25th United European Gastroenterology Week
Barcelona 2017

Abstract Issue
UEG and leading European gastroenterological societies concerned with digestive health help you to provide your patients with the best care options.

You are looking for...

- evidence-based guidelines
- clinical practice guidelines
- consensus
- guidance for your daily practice
- clinical standards
- position papers
- standard protocols

...in these fields of digestive health?

- Digestive oncology
- Endoscopy
- Gut microbiota
- Hepatobiliary
- Histopathology
- IBD
- Neurogastroenterology & motility
- Oesophagus
- Paediatrics
- Pancreas
- Primary care
- Radiology & imaging
- Small intestine & nutrition
- Stomach & H. pylori
- Surgery

25th UEG Week 2017

Barcelona, Spain, October 2017

Accepted abstracts available online at:
https://www.ueg.eu/publications/abstractbook
www.ueg.eu/education/library
http://ueg.sagepub.com

Disclaimer: United European Gastroenterology (UEG) is not responsible for errors or omissions in the abstracts. This abstract book was finalised on September 12, 2017, any changes received after this date have not been incorporated. Changes to presenters received after August 8 have been included in the online version of the programme and can be obtained at: www.ueg.eu/education/library.

Disclosure Policy: UEG is committed to ensuring scientific rigour and objectivity in all of its educational activities. These include all aspects of the educational programme at UEG Week including those that are directly and jointly sponsored activities.

All presenters, whether invited Faculty or abstract presenters, are required to disclose to those organising and attending meetings any relevant financial or other relationship that may lead to a potential bias. UEG reserves the right to review the information disclosed for potential conflicts of interest. Please note that the sole responsibility for the content of each presentation lies with the presenting author.

The UEG Scientific Committee requires all presenters to disclose any financial relationship with or any advisory role in the Biomedical Industry and the Biomedical Technology Industry during the past two years. These and any other potential conflicts of interest should be disclosed during introductory comments to the presentation. Invited speakers and oral abstract presenters are requested to disclose potential conflicts of interest on a PowerPoint slide to be shown immediately at the beginning of the presentation. Poster presenters are requested to disclose potential conflicts of interest at the bottom of their poster.

Conflicts of interest may exist through a financial relationship or when the individual has the opportunity to influence the content of a presentation, and can involve grants, honoraria, shares, paid positions on advisory boards, etc. Conflicts of interest are frequent and expected, and do not preclude an individual from giving a presentation providing the conflict is disclosed. If there is any doubt about the relevance of a potential conflict of interest UEG requires all presenters to err on the safe side and to disclose it.
Aims and scope

Launched in 2013, United European Gastroenterology Journal is the official Journal of United European Gastroenterology (UEG), a professional non-profit organisation combining all the leading European societies concerned with digestive disease. UEG’s member societies represent over 22,000 specialists working across medicine, surgery, paediatrics, GI oncology and endoscopy, which makes UEG a unique platform for collaboration and the exchange of knowledge.

United European Gastroenterology Journal provides an international forum for research in gastroenterology, publishing original articles which describe basic research, translational and clinical studies of interest to gastroenterologists and researchers in related fields. Articles from across all fields of gastroenterology are welcomed by the Editor-in-Chief, including luminal, liver and pancreatic diseases, gastrointestinal surgery, gastrointestinal oncology, paediatric gastroenterology and nutrition as well as endoscopy.

Published article types include original research, reviews, guidelines papers and news items. The journal is a member of the Committee on Publication Ethics (COPE).

2017 annual subscription rates

United European Gastroenterology Journal ISSN: 2050-6406 (print) 2050-6414 (online) is published in February, April, June, August, October and December by SAGE Publications (London, Thousand Oaks, CA, New Delhi, Singapore, Washington DC and Melbourne).

Annual subscription (2017) including postage: Institutional Rate (combined print and electronic) £786/US$1456. Note VAT might be applicable at the appropriate local rate. Visit sagepublishing.com for more details. To activate your subscription (institutions only) visit online.sagepub.com online. Abstracts, tables of contents and contents alerts are available on this site free of charge for all. Student discounts, single issue rates and advertising details are available from SAGE Publications Ltd, 1 Oliver’s Yard, 55 City Road, London EC1Y 1SP, UK, tel. +44 (0)20 7324 8500, email: subscriptions@sagepub.co.uk and in North America, SAGE Publications Inc, PO Box 5096, Thousand Oaks, CA 91320, USA.

Manuscript submission guidelines

To view the manuscript submission guidelines, please visit the Manuscript Submission link at journals.sagepub.com/home/ueg

Peer review policy

United European Gastroenterology Journal operates a conventional single-blind reviewing policy in which the reviewer’s name is always concealed from the submitting author. Papers will be sent for anonymous review by at least two reviewers who will either be members of the Editorial Board or others of similar standing in the field. The Editors' decision is final and no correspondence can be entered into concerning manuscripts considered unsuitable for publication in United European Gastroenterology Journal. All correspondence, including notification of the Editors decision and requests for revisions, will be sent by email.

Dear Colleagues,

On behalf of the UEG Scientific Committee, I would like to take this opportunity to thank you most sincerely for your contribution as an abstract reviewer for the original programme of the 25th UEG Week Barcelona 2017.

The abstract reviewing process has been again very important this year, with a number of innovations introduced to improve especially the poster abstract presentations.

I know just how much time and effort reviewing abstracts takes, but without your expertise we would not have the quality that I believe we have achieved in the free paper and poster sessions, and UEG Week would not be the top international digestive diseases meeting that it has become today. Thank you!

We received a total of 3438 abstracts for UEG Week Barcelona 2017. In total, 2341 abstracts were accepted, giving an acceptance rate of 68.13%. Of these, 378 abstracts will be delivered as oral presentations and 1963 as posters. I am even more pleased to tell you that standards have again reached a very high level, and we can expect to be exposed to most interesting research and great presentations.

This high volume and high standard confirm that UEG Week is the most important forum at which to present your best research. We have received 95 video cases which were formally evaluated by the Scientific Committee for presentation in Barcelona. As in previous years, late-breaking abstracts have been scored by the Scientific Committee for presentation in Barcelona.

The quality of reviewing this year was excellent, but if you have any further (positive or negative) comments, please do let us know!

Finally, but most importantly, thanks to all investigators both within and outside Europe who have submitted their research to the meeting, and who are clearly contributing to making the 25th UEG Week Barcelona 2017 such a great success!

Professor Magnus Simrén
Chair, UEG Scientific Committee, Barcelona 2017
Thanks to Partners, Sponsor and Exhibitors

Introduction: Computer-aided diagnosis (CAD) powered by artificial intelligence is attracting increased attention as an option to improve the performance of optical biopsy for evaluating colorectal polyps [1]. Although positive preliminary data have been shown for applying CAD to endoscopy (EC) (500-fold ultra-magnifying endoscopy; Olympus Corp., Tokyo, Japan) [2, 3], no prospective data have been shown for applying CAD to endocytoscopy.

Aims & Methods: The present study is an initial prospective trial to validate the feasibility of applying CAD to endocytoscopy in a routine colonoscopy practice. A total of 88 patients (38 women, 50 men; mean age 64 years) in whom colorectal polyps had been detected using EC for colonoscopy were prospectively enrolled in the study between January and March 2017. When a polyp was detected, an on-site endocytoscopist predicted the polyp pathology using the CAD system [2], which was designed to output the predicted pathology of the target lesion—whether neoplastic or non-neoplastic—based on the probability of the diagnosis (0–100%) immediately after obtaining a methylene blue-stained EC image. The endocytoscopist obtained as many images as he thought were needed, each of which was evaluated using image-based analysis. The diagnostic ability of the CAD for each image was assessed with reference to the final pathology of the resected specimen. The main outcome measures were diagnostic sensitivity specificity, accuracy, positive predictive value, and negative predictive value of the CAD system for identifying neoplastic change with high confidence (probability >90%). Prior to initiating the trial, 13,861 EC images were used for machine-learning the CAD model.

Results: Overall, 126 lesions (62 neoplastic lesions, 64 non-neoplastic lesions; mean size 6 mm) were detected, all of which were successfully analyzed using the CAD system. A total of 1014 EC images of neoplastic lesions and 1480 EC images of non-neoplastic lesions were obtained during the colonoscopies of these patients. Among them, 55% (1378/2494) were diagnosed with high confidence (CAD probability was >90%). The sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of the CAD system in identifying neoplastic change with high confidence were 97%, 67%, 83%, 78%, and 95%, respectively (Table). No complications occurred during the study.

Conclusion: This prospective trial revealed that applying CAD to EC was feasible, with a negative predictive value of >90%, which is likely to meet the threshold required for optical biopsy of colorectal polyps. Our next goal is to increase the proportion of high confidence diagnoses, which is currently limited to 55%.

Disclosure of Interest: All authors have declared no conflicts of interest.

OPENING SESSION: PART II - HALL 6

OP003 DIFFERENTIALLY O-GLYCOSYLATED CARBOXYL ESTER LIPASE CAUSES A MODY8-LIKE PHENOTYPE IN MICE
B. Mercanoglu, G. Wolters-Eisfeld, C. Günther, J.R. Izbicki, M. Beckhorn
Department Of General, Visceral And Thoracic Surgery, University Medical Center Hamburg-Eppendorf, Hamburg/Germany
Contact E-mail Address: b.mercanoglu@uke.de
Introduction: Maturity-onset diabetes of the young type 8 (MODY8) is a mono- genotype syndrome of diabetes and a pancreatic exocrine dysfunction caused by mutations in exon 11 of the Carboxyl Ester Lipase (CEL) gene where clustered O-GalNAc glycosylation sites are encoded.1 C-terminal truncated CEL reduces the viability of pancreatic acinar and beta cell models, indicating the induction of apoptosis in pancreatic cells.2 Aims & Methods: The aim of the present study was to establish a mouse model that allow for the investigation of the pathophysiological mechanisms in MODY8. Therefore, we hypothesized that truncated O-glycosylation of Cel (Cel-Tn) is responsible for the MODY8 phenotype and investigated the pathogenicity of differentially glycosylated Cel. For this purpose, we generated a transgenic mouse model with a conditional Cosmc knockout mediated by the pancreas specific translocation factor 1α (Pstf1α) mouse strain to induce Tn antigen expression in pancreatic acinar cells and thereby truncated O-glycan formation. Results: In accordance with the reported cluster of symptoms in MODY8 patients, characterization of Cosmc-deficient mice revealed symptoms of exocrine pancreatitis, a condition with autodigestion, altered exocrine function, impaired amylase granule release and decreased enzymatic elastase and lipase activity. Moreover, examination of fasting serum glucose and HbA1c displayed elevated levels and reduced amount of fasting serum C-peptide conformable with diabetes based on both clinical and biochemical measures. In addition, we observed reduced numbers of pancreatic acinar cells in Cosmc knockout mice indicating cytotoxicity of Cel-Tn. Our results indicate that the impairment of O-glycosylation on Cel was responsible for the observed MODY8-related phenotype, similar to mutation induced C-terminal truncation. Conclusion: This study demonstrates that deletion of Cosmc in pancreatic acinar cells leads to the loss of O-glycosylation, with consecutive expression of Tn-modified Cel, thus resulting in a MODY8 phenotype. These findings demonstrate the first generation of a MODY8-like phenotype in a mouse model and implicates the relevance of O-glycan formation.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter pylori (HP) eradication has been shown to reduce the risk of gastric cancer development, it remains elusive whether there is a point of no return on the HP-associated gastric carcinogenesis cascade. In particular, there are limited data on the benefits of HP eradication on gastric cancer prevention in the older population (>60 years).
Aims & Methods: We aimed to compare the age-specific risk of gastric cancer development in a large cohort of HP infected subjects who had received HP eradication therapy with the local general population.
Methods: The results were based on a retrospective cohort study that included all HP-infected subjects who had received a 7-day course of clarithromycin-based triple therapy between 2003 and 2012 in Hong Kong. These subjects were identified from a territory-wide health database, which captured all patients’ clinical information in the local public health care system. We excluded subjects with history of gastronomy, were diagnosed to have gastric cancer prior to or within 12-month of HP therapy, and those who failed clarithromycin-based triple therapy. Person-years at risk were derived for each patient from the first date of HP therapy until the date of gastric cancer diagnosis, death or the date of censoring. Expected number of gastric cancer cases in the general population were estimated from the standardized incidence ratio (SIR) of the HP eradicated cohort as compared to the general population (SIR = 0.75; 95% CI, 0.61 to 0.92), corresponding to a 25% reduction in gastric cancer incidence. In contrast, the corresponding SIR was 1.37 (95% CI, 0.43 – 3.30) in the <40 years and 1.07 (95% CI, 0.82 – 1.38) in the 40-59.9 years groups.
Conclusion: In this large population-based study of HP-eradicated subjects, we found that the risk of gastric cancer was significantly lower among those who received HP eradication at ≥60 years than the age-matched general population. Our results suggest benefits of HP eradication on gastric cancer prevention even in the aged population.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Filgotinib is an oral, selective Janus kinase 1 (JAK1) inhibitor, with demonstrated efficacy in rheumatoid arthritis. This 20-week Phase 2 study evaluated the efficacy and safety of filgotinib in patients with active moderate-to-severely active CD. The primary endpoint (CDAI remission at Week 10) was met with an acceptable safety profile.
Aims & Methods: The effect of disease duration and location on response was assessed post hoc on the primary endpoint. 174 patients with moderate-to-severely active CD (the primary endpoint) (CDAI remission at Week 10) was analysed by disease duration (<5 years, 5–10 years and >10 years) and histological location (ileal, ileo-colonic, colonic).
Results: Baseline disease characteristics were similar in both initial treatment groups, showing a population of active Crohn’s patients (mean CDAI 293, mean SES-CD 14.6, mean CRP 15.6 mg/L, 41% >10 mg/L, oral corticosteroids use 51%, mean daily dose 21.6 mg). Most patients were anti-TNF naïve, 58% were anti-TNF non-responder. Forty-three percent were diagnosed for less than 5 yrs, 30% between 5 and 10 yrs and 27% for >10 yrs. Most anti-TNF naïve patients (63%) had <5 yrs CD, whereas 71% of anti-TNF non-responders were diagnosed >5 yrs. A total of 62% of patients had ileo-colonic disease, whereas 18% had ileal involvement only and 20% had only colonic involvement. The percentage of FIL-treated patients in clinical remission at W10 was not impacted by longer disease duration while for PBO-treated patients the percentage of remitters was lower with disease duration of >10 yrs. In FIL-treated patients, consistently high remission rates in both anti-TNF naïve and (to a lesser extent) anti-TNF non-responders were seen, independently of disease duration (anti-TNF naïve: 59%, 60%, 62%; anti-TNF non-responders: 42%, 37%, 32%, respectively for <5 yrs, 5–10 yrs and >10 yrs). FIL treatment effect was also shown independent of disease location, although a higher percentage of remitters was observed in the subgroup with colonic disease only (Table 1).

