center, Mazandaran University of Medical Sciences, Sari/Iran
2 Mazandaran University of Medical Sciences, Sari/Iran

Contact E-mail Address: septirgar3@gmail.com

Introduction: According to the Maastricht IV consensus report, Clarithromycin-containing triple therapy can be considered as a suitable option for first-line Helicobacter pylori (H. pylori) eradication in areas with less than 20% resistance rates to Clarithromycin. On the other hand, resistance to Clarithromycin is increasing in Iran, influencing the efficacy of standard triple therapy in this country. Therefore, regimens containing other antibiotics have to be considered in Iran. Aims & Methods: One hundred and forty patients with peptic ulcer disease and naïve for H. pylori infection were randomly divided into two groups to receive either 10-day standard triple therapy (Pantoprazole 40 mg, Amoxicillin 1 gr and Clarithromycin 500 mg, all given twice daily) or 10-day Levofloxacin-containing triple therapy (Pantoprazole 40 mg BD, Amoxicillin 1000 mg BD and Levofloxacin 500 mg daily). Eight weeks after the treatment, H. pylori eradication was assessed by 13C-urea breath test.

Results: One hundred and thirty-three patients completed the study. According to intention to treat analysis, H. pylori eradication rates were 75.7% (95% confidence interval (CI): 65.7%–85.7%) and 58.5% (95% CI = 47.1%–70%) in standard and Levofloxacin-containing therapies, respectively. Also, per-protocol eradication rates were 83% (95% CI: 74%–92%) and 61% (95% CI = 49%–73%), respectively. The rates of severe adverse effects of therapy were 7.1% and 2.9% in the mentioned groups, respectively.

Conclusion: Both Clarithromycin-containing triple therapy and Levofloxacin-containing triple regimen do not seem to be suitable options for first-line H. pylori eradication in Iran. We suggest using Clarithromycin in quadruple regimens such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

P1261 EFFICACY AND TOLERABILITY OF REBAMIPIDE IN TRIPLE THERAPY FOR ERADICATION OF Helicobacter pylori: A RANDOMIZED CLINICAL TRIAL

S. S. Vyalov
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svialov@mail.ru

Introduction: Rebamipide is an orally prostaglandin E2 and I2 synthesis inducer. A latest clinical trial showed that the adhesion of H. pylori to stomach wall was reduced by rebamipide. This could improve eradication rates by increasing the accessibility of the drug to antibacterial agents.

Aims & Methods: We aimed to determine eradication rate, the effectiveness and advantage of rebamipide in triple eradication therapy of H. pylori infection. Subjects comprised patients undergoing eradication therapy for H. pylori infection in our clinics. Patients with a history of eradication therapy, gastrectomy, or allergy to medications in triple therapy were excluded. Written informed consent was obtained for each patient. This trial was performed as a randomised open-label study. All patients were referred to the institutional review board. All patients were tested on H. pylori infection. The number of cases was 160 (80 cases in each group). Each patient was randomly enrolled for rebamipide therapy group (RBD) (esomeprazole 40 mg, amoxicillin 1000 mg, clarithromycin 300 mg, rebamipide 600 mg twice a day for 14 days) or standard triple therapy group (STD) (esomeprazole 40 mg, amoxicillin 1000 mg, clarithromycin 500 mg, twice a day for 14 days). Before starting therapy, we checked the background characteristics of each patient (age, gender, weight, height; drinking habit; smoking habit; use of probiotics, bismuth, PPI, and esophageal findings). After the therapy, we asked physicians and patients about medication compliance and side effects. The primary endpoint was the eradication rate. The secondary endpoints were the rates of side effects.

Results: For RBD therapy group and STD therapy group, the eradication rates were 94.0% (95% confidence interval, 85%-100%) and 82% (95% confidence interval, 74%-95%) respectively, and the rates of side effects were 8.5% (95% confidence interval, 7.0%-26.5%) and 29% (95% confidence interval, 17.5%-41.0%) respectively. Many side effects, such as oral ptyalism, stomach pain, diarrhea and peroral ulcerations were observed significantly more often in the STD group.

Conclusion: The findings suggest that rebamipide is effective in eradication of H. pylori infection, significantly improving eradication rate in triple therapy. The advantage of rebamipide has efficacy and good tolerability.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intestinal graft-versus-host disease (GVHD) represents one of the most serious complications of allogeneic stem cell transplantation (allo-SCT). Almost 10%–40% of patients who undergo allo-SCT develop significant clinical acute graft-versus-host disease (GVHD) [1]. Endoscopic and histological proofs are required because of the number of differential diagnoses manifesting as diarrhea. Previous studies reported that endoscopic features, such atrophied terminal ileum, are useful in predicting acute GVHD. However, these previous studies did not address details of the random sequence, and were performed in a single centre.

Aims & Methods: The present study investigated the incidence of the characteristic finding, particularly microvilli atrophy of the terminal ileum, of colonscopic, and inter-observer agreement of the finding among experienced endoscopists in multiple centres. Concurrent cases who underwent allo-SCT with the permission of the institutional review board were selected. Patients were tested on the terminal ileum is present. Demographic information, disease, symptoms, and histological finding were obtained from the patients’ medical records retrospectively. All study participants provided informed consent. The local ethics review committee granted ethical approval (approval 1610-013), and was registered in the University Hospital Medical Network Clinical Trials Registry (UMIN-CTR) as number UMIN 000025390.

Results: Definitive pathological and non-pathological GVHD were found in 22 patients, and 32 patients, respectively, a significantly higher proportion of patients with definite GVHD found in this study compared to previous studies [2,3]; are useful in predicting acute GVHD. However, these previous studies did not address details of the random sequence, and were performed in a single centre.

Conclusions: Microvilli atrophy in the terminal ileum is an effective character finding for real-time predictive histological diagnosis of acute intestinal GVHD. We achieved substantial inter-observer agreement for the analysis of microvilli atrophy in the terminal ileum and excellent agreement for predictive histological diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

findings showed that crypt dilatation, villus stunting, and villus atrophy were of immune cell distribution by LAZ, hematopoietic cells in the lamina propria metabolites were analyzed by a CE-TOFMS platform. To examine the changes collected before and after LAZ administration. Genomic DNA of the gut microflora instilled intraperitoneally for two weeks. The ileal contents and feces were collected WBC count was performed with whole blood from Inferior vena cava of mice. The end points were villus height, villus/crypt ratio, histologic characteristics, and mRNA expression of tumor necrosis factor (TNF-α), and interleukin (IL)-6. Results: In 5-FU group, neutropenia was confirmed by laboratory test (5-FU, 0.650 K/μL), Control, 5.317 K/μL, indicating sufficient 5-FU effect. Histologic findings showed that crypt dilatation, villus stunting, and villus atrophy were reduced in EGCG plus 5-FU group than in 5-FU group (Figure 1). Quantitative mRNA expression (EGCG, 352 μm; 5-FU, 319 μm) and villus/crypt ratio (EGCG plus 5-FU, 3.26; 5-FU, 2.31) in EGCG plus 5-FU group, compared with 5-FU treated group, were significantly higher. mRNA expression of TNF-α was significantly lower in EGCG plus 5-FU group compared with 5-FU group (P < 0.05)(Figure 2). Figure 1. Effects of EGCG administration on intestinal epithelial cells in mice jejunum (Figure (B) control (B) 5-Fluorouracil (5-FU) group with significant villus atrophy and crypt dilatation (c) EGCG group (d) EGCG plus 5-FU group with mild villus destruction and less crypt dilatation). Unlike 5-FU, mRNA expression of TNF-α, IL-6, and TNF-α in the Peyer’s patch along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU. Conclusion: It was considered that the uptake capacity of amino acids, such as L-type amino acid transporter (LAT) transports a wide range of nonselective amino acids, including essential amino acids, it is considered to be a gastrointestinal transporter that is important for nutrient absorption. Furthermore, the involvement of other amino acid transporters in inflammation has been reported by several studies. Aims & Methods: We aimed to clarify the pathophysiologic role of an amino acid transporter in gastrointestinal tract inflammation caused by an antitumor agent in this study. The antitumor agent fluorouracil (5-FU) was orally administered to mice. The severity of mucositis was assessed based on the length, villus height, mucus production, cell infiltration, and immune response of the intestinal tract. We measured the mRNA expressions of LATs in the tissues of the small intestines. In addition, we analyzed the protein expressions among the small intestines using anti-LAT antibodies.

Results: After the administration of 5-FU, the body weight, food intake, water consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucosal damage with histological change was observed. The number of PAS-positive cells decreased in the small intestinal mucosa, and it was assumed that the defensive function of the epithelial cells had decreased. In addition, an increase in the mRNA expression of IL-1β, IL-6, and TNF-α in the Peyer’s patch along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU. Conclusion: It was considered that the uptake capacity of amino acids, such as Gly, Ala, Ser, Thr, Cys, Asn, and Gin, that transported through LAT may be decreased in case of small intestinal mucosal injuries. On the other hand, LAT1 expression associated with the production of inflammatory cytokines suggested that LAT1 is a gastrointestinal inflammatory marker.

**Introduction:** Acetyl salicylic acid (ASA) has been used for the secondary prevention of cardiovascular diseases. Especially, the enteric coated ASA is widely used to prevent ASA-induced gastric mucosal injury. Recent technology such as video capsule endoscopy and balloon endoscopy enabled us to look inside the small intestine in more detail. Consequently, not a few cases of ASA-induced small intestinal mucosal injury have been reported. However, the effective prophylaxis and treatment is not clear yet. Previously, we reported direct detrimental effect of ASA on small intestinal epithelial cells using an *in vitro* model [1]. However, there are the thick mucus layer between intestinal lumen and epithelial cells. The mucus has been reported to prevent foreign objects such as bacteria, medicine and food from epithelial cells.

**Aims & Methods:** This study was conducted to clarify the role of mucus on ASA-induced small intestinal mucosal injury using a rat model. Male Sprague-Dawley rats, 9 weeks old was used. These rats were divided into four groups; group 1: sham (carboxy methyl cellulose: CMC alone), group 2: polysorbate-80 (P80) alone, group 3: ASA alone, and group 4: P80 plus ASA. CMC and/or 50-200 mg/kg ASA was injected into the proximal duodenum of rats. P80, an emulsifier, which has been reported to reduce mucosal thickness [2], was administered via drinking water for 2 weeks before ASA treatment. Indeed, P80 also reduced the thickness of mucosal layer in our analyses. One hour after ASA treatment, blue color was injected into a vein of rats to visualize small intestinal lesions. Ninety minutes after ASA treatment, the entire small intestine was removed for histological assessment. To further investigate the importance of mucus, rebamipide (Reb, 300 mg/kg) or saline were orally administered for one week prior to ASA administration. Reb is a gastric mucoprotective drug widely used for the treatment of gastric ulcer, and increases mucus secretion by small intestinal goblet cell.

**Results:** Evans blue method suggested that high-dose ASA (200 mg/kg) induced severe mucosal lesions, which was further confirmed by the histological examination. Although lower doses of ASA (50 and 100 mg/kg) did not cause mucosal damage, P80 significantly induced Evans blue exudate and severe mucosal lesions in jejunum at these concentrations, suggesting the pivotal role of mucus in these lesions. Moreover, P80-administered Reb significantly suppressed reducing small intestinal mucus and the exacerbation of ASA-induced mucosal lesions by P80, indicating that mucus is inevitable in the protection of ASA-induced small intestinal mucosal injury.

**Conclusion:** Mucus secretion increasing therapy might be a useful strategy for the prevention of ASA-induced small intestinal mucosal injury.

**Introduction:** Food allergy is characterised by a T helper type-2 immune response against a food antigen, manifesting as symptoms including nausea, diarrhoea, vomiting or anaphylactic events. It is estimated that 10% of the Australian population have a food allergy, and common allergens include cow’s milk, shellfish and peanuts. Epidemiological studies have identified antibiotics as a significant risk factor for food allergy in infants.

**Aims & Methods:** We examined how the broad spectrum antibiotic amoxicillin influenced mucosal immune responses to peanut proteins and the development of peanut allergy in mice. Balb/C mice were treated daily with 5 mg/kg amoxicillin or PBS for 5 days (days 0-4). On days 5 and 6 animals received 0.2 mg peanut extract or PBS vehicle by oral gavage. Animals were rechallenged with peanut on days 11 and 13 and sacrificed on day 16. Immune responses to peanut challenge in blood and intestinal tissues were assessed by protein, mRNA and histological analysis.

**Results:** The proportion of circulating eosinophils was increased in the blood of mice treated with both antibiotics and peanut. Histological examination revealed an increase in small intestinal eosinophils, predominantly at the villous tips, indicating recruitment to the mucosa. RNA and protein analysis revealed an increase in IL-5 associated with increased Nod-Like Receptor Protein 3 (NLRP3) inflammasome activation.

**Conclusion:** These studies demonstrate that antibiotic treatment prior to food antigen challenge can lead to altered mucosal immune homeostasis, facilitating IL-5-mediated eosinophil recruitment, characteristic of allergic responses. Importantly, we have demonstrated an adjuvant-free model of food sensitisation and small intestinal eosinophilia. These findings contribute to a better understanding of how disruption of mucosal homeostasis by antibiotics contributes to the development of allergic sensitisation and reaction.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1268 PREBIOTIC EFFECTS ON HEALTHY AND CHEMOTHERAPY-INDUCED SMALL BOWEL INJURY IN RATS**

**Introduction:** Intestinal mucositis is a severe side-effect of chemotherapy. We investigated the potential to reduce the severity of 5-Fluorouracil (5-FU)-induced intestinal mucositis in rats. Female Dark Agouti rats (n=8/group) were orally gavaged with either 5% FOS, GOS, MOS or water (controls) for 16 days, and received an intraperitoneal injection of 5-Fluorouracil (5-FU: 150 mg/kg) or saline (controls), on day 13. Rats were housed in metabolic cages for the duration of the study, and metabolic data was recorded daily. Rats were killed on day 16 and visceral organ weights and lengths were analyzed post mortem. CRYPT depth, villus height and histological severity scores were quantified in haematoxylin & eosin stained sections. Sucrase and myeloperoxidase [MPO] activity were quantified by biochemical assay. White and red blood cell types were quantified by whole blood analysis. Fecal volatile fatty acids (VFAs), acetic, propionic, isobutyric, butyric, isovaleric and valeric acid were also measured. Statistical analysis was by one-way ANOVA or Kruskal Wallis and Mann Whitney U test, where p < 0.05 was considered statistically significant. Data are expressed as mean ± standard error of the mean

**Results:** %Bodyweight loss was significantly decreased in all treatment groups following 5-FU injection. The fecal output was increased in rats treated with MOS or FOS, pre and post 5-FU compared to saline treated controls (p < 0.05). Leal villus height was significantly higher in GOS treated rats pre 5-FU (284.16 ± 11.95 μm) compared to respective water controls (240.40 ± 8.33 μm; p < 0.05). A villus height and crypt depth was significantly decreased in all treatment groups after 5-FU injection (p < 0.05) and prebiotic treatment did not significantly modify this parameter. Similarly, jejunal and ileal sucrase activity was decreased in all groups after 5-FU injection (p < 0.05), correlating with histological measurements. Tissue MPO activity was significantly increased post 5-FU injection, reflecting increased neutrophil activation, and was unchanged by prebiotic treatment. Interestingly, MOS and GOS both lowered %circulating neutrophils pre 5-FU compared to water controls (p < 0.05). Pre 5-FU treatment with GOS significantly increased the fecal VFAs acetic acid (16.76 ± 1.22 mM/L) and propionic acid (4.60 ± 0.99 mM/L) compared to saline treated controls (7.7 ± 0.92 mM/L) and 3.05 ± 0.28 mM/L respectively; p < 0.05). MOS and GOS treatment also significantly increased fecal acetic and propionic acid post 5-FU compared to water control (p < 0.05).

**Conclusion:** Our study has found that prebiotics, MOS, GOS and FOS modified some parameters of intestinal health and immune regulation in healthy rats; however, these prebiotics were not protective against 5-FU-induced intestinal damage. Furthermore, our findings have demonstrated that prebiotic treatment significantly increases VFA production, suggesting functional changes to the intestinal microbiome. Further studies are indicated to investigate prebiotics, both alone and in combination, during the repair phase of intestinal mucositis, and to determine their effect on gut microbial composition.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Crohn’s disease has been thought to be caused by abnormal immune responses affecting many parts of digestive tract in which Th1 cells and M1 macrophages predominates. The recruitment of Th1 cells is regulated by interaction of their expression of chemokine receptor CXCR3 and its ligands. There have been many IBD murine models showing the increase of CXCR3 expression and its role in the disease promotion. However, there are limited evidences in the roles of CXCR3 in human IBD. In fact, a small study in large bowel in a cohort of 10 Crohn’s disease patients showed lower expression of CXCR3 on T lymphocytes, compared to colon cancer patients. In terms of inhibition of T-lymphocyte migration into intestine in IBD patients, anti a4β7 (Vedolizumab) therapy is currently shown to be effective.

Aims & Methods: Our study aimed to assess expression of CXCR3 by different subsets of small intestinal lamina propria T-cells and its association with a4 and b7 integrin expression in CD patients. Total of 56 duodenal biopsies were obtained from CD (n = 15), functional dyspepsia (FD)/irritable bowel syndrome (IBS) (n = 24) or iron deficiency patients (n = 17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and gradient density centrifugation with Ficoll. Expression of CXCR3, a4, and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistical significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (p < 0.05) compared to 61.6% in control group (FD/IBS deficiency). Although the expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was not different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive a4 CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different patient groups, with consistently higher expression seen in CD8 lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients’ small intestine may have protective role. This propose further study to clarify.

P1270 METHODOLOGICAL QUALITY OF CLINICAL PRACTICE GUIDELINES ON PROBIOTICS IN ACUTE GASTROENTRITIS IN CHILDREN FROM 2000 TO 2014: AN APPRAISAL OF THE GUIDELINES FOR RESEARCH & EVALUATION II INSTRUMENT (AGREEII)

A. Maruy Saito1, A. Moro2, A. Callaghan/Australia/NSW

Contact E-mail Address: a.maruy@iup.edu.au

Introduction: Acute Gastroenteritis (AGE) is one of the diseases that most frequently affects paediatric population. Successful treatment in AGE has been demonstrated to be effective in reducing its duration. The role of probiotics in the management of AGE in children under 5 years and 5. Use of probiotics for management of AGE. A position paper by the ESPGHAN Working Group for Probiotics and Prebiotics. All of the CPG consider that the administration of Lactobacillus rhamnosus GG and Saccharomyces boulardii should be considered in the management of children with AGE as an adjunct to rehydration therapy with different level of evidence. The concordance between evaluators was >0.9 and <1.0 for all guideline positions. Four CPG had probiotics among higher than 60% in 4 or more domains and one in only one domain. Only a CPG was greater than 60% in all domains. Four had an overall score greater than or equal to 5 and were recommended, and one with modifications, according to the instrument AGREE II. The CPG is a Position Paper of a Working Group, not a Guideline, and its the reason for the lower rates obtained.

Conclusion: Conclusions: The selected CPG have good methodological quality, but are not specific to probiotics. Despite, they should be spread for better decision making.

P1271 COMBINATION OF TWO IN VITRO MODELS TO STUDY THE IMPACT OF CHRONIC CO-EXPOSURE OF A PESTICIDE WITH A PREBIOTIC ON THE INTESTINAL ENVIRONMENT

Introduction: The excessive use of pesticides, often found as residues in our diet and as contaminants in drinking water, has become a public health problem. Most of these substances are considered as endocrine disruptors and their daily exposure is likely to have severe and irreversible consequences. Indeed, preliminary studies have shown that chronic exposure to low doses of chlorpyrifos (CPF) causes intestinal imbalance (dysbiosis) in vitro.

Aims & Methods: The objective of this study is to evaluate the preventive potential of a prebiotic (mulin) in co-exposure with the CPF on the intestinal dysbiosis, the bacterial translocation and the integrity of the intestinal mucosa. For this we used an in vitro system: the SHIME® (Simulator of the Human Microbial
Intestinal Ecosystem). The SHIME® consists of series of fermenters, mimicking the gastrointestinal environment from the mouth to the colon. The SHIME® was exposed to a daily dose of 3.5 mg of CPF- combined with 10 g of inulin for 30 days. The samples were collected at day 0 (baseline, without CPF or inulin), D15 and D30 to determine the profile and microbial metabolism.

Results: Contrary to the previous results with CPF alone showing dysbiosis, prebiotic supplementation seems to reestablish CPF-induced imbalance, particularly in the potentially pathogenic microflora (Staphylococcus), which is suppressed. A significant increase in pathogenic microflora (3.44-12.73) in controls. Regardless of the diagnostic modality, prevalence of SIBO is significantly higher in IBS-P than IBS-N (47.19 ± 2.62% vs. 40.74 ± 1.68%), significantly higher than that of HC (39.8% vs. 12.5%, P=0.005). IBS-D patients with high fat diet had higher LMBHT positive rate than that of non-high fat diet patients (54.2% (13/24) vs. 17.2% (11/64), P=0.001). The baseline of breath methane in IBS-P was significantly higher than that of in IBS-N (8.6 ± 0.39) vs. (6.39 ± 0.47) ppm, P=0.002. Breath methane peak value was positively related with the fat proportion of diet (r=0.413, P=0.022).

Conclusion: The CPF/inulin co-exposure therefore had a positive impact on bacterial profile and metabolism, suggesting that prebiotic supplementation could reduce some intestinal damages caused by an exposure to CPF.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Alterations to the gut microbiota and bacterial translocation have been implicated as relevant factors for the progression of chronic liver disease (CLD). While the results of events leading to translocation remain unclear, deficiencies in local host immune defences, increased permeability of the intestinal mucosal barrier and dysbiosis of the gut microbiota are suggested to play a role. Small intestinal bacterial overgrowth (SIBO), in which an excessive and/or abnormal type of bacteria is present in the small intestine has been implicated as a potential factor in translocation. However, systematic assessments of the extent of SIBO in CLD remain limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

Aims & Methods: Using the search terms ‘small intestinal bacterial overgrowth (SIBO)’ and ‘chronic liver disease (CLD)’ or ‘small intestinal bacterial overgrowth (SIBO)’ and ‘cirrhosis’, 19 case-control studies that met inclusion criteria were identified. Data were extracted to calculate prevalence rates and 95% confidence intervals (CI).

Results: The final dataset included 1,000 adult patients with CLD and 488 controls. Nine studies employed glucose breath tests (GBT), four lactulose breath tests and one hydrogen breath test (HBT). All studies employed a 13C-labelled glucose or xylose breath test. Five studies utilised culture methods and one quantitative PCR. Across all testing methods, the prevalence of SIBO in patients with CLD was 38.9% (95% CI 36.9-40.9) compared to 9.8% (95% CI 7.5-12.8) in controls. Regardless of the sample size of SIBO in CLD was increased as compared to controls (RR =7.15, 95% CI 4.9-10.4). In patients with cirrhosis the prevalence of SIBO was 40.1% (95% CI 36.6-43.8) compared to 7.3% (95% CI 4.9-10.8) in controls. The majority of researchers employed breath tests to detect SIBO, regardless of the diagnostic modality, prevalence of SIBO in CLD was 35.8% (95% CI 32.6-39.1) compared to 8.0% (95% CI 5.7-11.0) in controls. In contrast, based upon culture techniques, the prevalence of SIBO in CLD was 68.3% (95% CI 59.6-76.0) vs 7.94% (95% CI 3.44-12.73) in controls.

Conclusion: Regardless of the diagnostic modality, prevalence of SIBO is significantly increased in patients with CLD when compared to controls. It is notable that culture-based detection leads to a higher prevalence in CLD, suggesting breath tests may underestimate overall prevalence. Given the levels of SIBO detected, further studies need to explore the role of intestinal dysbiosis for the progression of CLD.

P1274 IS THERE AN ASSOCIATION BETWEEN ENTERIC METHANE (C14) PRODUCTION AND SYMPTOMS IN PATIENTS WITH UNEXPLAINED GI SYMPTOMS?
A. Shah1, P. Ghassemi2, M. Morrison1, L. Fletcher1, G. Holtmann4

Introduction: Enteric methane (C14) production is a common gastrointestinal symptom reported by patients. While the relationship between enteric methane production and symptoms is unclear, there is evidence suggesting that enteric methane production is associated with small intestinal bacterial overgrowth (SIBO). In this study, we aimed to assess the relationship between enteric methane production and SIBO in patients with unexplained GI symptoms.

Methods: Patients with unexplained GI symptoms who were referred to a tertiary gastroenterology centre were recruited. Enteric methane production was measured using a 13C breath test. SIBO was diagnosed using a breath test in patients with a positive result. Patients were classified into two groups: SIBO and non-SIBO. The relationship between enteric methane production and SIBO was assessed using a Chi-square test.

Results: A total of 100 patients were recruited. Of these, 50 patients had SIBO and 50 patients did not. The prevalence of SIBO was 50% (50/100). There was no statistically significant difference in enteric methane production between patients with SIBO and those without SIBO (50% vs. 47.5%, P=0.23).

Conclusion: There was no statistically significant association between enteric methane production and SIBO in patients with unexplained GI symptoms. Further studies are needed to explore the role of enteric methane production in the pathogenesis of unexplained GI symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: In humans, enteric methane (CH₄) production is highly variable and related to the gastrointestinal microbiome and diet. Previous work suggests that CH₄ production is more common in patients with ‘constipating’ conditions such as encopresis and diverticulosis. We aimed to explore the link between gastrointestinal symptoms breath CH₄ exhalation in patients with unexplained GI symptoms.

Aims & Methods: Consecutive patients (n = 100) with unexplained GI symptoms underwent a combined H₂/CH₄ breath test after ingestion of 75 g of glucose. H₂ and CH₄ were measured by Breathtracker microlyser (Quintron, USA). Gastrointestinal symptoms were assessed utilising the Structured Assessment of Gastrointestinal Symptoms Instrument (SAGIS). The association between methane exhalation and symptoms during the 2 weeks prior the test were evaluated using non parametric test.

Results: 100 consecutive patients (55f), aged 52.2 ± 15.7 yrs (mean ± SD) were included. Of these, 14 with positive GBT and 19 without SAGIS data were excluded, resulting in 67 data-sets available for analysis. Methane peak and baseline values were highly correlated (r all = 0.96, p < 0.001). Methane peak (and baseline) were inversely correlated with the SAGIS diarrhoea score (r = -0.35, p < 0.01, Figure 1). Contrary to current opinion, CH₄ exhalation was not associated with constipation (r = 0.1, P > 0.4). In addition, excessive belching and acid eructation were significantly associated with the baseline and peak CH₄ exhalation (r all >0.3, p all <0.04).

Conclusion: There is an inverse association between CH₄ exhalation and diarrhoea symptoms. At the same time, CH₄ is associated with bloating and acid eructation. These data suggest that CH₄ or metabolic products from CH₄ production microbes modulate human gut function.

conditions [4]. Although other Authors described similar patients [2,3], it is still unclear whether CRSs are two independent conditions or whether they are two faces of the same coin. Alternatively, they could be umbrella terms covering one or more atopic enteropathies still awaiting to be identified, as was the case of olmsartan-associated enteropathy until a few years ago. 

Our aim was to clarify the nature of these forms of FA. We retrospectively re-evaluated the clinical notes of patients referred to our Clinic from January 1999 to October 2016 with a previous diagnosis of refractory CD. Patients with VA in whom CD could not be confirmed and in whom other causes of malabsorption were not identified were selected.

**Results:** 7 patients (2F, age at diagnosis of VA 46 ±26 years, all with severe malabsorption) were identified, 3 were DQ2 positive and so were diagnosed as UC: case 1 (F, 32 years) died of ulcerative jejunitis 8 years later; case 2 (M, 38) died of pulmonary embolism complicating systemic candidiasis 1 year later and case 3 (M, 71) died of intestinal lymphoma after 4.5 years. The remaining 4 patients were HLA DQ2/DQ8 negative, so a diagnosis of NCRS was made. DQ2:5.4 positive: case 4, (F, 61) died of EATL type 2 after 4.5 years; case 5 (M, 64) died of intestinal lymphoma 10 years after diagnosis and in good conditions; case 6 (M, 69) is still alive but could be affected by a form of enteropathy due to celiac disease. He is in good clinical condition and has been refusing follow-up. The last patient, case 7 (M, 29) is DQ7.3 positive. He is still alive 11 years after the diagnosis of VA, although complains of diarrhoea.

**Conclusion:** We described 7 patients with VA unrelated to CD or other known enteropathies. Although overall mortality among them is very high (57%) and mainly due to lymphoproliferative disorders, 3 of the 4 DQ2/DQ8 negative patients are alive many years after the diagnosis of VA with no evidence of malignancy. This suggest that these 7 patients are not affected by the same condition. We speculate that DQ2 positive patients who died of lymphoma could have been affected by a form of CD who escaped diagnosis or get complicated. However, we feel that the 3 DQ2:8 negative patients with long survival are affected by a still unidentified form of VA.

**Introduction:** Strict gluten-free diet (GFD) in celiac disease is burdensome and difficult to maintain, which might predispose to poor dietary adherence and impaired quality of life. We aimed to evaluate adult patients’ experience of living with celiac disease diagnosed in childhood, and identify factors associated with possible everyday life restrictions caused by the disease.

**Aims & Methods:** 232 adults (women 69%, median age 27.0 yr) with a childhood diagnosis of celiac disease fulfilled a questionnaire evaluating their experiences about their social and lifestyle, possible co-morbidities, adherence and attitudes towards GFD and long-term follow-up of celiac disease. In addition, they were asked to rate the development of MS. The intergroup comparison among HS patients showed that those patients had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001) and had significantly lower PGWB vitality scores (median 17 vs 23, p = 0.001). Patients reporting restrictions had more often anemia (38% vs 22%, p = 0.013) and severe symptoms (16% vs 6%, p = 0.047) at diagnosis, whereas the groups did not differ in age, gender or other clinical and histological presentation. Current age (median 33 vs 28 years, p = 0.015) and time since diagnosis (18.6 vs 7.9 years, p = 0.468) were also comparable, as well as were self-reported general health and concern about health, presence of co-morbidities and complications, smoking, physical exercise, socioeconomic status, membership of celiac society and presence of celiac disease in relatives. There was no difference in specific gastrointestinal symptoms as measured by GRS1 scores, but patients considering the disease restrictive reported more overall symptoms possibly related to celiac disease than those without restrictions (32% vs 17%, p = 0.007). Furthermore, disease severity (suffering from severe symptoms) (32% vs 28%, p = 0.770) and experienced adhering to the diet more challenging (somewhat difficult 33% vs 7%, p < 0.001) and had significantly lower PGWB vitality scores (median 17 vs 18, p = 0.023).

**Conclusion:** Almost half of the patients diagnosed in childhood experienced celiac disease to cause marked restrictions in adulthood. This was associated with current symptoms, lower vitality scores and difficulties to maintain GFD. Patients with severe symptoms and anemia at diagnosis might require special attention and tailored follow-up in these circumstances.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
the severe grade of HS was more frequently observed in GG than in CC carriers (57% vs. 37%, p < 0.01). There were 192 patients with CD of whom, 160 fulfilled the inclusion criteria. 72 (23.9%) patients had developed MS (4.3% vs 23.9%; p < 0.001) of cases, and 37.5% (n = 60) were actually never referred for DEXA scan according to guidelines2,3, and 68% (n = 81) did not fulfil criteria for a DEXA scan. The use of PPI in patients with CD on GFD is unclear due to conflicting recommendations in current guidelines. The indication for a DEXA scan is unclear due to conflicting recommendations in current guidelines. The aim of our study was to audit our practice, with a focus on requests for DEXA scans where needed. Aims & Methods: This was a single-centre, retrospective study of CD patients under the care of 3 consultants. We reviewed the electronic records to identify if haematological and biochemical profiles were being monitored. We also identified patients who had their first DEXA scans and whether or not they were indicated.2,3 Results: Data were collected on 160 patients (Female = 107 [67%]), Annual checks of FBC occurred in 94% of patients, vitamin B12 in 74%, folic acid in 77%, calcium in 88%, and vitamin D in 69%. DEXA scans occurred in 74% of patients (n = 119), including 65% (n = 77) who were screened around the time of diagnosis. However, only 24% (n = 28) actually warranted the scan according to guidelines.2,3, and 68% (n = 81) did not fulfill criteria for a DEXA. In 8% of patients (n = 10), there was inadequate data. Of the 81 patients who did not warrant a DEXA scan, 77 results were available: normal in 48% (n = 37), osteopenia in 43% (n = 33) and osteoporosis in 9% (n7). Of the 7 patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the appropriate DEXA requests, 25% (7) were normal, 39% (n = 11) had osteopenia and 36% (n = 10) had osteoporosis. Conclusion: Most CD patients require very little clinical input at their routine appointments. Annual blood checks and adherence to a gluten-free diet are standard enquiries. However, there is a cohort of patients who are not getting their regular blood tests: 33% for bone profile and 25% for haematinsics. Clinicians tend to order a DEXA in most CD patients because it is easier than attempting to judge an individual’s risk in the setting of conflicting guidelines. The pick-up rate of osteoporosis in 36% of appropriately screened patients (vs 9% in inappropriate scan requests) suggests that targeted screening allows for a more rational and cost-effective use of a limited resource. We hope that the guidelines can now be updated with more clarity for the practitioners who request DEXA scans in CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** A life-long gluten-free diet (GFD) is the only available treatment for patients with celiac disease (CD). Adherence to the GFD is associated with symptoms remission, reversal of mucosal atrophy and, possibly, prevention of CD-related complications. However, data on the long-term effects of a good or poor adherence to the GFD are limited.

**Aims & Methods:** The aim of this study was to assess the rate and accuracy of compliance to a strict GFD in patients with a CD history of more than 30 years and to compare endpoints such as complications, symptoms and histology between patients following a strict GFD and patients not compliant to the diet. Between 2015 and 2016, data from all patients diagnosed with CD at the Fondazione IRCCS Ca’ Granda before 1985 were retrieved. Patients not undergoing regular follow-up at the clinic were contacted in order to collect recent clinical data, especially at a known time for symptoms, adherence to the GFD, laboratory data, and complications occurrence. All patients were asked to fill in a questionnaire investigating their knowledge on gluten free products and behavioral rules; in case of patients with CD diagnosis in childhood, the same questionnaire was administered to their parents.

**Results:** Clinical data from 196 patients were collected and analyzed. Patients were divided into 3 groups according to their adherence to GFD: 133 patients reporting a lifelong strict GFD, 29 patients on GFD at the time of follow-up but with a history of at least 5 years of gluten-containing diet (GCD), and 35 patients who reported to be on a GCD. No significant differences were found between groups regarding symptoms and histology at diagnosis, onset of associated autoimmune disorders, family history of CD and compliance to follow-up. The onset of complications at follow-up did not significantly differ in the three as well. Follow-up histology was available in 63 patients (32.1%). Persistence of villous atrophy was as expected more frequent in patients on GCD as on GFD (41% vs 7%, p = 0.008) however 20 patients showed normal histology during long-term GCD. The questionnaire was returned by 90 patients and 66 parents: a slightly better knowledge about the GFD and its behavioral rules was found between patients on lifelong GFD and patients with ongoing or past GCD (p = 0.03).

**Conclusion:** Poor adherence to the GFD is reported by almost one-third of patients with a long-term history of CD, confirming the high rate of poor compliance to such a strict diet among patients. Poor adherence to the GFD was confirmed as a major predictor of persistence of villous atrophy, but this does not necessarily imply the development of CD complications. Moreover, results from follow up biopsies showed that a GCD does not imply recurrence of villous atrophy in all patients, attesting the possibility that some CD patients may maintain a gluten tolerance over time.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

All patients were asked to fill in a questionnaire investigating their knowledge on gluten free products and behavioral rules; in case of patients with CD diagnosis in childhood, the same questionnaire was administered to their parents.

**Results:** Clinical data from 196 patients were collected and analyzed. Patients were divided into 3 groups according to their adherence to GFD: 133 patients reporting a lifelong strict GFD, 29 patients on GFD at the time of follow-up but with a history of at least 5 years of gluten-containing diet (GCD), and 35 patients who reported to be on a GCD. No significant differences were found between groups regarding symptoms and histology at diagnosis, onset of associated autoimmune disorders, family history of CD and compliance to follow-up. The onset of complications at follow-up did not significantly differ in the three as well. Follow-up histology was available in 63 patients (32.1%). Persistence of villous atrophy was as expected more frequent in patients on GCD as on GFD (41% vs 7%, p = 0.008) however 20 patients showed normal histology during long-term GCD. The questionnaire was returned by 90 patients and 66 parents: a slightly better knowledge about the GFD and its behavioral rules was found between patients on lifelong GFD and patients with ongoing or past GCD (p = 0.03).

**Conclusion:** Poor adherence to the GFD is reported by almost one-third of patients with a long-term history of CD, confirming the high rate of poor compliance to such a strict diet among patients. Poor adherence to the GFD was confirmed as a major predictor of persistence of villous atrophy, but this does not necessarily imply the development of CD complications. Moreover, results from follow up biopsies showed that a GCD does not imply recurrence of villous atrophy in all patients, attesting the possibility that some CD patients may maintain a gluten tolerance over time.

**P1206 POST-HOC ANALYSIS OF THE RELATIONSHIP BETWEEN PLASMA CITRULLINE AND PARENTERAL SUPPORT NEEDS IN PATIENTS WITH SHORT BOWEL SYNDROME WITH INTESTINAL FAILURE RECEIVING TEGLDULURATE**

**Introduction:** Plasma citrulline has been proposed as a biomarker for remnant intestinal length, but it is unclear if plasma citrulline levels reflect intestinal absorptive function.

**Aims & Methods:** This post hoc analysis investigated the relationship between reductions in parenteral support (PS) volume and changes in plasma citrulline levels with tegldulutide (TED) in patients with intestinal failure associated with short bowel syndrome (SBS-IF). STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of teduglutide (TED) in patients with intestinal failure associated with short bowel syndrome (SBS-IF). STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.5 mg/kg/day in patients with SBS-IF. Plasma citrulline levels were assessed at baseline and Week 24 in all patients randomised to TED and in patients stratified by bowel anatomy.

**Results:** In the TED arm (n = 42), plasma citrulline levels at baseline were significantly correlated with remnant small bowel length (R2 = 0.14; p = 0.02; n = 36) but not with baseline PS volume (R2 = 0.03; p = 0.30; n = 39). The correlation between baseline plasma citrulline and plasma citrulline change at Week 24 was significant (R2 = 0.80; p < 0.0001; n = 39). No correlation was found between change in plasma citrulline levels and change in PS volume at Week 24 with TED (R2 = 0.05; p = 0.16; n = 39). When patients were analysed by bowel anatomy subgroups, significant increases in Plasma citrulline were seen with TED but not placebo (Table).

**Table:** Mean (SD) Change From Baseline in Week 24 Volume and Plasma Citrulline Stratified by Bowel Anatomy

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel disease (IBD) and mesenteric vascular (Vasc) disease are underlying conditions for intestinal failure associated with short bowel syndrome (SBS-IF). Fluid balance, urine production, and parenteral support (PS) volume are variable among patients with SBS-IF.

Aims & Methods: This is a post hoc analysis of the impact of tegdulitide (TED) on fluid composite effect (FCE = sum of urine volume output increase, oral fluid intake reduction, and PS volume reduction) in patients stratified by diagnosis. STEPS (NCT01790967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Three groups were evaluated: SBS-IBD, SBS-Vasc, and Other.

Results: The SBS-IBD group included more patients with stoma (95%; SBS-Vasc, 19%; Other, 41%) and fewer with colon-in-continuity (11%; SBS-Vasc, 78%; Other, 62%). At Week 24 (Table), PS volume reductions were significantly higher in SBS-IBD patients treated with TED vs placebo (P = 0.02) and vs TED patients in the SBS-Vasc (P = 0.04) and Other (P = 0.02) groups. Change in FCE was greater in SBS-IBD patients treated with TED vs placebo (P < 0.02) and vs TED patients in the SBS-Vasc (P < 0.01) and Other (P = 0.05) groups.

Table: Components of Fluid Composite Effect at Baseline and Week 24 and Fluid Composite Effect at Week 24 by Diagnosis

Table 1: Induction of Gastrointestinal Symptoms with Lactulose, Lactose and Fructose

Table:

![Table Image]
were evaluated: Group 1 (no colonic/stoma present/no colonic-in-continuity), Group 2 (≥50% colonic/stoma present/colonic-in-continuity), and Group 3 (other bowel anastomoses). Clinical response was defined as ≥20% reduction from baseline in weekly parental support (PS) volume at Weeks 20-24. Data presented as mean (SD).

Results: The predominant diagnosis in Group 1 was Crohn’s disease, whereas the predominant diagnosis in Group 2 was vascular complications (Table). Group 1 patients required the highest baseline PS volumes compared with Group 2 or Group 3. TED-induced PS volume reduction (change in L/week) took longer to be realised in Group 2 (Week 12, -0.9 [1.2]; Week 24, -2.5 [2.1]) compared with Group 1 (Week 12, -5.5 [3.8]; Week 24, -6.4 [4.5]) or Group 3 (Week 12, -2.7 [1.2]; Week 24, -5.1 [3.7]). Response rates were higher with TED versus placebo in all groups, but the difference was significant only in Group 1 (76% vs 19%, P = 0.001; Group 2, 56% vs 40%, P = 0.36; Group 3, 57% vs 29%, P = 0.03). Adverse events were reported by 94%, 72%, and 86% of Group 1, Group 2, and Group 3 patients receiving TED, respectively.

Conclusion: Patients with SBS needs and responded most and fastest to TED with PS volume reductions, compared with patients in Group 2 or Group 3. This research was funded by Shire.

Disclosure of Interest: C. Olivier: I am an employee for Shire.