CDAI: Crohn’s Disease Activity Index.
Conclusion: This post-hoc analysis of the Phase 2 FITZROY study indicates that inhibition of JAK1 with filgotinib in Crohn’s patients is consistently associated with clinical remission, independently of disease duration and location.

Aims & Methods: Patients achieving clinical response after a single IV dose of UST in the UNITI-I&II induction studies were randomized 1:1:1 in IM-UNITI maintenance trial, but detailed exposure-response analyses using clinical efficacy, biomarkers of inflammation, and endoscopic substudy data have not yet been presented.

Results: Median ss troughs were approximately 3x greater with qw SC UST (2.11 g/mL and 0.62 g/mL for the qw and q12w regimen respectively). UST levels were lower in patients with higher baseline CRP (likely reflecting greater inflammatory burden), while oral AZA, 6-MP, or MTX use and weight did not have any notable effect. With qw and q12w regimens, higher proportions achieving clinical remission (eg >0.92 ml/g in qw Q8w), lower UST concentrations (in Qs > 0.5 ml/g), and endoscopic response and remission (in Qs > 0.5 ml/g) compared to PBO (Table). By ROC analyses, trough concentrations between 0.8 and 1.4 g/mL or greater were associated with greater maintenance of clinical remission.

Introduction: Ozanimod, an oral, once-daily immunomodulator designed to selectively target S1P1 and S1P3, has demonstrated clinical efficacy in ulcerative colitis (UC) (Sandborn NEJM 2016) and is being evaluated in active Crohn’s Disease (CD). This Phase 2 open-label study in CD examined endoscopic and clinical efficacy.

Methods: Patients with active CD (Crohn’s Disease Activity Index [CDAI] score 220-450, total simple endoscopic score for CD [SES-CD] ≥6 or mean CDAI and SES-CD > 12) were dosed with ozanimod 1 mg daily. All subjects achieving the aforementioned endpoints based on the exposure-response quartile corresponding to 24 mg BID dose. The predicted percentage of endoscopic endpoints was achieved in subjects within upadacitinib plasma exposures.

Results: Sixty-nine patients were enrolled. At baseline, mean age was 37.7 years, mean SES-CD was 13.3, and mean CDAI was 320. Mean CD duration was 10.0 years, with less endoscopic disease (baseline SES-CD mean was 13.3, and mean CDAI was 320. Mean CD duration was 10.0 years). Daily electronic diary records were used to collect CD symptoms (including stool frequency, with neither worse than baseline.

Endoscopic Remission 0# 10 (6, 13) 15 (11, 19) 18 (15, 22) 20 (16, 24) 22 (18, 26)

CDAI Remission 20 (15, 24) 27 (23, 32) 32 (26, 38) 34 (29, 40) 36 (31, 42)
SES-CD Remission 0 9 (6, 12) 12 (8, 15) 15 (11, 20) 20 (16, 24) 24 (19, 28)
Table 1: Endoscopic Efficacy Endpoints at Week 12 or 16

Conclusion: Oral ozanimod demonstrated meaningful clinical improvements as early as Week 4 and endoscopic improvements at Week 12 in patients with moderate to severe CD. No new safety signals were identified.

Modified Clinical Remission: average daily SF ≥ 2.8 and average daily AP score ≤ 0.2. 2) NAFLD worse than baseline CESD index. Crohn’s disease activity index. < 150 Endoscopic Remission: SES-CD ≤ 4 and ≥ 2 point reduction from baseline, no subscore > 1. Endoscopic Response: ≥25% decrease in SES-CD from baseline. Endoscopic Improvement: >50% decrease in SES-CD from baseline or endoscopic remission.

Conclusions: Upadacitinib exposures associated with 18 mg BID to 24 mg BID are predicted to maximize the response for clinical and endoscopic endpoints.

In this study we evaluated the variability of the N-terminal (PS) [3]. Although much attention has been given to the possible role that the N-terminal may play in those domains that are localized in the C-terminal have been studied [2]. Nonetheless, little is known about how it could cause different degrees of pathology. The interaction of CagA with PS binding with proteins in host cells helps to have a better understanding on how it could cause different degrees of pathology. The interaction of CagA with PS requires a set of positively charged residues that is highly conserved among the different species. The most variable position naturally found was the K636N mutation, which generated a higher free energy change and a lower hydrogen bonding respect to the crystal structure 4DYV when evaluating the entire docking models. Nevertheless, the amount of hydrogen bonds increased when considering other mutations, specifically the K636N which was lysing towards a carboxylic bond generated two additional hydrogen bonds. This mutation was also associated with a severe pathology, which means that there could be other molecular forces involved in the CagA-PS complex interaction. Conclusion: The study of molecular forces involved in the CagA binding with proteins in host cells helps to have a better understanding on how it could cause different degrees of pathology. The interaction of CagA with PS requires a set of positively charged residues that is highly conserved among the different species. The most variable position naturally found was the K636N mutation, which generated a higher free energy change and a lower hydrogen bonding respect to the crystal structure 4DYV when evaluating the entire docking models. Nevertheless, the amount of hydrogen bonds increased when considering other mutations, specifically the K636N which was lysing towards a carboxylic bond generated two additional hydrogen bonds. This mutation was also associated with a severe pathology, which means that there could be other molecular forces involved in the CagA-PS complex interaction. Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aims & Methods: In this study we evaluated the variability of the N-terminal CagA from 127 sequences. The major sites of conservation of the residues involved in the PS interaction were 617, 621 and 626, which had no amino acid position 636 had the lowest conservation score, so mutations in this position were evaluated in order to observe the differences in intermolecular forces of the CagA-PS complex. We evaluated the docking of 3 mutations: K636A, K636R and K636N. Results: The models of the crystal and mutations K636A, K636R and K636N presented a ΔG of −8.919907, −8.665261, −8.701923, −8.515097 kcal/mol, respectively. While, mutations K636A, K636R, K636N presented 0, 3, and 4 H-bonds, respectively, and the crystal structure had 1 H-bond. Likewise, the bulk effect of the ΔG and amount of H-bonds was estimated on the entire docking models. The type of mutation affected both, the ΔG (χ2(1)= 93.82, p-value <2.2×10−16) and the H-bonds (χ2(1)= 91.93, p-value <2.2×10−16). Of all the data, 76.9% of the strains that exhibit the K636N mutation produced a severe pathology. The average of the H-bond count diminished when comparing the mutations with the crystal structure of all the docking models. This means that other molecular forces are involved in the CagA-PS complex interaction.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: Medline, Embase, CENTRAL, and grey literature sources were systematically searched to February 2017. We included randomized controlled trials in adults with moderate to severe UC that compared infliximab, adalimumab, golimumab, vedolizumab and tofacitinib to each other or placebo. Outcomes were change in mean difference in Inflammatory Bowel Disease Questionnaire (IBDQ) score, in Short Form-36 (SF-36) physical and mental component summary scores (PCS and MCS respectively), IBDQ response (≥ 16-point increase from baseline) and IBDQ remission (total IBDQ score of ≤ 170 points). We combined direct and indirect evidence through multivariate random-effects network meta-analyses and relative ranking of treatments was assessed using surface under the cumulative ranking (SUCRA) probabilities. We also estimated Predictive intervals (PrI), which indicate the interval within which the relative effect of a future study is expected to be, in order to facilitate interpretation of the results in the light of the magnitude of heterogeneity.

Results: We included 12 randomized, double-blind, placebo-controlled trials (3 with infliximab, 3 with adalimumab, 1 with golimumab, 1 with vedolizumab and 4 with tofacitinib). All interventions as induction therapy resulted in significantly improved mean IBDQ score compared to placebo (table). Table also had significantly higher mean SF-36 scores and higher rates of IBDQ remission and response than placebo. However, only infliximab (MD 18.58; 95%CI 13.19 to 23.97) and vedolizumab (MD 19.09; 95% CI 11.08 to 27.29) achieved a clinically meaningful improvement in HRQL, with an increase in IBDQ score of more than 16 points. Compared to each other, differences among agents did not remain significant when Predictive Intervals were included, since respective Predictive Intervals crossed the line of no effect. In terms of relative ranking, infliximab, vedolizumab and tofacitinib had comparable high probability of being the best treatment across all outcomes. Due to limited data on impact of maintenance therapy on quality of life a network meta-analysis for maintenance therapy could not be conducted with vedolizumab (MD 21.10; 95% CI 11.93 to 30.27) and tofacitinib (MD 20.80; 95% CI 13.55 to 28.05) resulted in substantially significant improvement in IBDQ score compared to placebo. Network meta-analysis results of mean difference in IBDQ score. Data indicate column-to-row mean difference (MD), 95% CI and 95% PrI for change in IBDQ score (i.e. a MD higher than 0.00 favours the column-defining treatment).

Conclusion: Short-term treatment with all pharmacological therapies improved quality of life. Evidence suggests that no single agent is superior to other although infliximab and vedolizumab seems to have greater impact on HRQL. More research is needed to assess the long-term effect of therapies on HRQL. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Thiopurines and biologicals are important for maintenance of remission in immune-mediated inflammatory diseases (IMID). Since they modulate the immune system, the risk for opportunistic infections is theoretically increased. Several studies have reported an increased risk for severe infections associated with these drugs. However, few data are available on mild opportunistic infections in these patients. Since 2012, we use the telemedicine systems "myBiOCoch" (MIBD) for inflammatory bowel disease (IBD) patients and "myBiologicalcoach" (MBC) for all other IMID patients in our centre for monitoring and registration of medication (side-)effects and self-reported infections. We aimed to 1) validate the questionnaire on self-reported infections used in these systems and 2) describe the incidence of self-reported mild opportunistic infections in IMID patients.

Aims & Methods: Patients using MIBD or MBC were asked to fill out the questionnaire on self-reported infections every three months. For validation of the questionnaire, data on infectious events and their according therapy was collected from patients using MIBD from September 2014 through May 2016 and compared to pharmacy data and questionnaires of electronic patient records. Subsequently, data on infections reported by all patients using MIBD and MBC were included to calculate the incidence, nature, and severity of the infections. An infection was defined as mild if no antibiotic (AB) or antiviral medication (AV) was prescribed, as moderate if AB or AV was required and as severe in case of a hospitalisation.

Results: During the validation phase, 631 questionnaires were filled out by 86 patients. We found a 97% agreement between pharmacy data and questionnaires regarding infections and AB or AV use and a sensitivity and specificity of 58.3% (95% CI: 40.9–74.0) and 99.3% (95% CI: 98.1–99.8) respectively. In total, 425 IBD patients using MIBD and 197 IMD patients using MBC were included for evaluation of the incidence of self-reported infections. During a mean follow-up of 11.4 ± 4.9 months, 949 infections were reported, of which 75.8% were mild infections, 23.0% were moderate and 1.2% was severe (table 1).

Conclusion: The patient-reported infectious diseases questionnaire used in the telemedicine tools MIBD and MBC is a valid method to monitor infections in IMID patients. The overall incidence of self-reported infections in IMID patients was 1.7 infections per patient-year. The mild and moderate infections are underreported in previously published post-marketing surveillance studies. Systematic registration of all infections in relation with therapy is important to optimise country specific screening and vaccination protocols. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In an open-label, multicenter, 48-week randomized controlled trial of CDAI with moderate to severe Crohn’s disease (CALM), treat to target (T2T) approach, using biomarkers (Croative protein and fecal calprotectin) in addition to a response Activity Index (CDAI) and corticosteroid use was shown to improve the rate of mucosal healing compared to conventional clinical management (CM).1 As to whether favorable health economic effects associated with the clinical benefits have not been evaluated. Aims & Methods: A model was developed to evaluate the cost-effectiveness of T2T versus CM from the CALM trial using costs reflecting a United Kingdom (UK) setting. CDAI was used to map patients into four health states (remission: CDAI < 150, moderate: CDAI ≥ 150 to < 300, severe: CDAI ≥ 300 to < 450,
very severe: CDAI ≥450) weekly over the 48-week trial. Each health state was assigned a corresponding utility value to represent quality of life for a UK analysis.2 Average number of CD-related hospitalization was obtained from CALM. Hospital and health state cost data were derived from published UK-based research from the perspective of the National Health Service. Number of adalimumab (ADA) injections was estimated from CALM and current UK list prices were used for ADA costs. Proportion of patients in remission, CD-related hospitalizations, ADA injections, direct medical costs (including outpatient visits, lab tests, endoscopic procedures), quality-adjusted life years (QALYs), incremental cost-effectiveness ratio (ICER) and net monetary benefit (NMB) were calculated over 48 weeks. Deterministic and probabilistic sensitivity analyses (PSA) were conducted to assess uncertainty. Work productivity and activity impairment (WPAI) data from the CALM trial were also used in sensitivity analysis.

**Results:** At week 0, in the T2T cohort (n = 122), 73.0% were in moderate and 27.0% were in severe state; for the MC cohort (n = 122), 75.4%, 23.8%, and 0.8% were in moderate, severe, and very severe states, respectively. Over the 48 weeks, T2T was associated with higher remission rate (62.1% vs 47.3%), fewer CD-related hospitalizations (mean 0.13 vs 0.28), and more ADA injections (mean 30.87 vs 24.72) than CM. Total medical costs were £13, 296 in the T2T and £12, 627 in the CM treatment arms; 0.684 QALYs were observed for T2T and 0.652 for CM (table). T2T had 0.032 higher QALYs (95% confidence interval [CI] 0.024 to 0.025) and £669 higher total medical costs (95% CI £2, 529 to £3, 994). The ICER was £20, 913 per QALY (95% CI £94, 116 to -£61, 457 [TC dominant]), which was below the National Institute for Health and Care Excellence (NICE) threshold of £30,000.3 Analyses that included WPAI data from the trial also favored the T2T treatment algorithm. Results were robust in the sensitivity analyses.