Aims & Methods: This was a prospective pilot study on patients with a diagnosis of superficial SNADETs who were treated at the Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Hospital, Tokyo, Japan. Before enrollment, all patients had undergone endoscopic evaluation to preclude ampullary lesions, and had a preoperative histological diagnosis of either adenoma or adenocarcinoma. Patients with familial polyposis were excluded. Immediately before resection of the target lesions, a simple biopsy sample from the duodenal tumor and a paired sample from the surrounding normal duodenal mucosa were endoscopically obtained from each patient, followed by RNA extraction. Gene expression profiling with an oligonucleotide microarray was performed in a training set of 4 matched tumor-normal tissue superficial SNADETs pairs. Genes and pathways with differences between pairs were identified, followed by a set-level gene enrichment analysis with a pre-validated curated gene set. Results were confirmed with rt-PICR in all other independent SNADETs pairs.

Disclosure: From Nov 2014 to Jan 2016, a total of 12 consecutive patients were enrolled in this study. One patient was excluded due to a post-treatment diagnosis of familial polyposis. In a training set of 4 tumor-mucosa pairs, 626 probes (168 up-regulated, 458 down-regulated) which consistently demonstrated over a 2-fold expression difference between tumor and normal mucosa in all matched pairs were identified. Rq-PCR of genes most highly differentially expressed between the tumors and normal mucosa was performed in the 4 pairs in the training set as well as 7 independent pairs. Consistent gene expression patterns concurrent with microarray results were demonstrated in all pairs, confirming the results of this study. Gene set enrichment analysis of the training set using a curated data set demonstrated a strong association between SNADETS with colorectal adenomas (p < 0.0001) and APC down-regulation (p < 0.00001). No other significant associations were demonstrated.

Conclusion: Superficial SNADETs demonstrate gene expression characteristics with a strong resemblance to colorectal adenomas. Gene expression characterization of these lesions has also demonstrated the significant role of APC down-regulation in the pathogenesis of SNADETs, suggesting that an adenoma-carcinoma sequence similar to colorectal adenomas may be seen in SNADETS. Further analysis of genes which may play a key role in the carcinogenesis of these neoplasms is needed.

P1292 USE OF 3D COMPUTED TOMOGRAPHIC ENTEROCLYSIS TO OBTAIN INFORMATION ON THE LENGTH OF THE SMALL INTESTINE AND ON THE SIZE, SHAPE, LOCATION OF INTESTINAL NEOPLASIAS

T. Yodikawa, K. Ohno, T. Kurokami
Dept. Of Gastroenterology, Shizuoka General Hospital, Shizuoka,Japan

Contact E-mail Address: t-yoshi@med.nagoya-u.ac.jp

Introduction: We established a new imaging technique, 3D computed tomographic (CT) enteroclysis, to evaluate its safety, feasibility, and usefulness for small intestinal neoplasias. Data on 3D CT enteroclysis performed in our hospital from January 2010 to March 2017 were reviewed. In 3D CT enteroclysis, the small bowel was inflated with air using a nasoduodenal tube. CT images were taken, and then 3D overviews, virtual endoscopic views, and virtual dissection views were generated using a virtual colonoscopy system. Total volume of injected air, intraintestinal pressure, and length of the depicted small bowel were recorded. The images of small intestinal neoplasias were collected and compared with patients in Group 2 or Group 3. This research was funded by Shire International GmbH, Zug, Switzerland.

P1297 ELLIPSE BALLOON SYSTEM: OUR EXPERIENCE. A PRELIMINARY STUDY

Gastroenterology And Digestive Endoscopy. Azienda Ospedaliera San Giovanni Addolorata, rome/Italy

Contact E-mail Address: veronicaelie@hotmail.it

Introduction: Gastric balloons (IGB) are an emerging option for overweight and obese patients with a body mass index (BMI) greater than 31 kg/m2 and they provide greater efficacy with lower risks than do conventional surgical procedures. The balloon treatment is based on gastric space-occupying effects that increase the feeling of satiety and may also affect gut neuroendocrine signaling. However, widespread use of current generation IGBs has been limited by several factors: placement and removal endoscopes require sedation, special training and equipment; patients lost to follow-up are susceptible to IGB deflation and unplanned passage into the gastrointestinal tract. The EllipseTM is the world’s first intragastric balloon that does not require endoscopy or anesthesia.

Aims & Methods: We conducted a study to prospectively analyze the safety and effectiveness of IGB ELLIPSE in overweight adults. Six patients, 1 male and 5 female (average age 40, mean BMI = 40 kg/m2), were included in this study. Each patient swallowed EllipseTM balloon intended to remain in the stomach for 16 weeks. Each balloon was filled with 560 mL of filling fluid. Patients returned every 2 weeks for abdominal ultrasound which documented the correct positioning of the device. All patients were followed up by a nutritionist with a specific focus on the IGB.

Results: All 6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 Kg). In all of the patients, the balloon remained full throughout 16 weeks, self-emptied, and were passed spontaneously without needing endoscopic removal.

Conclusion: This study demonstrates the efficiency, security and simplicity of the IGB ELLIPSE in overweight adults. All patients were followed up by a nutritionist with a specific focus on the IGB. The ElipseTM system. Moreover, we highlighted the non necessity of deep sedation and use of invasive endoscopic examinations for positioning and removal of the IGB.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bariatric surgery is an effective treatment for morbid obesity. In Taiwan, the numbers of patients who received bariatric surgery increased gradually. However, for long-term follow-up, nutritional deficiency may develop in patients. We collected data on the utilization of nutrition department services for bariatric surgery patients. The aim of this study is to evaluate the change of Vitamin D and bone mineral density (BMD) in bariatric surgery patients.

Aims & Methods: We conducted a patient identification study at the bariatric surgery outpatient clinic (April 2012-2014) and one year after bariatric surgery (2013-2015). Blood samples were collected from patients for assessment of the calcium, Vitamin D and parathyroid hormone (PTH) levels. BMD (g/cm2) was also measured at lumbar spine (L2-L4) by dual energy x-ray absorptiometry (DEXA).

Results: Among 50 patients, 15 patients received laparoscopic sleeve gastrectomy (LSG), 24 patients received laparoscopic mini-gastric bypass (MGB), 5 patients received laparoscopic Roux-en-Y gastric bypass (RYGB) and 6 patients received laparoscopic duodenal-jejunal bypass with sleeve gastrectomy (DBJ-SG).

The characteristic of the study population was shown as Table 1. The differences of mean for calcium, Vitamin D, PTH and BMD after bariatric surgery were significant. BMD (g/cm2) in the LSG group was higher than that in the MGB group.

Conclusion: We aim to identify patients with bone mineral density (BMD) at risk who may benefit from vitamin D supplementation. Furthermore, we aim to identify patients who may develop osteopenia or osteoporosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

intragastric balloon. The intragastric balloon has been established as a valid endoscopic therapeutic option for weight loss, especially in patients with overweight and obesity. Moreover, up to 123 patients submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomosis dilation, although some studies use smaller diameters such as 14 mm similar to that created manually in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic diameter was measured using a 33-mm long Olympus Articulated device. Interval between an anastomotic dilation procedure was with a maximum of 03 applications. APC set was at 2-3 mL with 65-85W. GJ diameter target was 8-12 mm estimated with pre-measured grasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student’s t-test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (73.01–123.69). Mean and average weight loss reported in this interval was 22.08 kg (±11.05 kg). The mean diameter of the anastomosis was 24.78 mm (±6.04) and the average number of APC sessions was 1.78 times (±0.61). The average reduction of anastomotic diameter was 14.86 mm (±7.24) and the final average diameter was 10.01 mm (±4.13). The average weight loss between the first and last APC was 13.37 kg (±7.82) and the average decrease of BMI was 4.59 kg/m² (±2.78). 122 patients (22.0%) did not achieve the target GJ diameter and 05 patients (0.9%) did not lose weight even with the desired GJ diameter. From the 146 patients who had weight regain due to symptomatic stenosis at least once. No further complications were reported. Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The weight regained has been a described growing problem in patients undergoing bariatric surgery and this weight regained is multifaceted and associated with dilation of Gastrojejunal anastomosis (GJ). For the patients with significant weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described. Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastroanastomosis in patients who have undergone RYGB for morbid obesity and regained weight associated to dilation of the GJ From Jan-2014 to April-2017 554 RYGB subjects were reviewed and regain a dilated anastomosis (>18 mm) and at least 2 procedures were submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomosis dilation, although some studies use smaller diameters such as 14 mm similar to that created manually in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic diameter was measured using a 33-mm long Olympus Articulated device. Interval between an anastomotic dilation procedure was with a maximum of 03 applications. APC set was at 2-3 mL with 65-85W. GJ diameter target was 8-12 mm estimated with pre-measured grasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student’s t-test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (73.01–123.69). Mean and average weight loss reported in this interval was 22.08 kg (±11.05 kg). The mean diameter of the anastomosis was 24.78 mm (±6.04) and the average number of APC sessions was 1.78 times (±0.61). The average reduction of anastomotic diameter was 14.86 mm (±7.24) and the final average diameter was 10.01 mm (±4.13). The average weight loss between the first and last APC was 13.37 kg (±7.82) and the average decrease of BMI was 4.59 kg/m² (±2.78). 122 patients (22.0%) did not achieve the target GJ diameter and 05 patients (0.9%) did not lose weight even with the desired GJ diameter. From the 146 patients who had weight regain due to symptomatic stenosis at least once. No further complications were reported. Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastroenteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Introduction: Non-coeliac gluten sensitivity (NCGS) is a new entity with unknown prevalence and mechanisms, and there is a need for a standardized procedure to confirm the diagnosis. The objective of this study was to characterize the response to a gluten challenge, when performed according to the updated Salerno criteria.

Aims & Methods: Twenty patients (14F/6M, age range: 21–62 y) with suspected NCGS, without coeliac disease and wheat allergy, were included on a gluten-free diet. All patients went through four periods of double-blinded provocation with gluten and placebo containing muffins. They were instructed to eat two muffins a day (11 g gluten) for four days, followed by a three days’ wash-out.

Gastrointestinal symptoms were recorded with questionnaires at baseline and after each provocation, while fatigue and quality of life were registered at baseline and end of the trial.

Results: Four out of twenty patients (20%) correctly identified the two periods when they received muffins containing gluten, hence were diagnosed with NCGS. The non-diagnosed group tended to show higher symptom scores than the not-diagnosed group both at baseline, after gluten exposure and after placebo, but no clear difference was seen in symptom change after provocation with gluten and placebo.

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten diagnosed four patients with NCGS according to the Salerno criteria. However, according to the symptom registrations there are no clear differences between the diagnosed and the non-diagnosed group, or between symptoms after gluten provocation and placebo, indicating no specific effect of gluten in a group of patients with suspected NCGS.

Introduction: By targeting specific receptors into the vascular system, bile acids (BA) are cholesterol derivatives that are now considered as hormones. BA regulates the basal energy expenditure and gluco-lipidic metabolism. In animal models of atheroma developmentapoE-/- and LDL-/- mouse models) a powerful anti-atherosclerotic effect of circulating BA has been evidenced: BA are metabolites of the gut microbiota, suspected to play a role in the development of atherosclerosis. This study examined whether variations in BA or in the gut microbiota composition can be described in the human Coronary Artery Disease pathophysiology.

Aims & Methods: Consecutive patients undergoing coronary angiography between February and May 2015 were enrolled. To avoid physiological or induced variations in circulating BA or in the gut microbiota, highly restrictive exclusion criteria were applied. Circulating and fecal BA were quantified by high pressure liquid chromatography and tandem mass spectrometry. The fecal microbiota composition was assessed by 454 pyrosequencing of the total fecal bacterial DNA.

Results: 80 patients were prospectively included of 406 screened, and divided in two groups: with (n=45) and a group without (n=35) CAD. The serum mean concentration of total BA was 1.02 ±0.16 mmol/l in patients with, versus 2.16 ±0.38 mmol/l in patients without CAD (P=0.005). This decrease, (adjusted for gender and age) was an independent predictor of CAD (odd ratio = 0.51; 95% confidence interval 0.31, 0.85; P=0.01). The BA concentrations in feces were similar in both groups. There was no group-specific pattern in the fecal microbiota. In a subgroup of 17 patients, one month of statin therapy increased the serum BA concentration from 0.68 ±0.08 to 1.37 ±0.21 mmol/l (P=0.01).

Conclusion: There was no specific microbiota signature associated with CAD. However, a decreased serum BA concentration was a strong predictor of CAD in humans. With respect to the powerful anti-atherosclerotic effect of BA in animal models, and their role in human lipid metabolism and diabetes, this study unraveled the existence of a new metabolic disturbance associated with CAD.

both at T1 (4.4 ± 1.6) and T2 (8.2 ± 1.7). When starting, LFD patients considered a diet low in FODMAPs (67%), fructans (27%), fibre (17%), galacto-oligosaccharides (GOS) (17%) and polysaccharides (3%); the reintroduction phase (T2) enabled us to detect lactose in 70%, fructans in 30%, fructose in 37%, GOS in 33% and polysaccharides in 27%, as real triggers. The agreement (Cohen’s kappa) was moderate for lactose (κ = 0.50), fair for fructans (κ = 0.39) and fructose (κ = 0.32) and poor for polysaccharides (κ = 0.01).

Conclusion: Not only did reintroduction not affect the improvements achieved during the elimination phase, but it also precisely identified the foods responsible for the clinical manifestations. This enabled us to suggest a personalized diet for the patients. The real role played by FODMAPs in generating symptoms was abundantly underestimated and misunderstood by our patients. This underlines the fact that LFD has to be administered and carried out under the guide of an expert nutritional physician.

Introduction: Fructose malabsorption (FM) is a frequent finding in patients with abdominal symptoms due to high levels of fructose in Western diets. The role of monosaccharide transporter dysfunction in the small intestine is incompletely understood. The aim of this study was to investigate the histoanatomical distribution of the main fructose transporter GLUT5 in JH patients with FM.

Aims & Methods: The study included 257 patients with FM diagnosed by hydrogen breath test and grouped according to the response to a fructose-free diet. 42 healthy individuals and 31 patients with coeliac disease (CD) served as control. The fructose breath test was done with 50 g fructose. Fructose malabsorption was defined as an increase of 20 ppm of endogeneous hydrogen. Formalin-fixed and paraffin-embedded duodenal biopsy specimens were obtained in all cases. Histology was assessed using hematoxylin and eosin stained tissue sections. Expression of GLUT5 was studied by immunohistochemistry. Expression patterns of GLUT5 were correlated with clinico-pathological patient characteristics.

Results: The expression of GLUT5 did not differ significantly between patients with FM complete diet responders (n = 183) and healthy controls (n = 42) also patients with FM responding to a fructose free diet did not differ in GLUT5 expression or in max. H2 increase and AUC measured in fructose breath testing from patients not responding to the diet (n = 40). However, in patients with CD (n = 29) significant differences in GLUT5 expression were found compared to patients with FM and healthy controls (p = 0.009). The severity of CD assessed by the Marsh score significantly correlated with the GLUT5 expression (r = 0.563, p = 0.001).

Conclusion: Changes in GLUT5 expression may not cause symptoms in adult FM patients. FM symptoms may be associated with other factors not only with GLUT5 expression. In contrast, in CD with secondary malabsorption decreased GLUT5 expression was detected. Further investigation is needed to understand the essential factors in FM and the influence on functional gastrointestinal disorders.

Introduction: Previous studies have shown a reduction of gastrointestinal symptoms in patients with disorders of gut-brain interaction (FGID) when following a diet low in FODMAPs. Symptom relief due to a low FODMAP diet has especially been investigated in patients suffering from irritable bowel syndrome (IBS) and has proven to reduce gastrointestinal symptoms in up to 86% of patients with IBS. In addition, there is evidence for an association between gastrointestinal symptoms and joint hypermobility (JH). However, there is no clear data regarding response rates to a diet low in FODMAPs in patients suffering from JH. In this study we aimed to assess and compare the response to a diet low in FODMAPs in JH positive and JH negative patients with FGIDs.

Aims & Methods: Data of patients presenting with FGID at the tertiary ambulatory functional bowel clinic between January 2015 and July 2016 were analyzed. FGIDs were diagnosed according to Rome III criteria. JH was assessed by physicians using Beighton score and rated positive for scores >9/9 points. Patients received professional nutritional counseling on a diet low in FODMAPs. A global symptom response was assessed by a professional nutritionist after 4 to 6 weeks following a low FODMAP diet.

Results: Of all 84 patients screened for JH, 62 (73.8%) were female and 22 (26.2%) were male. Median age of the female was 35 (range 18-59) years, whereas males were more likely to exhibit JH compared to males (38.62 [61.3%] vs. 6.22 [27.3%]; p = 0.006). Global symptom response rate to a diet low in FODMAPs was 64/64 (76.2%). Our data showed significantly better response to a low FODMAP diet in JH negative patients than in JH positive patients (36/40 [90.0%] vs. 28/44 [63.6%], p = 0.005, ITT). Response of 7 patients was unknown because of early therapy discontinuation before nutritional re-counseling. When excluding 7 patients with therapy discontinuation from our calculations, the difference in diet response between JH negative and JH positive patients remained significant (36.39 [92.3%] vs. 28/38 [73.7%]; p = 0.036).

Conclusion: Our data indicate an association between global symptom response to a diet low in FODMAPs and joint hypermobility status in FGID patients. An understanding of the structural pathways underlying pathological fructan and polyol sensitivity (intestinal permeability) causing gastrointestinal symptoms in JH positive patients and limiting response to low FODMAP diet should be considered. Our findings represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

Introduction: Gastrointestinal symptoms are often associated with dietary intolerances and are common in the developed world consuming a western diet low in fiber. Aims & Methods: To determine the effect of a high-sugar, low-fiber diet on GI symptoms and duodenal physiological function, we conducted a double-blind clinical trial in a single-center study. Healthy adults with baseline fiber intake ≥14 g and ≥10 g of fiber/day (10 g/day; ≥5% of total daily calories) in response to increasing concentrations (0.003-300 μM) of serotonin (5-HT) on the submucosal side. These measurements were repeated after the dietary intervention. Data were presented as mean ± SEM. Data were analyzed using paired t-test unless specified and p < 0.05 was considered significant.

Results: A total of 10 participants (5 female; median age 26; 70% Caucasian) were recruited. Average BMI was 23.1 kg/m2. At baseline, all participants were asymptomatic. After dietary intervention, all patients endorsed at least one new symptom and 9/10 patients endorsed multiple (≥2) new symptoms. At baseline 4/10 patients had positive duodenal carbohydrate (≥100,000 CFU/mL) or other bacteria (≥100,000 CFU/mL) at baseline, all this was improved in participants who normally consumed a high-fiber diet. This was associated with changes in the gut microbiome. This was associated with changes in the gut microbiome. At baseline, the gut microbiome was characterized by a high proportion of Firmicutes and a low proportion of Bacteroidetes. After dietary intervention, the gut microbiome was characterized by a decrease in Firmicutes and an increase in Bacteroidetes. This was associated with changes in the gut permeability, increased inflammation, and decreased gut motility. At baseline, the gut microbiome was characterized by a high proportion of Firmicutes and a low proportion of Bacteroidetes. After dietary intervention, the gut microbiome was characterized by a decrease in Firmicutes and an increase in Bacteroidetes. This was associated with changes in the gut permeability, increased inflammation, and decreased gut motility.

Introduction: Recently roles of gut hormones on appetite control have been known. Among them, CCK is well known to suppress appetite and gastric motility. On the other hand, patients of functional dyspepsia (FD) have hyper sensitivity to CCK. And revels of CCK innard was shown to be high in FD patients. In FD patients, stress have important roles of pathogenesis of the disease.

Aims & Methods: We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress, we gave restraint stress, corticosterone-releasing factor (CRF) or urocortin (UCN1) injection intraperitoneally (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain. In the gastric emptying study, SD rats were fasted overnight. The amounts of the mixture (food and glass beads) left in the stomach 1 hr after the injection was measured at 2 hours after the periorally injection of mixed food, and gastric emptying rate was calculated. In the study on appetite, CCK was IP injected and the amounts of food was measured at 5 minutes after the injection. In some experiments, CRF or UCN1 was IP injected and the interaction with CCK on food intake was examined. In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (10µg/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was an synergistic action between CCK and UCN1 on food intake. Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. c-Fos expression of the neurons in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorectic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

Introduction: Cholecystokinin (CCK) and peptide tyrosine-tyrosine (PYY) have been shown to affect appetite and gastric emptying. Both peptides release in blood by feeding, and maintain high levels simultaneously for 1–2 hours. Therefore there might be possible to cause interactive actions between two peptides, inducing satiation to finish food intake.

Aims & Methods: In this study, we undertook to elucidate whether CCK and PYY have the interaction to decrease food intake. Study on gastric emptying. Male SD rats were fasted overnight, and 1 mL of mixture of food and glass beads was given into the stomach and then PYY or CCK followed by PYY was IP injected to the rats just before setting food to eat. The amounts of food were measured at 1 and 2 hours after the injection. To clarify the involvement of the brain in the interaction between CCK and PYY, c-Fos expression was examined.

Results: CCK (0.5–10 nmol/kg) dose-dependently inhibited gastric emptying (p < 0.001). CCK 10 nmol/kg maximally inhibited food intake (p < 0.01). PYY 25–250 pmol/kg significantly inhibited gastric emptying for 1 or 2 hrs after the injection (p < 0.01). PYY 250 pmol/kg significantly inhibited food intake for 1 hour after the injection (p < 0.01). The combination of CCK 10 nmol/kg and PYY 250 pmol/kg inhibited gastric emptying more than CCK alone(p < 0.01) or PYY alone (not significant). PYY and CCK additively inhibited food intake when PYY was injected 20 minutes later from CCK injection. PYY significantly amplified c-Fos expression induced by CCK in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) in the brain.

Conclusion: The combination of PYY with CCK amplified the suppression of gastric emptying and the result suggests that the sequence secretion of CCK and PYY might strengthen the inhibition of food intake through the activation of satiety center in the brain, that is important for terminating food intake and adjusting energy intake.

Introduction: Transcriptions factors belonging to the p53 family (p53, p63, p73) respond to cellular stress signals by inducing an accurately defined set of genes. In a number of tumors, also in hepatocellular carcinoma (HCC), p53 proteins can exert cancerogenic or tumor-suppressive functions. MicroRNAs are small, non-coding RNA molecules which play an important role in gene regulation. It is known that expression patterns of microRNAs can be controlled by the p53 family. Depending on disease and cellular origin different sets of p53-induced microRNAs have been identified.

Aims & Methods: Little is known about p53-dependent microRNA signatures in HCC. The aim of the study was therefore to identify p53-family-regulated microRNAs in HCC. Hep3B cells were transfected with rAd-p53 and -p73. Microarray analyses were performed to identify p53- and p73-regulated microRNAs. Verification of p53- and p73-dependent microRNA expression was performed by qPCR. To evaluate the effect of HCC-relevant therapeutics on p53-dependent regulation of microRNAs transfected Hep3B cells were incubated with UCN1 (3 nmol/kg) and CRF (5 µg/kg) for 1–2 hours. Results: Overexpression of p53 and p73 induced a range of microRNAs. P53 induced miR-34a by 2.4-fold, miR-145 by 2.7-fold and led to a slight reduction of miR-149. In the presence of p73 miR-34a was induced by 5.4-fold, miR-145 by 3.2-fold, and miR-149 by 5.5-fold. p53-dependant expression of miR-34a was further increased in the presence of Doxorubicin (5.7-fold), Regorafenib (2.5-fold) and Tivantinib (1.9-fold) compared to controls. Moreover, incubation with Regorafenib resulted in an up to 5.4-fold increase of p53-dependent expression of miR-149 and miR-192.

Conclusion: p53 proteins affect the microRNA signature in HCC. Beside the already known induction of miR-34a we demonstrate for the first time a regulation of miR-145 and –149 by p53 and p73. We hypothesized that regulation of tumour-suppressive microRNAs represents an effector mechanism by which p53 family members exert their role in tumor development and treatment response. The observed synergistic effect of p53 and HCC-relevant therapeutics on microRNA expression might provide new options for the development of therapeutic and prognostic markers in HCC.

Introduction: p53 transcription factors (p53, p63, p73) respond to cellular stress by transcriptional regulation of specific sets of genes. In hepatocellular carcinoma (HCC) and other tumors p53 family members exert cancerogenic or tumor-suppressive effects. Depending on their splice variants— with transactivation domain (TA)/dominant negative (DN)—and the characteristics of the particular binding site (BS) BS p53 proteins activate or inhibit specific target genes. We previously identified the IGFBP2 gene (Insulin-Like Growth Factor Binding Protein 2) as one out of 7 putative target genes for p53 proteins with prognostic relevance in HCC.

Aims & Methods: The aim of this study was to characterize the so far unknown regulation of the IGFBP2 gene by p53 family members in HCC. Hep3B cells were transfected with rAd-p53 and rAd-p73 and transcriptional regulation of IGFBP2 was determined by qPCR. Intra- and extracellular IGFBP2 protein levels were analyzed by Western Blot and ELISA. Transfected database analyses were performed to identify potential BS for p53 and p73 in the IGFBP2 locus. These sequences were cloned, mutated and analyzed for p53 family binding in luciferase reporter assays. Binding of p53 and p73 to the identified BS was confirmed by CHIP experiments.

Results: The transfection increased IGFBP2 expression by up to 60-fold and results showed that elevated intra- and extracellular IGFBP2 protein levels were detectable. IGFBP2 protein was not detected in controls. p53 transfection induced IGFBP2 expression by up to 7-fold. Two potential p53 and p73 BS were located in the promoter region, another 5 potential p73 and one p53 BS were identified in intron 1 of the IGFBP2 gene. Intron 1-dependent luciferase activity was increased by up to 110-fold after Tap73 transfection and up to 20-fold after p53 transfection. Mutation and deletion of the identified p53 BS in intron 1 resulted in a reduction of luciferase activity by up to 85%. Deletion of one

引言：UC的甲苯胺脱氢试验（UC-MBT）是用于筛选脱氧酶活性的试验，通过确定其代谢能力的强度和肝细胞恢复。

方法与结果：研究纳入了113名MS患者，年龄从37岁至82岁。男性75人，女性88人。研究的纳排标准是MS和BMI（≤25 kg/m2）。通过UC-MBT，对患者的肝脏功能进行了评估。

结论：结果分析表明，UC-MBT在MS患者中具有潜在的临床应用价值。通过UC-MBT，可以更准确地评估患者的肝脏功能，有助于制定个性化的治疗方案。
P1136 NONALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH 2 TYPES OF MULTIPLE SCLEROSIS AND CORONARY HEART DISEASE AGAINST THE BACKGROUND OF METABOLIC SYNDROME. HOW TO DIAGNOSE?

A. Ksentsiyuchuk, E. Sklyarov, N. Kurylak, A. Bochar
Therapy #1 And Medical Diagnostics, LNUMU by Danilo Galytskyi Dept. of Therapy, Lviv/Ukraine

Contact E-mail Address: akksrts@mail.ru

Introduction: It is known that to determine nonalcoholic fatty liver disease (NAFLD), which develops in progress of body mass index (BMI) from 19% to 35%, using instrumental and laboratory methods, which include an ultrasound, the determination of the transaminase levels, steatostest, 13C-methacetine test. However, these research methods do not allow to clearly differentiate steatosis from the steatohepatitis, that reduces their credibility.

Aims & Methods: 163 patients (75 men, 88 women) with 2 type diabetes mellitus and coronary heart disease with metabolic syndrome, were examined. The average BMI was calculated above criteria of metabolic syndrome. 3 patients were diagnosed as steatosis group, 66 - steatohepatitis group. In 25 patients liver pathology was not found, which identified as a control group.

For verification of steatosis and steatohepatitis diagnosis the level of ALT, diastolic blood pressure and data 13C-methacetine breath test were evaluated.

Results: The rate of liver metabolism based on 13C-methacetine test results in patients without NAFLD was 22.0±0.686%, in patients with steatosis - 17.1±0.84%, steatohepatitis - 14.3±0.62%. Cumeative dose of methacetine on 120 minute was 20.25±0.46% in patients without pathology of liver, 16.1±0.49% in patients with steatosis, 11.4±0.36 in patients with steatohepatitis. ALT level in control group was 0.4±0.05 mmol/l, with steatosis 0.6±0.09 mmol/l, with steatohepatitis 0.9±0.08 mmol/l. The diameter of vena portae in control group was 11.2±0.26 mm, in group of steatosis 11.9±0.21 mm, in patients with steatohepatitis 13.7±0.15 mm. There were investigated, that the rate of metabolism and its cumulative dose on 120 minute has decreased in steatosis group on comparison of the control group, with simultaneous significant increasing of ALT level and diameter of the portal vein. However, a significant reduction of the metabolism rate of methacetin and the cumulative dose of 13CO₂ in the background of the increase of a diameter of vena portae compared with a group of healthy examined in steatohepatitis group. The investigation found that in ALT and the diameter of the portal vein negatively correlated with cumulative dose of 13CO₂ on 120 minute in patients with steatohepatitis.

Conclusion: Therefore, a decrease in the metabolic capacity from 15 to 10% accompanied by an increase in ALT levels (more 0.686 mmol/l) and the diameter of the portal vein (13 mm).

Disclose of Interest: All authors have declared no conflicts of interest.

P1138 LIVER TRANSIENT ELASTOGRAPHY IN NON-ALCOHOLIC FATTY LIVER DISEASE: IS THERE ANY PREDICTIVE ROLE IN THE DEVELOPMENT OF COLORECTAL POLYPS?

Introduction: Recent studies have demonstrated an association between decreased glucose tolerance, dyslipidemia and metabolic syndrome; and increased risk of colorectal polyps. Patients with non-alcoholic fatty liver disease (NAFLD) often have these risk factors. The association between NAFLD and colorectal polyps has been poorly studied.

Aims & Methods: We aimed to evaluate the prevalence and risk factors of colorectal polyps in patients with NAFLD. This was a retrospective observational cohort study of 237 patients with NAFLD submitted to transient elastography by Fibroscan®, between 2015-01-02-2017. Exclusion criteria: age <18years, absence of total colonoscopy with good preparation <3 years, inflammatory bowel disease, hereditary polyposis syndromes and personal/family history of colorectal polyps/neoplasia. Compared patients with colorectal polyps(cases) and without colorectal polyps(controls). Demographic variables, cardiovascular/metabolic risk factors, comorbidities, laboratory parameters and Fibroscan® scores of steatosis(CAP > 300 dB/m) and fibrosis(F4: > 10KPa) were evaluated.

Results: Of the 237 NAFLD patients who performed Fibroscan®, 103 underwent total colonoscopy. The prevalence of colorectal polyps in patients with NAFLD was 28.2%(n=29): 19.4%(20/103) hyperplastic, 16.5%(17/103) adenoma and 4.8%(5/103) advanced adenoma/adeno/ carcinocarcinoma. The mean age was 58.32 ± 51.5 years (vs70.9±10.53;p=0.089), with men predominant (51.7%v63.5%; p=0.272), mostly located in the left colon (55.2%v44.8%;p=0.314) and number and mean size of 1.46±0.88 and 6.89±6.56 mm, respectively. After multivariate analysis, colorectal polyps were found associated with F4 liver fibrosis (34.5%/vs 14.9%;p=0.026; OR=3.01) and obesity (BMI > 30 kg/m²; 55.2%/vs 29.7%; p=0.016; OR = 2.91); hyperplastic polyps were associated with liver fibrosis for a cut-off value of 6.9kPa (AUCROC.0689;p=0.008; S=85.7%; Sp=51.2%); mainly F4 (42.8%/v14.6%; p=0.004; OR=4.38), hyperuricemia (23.8%/v8.5%;p=0.042; OR=3.35) and peptic ulcer disease (9.5%/vs 1.2%;p=0.043; OR = 8.53); adenoma was associated with liver steatosis (88.2%/v83.7%;p=0.024; OR=3.90), F4 liver fibrosis (41.2%/v16.2%; p=0.003; OR=3.35) and obesity (58.8%/v32.6%;p=0.040; OR=2.96), advanced adenoma/adeno/carcinocarcinoma was associated with F4 fibrosis (20.0%/vs1.2%;p=0.012; OR = 2.24); hyperuricemia/gout (40.0%/v10.3%; p=0.004; OR=4.01) and dilated cardiomyopathy (20.0%/v1.0%;p=0.003; OR = 2.94).

Conclusion: More than 1/4 of the patients with NAFLD have colorectal polyps, being 16.5% adenoma and 4.8% advanced adenoma/adeno/carcinocarcinoma. Obese and liver steatosis are independent risk factors for colorectal adenoma. Liver fibrosis, especially F4 is an independent risk factor for all types of colorectal polyps.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common clinicopathological picture of the liver that may progress from simple steatosis to NASHi, cirrhosis and hepatocellular carcinoma(HCC). Although obesity is accepted as the main risk factor for NAFLD, non-obese individuals are often diagnosed with NAFLD suggesting that high BMI may not be a "sine qua non" for the presence of NAFLD. Recent studies suggested that there might be a correlation between weight gain and metabolic diseases.

Aims & Methods: In our research; the relationship between NAFLD in non-obese individuals and the amount of weight gain during adulthood was investigated and a new index that is different from BMI was proposed. 362 individuals were included in the survey. The subjects were selected among patients who had abdominal ultrasonography(UUSG) in our clinic, during the last 6 months. A 5% increase in echogenicity detected in the UUSG was defined as the diagnostic
Results: Among 362 participants (169 [46.7%] were men with an average age of 44.81 ± 10.73. 78 [21.6%] participants were women, the average age of the group being 46.78 ± 9.12. Out of 78 obese individuals 73 (93.5%) were NAFLD(+). The average age of the 284 (78.4%) non-obese subjects was 44 ± 11.05. Among non-obese people 169 (59.5%) were NAFLD(+). The sensitivity was 78.8%, specificity was 65.8%, PPV was 76.9% and NPV was 75.7%.

Conclusions: We found that the cut-off value was set as SAMI 4 kg/m², sensitivity was 76.3%, specificity was 84.3%, positive predictive value (PPV) was 84.3%, negative predictive value (NPV) was 83%.

Introduction: cisplatin-treated cancer patients often face therapy failure caused by acquired cisplatin resistance. Development of resistance was previously associated with modulation of transporters mediating cellular copper metabolism. Overexpression of the Wilson disease protein ATP7B, a TGN copper transporter, was proposed to increase cellular copper efflux.

Aims & Methods: The human hepatoma cell line HepG2 was compared with a HepG2/varient lacking functional ATP7B expression (KO) in regard to cell sensitivity. Hepatoma cell lines were generated that displayed cisplatin resistance by stepwise increasing cp concentrations. Cells were examined via growth, cell viability assays (MTT), and analysed for apoptosis (Annexin V staining). Inducedly coupled plasma mass spectrometry was used to determine intracellular cp level. Gene expression analysis (RT-qPCR) was carried out to determine the expression of various transporters. Overexpression of individual transporter genes and siRNA treatment were used for confirmation of the data.

Results: Treatment of HepG2 and KO cells with various cp concentrations revealed no significant differences in cell viability and intracellular cp accumulations. None of the KO cells that lack ATP7B can adapt to high cp levels, a cp resistant subline (CpR) was generated. Cp resistance was confirmed by viability assays and intracellular cp load. Gene expression analysis of more than 16 transporters demonstrated an upregulation of metallothionein 1 (MTT: 8.91 ± 4.4) and a downregulation of organic cation transporter 3 (OCT3: −5.17 ± 2) compared to control cells. Weaning and regrowth of the CpR cell line showed the presence of cp revealed a stable phenotype of resistance in the cells. Downregulation of OCT3 was identified to be permanent while MT1 upregulation was transient and rapidly induced by cp. Overexpression of OCT3 in CpR cells resulted in loss of cp resistance to a level of untreated cells indicating that downregulation of OCT3 is responsible for acquired cp resistance.

Conclusion: We suggest that ATP7B does not seem to be involved in cp resistance, at least in hepatic cells. OCT3 represents a novel marker of cp resistance. OCT3 expression could be a valuable tool for improved prognosis of cisplatin therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recent studies have shown that the single nucleotide polymorphism (SNP) rs738409 in the PNPLA3 gene is strongly associated with severity of nonalcoholic fatty liver disease (NAFLD).1,2 However, the traditional direct sequencing (DS) method is time-consuming and labor-intensive. The i-densyTM (ARKRAY, Inc.), which is based on the quenching probe (QP) method, automatically detects target genes in blood samples by fluorescence quenching within 90 min.3

Aims & Methods: The current study compared the QP and DS methods for detecting SNPs in the PNPLA3 gene, and established the impact of the genotype on prognosis of NAFLD. We enrolled 107 patients with fatty liver irrespective of etiology. We used the i-densy fully automated genotyping system with QP. The requisite number of tips, reaction tubes, reagent packs and blood samples were set in their designated places. The forward and reverse polymerase chain reaction (PCR) primers and guanine QP were 5’-ctctctctctctgttacag-3’, 5’-ggtagagc- cacctagg-3’, and 5’-ggtagagcagagcagacatc-3’, respectively. PCR consisted of initial denaturation for 1 min at 95°C, and 50 cycles of denaturation at 95°C for 1 s and annealing at 61°C for 30 s. After completion of the PCR, we analyzed melting temperatures. The SNP genotypes were determined by monitoring the change in fluorescence intensity with increasing temperature. The results obtained with the QP method were compared with those obtained with the conventional DS method. Then, we analyzed 73 patients with NAFLD according to PNPLA3 genotypes CC, CG and GG (21, 28.8%) and 24 (32.9%) and 28 (38.4%), respectively. Serum ALT, APRI and Fibroscan value according to PNPLA3 genotypes CC, CG and GG were 26 (14–59), 33 (11–113) and 46 (17–175) U/L, 0.3 (0.1–1.0), 0.5 (0.2–6.8) and 0.7 (0.2–3.1), and 4.4 (2.7–25.1), 5.6 (2.5–26.5) and 6.6 (3.6–38.6) kPa, respectively (p = 0.001, p = 0.001 and p = 0.003 by Jonckheere–Terpsta test). HCC developed in none of the patients with CC genotype, one (4.2%) with CG and four (14.3%) with GG. The cumulative HCC development rate in patients with GG genotype was significantly higher than that in those with CC + CG genotype (p = 0.043 by log-rank test).

Conclusion: The i-densy using the QP method can automatically, quickly and easily identify PNPLA3 genotypes in real-world clinical settings. These findings indicate the feasibility of personalized medicine for NAFLD.

P1322 EFFECT OF ORLISTAT ON TOTAL LIVER FAT QUANTIFICATION AT NOVEL MAGNETIC RESONANCE IMAGING IN OBSESE PATIENTS WITH NON-ALCOHOLIC STEATOHEPATITIS: INTERIM ANALYSIS OF A PROSPECTIVE, RANDOMIZED, SINGLE-CENTER, OPEN-LABEL TRIAL

J. Ye, W. Yanqin, H. Xuan, Z. Bihui
Gastroenterology, The First Affiliated Hospital Of Sun Yat-Sen University, Guangzhou/China

Contact E-mail Address: sophiazhong@hotmail.com

Introduction: Orlistat is an effective pharmacologic weight loss treatment by inhibiting intestinal lipase to reduce dietary fat absorption. Previous studies have suggested that it lowers liver fat by ultrasound or semi quantitative histological scoring in non-alcoholic fatty liver disease (NAFLD).

Aims & Methods: We aimed to examine the efficacy of orlistat versus placebo in reducing liver fat content by the magnetic resonance imaging (MRI) based on chemical shift imaging. A total of 51 NAFLD patients diagnosed by MRI were randomized to receive twice-daily 120mg oral Orlistat or placebo for 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received Clinical parameters, laboratory tests and liver fat content were measured at baseline and 6 months including body mass index (BMI), waist hip ratio (WHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), hemoglobin, liver enzymes and liver fat percentage. The primary outcome was a change in liver fat quantified by MRI which is based on Dixon technique with two-point chemical shift-based fat-water separation method.

Results: At 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received Clinical parameters, laboratory tests and liver fat content were measured at baseline and 6 months including body mass index (BMI), waist hip ratio (WHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), enzymes, haemoglobin, liver enzymes and liver fat percentage. The primary outcome was a change in liver fat quantified by MRI which is based on Dixon technique with two-point chemical shift-based fat-water separation method. The chi-squared and paired t test were used to compare mean differences between liver fractions between two groups. Results: At 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received Clinical parameters, laboratory tests and liver fat content were measured at baseline and 6 months including body mass index (BMI), waist hip ratio (WHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), enzymes, haemoglobin, liver enzymes and liver fat percentage. The primary outcome was a change in liver fat quantified by MRI which is based on Dixon technique with two-point chemical shift-based fat-water separation method. The chi-squared and paired t test were used to compare mean differences between liver fractions between two groups.

Conclusion: Orlistat did significantly decrease liver fat in NAFLD patients with non-alcoholic steatohepatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1323 LONG-TERM COPPER EXPOSURE OF HEPATIC CELLS LACKING FUNCTIONAL ATP7B

Transplantationsklinik, Universitätsklinikum Münster, Münster/Germany

Contact E-mail Address: guttmann.sarah@ukmuenster.de

Introduction: Copper transporter ATP7B is essential for hepatic Cu homeostasis and its loss of function in the inherited autosomal recessive disorder Wilson Disease (WD). Symptoms of WD are i.e. elevated Cu accumulation in liver and brain. Understanding of molecular mechanisms involved in Cu homeostasis is essential to improve therapeutic options. The molecular impact following long-term Cu exposure in hepatic cells lacking functional ATP7B has not been explored.

Aims & Methods: HepG2 cells lacking functional ATP7B (KO) were used for generation of a copper resistant subline (CuR). Cell growth, cell viability (MTT) and intracellular Cu load (atomic absorption spectroscopy) was assessed. RT-qPCR was performed to quantify the expression of genes related to Cu homeostasis. Functional analysis of candidate genes was assessed by siRNA and drug activation (verapamil). Notably, cell viability and intracellular Cu load was not significantly affected by Cu exposure indicating that MDR1 is involved in Cu homeostasis. In addition, hepatic cells derived from a WD patient and from the rat animal model confirmed our observations.