*CDC-related hospitalization

**Conclusion:** In an economic model using clinical data from the CALM trial, T2T appears cost-effective compared to CM even after considering higher drug costs, by providing increases in remission, decreases in CD-related hospitalization and improvements in quality of life for patients with CD.

**Funding Statement:** Financial support for the study was provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the abstract. All authors contributed to the development of the publication and maintained control over the final content.

**Aims & Methods:** Adult pts with early UC (diagnosed ≤ 36 months) were enrolled in ICONIC irrespective of disease severity or treatment. For this analysis, we evaluated pts stratified by physician assessment of disease severity into severe, moderate, and remission groups. The following BL characteristics were described for the four groups: Simple Clinical Colitis Activity Index (SCCAI), UC-related HCRU measured during the 6 months prior to study enrollment (i.e., visits to treating physicians or other IBD-associated healthcare professionals, emergency room (ER) visits, hospitalizations and hospital admissions for surgeries); Health Related Quality of Life (HRQoL) (i.e., Short Inflammatory Bowel Disease Questionnaire (SIBDQ), pt-reported employment/ UC-related sick leave status and Work and Productivity Activity Index (WPAI:GH; including work time missed (absenteeism), impairment while working (presenteeism), overall work productivity impairment, and daily activity impairment domains). Data are presented as observed and summarized as means or proportions, as appropriate. Only available observed data are shown.

**Results:** A total of 1816 UC pts were enrolled in ICONIC; mean ± SD age was 38.5 ± 14.6 years and 833 (45.9%) were female. At BL, 230 pts (12.7%) were in remission, 672 pts (37.0%) had mild UC, 686 pts (36.8%) had moderate UC, and 234 (12.9%) had severe UC. SCCAI, HCRU, and SIBDQ measures at BL by UC severity are summarized in Table. Compared to pts in remission, pts with moderate to severe UC had 1.8 to 2.6-fold higher rates of hospitalizations and 1.6 to 2.5-fold higher rates of ER visits over the past 6 months. The total number of visits to the treating physician did not appear to differ across the disease severity groups. Pt with moderate and severe disease were associated with lower SIBDQ scores and higher WPAI:GH domain scores (i.e., greater impairment on work productivity) than pts with mild disease or those in remission. Of 172 (9.5%) pts, 1.8 to 2.6-fold higher rates of hospitalizations and 1.6 to 2.5-fold higher rates of ER visits over the past 6 months. The total number of visits to the treating physician did not appear to differ across the disease severity groups. Pt with moderate and severe disease were associated with lower SIBDQ scores and higher WPAI:GH domain scores (i.e., greater impairment on work productivity) than pts with mild disease or those in remission. Of 172 (9.5%) pts, who reported to be unemployed at BL. 24.4% (n = 42) considered their unemployment to be directly related to UC. Rates of unemployment due to UC were highest in severe UC (39.4%), followed by moderate (21.6%) and mild UC (18.4%) and lowest in pts in remission (16.7%). A total of 183 (10.1%) reported sick leave at BL. Sick leave time ranged from < 2 months (59.6%), 2-4 months (12.6%), > 4 months (22.4%). Among pts on sick leave, 81.4% (n = 149) indicated that it was UC-related, however for pts with severe UC in this group, 100% (n = 48) associated sick leave with UC. In pts with moderate UC, 43.6% (n = 65) reported UC-related sick leave. Table. Baseline SCCAI, HCRU, and HRQoL by UC severity.

**Table.** Baseline SCCAI, HCRU, and HRQoL by UC severity.

(continued)
Introduction: ICONIC is the largest ongoing, prospective, multi-country (n = 33) observational study, assessing cumulative burden in adult ulcerative colitis (UC) and Crohn’s disease (CD) patient population. The study population was adult UC and CD patients who underwent lower GI surgery defined as surgeries of the small intestine, colon, rectum and anus and categorized as resection, repair, bypass or drainage surgeries as defined by ICD-10-PCS. Patients were coded by relevant ICD-9-CM procedure codes, ICD-10-PCS codes and Current Procedural Terminology (CPT) codes after 1 September 2014 and had at least two diagnoses claims for UC or CD prior to surgery; were continuously enrolled for at least 6 months before and at least 30 days after surgery. Cases of postoperative infection within the study population were defined as postoperative wound infection, peritonitis, retroperitoneal infection, or sepsis occurring 2–30 days after the lower GI surgery [1]. Patient demographics, IBD characteristics, surgery-related variables, medical histories and medications use before surgery were assessed. Multivariate logistic regression analyses were used to identify risk factors for a postoperative infection.

Results: A total of 3360 IBD patients (mean age 51.2±17.9 years, women 52.5%, 1362.1/C00-2015 and 1998 CD, with mean age 55.1 and 48.2 years, respectively) had lower GI surgery during the study period and fulfilled the study criteria of being at risk of a postoperative infection. With 2 or more types of surgery, the index lower GI surgery lower period surgery was as follows: resection 60.8%, repair 17.5%, bypass 23.5%, postoperative infection incidence after the surgery was the 15.1% (95% confidence interval [CI]: 14.0%–16.4%) and was similar for UC (14.4%, 95% CI: 12.6%–16.4%) and CD (15.7%, 95% CI: 14.1%–17.3%) patients. Multivariable analysis in IBD patients identified the following as risk factors for a postoperative infection: prior history of postoperative infection (odds ratio(OR)=3.99, 95% CI: 3.11–5.12), open procedure (OR=2.33, 95% CI: 1.88–2.89), preoperative hospital stay at least 4 days (OR=1.90, 95% CI: 1.27–2.82), lower GI bypass surgery (OR=1.72, 95% CI: 1.39–2.13), lower GI resection (OR=1.61, 95% CI: 1.27–2.04), history of chronic obstructive pulmonary disease (OR=1.59, 95% CI: 1.14–2.23), use of systemic corticosteroids within 14 days before surgery (OR=1.53, 95% CI: 1.21–1.92), history of C. difficile infection (OR=1.53, 95% CI: 1.03–2.25), and anemia (OR=1.45, 95% CI: 1.17–1.80). The risk factor profile was similar for UC and for CD patients.

Conclusion: This study identified several risk factors for postoperative infection. Patients with these risk factors should be considered at an increased risk of postoperative infection.

Introduction: Ulcerative colitis (UC) is a systemic and debilitating disease; however, evidence regarding its progressive nature is limited. The objective of this study was to assess the disease burden associated with UC progression and to identify factors related to the progression in UC.

Aims & Methods: A retrospective cohort study was conducted using data obtained from electronic medical records in Uppsala County in Sweden and the Swedish longitudinal integration database for health insurance and labor market activities (LISA) between 1995 and 2014. Patients with UC aged ≥18 years with moderate disease activity (partial Mayo clinic score of 2–4 and treated with betamethasone or <40mg/day of other steroids) were identified and followed to observe the progression to severe UC. Severe UC was defined as having partial Mayo clinic score of 6 (or ≥6) and being treated with prednisone or ≥40mg/day of other steroids. Risk of all-cause hospitalization, UC-related hospitalization and UC-related surgery within one year were estimated among patients with progression vs non-progression using odds ratio (OR) estimated by logistic regression. Annual indirect costs were calculated and compared among patients who progressed and those who did not (age 18–65) based on the average number of sick leave days and the average annual Swedish salary (in 2014 SEK and Euro). Logistic regression models were used to examine the demographic and clinical factors associated with UC progression.

Results: Among 1361 patients with moderate UC identified, 321 (23.6%) progressed to severe UC in a median follow-up of 6.26 (interquartile range: 4.8) years. Use of biologic therapy was low (8.6%) during the follow-up.
 Compared to patients who did not progress, those who progressed to severe UC had a 1.45 times higher risk of a all-cause hospitalization (95% CI 1.12–1.87) and a 2.56 times higher risk of UC-related hospitalization (95% CI 1.86–3.52) within one year, adjusting for age and gender (table). A high but not statistically significant risk of UC-related surgery was observed (OR 1.78, 95% CI 0.36–3.59) in patients who progressed. Average sick leave days were significantly higher in patients who progress than those who did not (64.4 vs 38.6 days, p < 0.001), which translated to higher indirect costs of 141,574 SEK (or 15558 Euro) for progressed patients compared to 86,583 SEK (or 9153 Euro) for non-progressed patients (p = 0.001). Patients who were younger (OR 0.99, 95% CI 0.97–1.00, p = 0.005) and who used steroids (OR 11.84, 95% CI 4.74–29.59, p < 0.001) were more likely to progress from moderate to severe UC.

a adjusting for age and gender **measured within 1-year after index date

Conclusion: The disease burden associated with hospitalizations and sick leave days was significantly higher in patients who progressed to severe UC compared to those who did not. Younger age, longer disease duration and steroid use were significant factors associated with disease progression. Use of biologics was low in UC patients. Early identification of disease progression and intervention with appropriate treatment should be implemented to prevent considerable disease burden associated with UC progression.

OP021 DIFFERENCES IN ADENOMA AND PROXIMAL SERRATED POLYP DETECTION AND ITS EFFECT ON THE LONG-TERM IMPACT OF A BIENNAI FIT-BASED COLORECTAL CANCER SCREENING PROGRAM – A MICROSIMULATION STUDY

Introduction: Both adenoma detection rate (ADR) as well as the proximal serrated polyp detection rate (PSPDPR) are known to vary widely among endoscopy practices. However, little is known about the consequences of variances in both detection rates on the effectiveness of a screening program using biennial faecal immunochemical testing (FIT) as a triage modality. Using a microsimulation model, we aimed to evaluate the long-term CRC incidence and mortality, as well as the number of total colonscopies needed over 30 years after the implementation of a FIT-based CRC screening program. Overall ADR and PSPDPR levels of the participating endoscopists were varied in this model to evaluate its independent effect.

Methods: The ASCCA (Adenoma and Serrated pathway to Colorectal Cancer) model was set up to simulate the Dutch nationwide FIT-based screening program between 2014 and 2044. In this screening program, individuals aged 55–75 years are biennially invited, and FIT-positives referred for colonoscopy. The model predicted that the FIT-based screening program in the base-case scenario was associated with a long-term CRC incidence and mortality reduction 36.7% and 51.8% when compared to no screening. After 30 years of implementation of this screening program, an additional 102,862 colonoscopies per year were needed within the total Dutch population. At a fixed PSPDPR of 11.0%, an increase in ADR from 44.0% to 61.5% would result in a decrease in CRC incidence of 24.9% when comparing both scenarios. Similarly, long-term CRC mortality would decrease with 22.7%. For this increased in ADR, an additional 21,726 colonoscopies per year would be needed 30 years after the implementation of the FIT-based screening program using a fixed ADR of 59.0% and variable PSPDPR (from 3.0% to 14.5%) model outcomes did not substantially change; long-term CRC incidence reduction 35.7% to 37.4%, mortality reduction of 51.2 to 52.3%, number of additional colonoscopies needed per year of 120,834 to 120,872.

Conclusion: Based on the ASCCA model, an increase in ADR gradually reduces CRC incidence and mortality, whereas an increase of the PSPDPR does not decrease long-term CRC incidence and mortality on a population-level. This limited effect of the increase in the PSPDPR might be explained by the limited diagnostic accuracy of FIT for serrated polyps, only detected after a time delay in coexisting with adenomas. Other triage modalities, also aiming to detect advanced serrated polyps, should be further explored.

OP022 HEAD-TO-HEAD COMPARISON OF DIAGNOSTIC PERFORMANCE OF NINE QUANTITATIVE FAECAL IMMUNOCHEMICAL TESTS FOR COLORECTAL CANCER SCREENING

A. Gies1, K. Cuk2, P. Schrots-King3, H. Brenner2

1Preventive Oncology, German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT), Heidelberg/Germany

2Clinical Epidemiology And Aging Research, German Cancer Research Center (DKFZ), Heidelberg/Germany

Introduction: Faecal immunochromatological tests (FITs) are increasingly used for colorectal cancer (CRC) screening. A variety of FIT brands are being used whose diagnostic performance has been evaluated in different study populations. It is therefore unclear to what extent differences in reported sensitivities and specificities reflect true differences in diagnostic performance or differences in study populations or study logistics. We therefore aimed to provide an evaluation and head-to-head comparison of the diagnostic performance of nine different quantitative FITs (qFITs) within a single screening study.

Methods: In the BLITZ study, conducted in Southern Germany, pre-colonoscopy native stool samples were obtained from participants of screening colonoscopy and stored frozen at –80 °C. Stool samples were thawed, homogenized and for every qFIT, a defined amount of stool was extracted and stored using each brand’s specific buffer-filled faecal sampling device. On the next day, blinded analyses were conducted. Four point-of-care and five laboratory-based tests were investigated. Sensitivities and specificities for CRC, advanced adenoma (AA) and their combination, advanced neoplasm (AN) were calculated. Comparative evaluations were performed at pre-set manufacturing cut-offs, at adjusted cut-offs yielding defined levels of specificity (97% and 93%) and at one uniform cut-off (15 µg haemoglobin (Hb)/g stool).

Results: Out of 1667 participants, recruited between 2005 and 2010, who fulfilled predefined inclusion criteria, 626 (38%) AN (case-n = 216) and 300 randomly selected controls without AN at screening colonoscopy were included in the study. Mean age was 63 years and 56% were male. At pre-set cut-offs the sensitivities for AN of the various qFITs ranged from 22% (95% confidence interval (CI), 16–28) to 46% (95% CI, 40–53) with specificities between 86% (95% CI, 81–89) and 30% (95% CI, 95–99) (Table). Adjusting cut-offs to yield a specificity of 97% for each test, the sensitivities for AN ranged from 21% (95% CI, 16–27) to 24% (95% CI, 18–30); with cut-offs between 6.11 µg/g and 29.54 µg/g. Adjusting cut-offs to yield a specificity of 93%, the sensitivities for AN ranged from 30% (95% CI, 24–36) to 35% (95% CI, 29–42); with cut-offs between 1.70 µg/g and 12.27 µg/g. Setting all cut-offs to 15 µg/g, the sensitivities for AN ranged from 16% (95% CI, 12–22) to 34% (95% CI, 28–41), with specificities between 94% (95% CI, 91–96) and...