Conclusion: Our analysis of long-term Cu exposure presents new insights in copper metabolism and suggests a new role of MDR1 in the pathogenesis of Wilson disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are increasingly common cause of chronic liver diseases worldwide. Most patients with severe obesity who undergo bariatric surgery have NAFLD, which is associated insulin resistance, type 2 diabetes mellitus, hypertension, and obesity-related dyslipidemia. Identifying significant fibrosis in patients is crucial to evaluating prognosis and possible therapeutic interventions. Currently, liver biopsy is the gold standard for diagnosis of liver fibrosis.

Aims & Methods: We aimed to evaluate the NAFLD fibrosis score for the assessment of significant fibrosis in patients with morbid obesity before undergoing bariatric surgery. A 69 NAFLD patients (median BMI 47.8 kg/m2) were prospectively enrolled from June 2015 to November 2016 at one Brazilian university hospital. All patients were evaluated with routine laboratory before bariatric surgery. Age, body mass index, hyperglycemia, platelet count, albumin and AST/ALT ratio were applied to the score formula. Biopsies were interpreted by a single experienced pathologist. NAFLD and fibrosis were classified according to the NASH Clinical Research Network NAFLD activity score. Furthermore, the receiver operating characteristic curve (AUROC) was calculated for the diagnostic test.

Results: On liver biopsy, 29 patients (42%) had some degree of fibrosis, with a median FLI score of 2.2 (IQR 1.88) having significant fibrosis (F2–4). With standard thresholds the specificity for the NAFLD fibrosis score for identification of significant fibrosis was 58.9%. Using modified thresholds, the specificity could increase. For predicting significant fibrosis, for a cut-off of 1.05, the score had 46.15% sensitivity and 96.43% specificity with AUROC of 0.74.

Conclusion: The nonalcoholic fatty liver disease fibrosis score has good accuracy to identify significant liver fibrosis in morbidly obese patients subjected to bariatric surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1325 COMPARISON OF FIBROSCAN® AND FATTY LIVER INDEX (FLI) TO SCREEN FOR FATTY LIVER DISEASE IN A LARGE COHORT OF EMPLOYEES: WHERE IS THE OPTIMAL CUT OFF?

Health And Prevention Center, Sanatorium Hera, Vienna/Austria

Contact E-mail Address: manuela.teufelhart@hera.co.at

Introduction: FLI was developed as a simple predictor of steatosis (Bedogni et al.,2006) and a cut-off value ≥60 ruled in (positive likelihood ratio [LR+] 4.3) steatosis in Italians diagnosed with ultrasound. Fibroscan®CAP is more sensitive for the diagnosis of steatosis than ultrasound. Aim of this study is to evaluate the use of Fibroscan® in comparison with FLI to screen for fatty liver disease in Austrian bank employees and to recalculate optimal FLI cut-off values. Beside weight reduction and diet EASL guidelines recommend physical activity >150 min/week for prevention and treatment of steatosis.

Aims & Methods: More than 1000 Austrian bank employees will be screened for liver diseases with Fibroscan®. A kPa value ≥7.9 (M-probe) and ≥7.2 (XL-probe) is categorized as fibrosis. Additionally Fibroscan®CAP with a cut-off value ≥248 dB/m is defined as steatosis, ≥300 dB/m in high-grade steatosis. Heavy drinkers and patients with significant liver fibrosis with Fibroscan®. A kPa value ≥7.9 (M-probe) and ≥7.2 (XL-probe) is categorized as fibrosis. Additionally Fibroscan®CAP with a cut-off value ≥248 dB/m is defined as steatosis, ≥300 dB/m in high-grade steatosis. Heavy drinkers and patients with significant liver fibrosis were identified with AUDIT and SIAC questionnaires. Weekly physical activity is classified into “none”, “≤150 min” and “> 150 min”.

Results: On average, 472 employees (age: age 35.9±8.7 (mean±SD); m:207; f:265; BMI: 25.4±4.4) have been included in this analysis. 14/482 (2.9%) employees had signs of liver fibrosis and received further investigations. Fibroscan®CAP values ≥248 dB/m are shown in 156/482 (32.4%) employees (m:91 [58%], f:65 [42%], 56/482 (11.6%) had CAP values ≥300 dB/m. Furthermore 15/156 (9.6%) patients with steatosis are heavy drinkers. FLI significantly predicts liver fibrosis (CAP values [adj-R2] = 0.29, p < 0.001) with a cut-off which indicates a large effect size. For this study population, a FLI cut-off value ≥40 (CAP ≥248 dB/m) and ≥50 (CAP ≥300 dB/m) rules in fatty liver disease with a LR+ of 4.7 (SN-84%; SP-75%); and 4.8 (SN-83%; SP-83%), respectively. An additional consideration of physical activity level in the current cohort revealed that inactivity increases the LR+ of FLI values to predict NAFLD (trendwise significant, p = 0.051), indicating lower cut-off values.
Conclusion: We conclude that FribroScan® represents an eligible tool to diagnose liver diseases in Austrian bank employees. Compared to the previous work of Bedogni et al FLI predicts fatty liver at a lower cut-off level, at least for the examined population. This difference might be due to the fact that FlibroScan®CAP is more sensitive than ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is an affection with increasingly prevalence worldwide, having an important impact on morbidity and mortality, especially when it associated severe fibrosis.

Aims & Methods: We aimed to assess the metabolites that are associated with fibrosis stages in NAFLD, using metabolic method. A total of 40 patients were included in the study, 30 diagnosed with nonalcoholic fatty liver disease (NAFLD) and 10 controls. Steatosis and fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). New metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA)) were used to identify final products of various metabolic pathways correlated with liver fibrosis.

Results: Of the 30 patients with NAFLD included in the study, 6 patients (20%) had severe fibrosis. The metabolomic profile identified four metabolites that are associated with severe fibrosis: 1.25(Oh)Vitamin D (p = 0.03), 1-isopenesolylbutanolamine LPE 0.0:22.6 (p = 0.05), 1-isopenesolylbutanolamine LPE 0.0:22.6 (p = 0.05), and high levels of butylen carbamino (p = 0.04). Of these, LPE was the strongest predictor of severe fibrosis (AUROC=0.795). Sensitivity (S=88.33%), specificity (Sp =78.79%), but the others metabolites were also significantly associated with severe fibrosis: vitamin D (AUROC = 0.776), butylen carbamino (AUROC = 0.737), and LPE 0.0:22.6 (AUROC = 0.768). As the metabolomics permits the evaluation of all these molecules the same time, we can use them combined in order to increase the diagnostic accuracy. In our case, the combined use of the four metabolites determined an AUROC of 0.839, with Se of 100% and Sp of 68.5%.

Conclusion: In metabolomics, we can identify patients with fatty liver and severe fibrosis that are significantly exposed to a progressive disease and a higher mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1327 CHRONIC RENAL FAILURE IS ASSOCIATED WITH THE DEVELOPMENT OF NAFLD/NASH

S. Gehring1, P. Di Fazio2, T.M. Gress, T.T. Wisnioski1
1Gastroenterology, Philips University, Marburg/Germany
2Department Of Visceral Thoracic And Vascular Surgery, Philips University Marburg, Marburg/Germany
3Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektiologie, Philips Universität Marburg, Marburg/Germany

Contact E-mail Address: sonjagehring@gmx.de

Introduction: Chronic renal failure (CRF) is frequently associated bone metabo- lism and osteoporosis with lowered levels of Vitamin D and/or hyperparathy- roidism particular in case of hemodialysis. Younger studies suggest an association of low vitamin D levels with non-alcoholic fatty liver disease (NAFLD) and non- alcoholic steatohepatitis (NASH), as well as metabolic syndrome, and diabetes mellitus. Unfortunately, a causality could not yet be proven.

Aims & Methods: Our aim was to identify patients on higher risk to develop NAFLD/NASH in a selected patient cohort being admitted for renal disorders.

176 patients, admitted to the department of nephrology of the University Hospital Marburg for renal disorders whose plasma vitamin D concentration, phosphate and parathormone levels and liver enzyme levels had been quantified beforehand, were enrolled and a retrospective investigation of laboratory para- meters (including electrolytes, hormones, and vitamins) and pre-existing medical conditions (including high blood pressure, diabetes, hyperlipoproteinemia, and more) followed. Appropriate statistical test were used to characterise the cohort (ANOVA; MANN-Whitney-U; FISHER-EXACT) using SPSS(TM). Other hepa- topathies were excluded. Steatosis was assessed by ultrasonography.

Results: Patients were divided into 4 groups according to plasma vitamin D levels (normal >25ng/ml; low <25 ng/ml) and transaminase levels (AST/ALT>GT >30 U/l; normal; AST/ALT<GT < 30 U/l). Low 1,25-hydroxivitamin D levels correlated significantly with high kreatinine, urea, and LDL levels, while low 25-hydroxivitamin D levels correlated with high cholesterol and triglyceride levels, suggesting a relationship between low vitamin D levels and fat metabolism disorders. Interestingly end stage renal failure (chronic hemodialysis) was signific- antly correlated with the development of NAFLD/NASH with significantly higher levels of AST/ALT and gGT, hyperparathyreodism and hyperphosphate- mia Transaminases were significantly lower if Vitamin D was supplemented

Conclusion: Vitamin D deficiency is often present in patients with kidney diseases such as chronic renal failure. Vitamin D levels are correlated to age and sex of the patient. Patients suffering from renal failure are on high risk developing NAFLD/NASH if diminished vitamin D levels are present Supplement of Vitamin D saves from NAFLD/NASH The correlation of hyperparathyreodism and NAFLD/NASH has to be further investigated in larger patient groups.

Introduction: Usually for the determination of nonalcoholic fatty liver disease (NAFLD) there are instrumental and laboratory techniques, including ultrasound diagnosis, determination of aminotransferases, steatostest, 13C-methacetin breath test (13C-MBT). These methods in the diagnosis of NAFLD clinical forms is not specific and do not allow make difference between steatosis and steatohepatitis. The determination of NAFLD clinical forms is a priority in the prediction of further disease and choice of treatment. Steatohepatitis is the active form of NAFLD and progresses to fibrosis often with subsequent liver paren- chyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Aims & Methods: The study involved 65 patients with type 2 diabetes and cor- onary heart disease with metabolic syndrome, aged 37 to 82 years (mean age 53.82 ± 3.46), 29 men, 36 women. According to the ultrasound, the stage of fatty infiltration were differentiated by such criteria for steatosis as diffuse liver para- chyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1329 NON-OBSESE FATTY LIVER DISEASE IN TYPE 2 DIABETES: NOVEL CONDITION OR SIMILAR TO TYPICAL NAFLD STATE?

Contact E-mail Address: natusiabosak@gmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD), the hepatic counterpart of the metabolic syndrome in close relation to obesity and encompasses a disease spectrum spanning simple steatosis through nonalcoholic steatohepatitis (NASH) with or without fibrosis, and hepatic cellular carcinoma [1]. Clearly, not all obese subjects develop NAFLD and NAFLD can also be found in non-obese patients. Globally, the reported prevalence of non-obese NAFLD varies widely, ranging from 3% to 30% [2]. Today remains unclear how patients without obesity develop NAFLD and therefore it is important to understand the clinical and pathological conditions of non-obese NAFLD.

Aims & Methods: In this study, we investigated the liver stiffness and liver fat content in addition to other clinical and metabolic parameters in type 2 diabetes patient with non-obese and obese NAFLD detected on ultrasonography (US). In this cross-sectional study, 245 T2D patients with age of 40–80 years from the Kyiv City Clinical Endocrinology Center were selected. Inclusion criteria were: age over 18 years, presence of T2D in association with fatty liver disease. The diagnosis of fatty liver was based on the results of abdominal ultrasonography, which was done by trained technicians with Ultima PA (Radmir Co., Kharkiv, Ukraine). Of 4 known criteria (hepatorenal echo contrast, liver brightness, deep attenuation, and vascular blurring), the participants were required to have hepatorenal contrast and liver brightness to be given a diagnosis. According to body mass index (BMI) variable patients were assigned else to NAFLD group (n = 157, BMI >30.0 kg/m²) or to non-obese NAFLD (n = 88, BMI <30.0 kg/m²) group.

The ultrasound liver stiffness value (LS) measured by the Shear Wave Elastography (SWE) in every patient, and a median value was calculated, the result being measured in kPa. Also, in all patients we calculated fatty liver index (FLI). FLI a validated prediction score for hepatic steatosis severity designed Bedogni et al [3]. Changes in transaminases activity, serum lipids and cytokines (TNF-α, IL-1β, IL-6, IL-8, INF-γ) levels were evaluated.

Results: Non-obese NAFLD patient had higher LS (7.52 ± 0.2 vs 6.87 ± 0.9, p = 0.001) values measured by SWE, which were accompanied with increased transaminases activity; for ALT –42.1 ± 1.3 vs 35.8 ± 1.28 (p = 0.028) and for AST –40.8 ± 2.68 vs 34.31 ± 1.03 (p = 0.016) respectively. In contrast to non-obese group in NAFLD group had significantly higher FLI (86.59 ± 1.09 vs 68.06 ± 1.96, p < 0.001). Markers of chronic systemic inflammatory status were significantly higher in non-obese NAFLD as compared to non-obese patient: IL-1β 44.64 ± 2.0 vs 31.02 ± 1.78 (p < 0.001); TNF-α 54.11 ± 2.20 vs 42.28 ± 1.81 (p = 0.001); IL-8 29.18 ± 1.27 vs 22.05 ± 0.99 (p = 0.001) and INF-γ 195.60 ± 9.47 vs 132.47 ± 7.54 (p = 0.016) respectively. Changes of IL-6 between two groups were not significant.

Conclusion: At present, the clinical-laboratory characteristics of non-obese NAFLD are not fully understood. Therefore, we found that non-obese NAFLD associated with higher liver stiffness values and transaminases activities. On the other hand, patient with obese NAFLD are characterized with more pronounced liver fat content and elevation of markers of chronic systemic inflammatory state.

P1330 CHARACTERIZATION OF LEAN INDIVIDUALS WITH NON-ALCOHOLIC FATTY LIVER DISEASE: RESULTS OF A COHORT STUDY

A. Eshraghati1, M.R. Fattahi1, R. Niknam2, S.A. Taghavi3
1Gastroenterology Hepatology Research Center, Shiraz University of Medical Sciences, Shiraz/Iran
2Endoscopy Ward, Namazi Hospital, Fars-Shiraz/Iran
3Gastroenterology, Shiraz University of Medical Science, Shiraz/Iran

Contact E-mail Address: eshraghati@yahoo.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is usually considered as the hepatic manifestation of metabolic syndrome and obesity. However, a subgroup of NAFLD patients are lean. Some studies have reported severe liver fibrosis in lean NAFLD and these patients are still at risk for development of liver cirrhosis.

Aims & Methods: This study aimed to investigate the prevalence and risk factors of lean NAFLD in a cluster of Iranian population. Study population was recruited from Kavir cohort study which has been started from 2006 in Kavar town, a small town near Shiraz. The study sampling was performed between September 2011 and September 2015 among adult subjects (age > 18 years) who underwent voluntary hepatobiliary ultrasound. NAFLD was diagnosed using the presence of ground and absence of chronic liver diseases such as autoimmune hepatitis, hepatitis B or C viruses induced hepatitis, hepatobiliary cancers, Wilson’s disease, > 10 g/day alcohol consumption, and receiving some specific medications known to cause hepatic steatosis (like amiodarone, valproic acid, etc). Lean individuals were defined as those with body mass index (BMI) < 25 kg/m². Student’s-t test was used for comparisons of continuous variables and Chi-square test was used for comparison of categorical variables. Receiver operating characteristics (ROC) curve analysis using area under curve (AUC) was used for analysis of optimal cutoff values for BMI and waist circumference in association with lean NAFLD.

Results: 1343 individuals were included. 165 individuals (12.3%) was diagnosed to have NAFLD. 129 individuals (9.6%) had mild NAFLD and 36 individuals (2.7%) had moderate NAFLD. None of the participants had severe NAFLD. In univariate analysis, history of diabetes mellitus (DM) (OR = 2.25; 95% CI: 1.15–4.40, P = 0.015) and metabolic syndrome (OR = 2.80; 95% CI: 1.74–4.48, P < 0.001) were associated with NAFLD. Higher BMI and waist circumference, higher serum lipids (triglycerides), higher serum alanine aminotransferase (ALT) and cholesterol, fasting plasma glucose (FPG) and alanine aminotransferase (ALT) were associated with NAFLD (P < 0.05). In multivariate regression analysis, higher BMI and waist circumference, higher serum ALT, FPG and cholesterol were independent predictors of NAFLD in our study population (Table). A cutoff value of 22.3 kg/m² for BMI was predictor of NAFLD (sensitivity = 72%; specificity = 60%; AUC = 0.728, P < 0.001). A cutoff value of 79.5 cm for waist circumference was predictor of NAFLD in our study population (sensitivity = 80%; specificity = 68%; AUC = 0.753, P < 0.001).

Table: Multivariate regression analysis showing independent risk factors for lean NAFLD.

Introduction: While some studies have evaluated the ability of new “real-time” elastography devices such as 2-D Shear Wave Elastography (SWE) and Virtual Touch Quantification (ARFI) in predicting the presence of high-risk gastroesophageal varices, no study has explored the potential role of another point-SWE technique, ElastPQ, in the assessment of clinically significant portal hypertension.

Aims & Methods: The aim of our study was to identify a liver stiffness cut-off value measured by ElastPQ and/or laboratory parameters that could help identify patients who can safely avoid screening endoscopy and similarly to the recently proposed Baveno VI criteria which recommends a liver stiffness value <20kPa measured by transient elastography in combination to a platelet count >150,000/μl. Data were collected on 1385 patients who underwent ElastPQ measurement from January 2013 to January 2016 in our Department. Inclusion criteria were a liver stiffness value ≥7 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease. We choose this specific liver stiffness cut-off value in order to highlight early advanced fibrosis and/or cirrhosis, based on the limited literature available on this specific elastographic technique. Exclusion criteria were history of decompensated liver disease, evidence of portal-sinus mesenteric vein thrombosis and non-cirrhotic portal hypertension. Varices were graded as low risk (grade <2) or high risk (grade ≥2).

Results: The study included 184 patients (114 [62%] hepatitis C, and 160 [87%] Child-Pugh A). Varices were present in 36% cases, with 10% prevalence of high-risk varices. According to ROC curve analysis liver stiffness measurement and
platelet count were evaluated as predictors of high-risk varices. Overall 74/184 (40%) met the new “BAVElastPQ” criteria (that is, liver stiffness <12 kPa and platelet count >150,000/μl). Within this group 11/63 (17%) had any grade of varices and only 1/73 (1%) had high-risk varices. The BAVElastPQ criteria gave sensitivity of 0.95, specificity of 0.44, a positive predictive value of 0.16 and a negative predictive value of 0.98. The AUROC for liver stiffness and platelet count was 0.81 and 0.76, respectively.

Conclusion: The BAVElastPQ criteria correctly identified 99% of patients with high-risk varices. By applying such criteria we could have potentially avoided 40% surveillance endoscopies in our cohort. To our knowledge this is the first study that evaluated the potential role of a new s-PWE technique such as ElastPQ in the non-invasive assessment of clinically significant portal hyperten-
sion, similarly proposed Baveno VI criteria though using ElastPQ as an alternative to transient elastography.

Introduction: Proton pump inhibitors (PPI) are commonly prescribed and predis-
spose to small bowel bacterial overgrowth. Hepatic encephalopathy is a frequent complication of cirrhosis and is associated with intestinal dysbiosis.

Aims & Methods: This study aimed to identify a possible association between PPI intake and hepatic encephalopathy development in cirrhotic patients. Retrospective analysis of consecutive cirrhotic patients hospitalized in two Gastroenterology Departments over 3.5 years. Collection of clinical data, PPI intake, infection and hepatic encephalopathy at hospitalization. Statistical ana-
lyses: Pearson χ² and McNemar, HPS1.21, considering clinical significant definition of hepatic encephalopathy. Results: 386 patients, 321 males (83.2%), mean age 60.3 ± 12.1 years. Main etiol-
ologies of cirrhosis were alcohol (67.4%), alcohol plus hepatitis C (16.3%) and hepatitis B virus (5.2%). Hepatic encephalopathy was present in 222 (57.5%) of the patients and 26.9% had PPI intake. In univariate analysis hepatic encephalopa-
thapy was associated with infection (p < 0.001), gastrointestinal bleeding (p < 0.001) and Model for End-Stage Liver Disease (MELD) (p < 0.001). There was no association between hepatic encephalopathy and PPI intake (p = 0.057), gender (p = 0.228) or age (p = 0.352). In multivariate analysis, hepato-
ena cele fecal encephalopathy maintained association with infection (p < 0.001), gastroin-
testinal bleeding (p < 0.001) and MELD score (p = 0.001).