**Notes:**
- *MNP,* mean number of polyps; *ADR,* adenoma detection rate; *LPDR,* polyps of 1 cm or more; *NDR,* neoplasia detection rate.
- If rates of polyps and adenomas were higher than 35% and neoplasia higher than 5% after 50 years old (N = 4438), these rates remained higher than 26% and 29% and neoplasia approximately 4%, between 45 and 49 years old (N = 515), while they decrease strongly before 45 years old (N = 1076). Excluding patients with familial and personal history of polyps or cancer (irrespective of the age of the relative), detection rates were still significantly higher in patients from 45 to 49 years-old than in patients under 45 (N = 1076). Interestingly, we also found that ADR was negligible in patients between 30 and 39 years-old (N = 442) at 12.4 % with a low NDR at 1.1 %. As expected, in patients younger than 30, neoplasia is virtually absent and ADR very low (2.8 %).

### OP023: TAILORING COLONOSCOPY COLORECTAL CANCER SCREENING IN CHILDHOOD CANCER SURVIVORS: A MODELING STUDY

**A. Gini**, **S. Ahmed**, **I. Landsorp-Vogelhart**

**Department Of Public Health, Erasmus Medical Center, Rotterdam/Netherlands**

**Department Of Radiation Oncology, Princess Margaret Cancer Centre, University of Toronto, Toronto/Canada**

**Contact E-mail Address:** a.gini@erasmusmc.nl

**Introduction:** Childhood Cancer Survivors (CCS) develop colorectal cancer (CRC) more frequently than the general population. This increased risk varies according to the age of diagnosis of primary cancer and its treatment. The US Children’s Oncology Group has suggested tailoring CRC screening recommendations for those patients at highest risk of CRC (treated with abdominal, pelvic, and/or spinal radiation ≥30 Gray). In this study, we used a modeling-based method to evaluate cost-effectiveness of CRC screening in CSS.

* *MNP,* mean number of polyps; *ADR,* adenoma detection rate; *LPDR,* polyps of 1 cm or more; *NDR,* neoplasia detection rate. Rate of polyps and adenomas were higher than 35% and neoplasia higher than 5% after 50 years old (N = 4438), these rates remained higher than 26% and 29% and neoplasia approximately 4%, between 45 and 49 years old (N = 515), while they decrease strongly before 45 years old (N = 1076). Excluding patients with familial and personal history of polyps or cancer (irrespective of the age of the relative), detection rates were still significantly higher in patients from 45 to 49 years-old than in patients under 45 (N = 1076). Interestingly, we also found that ADR was negligible in patients between 30 and 39 years-old (N = 442) at 12.4 % with a low NDR at 1.1 %. As expected, in patients younger than 30, neoplasia is virtually absent and ADR very low (2.8 %).
Aims & Methods: We adjusted the existing Microsimulation Screening Analysis- Colon (MSAC) model for the US general population to reflect CRC and other-cancer mortality risk in CCS. CRC risks were based on epidemiologic studies investigating risk of secondary gastrointestinal cancer in CCS.1,2 Other-cancer mortality assumptions were informed by data from Surveillance, Epidemiology and End Results (SEER, 1973-2013). Costs and benefits of 75 colonoscopy screening strategies varying in screening intervals (3, 5, and 10 years), age to start (30, 35, 40, 45, 50), and age to stop screening (55, 60, 65, 70, 75) were separately evaluated for CCS with primary cancer diagnosis at age 5, 10, 15, 20, and 25 years. A willingness-to-pay threshold of $100,000 per life-year gained (LYG) was assumed to assess cost-effectiveness of CRC screening. Separate analyses were carried out to investigate optimal colonoscopy screening strategies in CCS at highest risk of CRC (Hodgkin Lymphoma, HL, or Wilms tumor, WT, survivors treated with abdominal and/or chest radiation).1,3

Results: Without screening, the number deaths due to CRC in CCS not at highest CRC risk varied according to age of primary cancer diagnosis: from 23 to 46 per 1000 CCS for primary cancers diagnosed at age 5 to 10 years. Screening with colonoscopy starting at age 50 could prevent more than 68% of all CRC deaths. Screening was most effective when started at age 40, preventing 74–80% of CRC deaths in CCS at acceptable costs (incremental cost-effectiveness ratios varied $67,000–99,000 per LYG according to age at primary cancer diagnosis). Fewer lower colorectal cancers may be considered in CCS at higher risk of CRC. 3-yearly colonoscopy starting at age 35 years was optimal in WT survivors, reducing 86% of CRC deaths; and, among HL survivors, 10-yearly colonoscopy screening starting at age 35 was optimal, averting 78% of CRC mortality.

Conclusion: In CCS, colonoscopy screening may be considered from earlier ages and with shorter screening intervals compared to the general population, due to their higher risk of CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP025 FOLLOW-UP OF COLORECTAL CANCER (CRC) PATIENTS INCLUDING 18FDG-PET-CT (PET-CT): AN OPEN-LABEL MULTICENTER RANDOMIZED TRIAL. (CLINICAL TRIAL: NCT 01504260)

I. Sobhani1, I. Baumgaertner2, C. Tounigand3, E. Ette4, F. Brunetti5, C. Gagniere1, A. Luciani6, I. Durand-Zaleski7, S. Bastuji-Garin8, G. Itep Study9

Aims & Methods: The aim of this study was [1] to quantify the effect of PET-CT on the chance of successful sphincter preservation in distal rectal cancer using MRI by comparing the height of tumours measured from the anorectal junction (AJR) on pre-and post-CRT MRI, which decreased to 27% after CRT. Area under the ROC-curve (AUC) to predict successfull sphincter preservation based on the confidence level score on post-CRT MRI was 0.81, sensitivity 91%, and specificity 61%. We assumed the post-CRT height measurements instead of the confidence level score, AUC was 0.86, sensitivity 70%, and specificity 90% (using a cut off of 28 mm).

Conclusion: The distance from the anorectal junction in distal rectal tumours increases as a result of CRT, thereby increasing the chance for successful sphincter preservation. Successful sphincter preservation can accurately be predicted using Receiver Operator Characteristics (ROC-curves) with the final surgical outcome as the standard of reference. Successful sphincter preservation was defined as a complete (R0) surgical resection of the rectum with preservation of the anal sphincter complex, without evidence of anastomotic tumour recurrence for a follow-up period of >2 years.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: iradj.sobhani@aphp.fr

Introduction: Curative surgery is the best therapy of CRC and related recurrences if detection early and small numbers. We have previously showed that 18F-FDG PET-Scan is a valuable tool in this field (1). Here, we assess whether adding semi-annual PET-CT to the usual surveillance would be cost-effective in high-risk recurrent CRC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

short-term outcomes (Kato et al. Endosc Int Open 2016; 4: E521-E526). However, the long-term outcomes are not yet elucidated.

Aims & Methods: The purpose of this study is to evaluate the efficacy of ESD for elderly patients who are 75 years over recruited in a prospective study regarding the expanded indication of ESD for early gastric cancer (Soetikno et al. J Clin Oncol 2005; 23: 4490-4498). Subsequently, 57 primary cancers were found in 50 patients (SIR, 2.70; 95% confidence interval (CI), 2.03–3.51). The risk of head and neck cancers was markedly elevated (15 patients; SIR, 28.35; 95% CI, 16.87–43.07), followed by liver cancer (seven patients; SIR, 8.39; 95% CI, 2.85–13.23), lung cancer (nine patients; SIR, 3.13; 95% CI, 1.56–5.99), and gastric cancer (nine patients; SIR, 3.12; 95% CI, 1.59–5.65). Five of seven liver cancers were hepatocellular carcinomas. All patients with liver cancer were negative for hepatitis B and C. The histopathology types of nine lung cancers consisted of adenocarcinomas, two squamous cell carcinomas, two small cell carcinomas, and two with no diagnosis. The 5- and 10-year overall survival rates after ER were 88% and 78%, respectively. Five patients died of metastatic ESCCs. SPCs led to death (seven patients), two with head and neck cancer, one with pancreatic cancer and one with myelodysplastic syndrome.

Conclusion: Because patients have extremely high risks of head and neck cancers after ER for ESCCs, these regions should be carefully surveyed by oesophagogastroduodenoscopy. The liver, lungs, and stomach also have higher risks of the lungs and liver is recommended for such patients.

Introduction: The incidence rate of a subsequent primary cancer (SPC) has been expected one. The incidence ratio (SIR) was obtained by dividing the observed incidence rate by the expected rate per 1000 person-years. The expected incidence rates in the general population and stomach were 5.5 and 1.4 per 1000 person-years. We retrospectively recommended surveillance for early detection of SPCs. We separated the elderly group into curative resection group; 273 cases, two according to JGCA Guideline, and non curative resection group; 16 cases. We compared the median observation period and 5-year overall survival rate. The survival rates were analyzed by Kaplan-Meier curves. Cox hazard model was used to evaluate their background.

Results: The median observation period and 5-year overall survival rate of elderly group 52.2±1.8 months and 90.0%, which is higher than the 75-year-old Japanese people’s general 5-year survival rate calculated by the national life tables. The non-elderly group and stomach were 96.3±1.3 months and 96.3%. The incidence rates of SPCs were measured after endoscopic resection for early cancers of the upper gastrointestinal tract. J Clin Oncol 2005; 23: 4490-4498.

OP029 SHOULD TAKING BIOPSY SAMPLES FROM APPARENTLY NON-CANCEROUS TISSUES AROUND THE LESION BE PERFORMED TO DETERMINE RESECTION Margin BEFORE GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION?
M. Shibata1, N. Kawata1, K. Takizawa1, N. Kakushima1, M. Tanaka1, M. Yoshida3, S. Ito1, K. Imai1, H. Ishiwatari1, K. Hotta1, H. Matusubayashi2, H. Ono1

Introduction: Endoscopic submucosal dissection (ESD) is widely performed for treating early gastric cancer (EGC) with little risk of lymph node metastasis. The preoperative identification of horizontal margin of EGC is important before ESD. There are some EGCs the margins of which cannot be determined by chromoendoscopy and magnifying endoscopy with narrow-band imaging (ME-NBI). Therefore, we performed biopsy samples from apparently non-cancerous tissues around the lesion (surrounding biopsy) to determine resection margins before ESD.

Aims & Methods: The aim of this study was to assess the predictors of cancer-positive results in surrounding biopsy before gastric ESD. From January 2015 through December 2016, EGCs which we performed more than two surrounding biopsies after the identification of the horizontal margin of EGC using by conventional endoscopy, chromoendoscopy and ME-NBI were enrolled in this study. To assess the predictors of cancer-positive results in surrounding biopsy, we performed univariate and multivariate analysis on the following factors; age (<75 vs. ≥75), sex (Male vs. Female), Helicobacter pylori (HP) infection (positive vs. negative vs. unknown), atrophy gastritis (positive vs. negative), macroscopic type (level type vs. depressed type vs. mixed type), location (Upper vs. Middle vs. Lower), color (reddish vs. discolored), lesion border by chromoendoscopy (clear vs. unclear), lesion size (<30 mm vs. ≥30 mm), ulceration (UL) (positive vs. negative), corkscrew vascular pattern (CVP) by ME-NBI (positive vs. negative), endoscopic diagnosis of invasion depth (cT1a vs. cT1b).

Results: A total of 811 EGCS in 768 patients (499 males, median age 72 years old, range 32–96 years old) were analyzed. Of these 60 lesions (7%) in 60 patients were cancer-positive results in the surrounding biopsies. Univariate analysis revealed that location, HP infection, macroscopic type, UL, lesion size and CVP were significant associated with cancer-positive results in the surrounding biopsy. Multivariate logistic regression analysis revealed that HP infection negative (OR 3.0 [95% CI 1.5–6.0], P=0.01), lesion size ≥30 mm (OR 3.1 [95% CI 1.3–6.8], P=0.01), UL positive (OR 2.7 [95% CI 1.2–5.7], P=0.01) and CVP positive (OR 4.0 [95% CI 1.4–10.4], P=0.007) were independent predictors for cancer-positive results in the surrounding biopsies. Four of 60 cases (7%) underwent surgery due to be out of ESD indications because of surrounding biopsies being cancer-positive. Among the 807 lesions in 764 patients who underwent ESD, only three (0.7%) were cancer-positive horizontal margin in ESD specimen.

Conclusion: This study successfully identified predictors of positive results in the surrounding biopsy. It can be useful to identify the horizontal margin of EGCs when lesions are ≥30 mm in size, negative for HP infection, UL positive and CVP by ME-NBI. When HP and CVP are negative, the evaluation of resection margins by surrounding biopsy would be necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: Endoscopic resection, including endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD), is widely used to treat early esophageal and gastric tumors in Japan, but is sometimes difficult to perform in high-risk patients who are elderly or who have difficult underlying diseases.

Aims & Methods: We aimed to clarify the local effectiveness and safety of endoscopic ampullectomy (CSP) for the curative treatment of early esophageal and gastric tumors in high-risk patients.

Subjects and Methods: We retrospectively studied high-risk patients with early esophageal and gastric tumors who met the inclusion criteria and underwent Ampullectomy (CSP) from October 2015 to February 2017. The inclusion criteria defining high-risk patients in whom endoscopic resection was difficult to perform were as follows: a) patients undergoing maintenance hemodialysis because of renal failure, b) patients in whom it was difficult to discontinue long-term anticoagulant or antiplatelet therapy, c) patients with a bleeding tendency due to factors such as liver cirrhosis and hematologic disease, d) patients in whom prolonged sedation was difficult, and e) patients in whom endoscopic resection was judged by their attending physicians to be difficult.

Results: CSP was performed in 208 patients with early esophageal or gastric tumors (esophageal tumors, 74 patients; gastric tumors, 134 patients). The median follow-up period was 33 months (range, 1 to 137) in patients with esophageal tumors and 31 months (range, 1 to 131) in patients with gastric tumors. CSP was completed in 97% (9/10) of patients with esophageal tumors and 78 years (range, 52 to 95) in patients with gastric tumors. The male:female ratio was 66:8 for esophageal tumors, and 103:31 for gastric tumors. The esophageal tumor diameter was 10 mm or less in 24 patients, 11 to 20 mm in 19 patients, and 21 mm or greater in 31 patients. The gastric tumor diameter was 10 mm or less in 63 patients, 11 to 20 mm in 51 patients, and 21 mm or greater in 20 patients. The histopathological diagnosis of the esophageal tumors was high-grade intraepithelial neoplasia in 23 patients, squamous-cell carcinoma in 44 patients, differentiated adenocarcinoma in 1 patient, and undetermined in 6 patients. The histopathological diagnosis of the gastric tumors was adenoma in 27 patients, differentiated adenocarcinoma in 96 patients, poorly differentiated carcinomia in 10 patients, and unknown in 1 patient. The preoperative depth of invasion of the gastric tumors was the submucosa or deeper layer in 67 patients, the muscularis mucosae or first layer of the submucosa in 6 patients, and the second layer of the submucosa in 1 patient. The preoperative extent of the lesion was classified as 0-IIa in 16 patients, 0-IIb in 12 patients, 0-III in 1 patient, and 0-IV in 1 patient. The vertical margins were negative in 77 patients, positive in 1 patient, and undetermined in 11 patients. The horizontal margins were negative in 9 patients, positive in 1 patient, and undetermined in 11 patients. The vertical margins were negative in all cases. In follow-up endoscopy at 3 months after CSP, all ulcers became scar and no recurrence was detected endoscopically. All biopsies from scar revealed non-neoplastic.

Conclusion: CSP could be performed safely for small SNADET. Efficacy of CSP should be evaluated at next phase III study.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP031 PHASE II STUDY OF COLD SNARE POLYPECTOMY FOR SUPERFICIAL NON-AMPULOID DUODENAL EPITHELIAL TUMOR (D- CSP TRIAL)

1Division Of Endoscopy, Shizuoka Cancer Center, Shizuoka,Japan
2Clinical Trial Coordination Office, Shizuoka Cancer Center, Nagazumi,Japan

Contact E-mail Address: k.takizawa@sechr.jp

Introduction: Small superficial non-ampullary duodenal epithelial tumor (SNADET) is often observed without any treatment in consideration of high complication rates in endoscopic treatment such as endoscopic submucosal dissection (ESD) and endoscopic mucosal resection (EMR). However, treatment is becoming more difficult to resect after tumor growth or many biopsies. Cold snare polypectomy (CSP) has been reported to minimize the risk of complications, and it has become a standard treatment for small colorectal polyps. We considered that CSP could also be suitable for small duodenal polyps.

Aims & Methods: The aim of this study was to evaluate the safety of CSP for SNADET. The major indication criteria were as follows: 1) endoscopically diagnosed SNADET (biopsy before treatment was not necessary, but definitive cancer was excluded), 2) <10 mm in size, 3) a single primary lesion. After registration, CSP was performed using an electrosurgical snare without electrocautery. Follow-up endoscopy and biopsy from scar was performed at 3 months after CSP. The primary endpoint was the rate of delayed complications (perforation and bleeding), secondary endpoints were the rate of spurring bleeding just after CSP, en bloc resection, residual tumor 3 months after CSP, adverse events. All patients provided written informed consent. This study was approved by the ethics committee of the University of Shizuoka. All data were collected and analyzed with University Hospital Medical Information Network Clinical Trials Registry(UMIN000019157).

Results: A total of 21 patients (pts) (male:female: 16:5, median age 71 years (range 60–85); 12 pts) had a history of at least one gastrointestinal surgery. The inclusion criteria were 66:8 for esophageal tumors, and 103:31 for gastric tumors. The esophageal tumor diameter was 10 mm or less in 24 patients, 11 to 20 mm in 19 patients, and 21 mm or greater in 31 patients. The gastric tumor diameter was 10 mm or less in 63 patients, 11 to 20 mm in 51 patients, and 21 mm or greater in 20 patients. The histopathological diagnosis of the esophageal tumors was high-grade intraepithelial neoplasia in 23 patients, squamous-cell carcinoma in 44 patients, differentiated adenocarcinoma in 1 patient, and undetermined in 6 patients. The histopathological diagnosis of the gastric tumors was adenoma in 27 patients, differentiated adenocarcinoma in 96 patients, poorly differentiated carcinomia in 10 patients, and unknown in 1 patient. The preoperative depth of invasion of the gastric tumors was the submucosa or deeper layer in 67 patients, the muscularis mucosae or first layer of the submucosa in 6 patients, and the second layer of the submucosa in 1 patient. The preoperative extent of the lesion was classified as 0-IIa in 16 patients, 0-IIb in 12 patients, 0-III in 1 patient, and 0-IV in 1 patient. The vertical margins were negative in 77 patients, positive in 1 patient, and undetermined in 11 patients. The horizontal margins were negative in 9 patients, positive in 1 patient, and undetermined in 11 patients. The vertical margins were negative in all cases. In follow-up endoscopy at 3 months after CSP, all ulcers became scar and no recurrence was detected endoscopically. All biopsies from scar revealed non-neoplastic.

Conclusion: CSP could be performed safely for small SNADET. Efficacy of CSP should be evaluated at next phase III study.

OP032 ENDOSCOPIC AMPULLECTOMY FOR NON-INVASIVE AMPULLARY LESIONS: A SINGLE-CENTRE 10 YEAR RETROSPECTIVE COHORT STUDY

R. Lee, A. Huelen, L. Hourigan

Gastroenterology And Hepatology, Princess Alexandra Hospital, Brisbane, Australia

Contact E-mail Address: avantgarde84@gmail.com

Introduction: Benign tumours of the ampulla of Vater are rare, but the majority have malignant potential. Surgical resection was traditionally considered the standard of care; however, endoscopic ampullectomy is a minimally invasive alternative. Only a few case series have been published with relatively small sample sizes and short follow-up.

Aims & Methods: This study aims to retrospectively evaluate the safety and efficacy of endoscopic ampullectomy in a single tertiary referral centre over a 10-year period. All patients who underwent endoscopic ampullectomy were identified through the hospital endoscopy and pathology databases, and included in this study. The medical records were retrieved and reviewed with an extensive data analysis. The data points analysed included patient details, lesion characteristics, efficacy, adverse outcomes and recurrence rates.

Results: Fifty-three ampullectomies were performed on 26 female and 27 male patients with a mean age of 64 years (range 35–88 years). Patients with familial adenomatous polyposis (FAP) (n = 14) were significantly younger than those with sporadic lesions (n = 39) (51 vs. 69 years; P < 0.001). Ampullary tumours were most commonly detected during screening endoscopy in FAP patients (P < 0.001), followed by incidental discovery in patients without FAP who were investigated for abdominal pain (P = 0.001). Pre-ampullectomy assessments included a side-viewing endoscopic ultrasound (EUS) in all patients, endoscopic ultra sound (EUS) in 36% and magnetic resonance cholangiopancreatography (MRCP) in 19% of patients. The mean ampullary lesion size was 20 mm (range 6–50 mm) and in 37 patients confined to the ampulla. A lateral spreading tumour of the papilla (LST-P) was present in 16 patients. Lesions were resected en bloc when possible (57%), and the pancreatic duct was stented if feasible as prophylaxis against pancreatitis (83%). In addition, biliary sphincterotomy was performed in 28% of patients to mitigate the risk of cholangitis. Endoscopic
Conclusion: The study substantiates that endoscopic ampullectomy is a safe and highly efficacious procedure for managing non-invasive ampullary tumours. Aside from its therapeutic utility, endoscopic resection also confers the additional benefit of assessing the true histological diagnosis of the tumour which has implications to regard to prognosis and further management. A structured approach to initial lesion assessment, endoscopic treatment and surveillance is required to ensure the best outcomes in patient safety and lesion clearance.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Von Willebrand factor (vWF) antigen has been shown to indicate the presence of clinically significant portal hypertension (CSPH), and thus precede the development of clinical events in patients with cirrhosis.

Aims & Methods: We aimed to investigate the impact of bacterial translocation and inflammation on vWF, as well as the association between vWF and procoagulant imbalance, and vWF antigen levels and complications of cirrhosis, independently of the severity of portal hypertension. Our study population comprised 225 patients with CSPH (hepatic venous pressure gradient [HVPG] ≥ 10 mmHg) without active bacterial infections or a history of hepatocellular carcinoma.

Results: Patient characteristics: Child-Turcotte-Pugh class [CTP]: A3:32%/B34%/C24%; median HVPG-19 (interquartile range [IQR]7) mmHg; median vWF antigen levels: 337(IQR:137)%. In addition to indicators of liver function and coagulation, vWF antigen levels were also independently associated with the presence of clinically significant portal hypertension (CSPH), and thus predicted the development of clinical events in patients with cirrhosis.

Conclusion: These study substantiates that endoscopic ampullectomy is a safe and highly efficacious procedure for managing non-invasive ampullary tumours. Aside from its therapeutic utility, endoscopic resection also confers the additional benefit of assessing the true histological diagnosis of the tumour which has implications to regard to prognosis and further management. A structured approach to initial lesion assessment, endoscopic treatment and surveillance is required to ensure the best outcomes in patient safety and lesion clearance.

Introduction: Cirrhosis is a well-recognized risk factor for portal vein thrombosis (PVT). Obesity has been described to be a risk factor for thrombosis. However, limited information is available on how obesity impacts the development of PVT in patients with hepatitis C. As no large study has examined this relationship in cirrhotic patients, this study is to determine the impact of obesity on PVT development in cirrhotic patients.

Aims & Methods: This was a retrospective cohort study using the 2013 National Inpatient Sample, the largest publically available inpatient database in the US. Patients older than 18 years with an ICD-9 CM code for any diagnosis of liver cirrhosis (ICD-9 CM 571.2, 571.5, 571.6) were included. There were no exclusion criteria. The primary outcome was the impact of obesity on development of PVT (ICD 9 CM 452). Obesity was further sub-classified according to body-mass index (BMI) using ICD 9-CM codes. Secondary outcomes were in-hospital mortality, resource utilization measured by length of hospital stay (LOS) and total hospitalization charges. Odds ratios and means were adjusted for differences in morbidity, median income in the patient’s zip code, Charlson Comorbidity Index, hospital region, rural location, size and hospital teaching status on multivariate regression.

Results: 8842 patients with liver cirrhosis were included. 69.934 (12%) were obese, of which 1125 patients had PVT (mean age 59 years, 35.7% female). Overall in-hospital mortality rates were 9% (11% with PVT vs. 5% without PVT). On multivariate analysis for the primary outcome, cirrhotic obese patients did not have significantly different odds of OR of PVT compared to the non-obese. However, when stratifying by obesity subtype, obesity class 1 was associated with increased odds of PVT (OR:1.45, 95% CI 1.06–1.96, P = 0.02), while obesity class 3 was associated with a decreased odds of PVT (OR:0.72, 95% CI 0.58–0.88, P < 0.01) compared to the non-obese. For secondary outcomes, only increased odds of abdominal CT scan were evident (OR: 3.75, 95% CI 1.18–11.02, P = 0.02). PVT patients with PVT had longer lengths of stay and hospitalization charges compared to patients without PVT, though these were not significant on multivariate analysis. There were no significant differences in morbidity or in-hospital mortality when compared with patients without PVT.

Conclusion: Class 1 obesity is associated with increased odds of PVT, while class 3 obesity is associated with decreased odds of PVT in patients with cirrhosis. PVT is not associated with increased morbidity, mortality or resource utilization. A diagnosis of PVT in this population leads to an approximate four-fold increase in utilization of CT scan.

Introduction: Non-alcoholic steatosis of the liver (NAFLD) has become the most common liver disease in industrialized western countries. NAFLD is the most common liver disease in industrialized western countries (1, 2). Patients with NAFLD are at increased risk for chronic liver disease (CLD), liver-related morbidity and mortality caused by complications of cirrhosis and hepatocellular carcinoma (HCC). The golden standard in evaluation of liver steatosis and inflammation is liver biopsy. With differentiated non-alcoholic fatty liver (NAFL) from non-alcoholic steatohapathies (NASL) is the liver biopsy. Unfortunately liver biopsy is invasive with some risk of complications, it’s costly and contains risk of sampling error. Therefore non-invasive steatosis measurement is preferred whenever biopsy is not mandatory. With Controlled Attenuation Parameter (CAP) integrated in the widely used Elastography tool Fibroscan a new tool was introduced for non-invasive quantitative and qualitative steatosis measurement recently. To date the CAP measurement had to be done within the same week as the biopsy and quality standards for CAP measurement were defined. Liver biopsies were classified according NAS Score: S0 ≤ 5%; S1 5–33%; S2 34–66%; S3 ≥ 66%. In addition data about fibrosis, inflammatory

Aims & Methods: The aim of this study was to analyse the accuracy of CAP values compared to the histologically quantified steatosis and to determine the CAP values in an unselected collective undergoing liver biopsy for any reason in a tertiary liver centre in Switzerland. Method: Between March 2015 and August 2016, all patients who underwent liver biopsy for any reason were screened to meet the inclusion criteria. The CAP measurement had to be done within the same week as the biopsy and quality standards for CAP measurement were defined. Liver biopsies were classified according NAS Score: S0 ≤ 5%; S1 5–33%; S2 34–66%; S3 ≥ 66%. In addition data about fibrosis, inflammatory

Disclosure of Interest: All authors have declared no conflicts of interest.
activity, body mass index (BMI) and liver disease were recorded. For diagnosis of NAFLD, the STE-Fire score was used. Results: From 3,2015 to 8,2016 290 subjects were screened and 224 were included. 146 (65%) were male. Steatosis grades were S0 (0–5%) n = 85 (38%), S1 (6–33%) n = 82 (37%), S2 (34–66%) n = 33 (15%) and S3 (>66%) n = 24 (11%). BMI mean was 26.8 kg/m² (SD 5.0). Mean BMI for the S0: 24.9 kg/m² (SD 3.3), for S1: 26.5 kg/m² (SD 4.2), for S2: 27.3 kg/m² (SD 4.9) and for S3: 32.5 kg/m² (SD 7.1). 114 patients had BMI ≥ 25 kg/m². Median CAP values for S0: 227 dB/m (IQR 199–249), S1: 265 dB/m (IQR 228–295), S2: 307 dB/m (IQR 283–336), S3: 335 dB/m (IQR 319–351), p < 0.0001. Steatosis groups compared separately to the next high or lower group showed the following p values: S0 vs S1: p < 0.0001, S1 vs S2: p = 0.00012 and S2 vs S3: p = 0.03. The group BMI ≥ 25 kg/m² had median CAP 229 dB/m (IQR 206–267) and for BMI < 25 kg/m²: 280 dB/m (IQR 232–321), p < 0.0001. In the subgroup NAFLD and NASH (n = 52) median CAP was 324.5 dB/m (IQR 297–352.25), the group including all the other diagnoses (n = 172) median CAP was 239.5 dB/m (IQR 214.75–280), p < 0.0001. Median CAP of the NASH group (n = 38) vs NAFLD group (n = 14) were not significantly different, 330 dB/m (IQR 300–358) vs CAP 310 dB/m (IQR 276–324), p = 0.506. Optimal cut-off values using the maximum Youden index were: 258 dB/m for S0 vs S1, 2, 3; 282.5 dB/m for S0, 1 vs S2, 3; and 307.5 dB/m for S0, 1, 2 vs S3. AUROC see table.

Conclusion: CAP shows strong association to steatosis grading also in an unselected population. Especially the groups NAFLD/NASH vs other liver diseases and the groups BMI < vs. > 25 kg/m² showed highly significant different CAP values. Comparing CAP for NAFLD vs NASH showed no significant difference.

*Tropical Medicine Department, Tanta university, Tanta/Egypt*

Contact E-mail Address: sherif_tropical@yahoo.com

**Introduction:** Hepatic encephalopathy (HE) is a reversible neuropsychiatric syndrome associated with acute and chronic liver dysfunction. Lactulose is a non-absorbable disaccharide currently used as a first-line agent for treatment of HE. Nitazoxanide has a broad-spectrum activity against urease-producing bacteria, severe alcoholic hepatitis has very high short-term mortality. Compared to standard medical therapy (SMT), GCSF improves clinical and biochemical profiles, morbidity and mortality in these patients. We evaluated efficacy of G-CSF in modulating the disease course of severe alcoholic hepatitis over a period of 3 months in terms of mortality, morbidity by Discriminant function (mDF), Child–Turcotte–Pugh (CTP) and Model for End-Stage Liver Disease (MELD) scores and various complications viz. sepsis, GI bleed, encephalopathy, hepatorenal syndrome (HRS) in comparison to SMT. We also studied the mobilising effect of G-CSF on bone marrow stem cells measured by counting CD34+ cells from peripheral blood.

**Aims & Methods:** The present study was performed to evaluate the safety and efficacy of G-CSF on mortality and complications viz. sepsis, encephalopathy, hepatorenal syndrome (HRS) and quality of (GI Bleed) and also to investigate whether G-CSF therapy could improve the indices of severity of liver disease, such as Discriminant function (mDF), Child–Turcotte–Pugh (CTP), Model for End-Stage Liver Disease (MELD) score in patients with severe alcoholic hepatitis. 90 patients with severe alcoholic hepatitis were randomly assigned to groups A and B (25 in each). Both groups were given SMT, while in addition, patients in group A were given 5 ug/kg GCSF subcutaneous (10 doses for 5 days). We assessed survival, changes in CTP, MELD and mDF scores and the development of complications till 90 days.

**Results:** The baseline parameters in both groups were comparable. On day 6 group A had higher mean leucocyte and CD34 counts than group B (848–855). On day 90 days follow-up patients in group A (n = 25) vs group B (36%) survived (p = 0.04). Mean changes for different scores were greater in group A then group B i.e. CTP (–41.97% vs –8.84%), MELD (–50.89% vs 10.09%) and mDF (–7.4% vs 18%) (p < 0.001). The percentages of patients who developed HRS, HE, or sepsis were lower in group A than in group B (28% vs 64%, 32% vs 64% and 28% vs 68%, respectively) (p < 0.001). There was no significant difference in GI bleed in both groups.

**Conclusion:** In severe alcoholic hepatitis, GCSF therapy significantly improves the survival. It also significantly reduces CTP, MELD, and mDF scores and prevents the development of complications.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Bariatric surgery remains the most effective treatment for morbid obesity, and laparoscopic Roux-en-Y gastric bypass (LRYGB) continues to be the preferred operation. However, extreme obesity increases morbi-mortality in bariatric surgery. In super-obese patients (BMI ≥ 50 kg/m²), pre-operative weight loss can be achieved with minimally invasive endoscopic intragastric balloon (IGB) placement.

**Aims & Methods:** We aimed to explore the potential benefits of preparative IGB on the outcomes of LRYGB in super-obesity. Methods: We performed a
retrospective analysis of the patients with a BMI > 50kg/m² treated at our obesity center between 2008 and 2016 with LRYGB alone (controls) or with prior placement of an IGB (cases). Clinical success of IGB was considered a body weight loss (BWL) of ≥10% and surgical success – an excess body weight loss (EBWL) ≥50% by the second year of post-operative follow-up (FU). Mean age was 42 vs. 40 (p = 0.004), BMI 56.3 vs. 51.7 (p = 0.0001). The proportion of females was 53% (cases) vs. 45% (controls); 52% (cases) vs. 49% (controls) with comorbidities): 46 cases vs. 87 controls. Cases were significantly more overweight than controls (BMI 57.5 vs. 53Kg/m²; p = 0.05, excess body weight 83.7 vs. 70.2 Kg; p < 0.01). The median time of IGB therapy was 196.8 days with 100% technical success rate in placement and removal of the device. 16 patients (34, 8%) had any complaint during IGB treatment (nausea, vomiting, epigastric pain) and in (2%) of these, the IGB was removed before the scheduled date. Average weight effects of IGB were: weight loss: 27Kg, BWL: 11%, BMI loss 10.4Kg/m² and EBWL of 32.6%, with a clinical success rate for IGB of 87%. 71, 7% of cases had more than 25% EBWL at time of removal. 26.1% improved fitness for surgery as assessed by ASA score (drop from III to II) and 6.5% reported improvement in comorbidities during IGB treatment. The average weight loss for IGB to surgery was 139 days, with a mean increase of 4.9Kg. At time of surgery, average BMI was lower in cases than controls (48.6 vs. 53Kg/m²; p = 0.01). There were no records of major surgical complications. Average EBWL effect of LRYGB in cases vs. controls was: 46.6 vs. 53.5% (p = 0.05) at 6 months, 56.9 vs. 70.7% (p = 0.05) at 12 months and 51.2 vs. 73.8% (p < 0.02) at 2 years after surgery. When initial excess body weight was compared, EBWL in controls maintained superiority over the cases (73.8% vs. 64% (p = 0.05) at 24 months. 74.4% (n = 99) had a post-surgical FU of more than 2 years and of these, 81% had reached a clinical success (EBWL ≥ 50%). At most recent post-surgery FU (average 42.8 months), there was no difference between the two groups in total EBWL (63.7 vs. 66.5, p > 0.05). 57.8% (n = 77) reported improved in comorbidities after surgery. Dyslipidemia, type II diabetes and joint pain were the comorbidities that most frequently improved.

Conclusion: IGB is a safe and effective method to promote weight loss in super-obese patients undergoing bariatric surgery, with subsequent improvement in aneurotic risk in a quarter of patients. Prior to surgery, patients submitted to IGB had lower BMI, despite initially being more overweight and at last post-surgical follow-up, there was no statistical difference in EBWL between the two groups. Aims & Methods: We aimed to prospectively evaluate the prevalence of gastroesophageal reflux disease in obese individuals and following laparoscopic sleeve gastrectomy (LSG). Gastroesophageal reflux disease was measured after a standardized nutrient drink pre-and post-LSG. Tissue morphology was determined by morphometric analysis. Tissue expression levels of chromogranin A, gut hormones, a-defensin, mucus 2 and Na+/glucose co-transporter 1 (SGLT1) were assessed by combination of immunohistochemistry, western blotting and quantitative PCR. Protein expression of transcriptome (He1, HATH1, NeuroD1, and Ngn3) were determined by western blotting. Results: In the obese, the total number of enteroneuroendocrine cells (EEC) containing gastrointestinal peptides was significantly reduced (p < 0.001); they were restored post-LSG (p < 0.01). This profile matched the levels of circulating gastrointestinal peptides (p < 0.001, respectively). A significant increase in SGTL1 (p < 0.05) expression was detected in the obese duodenum. Expression levels of transcription factors required for differentiation of absorptive and secretory cell lineages were reduced (p < 0.05).

Conclusion: In conclusion, obesity, there is a deregulation of developmental programming of intestinal epithelial cell lineages. The programming is restored post-surgery leading to an increase in secretion of gut hormones and reduced blood glucose levels.

OP040 EROSION EROSIVE ESOPHAGITIS IS PREVALENT AND PREDICTABLE BY PRE-OPERATIVE GERDQ QUESTIONNAIRE IN GASTRECTOMY: A PROSPECTIVE STUDY IN SUBJECTS WITH THE NEED FOR CONTINUED PPI USE AFTER LAPAROSCOPIC SLEEVE GASTRECTOMY

Internal Medicine, American University of Beirut Medical Center, Beirut/Lebanon

Contact E-mail Address: husseinrimmani@gmail.com

Introduction: Gastroesophageal reflux disease (GERD) is common in obese individuals and following laparoscopic sleeve gastrectomy (LSG). There is limited information on the true prevalence, risk factors, and outcome of GERD before and after LSG.

Aims & Methods: We aimed to prospectively evaluate the prevalence of gastroesophageal reflux disease in obese patients considered for bariatric surgery and to identify risk and predictive factors for erosive esophagitis (EE) and continued PPI therapy post-LSG.

Methods: Consecutive patients undergoing routine esophagogastroduodenoscopy (EGD) for bariatric surgery were enrolled after informed consent. Patients completed the GERDQ and Nocturnal GERD Symptom Severity and Impact Questionnaires (N-GSIIQ). Demographic data included gender, age, BMI, waist circumference, and use of PPI or H2-antagonists. Endoscopic data included presence of erosive esophagitis (EE), hiatal hernia (HH), and gastroesophageal flap valve, endoscopic grade (HI). Patients were assessed 6 months post-LSG for BMI, GERDQ, and need for PPI. Results: Patients included were recruited to date (76 males and 99 females). The mean age was 38.4 ± 11.7 and mean BMI was 40.0 ± 6.6, nearly equally divided between BMI < or ≥ 40. Forty four patients (25.1%) were on PPIs at baseline. EE was documented in 48 of 131 patients on no PPI (36.6%). [EDP] patients with PPIs was 85.0%. On multivariate analysis, presence of HH and a high GERDQ score (38) were significantly associated with EE (p = 0.025 and <0.001 respectively). Patients with high probability GERDQ scores had a significantly higher prevalence of EE compared to those with 5% or less (5.8% vs. 21.6%, p < 0.001), 18.2% and 41.8%, respectively. DPP was measured in 100% of patients. In patients with HH vs. those without (48.4% vs. 27.8%, p = 0.025), BMI ≥40 vs. < 40 and WC were not associated with the presence of EE. Logistic regression analysis showed that GERDQ > 30 was the only independent risk factor for EE (OR: 7.6, 95% CI 1.5-5.96). Forty-seven patients had LSG and completed the follow-up assessment. At 6 months post-LSG, mean BMI declined to 29.8 ± 11.5 and 15 of 47 patients (31%) continued required PPI therapy to control their symptoms. EE on baseline EGD was the only factor associated with need for continued PPI use (58.8% in EE patients vs. 16.7% without EE; p = 0.003).

Conclusion: Gastroesophageal reflux disease is very prevalent in obese patients undergoing GERDQ score ≥38 with the presence of erosive disease in this population. The presence of erosive esophagitis, but not PPI use pre-operatively is highly predictive of the need for continued PPI requirement post-laparoscopic sleeve gastrectomy.

Introduction: Low-grade inflammation and dietary habits are possible explanations for the high prevalence of irritable bowel syndrome (IBS) in subjects with morbid obesity.

Aims & Methods: We aimed to study changes in bowel symptoms, BMI, physical and mental health and a selection of blood tests during a weight loss intervention, and to study the associations between the changes in bowel symptoms and the other variables. Subjects referred to a hospital for treatment of morbid obesity were included. The intervention included personalized personalized (regular, healthy meals and physical activity) and frequent group-based follow-up for six months. IBS was diagnosed with the Rome III criteria. Bowel symptoms were assessed with the irritable bowel syndrome symptom severity scale (IBS-SSS) and gastrointestinal symptom rating scale for IBS (GIRS-IBS). Health was assessed with eight questionnaires including WHO-5 Well-Being Index for emotional well-being and the Sense of Humor Questionnaire. CRP, lactoferrin, neopterin, low-density lipoprotein, high-density lipoprotein, cholesterol, HbA1c, thyroid stimulating hormone, fasting blood glucose levels.

Results: Eighty-eight subjects (71% (81) females) with mean age 44 years (SD 8) were included. BMI was reduced from 42 (SD 4) to 39 (SD 4) kg/m² (p < 0.001). The prevalence of IBS was 24.8% (27%) before and 17.8% (19%) after the intervention (p = 0.19). The IBS-SSS was reduced from 116 (SD 104) to 81 (SD 84) (p = 0.001). The GIRS-IBS was reduced from 1.8 (SD 0.8) to 1.6 (SD 0.6) (p = 0.006). Scores on GRS-IBS subscales changed significantly: Bloating, diarrhea and satiety decreased while constipation increased. The markers of low-grade inflammation and most of the other health scores and blood tests improved significantly. The reduction in IBS-SSS was negatively associated with reduction in BMI (partial correlation (ρ) = −0.29, p = 0.012) and associated with improved sense of humor (ρ) = −0.30, p = 0.012). The reduction in GRS-IBS
was associated with improvement in emotional well-being (p = 0.23, r = 0.038) and increased satisfaction (p = 0.29, r = 0.010). Neither the changes in IBS-SSI nor GSRS-IBS were significantly associated with changes in inflammatory markers, the other health scores or blood tests.