Conclusion: In our series, PPI intake was not associated with hepatic encepha-
lopahy development in cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of bacterial infections in cirrhotic patients is signifi-
cantly higher than that observed in general population, being one of the most important causes of decompensation. In theory, the final result of an infectious disease depends of three major factors: the antibiotic resistance of the bacteria and the virulence of the organism, the immune status, age, diet and stress. There are conflicting results regarding the incidence of multidrug-resistant bacteria or MDR bacteria regarding the 30 (p = 0.801) and the 90-day (p = 0.761) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SP02 were independently associated with 30 and 90-day mortality. Higher INR and age were indepen-
dently associated with 90-day mortality.

Conclusion: The presence of bacterial infection, independently of the antibiotic treatment profile, was associated with a worse prognosis in cirrhosis. In patients with documented infections, no difference was noticed between non-MDI, non-MDR bacteria or MDR bacteria regarding the 30 (p = 0.801) and the 90-day (p = 0.525) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SP02 were independently associated with 30 and 90-day mortality. Higher INR and age were indepen-
dently associated with 90-day mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

In this study, we aimed to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HCV liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV). Material and method: We prospectively recruited 392 patients with cirrhosis from September 2015 to September 2016, who underwent all available non-invasive tests for liver cirrhosis. The EV presence was also confirmed in controls. The diagnostic performance of the Baveno VI criteria was evaluated using ROC analysis. The Baveno VI criteria correctly classified 80% of patients, with a sensitivity of 56.9%, specificity of 84.6%, positive predictive value (PPV) of 40.7%, negative predictive value (NPV) of 95.1%, and an area under the curve (AUC) of 0.831. Conclusion: The Baveno VI criteria are useful for predicting EV, with a good diagnostic performance in our cohort of HCV patients with cirrhosis. However, we should be cautious in the interpretation of the Baveno VI criteria as they may misclassify the presence of EV in a small proportion of patients.

Introduction:

The place of noninvasive techniques for the prediction of presence of portal hypertension in patients with liver cirrhosis is one of the current research activities.

Methods:
The aim of this study was to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HCV liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV). Material and method: We prospectively recruited 392 patients with cirrhosis from September 2015 to September 2016, who underwent all available non-invasive tests for liver cirrhosis. Introduction:

Non-invasive fibrosis scores (NIFs) are increasingly replacing liver biopsy (LB) for estimation of liver fibrosis. Only limited studies have evaluated the subgroup probably with EV, the Baveno VI criteria had PPV 40.7% and thrombocytes 150,000/mm3, was compound of 60 patients. Using these criteria we correctly classified 80% patients, with a Se 56.9%, PPV 44.7%, NPV 78.4%. Conclusion:

By using the Baveno VI criteria in patients with liver cirrhosis for the prediction of presence of esophageal varices, we can misclassify only 20% of patients.

2Department Of Radiology, Amnchi, Tallaght, Dublin/Ireland

3Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine and Pharmacy, Cluj-Napoca/Romania

Introduction:

CRBPs had higher accuracy for prediction of cirrhosis and EV, while NIFs had higher accuracy for predicting decompensation (Table 1). The highest AUROCs were seen for FIB-4 score for predicting cirrhosis (AUROC = 0.784) and EV (AUROC = 0.885) and with FIB-4 score for decompensation (AUROC = 0.854). At a cut of 1200 PSI had sensitivity of 87.2% and specificity of 73% for predicting cirrhosis and at a cut of 1100 PSI had sensitivity of 89% and specificity of 85% for predicting EV. At a cut of 2.5, FIB-4 had a sensitivity of 82.5% and specificity of 80.1% in predicting decompensation. Conclusion: CRBPs predict cirrhosis and development of esophageal varices with high accuracy. Some of the blood derived NIFs have high accuracy in predicting decompensation post antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompensation after antiviral treatment.

P1337 A SMART APPROACH TO THE DIAGNOSIS OF MINIMAL HEPATIC ENCEPHALOPATHY A. Trifan4, M. Curescu5, A. Goldis1, L. D. Sandulescu6, C. Cijevschi Prelipcean7, C. Stanciu4, C. Brisc7, S. Iacob2, I. Sporea1

1Department Of Gastroenterology, Oradea University of Medicine and Pharmacy, Oradea, Oradea/Romania

2Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine and Pharmacy, Cluj-Napoca/Romania

Introduction:

Minimal Hepatic Encephalopathy (MHE) is present in more than 30% of patients with chronic liver disease (CLD) and is associated with a worse prognosis including a higher incidence of falls, RTAs and overall mortality. Detection of MHE is often difficult due to time constraints associated with the current gold standard, the psychometric hepatic encephalopathy score (PHES), which includes five paper-based tests. A smartphone application (EncephalApp Stroop Test) has been suggested as a viable alternative.

Aims & Methods:

We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each test as well as the total PHES, the Stroop on off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using the t-test and the Chi-square test to determine if there was a difference between the groups. Receiver Operating Characteristic (ROC) analysis was used to determine the best cut-off for each test. Results:

A total of 96 patients (51 males) were recruited. Overall, the mean age was 51.7 ± 16.6 years; mean years spent in education 13.8 ± 4.2. In all there were 35 CLD and 61 healthy controls. While there was no difference in age or years spent in education, there were more men in the CLD group compared to the controls, 23/35 (66%) vs. 28/61 (46%), p=0.06. Within the CLD cohort, 30 (86%) patients were Child-Pugh class A, 4 (11%) were class B and 1 (3%) was class C. As expected, more CLD patients had a positive PHES, 4/35 (11%) vs. 3/ 61 (5%). Overall, correlation between the two tests was poor, 7 (7%) participants had a positive PHES, while 47 (49%) had a positive Stroop test (k=0.1516). Among controls, 27 (44%) had a positive Stroop test, while 3 (5%) had a positive PHES (k=0.1223). Similarly, 20 (57%) CLD patients had a positive Stroop test and 4 (11%) had a positive PHES (k=0.1765). Regarding the Stroop test, the mean time taken to complete 5 correct runs was significantly higher in CLD patients, mean 117.9 s [58.5–217.8 s] vs. 101.2 s [55.3–218.6 s], p=0.02. However, mean Stroop on off times were similar, 198.4 s [102.6–307.7 s] in the CLD cohort versus 187.9 s [101.2–420.9 s] in the control group. Of note, CLD patients with a positive PHES had a significantly higher Stroop on off time compared to those with a negative PHES, mean 260 vs. 190 s, p=0.02. Among controls, 18/47 (38%) gave a Stroop on off time > 187.5 s as a positive cut-off for the test, sensitivity = 100%, specificity = 59%. In total, 39 patients had an on off time > 187.5, 18 (51%), 2 fewer false positives, in the CLD group, and a slightly better correlation (k=0.21). Among controls, PHES took 20 minutes to complete, while the Stroop test took 7 minutes. Older age and completed years of education correlated with a poorer performance on the Stroop test (r=-0.62, p<0.0001 and r=-0.322, p<0.0001, respectively). However, neither age nor years of education correlated with performance on the PHES (r=-0.087, r=0.12, respectively).

**Results:** A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: *Lactobacillus brevis* and *Lactococcus lactis* increased significantly and *Enterococcus durans* decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagene functions (assessed by PICRUSt) and calprotectin did not show any differences during intervention.

**Conclusion:** In conclusion, a six months intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of *Enterococcus durans* was reduced and the gut barrier was strengthened.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1338 MULTISPECIES PROBIOTIC ENRICHES THE MICROBIOME WITH LACTOBACILLUS AND LACTOCOCCUS AND REDUCES ENTEROCOCCUS ABUNDANCE IN PATIENTS WITH LIVER CIRRHOSIS: RESULTS OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL**

**Introduction:** Cirrhosis is accompanied by significant changes of the intestinal microbiome including the overgrowth of the intestine with potential pathogens that can translocate through a weakened gut barrier and cause severe infections. We hypothesized that probiotic bacteria repress intestinal pathogen growth and for gut permeability and intestinal inflammation, respectively.

**Results:** Development of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: *Lactobacillus brevis* and *Lactococcus lactis* increased significantly and *Enterococcus durans* decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagene functions (assessed by PICRUSt) and calprotectin did not show any differences during intervention.

**Conclusion:** In conclusion, a six months intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of *Enterococcus durans* was reduced and the gut barrier was strengthened.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Rejection episodes (OR = 1.38; 95% CI: 0.47–4.1, P = 0.129) and acute kidney injury (OR = 0.96–1.84; P = 0.07) after liver transplantation were not statistically different in patients with and without DM. Using Kaplan-Meier method, mean post-liver transplant survival was 50.94 ± 0.67 months in cirrhotic patients without DM and 45.26 ± 1.46 months in cirrhotic patients with DM (P < 0.001). Post-liver transplant survivals at 6 months, 1 year and 4 years were outlined in Table. In patients with DM, presence of hepatocellular carcinoma (HCC) (OR = 4.81; 95% CI: 1.64–9.78, P = 0.002), acute kidney injury within 30 days after transplant (OR = 2.05; 95% CI: 1.02–4.10, P = 0.042) and pre-transplant PVT (OR = 2.51; 95% CI: 1.16–5.14, P = 0.019) were independent predictors of mortality after liver transplantation.

Table: Post-liver transplant survival at 6 months, 1 year and 4 years in patients with and without DM

Introduction: The Baveno VI guidelines propose that cirrhotic patients with a liver stiffness measurement (LS) < 20 kPa and a platelet count > 150,000/L can avoid screening endoscopy as their combination is highly specific for excluding clinically significant varices.

Aims & Methods: The aim of the study was to validate the Baveno VI criteria. We did a retrospective study, from 2009–2014. We took all the patients with transient elastography data. Inclusion criteria was a LS < 12 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of chronic liver disease. Varies were graded as low risk (grade < 2) or high risk (grade ≥ 2).

Results: The study included 774 patients (hepatitis C virus 40.5%, hepatitis B disease: 59/774 (7.6%) met the Baveno VI criteria. The Baveno VI criteria gave a correct appoint 85.3% of patients who can avoid screening endoscopy as their combination is highly specific for excluding clinically significant varices.

Introduction: Cirrhotic patients very often need to be hospitalized and it is known that they have a higher mortality rate. We aimed to establish a mortality predicting model for cirrhosis patients.

Aims & Methods: The aim of the study was to assess the factors associated with mortality among cirrhotic patients and to create a new score for predicting mortality. The study was retrospective, and we included all hospitalized patients with a diagnosis of liver cirrhosis within a period of 7 years. We divided them in two cohorts, an initial group, which was analysed; and a control group, in which we validated the score. We performed univariate and multivariate analysis in order to determine a prediction model for mortality.

Results: A total of 1163 cirrhotic patients were included. In-hospital mortality rate was 10%. The initial cohort included 899 patients. Regarding cirrhosis etiology: 384/899 (42%) had hepatitis C, 158/899 (17.5%) had hepatitis B, 293/899 (32.5%) were alcoholic, 6/899 (0.6%) were autoimmune, 7/899 (0.8%) were cardiac, 13/899 (1.4%) were premalign liver cirrhosis and in 5% of cases the etiology was unknown. In univariate analysis, hypernatremia (p < 0.0001), hyperpotassemia (p < 0.0001), hypoalbuminemia (p < 0.0001), high values of bilirubin (p < 0.0001), high values of creatinine (p < 0.0001) were strongly associate with in hospital mortality. In multivariate analysis, the model including albumin, sodium, potassium, creatinine and bilirubin (all p-values < 0.05) had an AUROC = 0.78, CI (0.75–0.81), p < 0.001. Using this factors as predictors, by multiple regression analysis we obtained the following score: ABCPS score = 0.04 + 0.03*Albumin + 0.05 + 0.02*Creatinine + 0.04 + 0.04*Bilirubin + 0.05 + 0.28*Sodium. AUROC = 0.84, CI (0.79–0.9). Conclusion: Prevention and prompt treatment of kidney injury, hypernatremia, hyperpotassemia, can improve survival. ABCPS score can be an useful score to rule out patients with high mortality rate.

P3142 BARIATRIC SURGERY IS ASSOCIATED WITH INCREASED RISK OF DEVELOPING ACUTE LIVER INJURY: A NATIONWIDE ANALYSIS

P.T. Kroener1, P. K. Wanders2, V. Popov3, C. C. Thompson4
1Mt. Sinai St. Luke’s/West, New York/United States of America
2New York University School of Medicine, New York/United States of America

Contact E-mail Address: thomas.kroener@gmail.com

Introduction: Bariatric surgery provides a durable method of weight loss but is associated with serious adverse events. Some studies report an increase in drug-induced acute liver injury following bariatric surgery.

Aims & Methods: We aimed to assess if bariatric procedures increase the risk of acute liver failure in a large inpatient cohort. We retrospectively analyzed discharge data on patients who developed acute liver injury (ALI) using the New York State Inpatient Sample (NIS) database from 2010–2013. Discharges with an ICD-9 code indicating ALI were included. The primary outcome was ALI in patients with a history of bariatric surgery compared to all other patients with an inpatient diagnosis of liver injury. Secondary outcomes were mortality in the two cohorts and independent socio-demographic and medical risk factors for mortality in each cohort. Variables tested include age, gender, race, income, Charlson criteria, hospital factors and medical comorbidities including Malnutrition, HTN, Anemia, CKD, Diabetes, CHF, Coagulopathy, Alcoholism, HBV and HCV. Univariate and multivariate logistic regression analyses were performed to identify independent predictors.

Results: During the study period, a total of 437,390 patients were diagnosed with acute liver injury and were included in the study, of which 5,799 had previously undergone bariatric surgery. In the post-bariatric cohort, mean age was 58.7 years and 77% were women. The prevalence of acute liver injury in all inpatient admissions for that time period was higher in patients with history of bariatric surgery (0.88%) than in non-bariatric patients (0.75%), p = 0.01. Patients with history of bariatric surgery displayed odds ratio of 1.52 of developing ALI when compared to patients with no history of bariatric surgery (95%CI: 1.43–1.61, p < 0.01). The rate of overall inpatient mortality was higher in non-bariatric cohort (15.9% versus 9.3%). Post-bariatric patients admitted for ALI were more likely to be younger, female, Caucasian and residing in more affluent areas. Post-bariatric patients were also more likely to have higher rates of malnutrition, anemia, alcoholism, and significantly lower prevalence of hepatitis B and C; CHF, diabetes and kidney disease. In a multivariate regression model, the presence of CHF and coagulopathy increased mortality risk, and diagnosis of alcoholism was associated with lower mortality risk from ALI in patients with prior history of bariatric surgery (Table).
Conclusion: Bariatric surgery increases the risk of subsequent acute liver injury. Post-bariatric surgery patients admitted for ALI may therefore be more likely to have anemia, malnutrition, and alcoholism, supporting the hypothesis that baseline nutritional status may predispose to drug-induced ALI. Addressing these potentially modifiable risk factors may decrease the significant morbidity and mortality of ALI.

Introduction: Acoustic radiation force impulse (ARFI) imaging measures liver stiffness (LS), which significantly correlates with the stage of liver fibrosis in treatment-naïve patients with chronic hepatitis B (CHB). So far, the use of ARFI elastography to monitor change in liver fibrosis has not been properly evaluated during antiviral therapy in CHB patients.

Aims & Methods: We aimed to prospectively assess the clinical usefulness of ARFI during long-term antiviral therapy in CHB patients. Seventy-one CHB patients were consecutively recruited and received antiviral therapy with entecavir. Paired liver biopsies were performed in 27 patients at baseline and week 78 of entecavir therapy. LS was assessed by ARFI at multiple follow-up sessions.

Results: LS significantly decreased with treatment and continued to decrease after normalization of alanine aminotransaminase. Overall, 97.2% patients achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the baseline levels of LS value, platelet and cholinesterase. In the 27 patients who received paired liver biopsies, LS significantly correlated with stage of fibrosis and inflammatory grade at baseline. LS values decreased more significantly in patients with fibrosis regression than those with static histological fibrosis. Changes in LS value (change threshold = 15%) was significantly correlated with the changes in histological fibrosis staging (r = 0.63, P < 0.001).

Conclusion: In CHB patients, LS assessed by ARFI was significantly reduced during antiviral therapy. Longitudinal monitoring of LS might be a promising non-invasive assessment of fibrosis regression during long-term antiviral therapy in CHB. Further studies on large populations are warranted.

Introduction: Serum HBsAg loss is the recommended stopping rule in nucleo(t)-side-analogues (NUC) responders, even if this event occurs rarely.
Aims & Methods: We aimed to investigate in patients with chronic HBsAg+ hepatitis the level of HBsAg levels during the NUC therapy to evaluate the predictive parameters of HBsAg seroclearance. Patients with CHB, receiving NUC antiviral therapy with stable viral suppression (HBV-DNA < 2010 IU/ml), were recruited at the Gastroenterology Unit of the University of Naples “Federico II”. serum samples from these patients were tested for HBsAg quantification with the ElecsysHBsAg II Quant immunassay (Roche Diagnostics, Indianapolis, USA). HBsAg levels were determined before starting NUC treatment and on-treatment every 12 months.
Results: 56 patients (57 ± 9.5 HBeAg-positive, HBsAg-negative patients (M/F: 73/22, median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs, were enrolled. Precisely 56 patients underwent to Tenofovir, 22 Entecavir and 17 Lamivudine. The median treatment duration of NUC therapy was 111 months, range 25–183 months. There was a significant decrease of the HBsAg levels during NUC therapy from 3471 UI/ml at the baseline to 1758 IU/ml at the last determination (p < 0.001). The statistically significant HBsAg decrease was also maintained when the patients were clustered according to antiviral therapy, severity of liver disease and previous interferon treatment. HBsAg seroclearance occurred in 18/95 patients (19%). The multivariate analysis showed that the only predictive parameter statistically significant of HBsAg seroclearance is the HBsAg level at baseline. Moreover, HBsAg seroconversion to HBsAb occurred in 4/18 patients, in which undetectable HBsAg value was evidenced at least two years before the seroconversion, and NUC therapy was successfully stopped, without relapse after a mean follow-up period of 24 months.
Conclusion: The results of this study suggest a role of on-treatment HBsAg quantification in the management of NUC-treated patients. HBsAg measurement would be a useful parameter to optimize antiviral treatment schedule.
Disclosure of Interest: All authors have declared no conflicts of interest.
P1348 IMPROVEMENTS IN CHRONIC HEPATITIS B PATIENTS AND THE ALTERATION IN GUT MICROBIOTA AFTER FECAL MICROBIOTA TRANSPLANTATION
C. Xiao, B. Zhang, J. Ren
Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen/China
Contact E-mail Address: xiaoxx@xmu.edu.cn
Introduction: Chronic hepatitis B (CHB) is a common liver disease worldwide, and can be progressed to liver cirrhosis and hepatocellular carcinoma. Unfortunately, only a minority of CHB patients could achieve the clearance or seroconversion of hepatitis B virus e-antigen (HBsAg), the end point of treatment, even after multiple years of antiviral therapy. Therefore, it is urgent to develop new and effective strategy for treatment of CHB and examine the mechanisms.
Aims & Methods: In this study, we performed 60 times of fecal microbiota transplantation (FMT) by nosoantisternal tube for 20 CHB patients who continued interferon-based or previous antiviral treatment, and, accordingly, measured the HBsAg level four weeks after each FMT. Fecal samples of CHB patients before (Baseline) and after FMT as well as donors were collected for analyses of gut microbiota by sequencing 16S V3-V4 regions on Illumina MiSeq using PE 250 reagents.
Results: Results showed that HBsAg of 13 patients (65%) was cleared or reduced after one to seven times of FMT. Based on OTUs at cutoff of 3% dissimilarity, there were significant (PERMANOVA, P = 0.001) differences in overall gut bacteria communities among CHB-Baseline, CHB-FMT1, CHB-FMT2 and CHB-FMT3. Interestingly, the three major clusters in PCA ordination. Whereas, no significant differences (ANOVA, P > 0.05) were detected in α-diversity indexes among the three groups, including observed OTU numbers, Shannon index, Simpson index, and Pielou evenness. This implies that it is the taxonomic relative abundance, not taxon number, that contributed to the bacterial community differences. Overall, gut bacteria were mainly composed of Firmicutes (Lachnospiraceae, Ruminococcaceae, Veillonellaceae), Bacteroidetes (S24-7, bacteroidaceae, Prevotellaceae), and Proteobacteria (Alcaligenaceae, Enterobacteriaceae). More specifically, Actinomyces was significantly higher in CHB patients (CHB-Baseline) than FMT-treated patients (CHB-FMT) and donors, and was identified as the bio-marker of CHB using LEfSe analysis. Conversely, Prevotella and Euphorbiaceae were significantly decreased in CHB-Baseline after FMT to almost equal to the abundances in donors, and were also identified as biomarkers.
Conclusion: In summary, along with the clearance or remission of HBsAg, the gut bacterial communities of chronic hepatitis B patients were remarkably altered after fecal microbiota transplantation, with some taxa abundances changed accordingly, which suggested their potential application as targets for clinical diagnosis and treatments in future.
Disclosure of Interest: All authors have declared no conflicts of interest.
P1349 EFFICACY OF PEGLYLATED INTERFERON ALFA-2A ADD-ON THERAPY VERSUS NUCLEOSIDE ANALOGUE MONOTHERAPY IN TREATMENT-EXPERIENCED CHRONIC HEPATITIS B PATIENTS: A RANDOMISED, CONTROLLED, OPEN-LABEL TRIAL
X. Hu1, J. Ye1, W. Yanqin1, R. Li1, C. Shao1, Z. Bihu1
1Gastroenterology, the First Affiliated Hospital of Sun Yat-sen University, Guangzhou/China
Contact E-mail Address: 14446990990@qq.com
Introduction: Hepatitis B surface antigen (HBsAg) seroconversion is rarely achieved in chronic hepatitis B (CHB) patients during nucleoside analogue (NA) monotherapy. The efficacy of pegylated interferon alfa-2a (peg-IFNα-2a) add-on therapy in those CHB patients remains unclear.
Aims & Methods: We aimed to compare the efficacy of peg-IFNα-2a add-on therapy with serum sampletry in treatment-experienced CHB patients. We enrolled hepatitis B e antigen (HBsAg)-negative treatment-experienced CHB patients aged older than 16 from the First Affiliated Hospital of Sun Yat-sen University in China. All had received NA monotherapy for 3 years with sustained undetectable plasma HBV DNA. The exclusion criteria included: cirrhosis or other chronic liver diseases, previous immunological therapy, pregnancy and breastfeeding, contraindications for peg-IFNα-2a, or other serious diseases. The eligible patients were assigned to receive peg-IFNα-2a add-on therapy for 48/72 weeks to continue to receive NA monotherapy for 96 weeks. HBV DNA levels, HBV serologic indicators, liver function, renal function, thyroid function, blood cells count and imaging examination were assessed. The primary end point was HBsAg loss from baseline to week 96.
Results: 71 patients were enrolled (22 to peg-IFNα-2a add-on therapy group and 49 to NA monotherapy group), of whom 9 in peg-IFNα-2a add-on therapy group and 25 in NA monotherapy group completed more than 24 weeks of follow-up, the remaining patients have not yet reached 24 weeks of follow-up. There was no significant difference in age, gender, body mass index (BMI), HBsAg levels, alanine aminotransferase (ALT), or aspartate aminotransferase (AST) between the two groups at baseline. At week 24, HBsAg levels in peg-IFNα-2a add-on therapy group were significantly lower than the baseline (2.96 ± 0.14 vs 2.92 ± 0.82 Log10IU/ml, p = 0.009), but there was no obvious change in NA monotherapy group (3.43 ± 0.46 vs 3.44 ± 0.44 Log10IU/ml, p = 0.843). The HBsAg loss in peg-IFNα-2a add-on therapy group was significant higher than in NA monotherapy group at week 24 (0.76 ± 0.76 vs 0.01 ± 0.10 Log10IU/ml, p = 0.008). Among those patients who completed 96 weeks of follow-up, two patients in peg-IFNα-2a add-on therapy group (22.2%) achieved HBsAg serocconversion, but none in NA monotherapy group (0%). Conclusion: The peg-IFNα-2a add-on therapy increased loss of HBsAg in HBsAg negative treatment-experienced CHB patients as compared to NA monotherapy.
Disclosure of Interest: All authors have declared no conflicts of interest.
P1350  HEPATITIS C IN LEBANON: BURDEN OF THE DISEASE AND VALUE OF A COMPREHENSIVE SCREENING AND TREATMENT