Conclusion: The bowel symptoms were markedly reduced during the weight loss intervention. Gastrointestinal and abdominal symptoms were not associated with the changes in low-grade inflammation. These results weaken the hypothesis that low-grade inflammation from adipose tissue is the cause of the high prevalence of IBS in subjects with obesity. Dietary habits (size of meals, fat intake) or psychosocial factors are alternative explanations.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is characterized by atherogenic dyslipidemia. NAFLD patients are at an increased risk for both cardiovascular and non-cardiac vascular diseases. The effect of bariatric surgery on fat distribution in the liver has so far been studied with liver biopsies and single voxel MR techniques. The objective of this study was to assess liver fat fraction (LFF), subcutaneous (SAT) and visceral adipose tissue (VAT) using MRI in combination with blood lipids to monitor the efficiency of bariatric surgery.

Aims & Methods: In 15 morbidly obese patients an iterative decomposition of water and fat with echo asymmetry and least-squares estimation (IDEAL) approach was used for whole liver fat quantification in combination with a 2-point Dixon technique for volumetric fat imaging of adipose tissue pre- and post 6, 12, and 24 months after surgery. SAT, VAT and adipo- se tissue volumes were assessed from fat images and separated by statistical shape models. Serum: total cholesterol, HDL, LDL and TG were measured.

Results: LFF, SAT and VAT volumes decreased postoperatively with a good positive correlation using an iterative decomposition and model of form. t is the time (in days) after intervention, $A = [A_1, A_2, \ldots, A_t]$ refers to the individual patient specific LFF, SAT or VAT volumes, in combination with a global time constant $T_{sat}$, SAT, SAT for each measure. The LFF reduced the fastest, (time constant $T_{sat}$ = 21 ± 0.21 d). LFF measures showed a clear correlation with total cholesterol, cholesterol/HDL ratio and LDL (each: p < 0.001) and a trend for HDL (p = 0.006). Decrease in VAT and SAT did not correlate with blood lipids.

Conclusion: In conclusion, the decrease of body fat after bariatric surgery follows a distinct time pattern: liver fat decreases fastest followed by subcutaneous and last visceral fat, and decrease in liver fat correlates with changes in blood lipids.

Disclosure of Interest: All authors have declared no conflicts of interest.

QF044 FINAL RESULTS OF MULTI-CENTER, PROSPECTIVE, CONTROLLED TRIAL OF THE DUODENO-JEJUNAL BYPASS LISS FOR PREVENTION OF TYPE 2 DIABETES MELLITUS IN OBSESE PATIENTS: EFEICACY AND FACTORS PREDICTING A SUBOPTIMAL EFFECT

M. Benes, P. Drastich, T. Hucl, J. Spicak

Contact E-mail Address: marek.benes@iukem.cz

Introduction: The global increase in obesity incidence results in an increase of type 2 diabetes mellitus (T2DM). Surgical treatment has proven to be effective; however, it carries a high risk of complications. The duodenal-jejunal bypass line (EndoBarrier®, GI Dynamics, EB) is an endoscopic implant that mimics the intestinal bypass portion of the Roux-en-Gastric Bypass. It results in weight loss and improvements in glucose control in obese patients with T2 diabetes mellitus (T2DM).

Aims & Methods: This is a final report of a prospective, controlled, multicentre study aimed to determine the effectiveness of EB and to identify factors associated with a sub-optimal outcome of EB.

Results: Seventy subjects (45 with an implant, 25 controls) were included in the study. The groups were comparable with respect to age, gender, BMI (mean 41.7 vs. 39.5 kg/m2), T2DM duration (7.8 vs. 8.3 years), HbA1c level (88 vs 86 mmol/mol, respectively). In the EB group all devices were fully implanted. Only 6 devices had to be explanted prior to the end of the 10 months study period (bleeding, dislocation and need for ERCP because of cholelithocholitis). The mean procedure time was 17 minutes for an implantation and 16 minutes for an explantation. At 10 months there was significantly greater weight loss and %EWL (19% vs. 7% and 43 vs. 12) and significantly improved long-term compensation of T2DM marker HbA1c (decreased by 25 vs. 10 mmol/mol) in the EB group. T2DM medication could be reduced in more device subjects than controls. There was no serious adverse event. Mild abdominal pain and nausea after implantation was not associated with the changes in low-grade inflammation. These results weaken the hypothesis that low-grade inflammation from adipose tissue is the cause of the high prevalence of IBS in subjects with obesity. Dietary habits (size of meals, fat intake) or psychosocial factors are alternative explanations.

Conclusion: Compared with GIP, UWP including UEMR achieved comparable proportions of en bloc and R0 resections, and R1A; with a significantly shorter resection time (all polyps) and lower bleeding episodes (pedunculated polyps) than in the GIP group. These results suggest that UWP can be easily and safely used in routine clinical practice, also by not very expert colonoscopists. Its use should be encouraged.

Introduction: Endoscopic Submucosal Dissection has become the standard of care for large superficial rectal precancerous and cancerous lesions. Despite increasing practice in the western world, few European studies have been reported. First French results were far from those reported by Japanese teams: En bloc resection: 64%; R0 resection: 53%. Since these first results, experts teams have trained with animal models or in Japanese centers. We report here the largest European retrospective multicenter study of four French leading teams in rectal ESD.

Aims & Methods: We performed a retrospective multicenter study of all cases of rectal resection performed for precancerous or superficial cancerous lesions in four French teams that performed more than 150 ESDs in the last 5 years. All these teams had individual databases of their cases of rectal ESDs that were merged. Primary Endpoint was to evaluate the En bloc, R0 and curative resection rate. Secondary endpoints were: -evaluation of risk factors for non R0 resection -evaluation of risk factors for non en bloc resection -evaluation of the effect of learning curve (before and after 40 ESDs) on the results.

Results: 349 rectal ESDs were performed between 01/06/2010 and 31/12/2016. Demographic results: male 49.7%; mean age of the specimen: 56.4 years; mean duration of procedure 118.9 min, mean speed of ESD: 23.9 mm2/min, perforation rate: 6%, post procedural bleeding rate: 6.3%, secondary surgery 6.6% (p = 0.009) for a complication; 95% for a pathology risk factor or lymph node metastasis; 5% for ulcerative lesions. Pathological analysis: low grade dysplasia in 22%, high grade dysplasia in 32, 4%, superficial submucosal carcinoma in 6, 3%, deep submucosal carcinoma in 4.6% and T2 adenocarcinoma in 23%. 5 patients (1.5%) had a recurrent disease during endoscopic follow up: 2 that had an ESD failure and a piece-meal resection, 2 that had low-grade dysplasia in lateral margin and one high-grade dysplasia lesion R0 resected. Primary Endpoint: En bloc resection rate: 95.3%, R0 resection rate: 73.5%, curative resection rate: 68.5%. Secondary endpoints: non-en bloc resection was associated with a longer procedure duration (221 vs 113 min, p = 0.002); a lower speed (12.9 vs 24.2 mm2/min, p = 0.0005); a higher perforation rate (21.05% vs 5.2%, p = 0.005); a higher rate of secondary surgery (21% vs 5.2%, p = 0.002) and a higher rate of recurrent disease (10.5% vs 0.9%, p = 0.02) -the beginning of the learning curve (<40 ESDs whatever the location) was associated with a higher procedure duration (165.2 vs 105 min, p = 0.002); a lower speed (17.4 vs 25.9 mm2/min, p = 0.0005); a higher rate of non exclusive ESD (17.2% vs 1.7%, p = . . .) and a higher rate of non exclusive ESD (4.3% vs 0.4%, p = 0.02) -the beginning of the learning curve (<40 ESDs whatever the location) was associated with a longer procedure duration (167 vs 107 min, p = 1.2 x 10−5); a lower speed (15.49 vs 25.83 mm2/min, p = 1.6 x 10−5); a higher rate of post procedural bleeding (13.3% vs 4.4%, p = 0.004) a lower rate of deep sm or T2 adenocarcinoma (0% vs 5% and 0% vs 2.6%, p = 0.05); a lower rate of secondary surgery (0% vs 8.4%, p = 0.009) and longer hospital stay (3.76 vs 2.82 days, p = 0.0011).

Patients with superficial colorectal neoplasms (SCNs) were enrolled and randomly assigned to conventional-ESD group or TAC-ESD group to fully evaluate the efficacy of TAC-ESD.

Introduction:

Contact E-mail Address: yamamoto-kts@umin.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) is technically challenging because of poor visualization and instability in the operative field. Although mucosal flap formation improves visualization of the cutting area, it is difficult to achieve, especially in colorectal ESD. To facilitate mucosal flap creation, we developed the “clip-flap method” as a strategy for submucosal dissection. In a small number of cases, ESD in the rectum was performed using the clip-flap method, but we have not evaluated the efficacy of the clip-flap method in this organ. In this study, we report the results of the largest study of rectal ESD in the western world.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Full-Thickness Resection Device (FTRD) is an over-the-scope system approved for endoscopic full-thickness resection (EFTR) in the lower GI tract. Small retrospective studies and a recent prospective study have shown good efficacy and acceptable safety of the device. We present the interim analysis of the German multicenter registry.

Aims & Methods: The prospective multicenter German online registry was designed to generate “real-life” data on efficacy and safety of the device. Data of patients (n = 250) which was entered by 31 German centers between 09/2015 and 10/2016 was analysed.

Results: 250 FTRD procedures were registered. Major indications for EFTR were non-lifting adenomas (49%), early carcinomas (21%), adenomas at the antecolic orifice (7%) and subepithelial tumors (6%). 173/250 lesions (69%) were located in the colon and 77/250 (31%) were located in the rectum. Median lesion size was 20 x 15 mm. Median procedure time was 45 min (5–150 min). 80 resection rate was 79%. Adverse events were recorded in 20/250 (8%) of cases including 8 perforations (3.2%; 5/8 were due to wrong sequence of procedural steps) and 7 minor bleedings (2.8%). Follow-up was available from 200 cases, median follow-up time was 10 weeks (0.5–77). Residual or recurrent lesions were observed in 12% of cases.

Conclusion: The preliminary results of this registry show good efficacy and safety of EFTR with the FTRD system. These “real-life” results are consistent with previous studies.

Introduction: Endoscopic submucosal dissection (ESD) for colorectal tumors has been widely accepted in the last decades as a minimally invasive treatment option with a higher en bloc resection rate and a lower recurrence rate. Although structure formation after ESD of large colorectal tumors has been reported, underlying mechanisms in developing structure is not fully understood. Mesenchemal stem cells (MSCs) are a valuable cell source in regenerative medicine, and MSC culture supernatant (MSC-CS) has reportedly inhibited inflammation and fibrosis.

Aims & Methods: The aims of this study were to investigate whether circumferential ESD in the colorectum causes structure formation, and to examine the effect of MSC-CS enema on post-ESD structure. We performed circumferential...
ESD with 5 cm long axis in the rectum or distal colon in 20 kg pigs. We prepared M5CS-CS with 5% collagen gel and administered into the rectum immediately after ESD from day 1 through day 4. We applied standard medium gel as a control group. We euthanized the pigs on day 22, measured the rectal size, and performed histological analysis. The experimental protocol was approved by the Animal Care and Use Committee of Hokkaido University.

Results: Severe stricture was observed in the rectum but not distal colon (Stricture rate: 60.7 ± 16.8% versus 16.1 ± 12.6%, P < 0.01, n = 4 in each group). Moreover, extensive fibrosis and hypertrrophy of the muscularis propria were observed in the rectum, but not distal colon. In addition, the numbers of infiltrated neutrophils and activated myofibroblasts were significantly higher in the rectum than in the distal colon. Rectal stricture rate was significantly lower in the M5CS-CS group compared with control group on day 22 (14.7 ± 0.0% versus 63.9 ± 27.4%, P < 0.05, n = 3 in each group). Furthermore, M5CS-CS significantly attenuated the numbers of infiltrated neutrophils and activated myofibroblasts as well as fiber accumulation on day 22.

Conclusions: Stricture after circumferential ESD was developed only in the rectum, and associated with the activation of myofibroblasts and fiber accumulation. In addition, M5CS-CS enema prevented the stricture formation after circumferential ESD in the rectum by suppressing the infiltration of neutrophils and following myofibroblast activation and fibrosis. MSC-CS enema was a promising treatment to prevent post-ESD stricture.

Introduction: Endoscopic submucosal dissection (ESD) can remove large size of early cancers in the stomach or colorectal cancer en bloc; however, this procedure has a risk of intraprocedure perforation. Although an appropriate endoscopic closure using endoclipping is required, this technique is sometimes technically difficult. Recently, we developed a biodegradable injectable collagen sol that forms liquid to gel formation in response to body temperature.

Aims & Methods: The aim of this study was to determine the feasibility of this novel injectable collagen sol for endoscopic closure of iatrogenic perforation. The ethics committee of our institution approved the use of four living 25–30 kg female pigs under the general anesthesia in this experiment. An ESD knife with an electric current made a 3–5 mm perforation hole in the colon at 30 to 40 cm from the anal verge resulting in the collapse of the colonic lumen. We performed two studies using 12 and 5 perforation holes on 4 and 3 pigs, respectively. Study 1: At the beginning of the collapse of the colon due to perforation, the 1.4–1.6% neutral collagen sol containing 4 mM of genipin was delivered to the perforation hole using an endoscopic catheter. When the colon was expanded by CO2 insufflation, one-minute pass of endoclips were applied to the perforation area. Study 2: We only included the use of the collagen sol for endoscopic closure. Collagen sol which was adjusted based on the result of Study 1 was delivered to perforation holes in the same manner to Study 1. After expanding an expanded colon by CO2 insufflation after one-minute pass, an endoscope was withdrawn. All pigs were euthanized immediately after clipping and an hour after endoscopic evaluation in Study 1 and 2, respectively. A leak test was performed for every colon and we also evaluated histology of all perforation sites.

Results: In both studies, collagen sol was smoothly delivered to the target area and fixed as a gel on perforation hole in response to body temperature. Study 1: Although collagen gel was not fixed on two perforation holes, ten of 12 perforation holes were completely closed and then endoclips were placed with com- porure. There was no leak from the perforation hole. Study 2: An endoscope confirmed complete closure of the perforation holes with collagen gel in all pigs. There was also no leak from the perforation hole. Histology revealed a fixation of collagen gel as a thrombus agent in the perforation hole.