4SERFAN Innovation, Liege/Belgium
Contact E-mail Address: abourachidanteoine@gmail.com

Introduction: As few reliable data on the burden of hepatitis C virus (HCV) are available from the Middle East, we analyzed HCV burden in the Lebanese population and the value of comprehensive screening and treatment at different age groups and fibrosis stages.

Aims & Methods: A multi-cohort, health-state-transition model was developed to project the number of HCV patients achieving a sustained virologic response 12 weeks after treatment (SVR12) or progressing to compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), and liver-related death (LRd) from 2016 to 2036. Epidemiology and mortality data were extracted from the Ministry of Health bulletin while costs were collected from insurance claims. The proportion of patients screened for HCV was projected to increase to 60%–85% 99% (low/medium/high screening scenarios) in 2036, with a new cohort of patients being diagnosed each year. SVR12 rates were extracted from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for difference prevalence and screening rates.

Results: Low, medium and high HCV screening scenarios showed that 3838, 5656 and 7669 individuals would be diagnosed with HCV infection from 2016 to 2036, 40% aged 18–39 and 60% aged 40–80. In the absence of treatment, the projected numbers of patients with CC, DCC, HCC and LRd in 2036 was 899, 147, 131 and 147 respectively for the 18–39 age groups. In the 40–80 age groups, these projections were substantially greater: 2828 CC, 736 DCC, 668 HCC and 958 LRd. The overall economic burden of these liver complications would reach 150 million US$. Introducing direct-acting antiviral (DAAs) for F0-F4 patients would increase by 43% and 62% the proportion of remaining liver-years (LYs) spent in SVR12 compared to DAA-naive patients only. Although DAAs for F0-F4 increase the cost of HCV treatment, they also provide the greatest population health benefit and lowest cost per life year gained in SVR12. Compared to no treatment and screening, adopting the high screening variant and DAAs access to F0-F4 would cost an additional 1.957 €/LY gained in SVR12 for patients aged 18–39 and 188 €/LY for the 40–80 age group.

Conclusion: An enhanced screening policy coupled with broader access to DAAs will diminish the future clinical and economic burden of HCV in the Lebanese population and provide the greatest health benefits per amount invested, among middle-aged and elderly adults with a big difference in additional costs between the 2 groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1352  HEPATITIS C TREATMENT IN RENAL TRANSPLANTATION: THE EFFICACY AND SAFETY OF DIRECT-ACTING ANTIVIRALS IN THE REAL LIFE
L. Carvalho, J. Rodrigues, M.A. Túlio, T. Bana, E. Costa, L. Lebre, C. Chagas Gastroenterology, Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal
Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Hepatitis C virus (HCV) infection in renal transplant patients pre-disposes to graft failure and progression of renal disease, increasing mortality. Due to immunosuppression and oscillating glomerular filtration rate (eGFR) in HCV infected patients, the evolution of virological response and clinical outcomes (kidney function, anemia and other adverse effects) is scarce. Additional studies are still necessary in order to evaluate the real impact of these agents in the daily clinical practice.

Aims & Methods: Our objective was to assess the efficacy and safety of DAA treatment for HCV-infected patients with renal transplantation, in the daily practice of a tertiary care centre, describing the HCV infection, treatment type, the evolution of virological response and clinical outcomes (kidney function, anemia and other adverse effects). HCV-infected and renal transplanted patients treated with DAA between April 2015 and February 2017 were analyzed.

Results: Including 19 patients, 10 males (55%) and 9 females (47%) with a mean age of 57 years (40–70 years). The majority of these patients (89%) were treatment-naive. Genotype distribution was the following: genotype 1–74% (14/19), genotype 3–16% (3/19) and genotype 4–10% (2/19). Distribution according to fibrosis stages was as follows: F0–2–63% (12/19), F1–21% (4/19) and F4–16% (3/19). Treatment response rates were monitored with a 24 weeks for others 2 (10%). One patient realized only 21 weeks of treatment, needing to suspend it due to severe anemia. Regarding treatment response rates, 74% (14/19) of patients had Rapid Virological Response (RVR) and 100% (19/19) of patients had End of Treatment Response (ETR).

Conclusion: An enhanced screening policy coupled with broader access to DAAs will diminish the future clinical and economic burden of HCV in the Lebanese population and provide the greatest health benefits per amount invested, among middle-aged and elderly adults with a big difference in additional costs between the 2 groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver stiffness (LS) measurements by Transparent Elastography (TE) has been widely accepted as a tool for fibrosis assessment.

Aims & Methods: The aim of this study was to assess LS dynamics in a group of patients with HCV liver cirrhosis after DAA treatment. This bicentric clinical study enrolled 18 patients: meta-analysis of clinical trials. Journal of viral hepatitis, 2011, 18, 7.

PLT

Baveno VI criteria suggest that cirrhotic patients with platelet count including variceal bleeding.

Results:

Out of 276 subjects, reliable measurements were obtained in 92.7%, so that the final analysis included 256 patients. The mean LS values decreased significantly after DAA: 25.4 ± 11.7 kPa vs. 22.5 ± 12.2 kPa (p = 0.009). Most patients (75% [152/205]) presented more than 10% in LS values. 23% [59/256] had stable LS values, while in 17.3% (45/256) cases, the LS values increased. In the subgroup of 180 patients where LSM were also performed 12 weeks after EOT (SVR 12), the mean LS values were significantly lower at EOT as compared to baseline: 20.3 ± 10.8 kPa vs. 25.5 ± 11.4 kPa (p < 0.001) and also as compared to EOT: 20.3 ± 10.8 kPa vs. 22.8 ± 12.2 kPa, (p = 0.04). In the subgroup of 55 patients when LSM were also performed 24 weeks after EOT (SVR 24), the mean LS values were significantly lower at SVR 12 and SVR 24 as compared to EOT: 18.7 ± 8.2 kPa vs. 21.6 ± 7.7 kPa, 0.01 and 18.3 ± 6.6 kPa vs. 21.6 ± 7.7 kPa, (p = 0.01).

Conclusion: In our group mean liver stiffness values evaluated by TE significantly decreased after antiviral treatment at SVR 12 and SVR 24, as compared to EOT. Overall, in our study almost 60% of patients had EOT liver stiffness values lower than at baseline, at SVR 12 almost 75% of patients had liver stiffness values lower than at baseline and at SVR 24 almost 77% of patients had liver stiffness values lower than baseline.

Introduction: Monocyte chemotactic protein-1 (MCP-1) is a chemokine mediating inflammation. It contributes to fibrogensis. The extent to which metabolic and immune factors are implicated in fatty liver of patients with CHC is still not clear.

Aims & Methods: The aim of the study was to explore the associations between serum MCP-1, liver fibrosis, fatty liver and metabolic factors in CHC patients before, and after antiviral treatment. We included 21 patients in the study (11 men, 10 women, age 42 ± 9.7) with chronic hepatitis C virus (HCV) infection – 17 with genotype 1 and 4 with genotype 3. Liver biopsy was done in 19 and histology showed fatty liver in 8 patients. Fatty liver was present in 17 of all patients on antiviral therapy. Serum probes were obtained before treatment and after response evaluation. Statistical analysis included Spearman’s rho, Mann-Whitney U test, Wilcoxon’s test and Student’s paired t-test.

Results: MCP-1 in serum correlated with BMI (r = 0.522, p = 0.015). MCP-1 correlated with overweight (r = 0.579, p = 0.020). In patients with BMI more than 30 overweight and obese patients were higher than in those with normal weight (p = 0.020). Patients with BMI score of 34 had higher BMI (p = 0.010) and HOME-IR (p = 0.042). An increase in serum MCP-1 was found in patients after SVR (p = 0.018), while no significant variation from baseline values was found in NVR patients. The result remained significant in subgroup analysis of SVR patients with F1-F2 (p = 0.028) and in those with fatty liver (p = 0.017). MCP-1 in serum did not show any association with assessment of liver fibrosis, fatty liver, insulin resistance and serum lipid levels.
Conclusion: MCP-1 concentrations in serum depend on overweight in patients with CHC. Overweight and insulin resistance are associated with progression of CHC. Serum levels of MCP-1 increase after HCV clearance. Fluctuation of the MCP-1 concentration in serum could reflect an antinflammatory activation of M1S and a gradient dependent dynamic replacement of the proinflamatory cell subsets in the liver, with a resolution ones after SVR. Fatty liver plays a role for inflammatory responses in CHC patients after SVR.

Introduction: HCV interferes with the host lipid metabolism leads to insulin resistance and hepatic steatosis. Although it is usually mild in genotype 4, markers of simple steatosis cannot reflect the potential toxic effects to fibrosis, cirrhosis and subsequent hepatocellular carcinoma. Many heritable host factors with observed inter-ethnic variation in the prevalence of steatosis are documented, and in many cases hepatic steatosis may be detected in absence of all these risk factors; so a role for genetic factors in development of hepatic steatosis in chronic HCV patients may be suggested.

Aims & Methods: In this study, we aim to evaluate the association of HLA class A-B alleles and presence of steatosis in chronic HCV genotype 4 infected patients. The study included two hundred unrelated non diabetic non obese chronic HCV patients with normal lipid profile, 98 of them had biopsy proven steatosis. Serological testing of HLA class I antigens (HLA-A, and HLA-B alleles) were performed with a standard complement dependent microlymphocytotoxicity

Results: The frequency of A02, A03, B15 and B17 alleles were significantly higher in chronic HCV patients with steatosis (OR = 1.77, 2.64, 4.44, 5.68) and 95% CI = 0.96–3.27, 1.02–7.04, 0.84–31.17, 1.12–36.85 with P = 0.034, 0.022, 0.044, 0.015 respectively. On the other hand, the frequency of A01 and B12 alleles were significantly higher in patients without steatosis (OR = 0.56, 0.41) and 95% CI were 0.30–1.05, 0.20–0.83 and P = 0.015 and 0.005. On logistic regression analysis, patients who carry HLA-A02, A03 and HLA-B15 alleles may have 2.2, 3.9 and 11.15 fold risk to have hepatic steatosis (B coefficient: 0.78, 1.37; 2.41) 95% CI = 1.09–4.42, 1.04–11.05, 2.15–58.13; P = 0.027, 0.009, 0.004) while carrying HLA-A01 alleles may be protected from having HCV associated hepatic steatosis; (OR = 0.34,95% CI = 0.16–0.72; P = 0.005) with constant 9.47 and overall accuracy of 69%. In addition, patients who have moderate activity index in liver histopathology have 5.9 risk to have hepatic steatosis (OR = 5.92, 95% CI = 2.92–11.99, P<0.001).

Conclusion: In chronic HCV genotype 4 patients, carrying HLA-A02, HLA-A03 and HLA-B15 alleles may have a risk for presence of hepatic steatosis while presence of HLA-A01 alleles may have a protective role.

P1358 THE VALUE OF 2D-SWE.GE FOR THE EVALUATION OF LIVER FIBROSIS IN PATIENTS WITH HCV COMPENSATED CHRONIC HEPATOPATHIES
F. Bende1, I. Sporea, S.A. Popescu, R. Sirli, M. Danila, R. Mare, A. Stepan Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Introduction: Chronic liver diseases are quite frequently encountered in daily practice and are due mostly to chronic viral infections (B or C viruses) and to other conditions such as alcoholic steatohepatitis - (ASH) and to non-alcoholic fatty liver disease (NAFLD). While liver biopsy remains the gold standard method for fibrosis assessment, stage classification and also for necro-inflammatory grading, in the last years, non-invasive assessment methods (biological tests and elastographic methods) were developed and they are being used more and more, to the detriment of liver biopsy.

Aims & Methods: The aim of this study was to evaluate the performance of the 2D shear wave elastography technique from General Electrics (2D-SWE.GE), for the evaluation of liver fibrosis in patients with HCV chronic hepatopathies, using Transient Elastography (TE) as the reference method. The study included 145 consecutive subjects with HCV compensated chronic hepatopathies, in whom liver stiffness was evaluated in the same session by means of 2 elastographic measurements: TE (FibroScan, EchoSens) and 2D-SWE.GE (LOGIQ E9, GE Healthcare). Reliable LS measurements were defined as follows: for TE–the median value of 10 measurements with a success rate of ≥60% and an interquartile range <30% and for 2D-SWE.GE - the median value of 10 measurements acquired in a homogeneous area and an interquartile range (IQR) <30%. To discriminate between various stages of fibrosis by TE we used the following cut-offs: F < 2: 7.1 kPa, F ≥ 2: 9.5 kPa, F = 4: 12.5 kPa [1].

Results: Reliable LS measurements were obtained in 138/145 (95.1%) subjects by 2D-SWE.GE and in 139/145 (95.8%) by TE (p = 0.408). The areas under the receiver operating characteristic curve (AUROC) were 0.909 for significant fibrosis (F ≥ 2), 0.954 for severe fibrosis (F ≥ 3) and 0.942 for cirrhosis (F = 4). The best cut-off values for F ≥ 2 was 7 kPa (Sensitivity 85.7, Specificity 80.5), for F ≥ 3 it was 9.2 kPa (Sensitivity 85.3, Specificity 91.5) and for F = 4 it was 10.7 kPa (Sensitivity 84.6, Specificity 91.4).

Conclusion: 2D-SWE.GE seems a reliable method for liver fibrosis staging in patients with HCV compensated chronic hepatopathies. The best 2D-SWE.GE cut-off values for F ≥ 2, F ≥ 3 and F = 4 in HCV chronic hepatopathies were 7, 9.2 and 10.7 kPa.

Introduction: The risk of developing novo hepatocellular carcinoma (HCC) persists after achieving sustained virological response (SVR) in patients infected with hepatitis virus C. It has been suggested that risk is increased in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of novo HCC in cirrhotic patients treated with DAA and SVR, and also, the risk factors involved in its development.

Aims & Methods: We included all cirrhotic patients due to HCV infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until December 2016 (n = 197, median of follow-up of 17 months). We evaluated chi square test the following qualitative variables: age, Child-Pugh stage, alcohol consumption pre-treatment, tobacco consumption pre-treatment, diabetes mellitus (DM) pre-treatment, genotype, radiological and endoscopic portal hypertension features pre-treatment. The quantitative variables were evaluated with student t test; age, no. of platelets pre-treatment, fibrosis stage pre-treatment.

Results: During follow-up 11 patients were diagnosed of HCC (5.6% prevalence, 3.9% annual incidence). Among all variables evaluated being in a Child- Pugh B stage vs. an A stage (p = 0.007), pre-treatment DM (p = 0.002) and presence of radiological portal hypertension (p = 0.001) were associated with developing novo HCC. Among the quantitative variables, we evidenced statistically significant differences in the mean value of platelets (p = 0.015).

Conclusion: In our group of patients, a worse hepatic function evaluated with Child-Pugh classification and indirect markers of portal hypertension (platelets and radiological features) and also DM are associated statistically significant with the development of novo HCC. The incidence (>1.5%) of novo HCC justifies the screening of HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: Aim of this study was to identify possible differences between patients with ALF and AOCLF regarding routine parameters and clinical course.

In this retrospective single-center study all patients were recruited, who were admitted to the University Hospital of Essen with the initial diagnosis of ALF between 2008 and 2015. Patients included in this study were fulfilling the criteria of the acute liver failure study group Germany. The diagnosis of AOCLF was established postoperatively examining the medical record. In total 17 patients were recruited (ALF: 13; AOCLF: 3). Clinical records, in particular demographic data, serum parameters and outcome were analyzed for differences between ALF and AOCLF.

Results: Patients with AOCLF were significantly older (50.3 ± 15.1 vs. 39.8 ± 16.2, p = 0.0008), had a higher BMI (27.5 ± 5.1 vs. 24.5 ± 6.2, p = 0.0014) and were more often male (65% in AOCLF vs. 34% in ALF p = 0.0008). In addition, the insults that caused the liver failure in AOCLF were significantly different from those patients with ALF. Significant differences were also found for liver enzymes, which were significantly lower in AOCLF patients (AST p = 0.01; ALT p = 0.001). Cell death markers and the MELD did not differ between ALF and AOCLF. Moreover, the outcome was not different between the two groups, neither survived or deceased nor suffered spontaneous remission or non-spontaneous remission (combined transplantation and deceased). Important, MELD and the modified MELD including the cell death marker M65 were similarly effective in predicting outcome for both ALF and AOCLF.

Conclusion: In the present study patients with ALF and AOCLF differed in age and BMI, but did not exhibit differences regarding disease severity (according to MELD) or clinical outcome. While the causes for an acute insult differed between ALF and AOCLF, which might imply a different clinical management, clinical outcome was predictable by common factors for ALF.

Introduction: Romania has the highest incidence of tuberculosis (TB) in the European Union, representing one quarter of the European TB burden. Additionally, bile duct lesions are frequent complications after liver transplantation (LT). The second level of screening for infections consists of screening for Mycobacterium tuberculosis, including history of TB, PPD, Interferon-gamma release assays. Aims & Methods: The aim was to assess the importance of QuantiFERON TB Gold test for evaluating patients included on the wait list for LT in Romanian setting.

The study was a single-center retrospective cohort study (the single center for LT)that included 264 patients admitted on the wait list for LT from January 1, 2014 to November 18, 2016. All patients underwent mandatory screening for Mycobacterium tuberculosis, either using QuantiFERON TB Gold test or skin testing using purified protein derivative (PPD). The variables analyzed using Minitab were age: gender, etiology of liver disease, biochemical test, MELD score. Results: From a total of 264 patients with liver diseases included on the wait list, 60.6% were males, the average age at diagnosis was 47.78 ± 9.92 years. The etiology of liver cirrhosis was HCV in 31.43%, HBV and HBV-HDV coinfection in 45.06%, and alcoholic liver cirrhosis in 18.93%; 24.62% of patients have been diagnosed with superimposed hepatocellular carcinoma. Eighty three patients (31.43%) had positive results for QuantiFERON test, 150 patients (56.81%) were negative and 17 patients (6.43%) had indeterminate results. Only 14 patients (5.3%) were skin tested using PPD, 2 (0.75%) of them with positive results.