Conclusion: A novel temperature-responsive, biodegradable and injectable collagen sol may be used for endoscopic closure of intra-procedure perforation.

Introduction: Golimumab (GOL) is registered for moderate to severe ulcerative colitis (UC). Data on the use of GOL in daily clinical practice are limited. Currently, it is unclear which factors are predictive for a favorable outcome.

Aims & Methods: The aim of the study is to evaluate the mid-term outcome of GOL in patients with moderate-to-severe UC and to determine predictors of favourable outcome. Patients included in the SMART study (NCT02155335) were evaluated for their mid-term outcome. Demographic data, disease charac- teristics and medical history were recorded retrospectively. Data on disease activity based on total Mayo score, previous and concomitant medication, GOL dosing, mucosal healing (Mayo 0 or 1), adverse events (colectomy, hospitaliza- tion) and biomarkers (C-reactive protein, fecal calprotectin, histamine and albumin) were collected at baseline, week 2, 6, 14, 26 and 52. The primary end- point was steroid-free GOL continuation at week 26.

Results: Eight out of 100 patients from the SMART study had to be excluded (low baseline disease activity, undiagnosed, loss of follow-up). From the 92 patients (42% female, median age 41 years, median disease duration 5 years) 4% were active smokers, 25% had extensive colitis, and 38% had an endoscopic Mayo score of 3 at baseline. The median (IQR) Mayo score was 9 (0-10). With 76% of patients having previously failed immunomodulators (IMM), the majority (87%) were anti-tumor necrosis factor (TNF) naïve. GOL was started in combination with IMM and steroids in 38% and 64%, respectively. The median (IQR) follow-up of GOL therapy was 36 (12–106) weeks. Twenty six weeks after GOL induction, 38 patients (41%) were steroid-free and still on GOL, of whom 6 required GOL dose optimization. Short-term mucosal healing (STMH) at week 14 could be evaluated in 52% of the patients and was achieved in half of them. In multivariate analysis, only concomitant systemic steroids (p = 0.044) were pre- dictive of STMH. Patients with STMH more frequently achieved the primary endpoint [67% vs. 29%, OR 4.86 (95%CI 1.43–16.50), p = 0.011]. During a median (IQR) follow-up of 26 (23–30) months, 78% needed a therapeutic inter- vention and 63% discontinued GOL. STMH was significantly associated with intervention free survival (p = 0.030) and prolonged treatment of GOL (p = 0.002).

Conclusion: Real-life data confirm the effectiveness of GOL on the mid-term in moderate to severe UC, although therapeutic interventions are needed fre- quently. Short-term mucosal healing predicts a favorable outcome.

Conclusion: This prospective multicenter study confirms that CLE can reveal CD-related features of mucosal inflammation during ongoing endoscopy, thereby predicting two highly reproducible histopathological hallmarks of active large-bowel mucosal inflammation. In addition, the CLE assessment allows for early prediction of relevant clinical outcomes related to CD such as the need for treatment escalation and the risk of transmural complications at one-year follow-up. Further studies should now address whether this promising prognostic tool could refine the timing of treatment strategies in patients suffering from CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

explicit clinical and laboratory data, including fecal calprotectin (FC), at disease onset or thereafter. PCDAI items, laboratory tests and FC were associated with the Simple Endoscopic Score for CD (SES-CD) in a multivariate analysis and validated on an independent prospective cohort from Korea of children whose workup included ileocolonoscopy, clinical and lab assessment and FC. We employed a blinded clinimetric judgmental and psychometric mathematical approach.

Results: The derivation and validation cohorts included 134 and 86 children, respectively (n = 240; age 14.6 ± 2.6 years; SES-CD 7.8 ± 8.2), of whom 24 (16%) and 9 (10.5%) had a RS of 0–1 (i.e. SESCD < 3), respectively. In a multivariable regression analysis, the stool and weight items of the PCDAI, ESF and FC were associated with SESCD (all p < 0.05). Judgementally, we removed the weight item and included CRP, to form a weighted categorized MINI index (Table). In the validation cohort the sensitivity, specificity, PPV and NPV of the MINI to reflect MH using a cutoff of ≤ 8 was 91%, 67%, 84% and 80% (AUROC curve 0.90 (95%CI 0.84–0.96)). In the entire cohort (n = 216) the correlation between MINI and SESCD was r = 0.783 (p < 0.001).

**ITEM** | **POINTS**
---|---
1. Stool | 0–1 liquid stools, no blood ≤ 2 semi-formed with small blood, or 2–5 liquid Gross bleeding, or ≥ 6 liquid, or nocturnal diarrhea | 0 4 8
2. Fecal calprotectin | < 50 50–99 99–399 300–599 600–899 ≥ 900 | 3 0 4 7 9 12
3. ESR (mm/hr) and CRP (mg/L) | ESR < 30 and CRP < 10 50 > ESR > 30 Or 50 > CRP > 10 30 ESP ≥ 50 | 0 2 5
4. SUM OF MINI (0–25)

Conclusion: In children with ileocolonic CD, the MINI-index can reflect MH with a good accuracy. The likelihood of MH with a MINI-score ≤ 8 points is 84%.

OP059 TOFACITINIB FOR MAINTENANCE THERAPY IN PATIENTS WITH ACTIVE ULCERATIVE COLITIS IN THE PHASE 3 OCTAVE SUSTAIN TRIAL: RESULTS BY LOCAL AND CENTRAL ENDOSCOPIC ASSESSMENTS

Contact E-mail Address: brian.feagan@robartsinc.com

Introduction: Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for ulcerative colitis (UC). A Phase 3, randomised, double-blind, placebo-controlled maintenance study (OCTAVE Sustain, NCT01458574) demonstrated the efficacy of tofacitinib 5 and 10 mg twice daily (BID) vs placebo in patients (pts) with moderate to severe UC. Aims & Methods: We describe the clinical endpoints assessed by local endoscopy readings and previously reported results assessed by central readings. Pts who completed one of two studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01458951) and achieved clinical response were for time from index endoscopy to CR, ED and NSI and compared through Log rank test.

Results: The study population consisted of 296 patients [123 males, median age 40 years]. At index endoscopy, 61 patients (20.6%) had a RS of ≥ 2, 24 (8.1%) 1, 81 (27.4%) i2a, 69 (23.5%) i2b, 35 (11.5%) i3 and 26 (8.8%) i4. Medical treatment was optimized according to index colonoscopy in 4 (4.7%) patients with a RS of i0/i1 and 88 (41.7%) with > i2a [Odds ratio 11.0 (95%CI 5.6–24.4), p < 0.001]. During a median (IQR) follow-up of 76 (48–113) months, CR, ED and NSI were observed in 150 (50.7%), 51 (17.2%) and 36 (12.2%) patients, respectively. Patients with a i2a and i2b had a similar risk for CR, ED or NSI (Log Rank p = 0.19, p = 0.10 and p = 0.30, respectively). Also after exclusion of patients with immediate post-endoscopy treatment optimization, i2a and i2b scores were not predictive (Log Rank p = 0.22, p = 0.21 and p = 0.41, respectively). Probability of CR was higher in patients with an i3 or i4 compared to the others (Log Rank p < 0.001). A RS ≥ i2a [1.62 (1.06–2.50), p = 0.03], active smoking at endoscopy [1.61 (1.08–2.39), p = 0.02] and CRP > 5 mg/L at endoscopy [1.76 (1.17–2.63), p = 0.01] were associated with CR during the follow-up in patients without clinical relapse at endoscopy. In patients with a RS = i2, initiation of an immunosuppressant or biological therapy after endoscopy was not associated with a different outcome in terms of CR or NSI (p = 0.59 and p = 0.66, respectively). Only a modest benefit in terms of CR was observed for patients with a RS = i3 or i4 when an immunosuppressant or biological therapy was introduced after endoscopy (p = 0.03), but the risk of NSI was not influenced (p = 0.14).

Conclusion: No difference was observed in terms of clinical relapse and need for endoscopic/surgical intervention between patients with i2a or i2b endoscopic recurrence after ileo-colonic resection with ileo-colonic anastomosis. In patients with a RS = i2, no effect on probability of clinical relapse or need for a new intervention was observed when an immunosuppressant or a biological treatment were initiated after the index endoscopy. Despite intensification of therapy based on endoscopic findings, outcomes of i3 and i4 patients remain poor in our cohort.

eligible to participate in OCTAVE Sustain. Clinical response was defined by a decrease from induction study baseline in Mayo score of ≥5 points and ≥30%, with an accompanying decrease in rectal bleeding subscore ≥1 or an absolute rectal bleeding subscore ≤1. 593 pts were randomised (1:1:1) to receive placebo, tofacitinib 5 or 10 mg BID for 53 weeks (wks) in OCTAVE Sustain. Pts eligibility was assessed based on central endoscopic readings. Pts entering OCTAVE Sustain were permitted concomitant treatment with oral corticosteroids, although tapering was mandatory from study baseline. Concomitant treatment with immunosuppressants and biologics was prohibited. Efficacy endpoints assessed at Wk 52 included remission (primary endpoint: Mayo score ≤2, no individual subscore >1 and rectal bleeding subscore of 0), mucosal healing (Mayo endoscopic subscore ≤1) and clinical response.

Results: At Wk 52, remission was achieved by significantly more pts treated with tofacitinib 5 or 10 mg BID compared with placebo, as demonstrated by both central and local endoscopic readings (Table). Similar results were observed at Wk 52 with mucosal healing, clinical response and sustained, steroid-free remission among pts in remission at baseline. Efficacy assessed by local endoscopic readings was numerically greater than central readings, except for clinical response. There was good agreement between locally and centrally read endoscopic subscores (kappa = 0.6 [95% CI 0.5, 0.6]).

Conclusion: Efficacy assessed by local endoscopic readings was numerically greater than efficacy assessed by central readings for tofacitinib 5 and 10 mg BID compared to placebo. Overall, local endoscopic readings were consistent with central readings. Both methods demonstrated that tofacitinib 5 and 10 mg BID were both more effective than placebo for maintenance therapy in pts with moderately to severely active UC.

Contact E-mail Address: bob@immusant.com

Introduction: The explanation for symptoms experienced by celiac disease (CeD) patients within hours of gluten ingestion has puzzled researchers because the early onset seems incompatible with a T-cell mediated (delayed hypersensitivity) effect. We hypothesized the role for gluten-specific CD4+ T cells in gluten-responsive symptoms could be tested by comparing acute immune effects of ingesting gluten with intradermal injection of Nexvax2®, an experimental adjuvant-free therapeutic vaccine that is a mixture of three short peptides including immunodominant epitopes for gluten-specific CD4+ T cells.

Aims & Methods: To assess changes in circulating cytokines in CeD volunteers on GFD after eating gluten or after intradermal administration of Nexvax2.

Methods: A time course assessment of 19 cytokines and chemokines in plasma and sera from adult HLA-DQ2.5+ CeD volunteers on a GFD were compared from two separate studies. The first was a double-blind, placebo-controlled food challenge (DBPCFC) with ~3g wheat gluten flour compared to a matched gluten-free drink over 10min. The second study was a double-blind, placebo-controlled phase 1 clinical trial of Nexvax2 (Goel et al. Lancet Gastro Hepatol 2017) with plasma assessed after the first dose of Nexvax2 150 mg or normal saline i.d. in 0.1 mL. Chemokines (eotaxin, MIP-1B, eotxin-3, TARC, IP-10, MIP-1α, MCP-1, MDC, MCP-4) and cytokines (IFN-γ, IL-1B, IL-2, IL-4, IL-6, IL-8, IFN-γ, IL-12/20, IL-13, TNF-α) were measured by the Meso Scale Discovery multiplex ELISA platform.

Results: Cytokine and chemokine assessments were performed in 19 subjects after DBPCFC (11 administered gluten, & 8 non-gluten), and in 14 subjects in the final “biopsy” cohort of the phase 1 study of Nexvax2 (7 administered Nexvax2, & 7 placebo). In the first 5 subjects after gluten ingestion, hourly profiling indicated IL-2 elevation from 2h (median 5-fold rise compared to predose, range 1.1–117) and plateauing between 3 to 5h (median maximal fold-change 21, range 2.6-94). Median fold increase in IL-8 was between 1.8 and 2.4 from 3 to 6h (median maximal fold-change 2.5, range 1.3–28). Median fold increases were less than 2 from placebo for other cytokines and chemokines for all time points. Overall, serum assessed from before, and at 4 and 6h showed median IL-2 fold change of 15 at 4h after...
gluten (range: 1.9–39, n = 11) compared to 1.0 for non-gluten (0.5–1.6, n = 8; p = 0.05). For IL-4, median fold change at 6 h post-dose in IL-4 was 2.4 (range: 1.0–8.4, n = 11) compared to 1.1 for placebo (0.7–1.3, n = 8; p = 0.012 Mann Whitney). Apart from IL-2 at 6 h, no other cytokines or chemokines showed median elevation above 2-fold at any time points after gluten ingestion. After Nexva2, median fold changes at 2, 4 and 6 h post-dose in IL-2 were 14 (range: 1.3–68), 127 (range: 2.1–915), and 70 (range: 1.6–396), and in IL-8 were 1.6 (range: 0.9–2.8), 11 (range: 2.1–28), and 5.3 (range: 2.0–12). Weaker median fold rises of at least 2 were observed after Nexva2 but not placebo in MCP-1, IL-1β, IL-10, IFN-γ, MIP-1β, IP-10, IL-4, IL-13, eotaxin, and TNFα.

Conclusion: IL-2, a T-cell specific cytokine, dominates the cytokine signature present between 2-6 h after gluten ingestion or intradermal administration of Nexva2. These findings suggest gluten ingestion or injection of peptides activating T cells rapidly and could account for symptoms triggered by gluten.

OP061 BACTERIAL MODULATION OF INTESTINAL INNATE IMMUNE ACTIVATION INDUCED BY WHEAT AMYLASE TRYSIN INHIBITORS (ATI) IN NOD-DQ8 MICE
V.F. Zevallos1, J. McCarville2, A. Caminero2, E. Verdú3, D. Schuppán1
1Institute