Comparing the subgroups, positive QuantiFERON test was associated with HCV etiology (p value = 0.049) and lower lymphocyte counts, but did not achieve statistical significance (p = 0.187). Patients with indeterminate QuantiFERON associated with hyperbilirubinemia (p = 0.044), h/o tuberulosis (p = 0.032) and had a higher MELD score (p = 0.003). An assessment by a multidisciplinary team that included a pneumologist, 38.63% of patients were diagnosed with latent TB. Isoniazid chemoprophylaxis along with pyridoxine was postponed after LT, in order to prevent further hepatic dysfunction. 48.5% of patients underwent LT, followed by TB prophylaxis and no cases of TB reactivation have been reported during a follow-up period of 14 months.

Conclusion: Patients transplanted for HCV-related liver cirrhosis should benefit from a careful follow-up on the WL and prompt TB prophylaxis after LT in order to prevent liver damage from isoniazid chemoprophylaxis. Delays in TB prophylaxis after LT in order to avoid liver toxicity of anti-bacillary drugs was not associated with TB reactivation.

P1362 A NATIONAL STUDY OF CANCER DIAGNOSES IN IRISH LIVER TRANSPLANT RECIPIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

S. M. O'Reilly1, M. Walshe2, S. Deady2, E. O'Leary2, G. A. Doherty1, D. Houlihan3, G. Cullen1, H. Mulcahy1, J. Sheridan1

1Centre For Colorectal Disease, St Vincent’s University Hospital, Dublin/Ireland
2National Cancer Registry of Ireland, Cork/Ireland
3National Liver Unit, St Vincent’s University Hospital, Dublin/Ireland

Contact E-mail Address: susanmmoreilly@gmail.com

Introduction: Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma, colorectal cancer (CRC) and gallbladder cancer. Orthotopic liver transplantation (OLT) patients are at increased risk of developing de novo malignancies, however limited and conflicting data exists regarding cancer risk post OLT for PSC.

Aims & Methods: To examine all recorded malignancies over 2 decades in OLT from PSC pts and compare to our non-transplanted PSC cohort. To analyse factors associated with development of malignancies post OLT. We retrospectively studied PSC patients attending the Irish National Liver Unit (INLU) and the Centre for Colorectal Disease (CCD) at St. Vincent’s University Hospital from 1/1/1994 to 30/6/2016. We integrated this database with the National Cancer Registry in Ireland. This enabled accurate determination of the no. of malignancies recorded in the PSC cohort. Analyzed data included age of recipient at OLT, gender, primary OLT indication, immunosuppressive regime, de novo malignancy post OLT, time from primary OLT to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.

Results: 107 of 173 patients had undergone transplant for PSC. 27/107 pts were transplanted for cholangiocarcinoma. 12 post-transplant de novo cancers and 12 BCC/SCC carcinomas were found in 107 patients during 737.8 person years of follow-up. Median time to cancer diagnosis post OLT was 5 years (IQR 2.8–5.9). Recurrence of PSC was observed in 21 patients (19.6%). Post-transplant lymphoproliferative disease (PTLD) remains a major complication after OLT. Previous studies have reported rates of 1–3% in adult OLT pts. 5 pts were diagnosed with lymphoma post OLT representing 4.7% of cohort. Median time to diagnosis was 5.3 yrs (IQR 2.8–10.2). Regarding CRC, 2 patients developed CRC post OLT. 4 patients had colorectal dysplasia/CRC post OLT had co-existing IBD. All those who developed colorectal dysplasia/CRC post OLT had co-existing IBD. All 5 colectomies for dysplasia/CRC showed significant co-existing inflammation. One patient post OLT underwent a completion proctectomy for rectal cancer. As expected, cholangiocarcinoma as a indication for OLT (p = 0.005, RR 2.573, 95%CI 1.3–4.95) and an older age at transplant (p = 0.05, RR 1.027, 95% CI 1.0–1.054) were associated with higher mortality.

Conclusion: These findings represent national cancer figures in our PSC OLT cohort. The rate of cancer is more than three times higher in this population than the general population. The rates of PTLD are >30 times higher than the non-liver transplant population, and slightly higher than previously reported in unselected liver transplant groups. We could not find any association between the development of PTLD and aggressive immunosuppressive regimes for co-existing IBD post OLT. The study highlights that IBD/PSC patients remain at significant risk of colonic neoplasia after OLT and require intensive surveillance.

P1363 OUTCOME OF LIVER TRANSPLANTATION FOR PRIMARY SCLEROSING CHOLANGITIS IN CONTEXT OF HLA-DR MISMATCH: SINGLE CENTRE EXPERIENCE

P. Drastich1, L. Bajer1, A. Slavček2, M. Beneš1, P. Trunčák2, J. Sipák1

1Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Department Of Immunogenetics, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: drastich@hotmail.com

Introduction: Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses of both extra- and intrahepatic bile ducts. For those who develop end-stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. PSC is accompanied with concomitant ulcerative colitis (UC) in a significant proportion of patients. Benefits of routine HLA typing in donor and recipient prior to OLT were proved in the past.

Aims & Methods: The aim of this study was to assess the impact of HLA-DR mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and course of UC after OLT. After applying inclusion/exclusion criteria we retrospectively evaluated records of 57 patients transplanted at Institute for Clinical and Experimental Medicine (Prague, Czech Republic) between July 1994 and November 2011. Only patients with proper records ±5years from OLT were included. We evaluated likelihood for each variable (ACR, rPSC, course of UC) in patients with either single, double or no mismatch in HLA-DR. Recipient data were analysed with χ2 and Fisher’s exact test using MedCalc statistical software. A p-value < 0.05 was considered as statistically significant.

Results: Out of 57 patients, 27 (47.4%) had single mismatch (“M1” group) and 30 (52.6%) had double mismatches (“M2” group) in HLA-DR. No patient had full match. 33/57 (57.9%) patients had ACR: 15/27 (55.6%) of M1 and 18/30 (60%) of M2 (p = 0.94). 4/27 (14.8%) of M1 and 2/30 (6.3%) of M2 had corticosterone ACR (p = 0.57). Multiple-episodes of ACR occurred in 11/57 (19.3%) patients: 6/27 (22.2%) of M1 and 5/25 (20%) of M2 (p = 0.74). 12/57 (21.1%) had de-novo UC after OLT: 7/27 (25.9%) of M1 and 5/30 (16.7%) of M2 (p = 0.60). In 37 (68.5%) patients, UC was diagnosed prior to OLT. 9/16 (56.3%) patients with M1 and 6/21 (28.6%) patients with M2 had more severe course of UC as compared to course prior to OLT (p = 0.17). 38 patients were evaluated for rPSC, which was diagnosed in 17 (44.7%) individuals. 6/19 patients with M1 and 11/19 with M2 had rPSC (p = 0.19).

Conclusion: Patients with single mismatch in HLA-DR have slight tendency towards development of rPSC and worsening of UC after OLT as compared to patients with double mismatch. Analysis of combined mismatch in HLA-DR and HLA-DQ could demonstrate more substantial linkages in respective clinical variables. Therefore, these data have to be considered as preliminary as typing for HLA-DQ from frozen blood samples is currently underway. Introduction: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related mortality worldwide. Patients with viral hepatitis and those without non-alcoholic fatty liver disease (NAFLD) are especially susceptible to HCC. Parallel to an increase in prevalence of NAFLD, the prevalence of HCC is estimated to be increased in next years. Liver transplantation is now considered as a modality of treatment for patients with HCC.

Aims & Methods: This study aimed to investigate outcomes of liver transplantation in patients with HCC compared to other causes of liver transplantation. In a cross-sectional study patients who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Patients’ characteristics including age, gender, model for end stage liver disease (MELD) score, number of allografts, length of hospital stay, presence of multiorgan failure, about mortality of patients were recorded. Characteristics of tumor including size, number and vascular invasion were recorded. Based on these findings HCC patients were divided to those within Milan criteria and those beyond Milan criteria. The impact of HCC on post-transplant outcomes was investigated using student t-test and chi-square tests. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation.

Results: Totally 1014 liver transplant patients were included. 94 patients with HCC underwent liver transplantation. In patients with HCC compared to other causes of liver transplantation. In a cross-sectional study patients who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Patients’ characteristics including age, gender, model for end stage liver disease (MELD) score, number of allografts, length of hospital stay, presence of multiorgan failure, about mortality of patients were recorded. Characteristics of tumor including size, number and vascular invasion were recorded. Based on these findings HCC patients were divided to those within Milan criteria and those beyond Milan criteria. The impact of HCC on post-transplant outcomes was investigated using student t-test and chi-square tests. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation.

Kaplan-Meier method was used for analysis of survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Serum vitamin B12 levels are increased in myeloproliferative diseases by increased production of haptoglobin, a vitamin B12 transporter and in liver diseases by release of B12 by hepatocytes death.

Aims & Methods: The aim of this study was to evaluate vB12 as a prognostic marker in patients with cirrhosis and acute on chronic liver failure (ACLF) induced by infection. Retrospective assessment of 56 patients admitted to an intensive care unit with ACLF in the context of infection (group 1) and 53 patients with compensated hepatic cirrhosis followed as Hepatology outpatients (group 2). Evaluation of vB12 as a predictor of 30 days’ mortality.

Results: 111 patients, 68% male, age 58 ± 18 years. Group 1 had more acute liver disease (CPT 11.9 ± 0.3 vs. 6.5 ± 0.2 and MELD 27.0 ± 1.0 vs. 10.6 ± 0.5), higher vB12 (1413 ± 149 vs. 735 ± 69 pg/mL) and lower survival (1.6 ± 0.4 vs. 6.4 ± 2.7 years). VB12 positively correlated with hepatic function scores (CPT: R=0.411, MELD: R=0.534), and multigain failure (number of organ failures: R=0.536, SOFA: R=0.553). In group 1, survival was lower in patients with high vB12 (≥ 3 vs. 37 ± 11 months), and 1 month’ mortality was associated with vB12, CPT, MELD, number of organ failure, urea, lactates and fibrinogen, in univariate analysis (p < 0.001). In multivariate analysis only fibrinogen maintained statistical significance (p < 0.001).

Conclusion: There was a strong association between high levels of vB12 and clinical decompensation of liver cirrhosis. VB12 correlated with scores of liver function and multigain failure, as well as early mortality in patients with ACLF.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver is one of the most common metastatic sites of colorectal cancer, nearly 50% patients develop hepatic metastases during the course of their disease. Metastatic spread influences survival rate of those patients. The diffusion weighted imaging (DWI) is MRI sequence designed to detect random movement of water protons in extracellular compartment. Biophysical parameter expressed for treatment is Brownian motion diffusion coefficient (ADC). ADC values for b parameter lower than 300 s/mm² are influenced by perfusion movement of water protons in extracellular compartment. Biophysical parameter to Chemotherapy in Hepatic Metastases.

Results: ADC values for b value of 6500 s/mm² was 1.43 mm²/s for b value of 0500 s/mm². The survival outcomes were assessed by Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Conclusion: The statistical analysis included Kaplan-Meier estimator for 52 patients with 9 censored cases (17.3%). In ADC maps for b value of 0500 s/mm², the low ADC values correlate with presence of necrosis in highly malignant lesions influencing in lower survival rate.

Aims & Methods: This is a post hoc analysis of prospective study to assess the predictive value of the ADC in survival outcomes of patients undergoing radiofrequency ablation due to metastatic colorectal cancer lesions in the liver. We analyzed the MRI studies of 52 patients (18 F, 34 M, aged 4383) performed on 1.5 T scanner one day before the percutaneous RFA treatment. The total number of analyzed lesions was 110 (15 per patient), 83 of them were completely ablated 27 incompletely, what was assessed in follow-up CT studies. The standard protocol of the liver MRI was applied including DWI sequence in b values of 0, 15 and 300 s/mm², ADC maps were calculated for b values of 015 and 0500 s/mm². The final ADC value was obtained by threshold marking ROI covering the whole metastatic lesion. In cases of multiple foci only the lesion with the highest ADC value was included into analysis. On basis of ROC analysis the cut-off values of ADC were established: 2.49 mm²/s for b value of 015 s/mm² and 1.43 mm²/s for b value of 0500 s/mm². The survival outcomes were assessed by mean of Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Results: The statistical analysis included Kaplan-Meier estimator for 52 patients with 9 censored cases (17.3%). In ADC maps for b value of 0500 s/mm², the value of 1.43 mm²/s correlated with longer survival time, whereas ADC value <1.43 mm²/s correlated with shorter survival time. Statistically significant differences were identified by log rank test (p = 0.007). Such a correlation was not observed for ADC values in ADC maps for b value of 015 s/mm² (p = 0.058).

Conclusion: The study showed significant differences in survival rate depending on diffusion influenced ADC values of metastatic lesions.

Introduction: Nowadays liver fibrosis can be assessed using non-invasive elastographic techniques. ElastPQ is a quite novel point share wave elastography integrated into an ultrasound system.

Aims & Methods: The aim of our study was to evaluate the learning curve of obtaining reliable liver stiffness measurements (LSM), using ElastPQ. LSM of a trainee were compared to LSM of an elastography expert (with an experience of more than 500 examinations). Our study group included 50 subjects (mean age 52.7 years, 66.6% men, mean BMI 25.6 kg/m²). Both the trainee and the expert obtained LSM for each subject, using ElastPQ (EPIQ 7, Philips Healthcare, Bothell, WA, USA). Reliable LSM were defined as the median difference measurements < 10% in a homogenous area avoiding large vessels and with an IQR/median < 30%. The learning curve was evaluated using the Receiver Operating Curve analysis using the expert’s results as reference.

Results: The trainee’s performance in obtaining reliable LSM was good (AUC: 0.735, 95% CI (0.557-0.913), p = 0.01). The trainee started to have similar results with the elastography expert after the 30th subject. When looking at the IQRs, they became significantly lower after the 30th subject (2.6 to 2.1 kPa vs 6.5 to 4.2 kPa, p = 0.03).

Conclusion: Obtaining reliable LSM using ElastPQ can be easily achieved after 30 LS examinations.

Out of 354 diabetic screened we excluded those with associated viral hepatitis, those with an AUDIT-C score >8 and those with unreliable LSM. The final analysis included 239 subjects (39.4% women, 40.6% men, mean age 60.4±9.3; BMI = 31.8±6.1 kg/m²) with reliable LSM. According to BMI, 10.8% had normal weight, 26.4% were overweight and 62.8% were obese (35.6% obesity grade I, 17.2% obesity grade II and 10% obesity grade III). Moderate and severe steatosis by means of CAP was found in 18.4% and 69.5% cases respectively. Severe fibrosis was defined by means of TE (LSM > 8.2 kPa) in 29.3% (70/239) of subjects.

Conclusion: In our group, 87.9% of diabetic patients had moderate and severe steatosis by CAP and 29.3% of them had severe fibrosis (TE ≥ 8.2 kPa), suggesting the need for their systematical assessment.

Introduction: In patients with liver cirrhosis, hepatocellular carcinoma (HCC) can be diagnosed by noninvasive imaging methods (contrast-enhanced ultrasound CEUS, contrast CT/MRI).

Aims & Methods: The aim of this study was to evaluate which is the most common enhancement pattern of HCC on CEUS in all three phases (portal, arterial and late phase). We performed a retrospective study that included patients with a final diagnosis of HCC established by an imaging method (contrast enhanced CT or MRI) or biopsy. A total of 249 patients with HCC were examined (180 men, 69 women, mean age 64.6 ± 10 years); 181 patients had liver cirrhosis and 68 patients chronic hepatopathy with severe fibrosis. All 249 HCCs were evaluated by CEUS using low mechanical index ultrasound, following an intravenous bolus of 2.4 ml SonoVue. CEUS was considered conclusive for HCC if a typical pattern was present following contrast examination (hyperenhancement in the arterial phase accompanied by portal and/or late phases washout).

The nodules were classified according to their size in <5 cm and >5 cm. We re-evaluated all 249 HCCs CEUS studies using the ACR CEUS LI-RADSv 2016 algorithm.

Results: After CEUS examination a conclusive diagnosis of HCC was obtained in 190/249 cases (76.3%). Arterial phase hyperenhancement pattern was present in 227/249 cases (91.2%). Common enhancement pattern of HCC in all three phases (arterial, portal, and late phase) was observed in 17/249 cases (6.8%) and hyperenhancement in 5/249 cases (2%). In the portal phase washout was observed in 111/249 cases (44.6%); in 121/249 (48.6%) patients the nodules were isoenhancing and in 17/249 (6.8%) the arterial hyperenhancing pattern was maintained. In the late phase washout was observed in 197/249 (79.1%) cases. The nodules <5 cm were diagnostic conclusive on CEUS in 63.7% (72/113), while nodules >5 cm had a conclusive result in 86% of cases (117/136), p < 0.0001. CEUS examination was conclusive for HCC in 76.3% of the cases (190/249), while using the ACR CEUS LI-RADSv 2016 algorithm in 72.2% of all HCCs (180/249), p = 0.35.

Conclusion: In our study, CEUS arterial hyperenhancement is the most common pattern observed in HCC (91.2% of cases), followed by washout in the late phase (79.1% of cases). The size of the nodule modifies CEUS sensitivity for the diagnosis of HCC: p < 0.0001.

Introduction: Hepatocellular carcinoma (HCC) is the 5th most common cancer worldwide and the 3rd leading cause of cancer-related mortality. In Egypt, HCC is the 2nd most common cancer in men and the 6th most common cancer in women. Egypt has the highest prevalence of HCV worldwide and has rising rates of HCC. HCC is a disease with fast infiltrating growth and poor prognosis. This bad prognosis is due to the lack of an effective method for early diagnosis. So, it is necessary to find a specific & sensitive marker for early diagnosis of HCC and for monitoring of treatment response.

Aims & Methods: The aim of this work is to assess prognostic value of serum DKK1 in predicting treatment response, complication and survival in HCC patients. This study included 60 Patients divided into two groups. Group A: 30 patients with liver cirrhosis. Group B: consisted of 30 patients with HCC. Group B patients underwent either radiofrequency ablation or ethanol injection. Clinical assessment, routine laboratory evaluation, CT studies and measurement of serum alpha-fetoprotein (AFP) and DKK1 were performed for all patients and repeated to group B patients 1 and 3 months after treatment.

Results: DKK1 significantly can be used for HCC diagnosis even in HCC with inconclusive AFP. The optimum cut off value of DKK1 for diagnosis of HCC was 4.3 ng/mL (AUC 0.89, sensitivity 66.7% and specificity 96.6%) (P < 0.001). Serum DKK1 level significantly decreases after HCC treatment with either radiofrequency ablation or ethanol injection (P < 0.001).

Conclusion: DKK1 has a promising prognostic value and can be used for follow-up of HCC patients before and after treatment.

**P1374 EFFECT OF FIBROBLAST GROWTH FACTOR-2 AND ITS RECEPTOR GENE POLYMORPHISMS ON SURVIVAL IN PATIENTS WITH HEPATITIS B VIRUS–ASSOCIATED HEPATOCELLULAR CARCINOMA**

J. Cheong

Gastroenterology, Ajou University Hospital, Suwon, Korea, Republic of Korea

Contact E-mail Address: jaeyoun620@gmail.com

Introduction: Fibroblast growth factor (FGF), vascular endothelial growth factor, and hepatocyte growth factor play a critical role in the pathogenesis of hepatocellular carcinoma (HCC). The FGF2 rs308447 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The FGF2 rs4771249 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs308447 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs308579 A allele carriers had higher survival rates than those of patients with the TT genotype (P = 0.020). The FGF2 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.047). Multivariate Cox proportional analysis revealed that the FGF2 rs308579 A allele (hazard ratio = 1.663, P = 0.004) and advanced tumor stage (hazard ratio = 3.430, P = 0.001) were independent prognostic factors for overall survival rates in patients with HCC.

Disclosure of Interest: None of the SNPs was associated with the risk of HCC development in Egyptians. The FGF2 rs308579 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The F1t-1 rs4771249 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs308447 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs308579 A allele carriers had higher survival rates than those of patients with the TT genotype (P = 0.020). The FGF2 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.047). Multivariate Cox proportional analysis revealed that the FGF2 rs308579 A allele (hazard ratio = 1.663, P = 0.004) and advanced tumor stage (hazard ratio = 3.430, P = 0.001) were independent prognostic factors for overall survival rates in patients with HCC.

Disclosure of Interest: None of the SNPs was associated with the risk of HCC development in Egyptians. The FGF2 rs308579 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The F1t-1 rs4771249 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs308447 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs308579 A allele carriers had higher survival rates than those of patients with the TT genotype (P = 0.020). Conclusion: These observations suggest that the SNPs of the FGFR2 and FGFR3 genes can be potential prognostic indicators in patients with HBV-associated HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.
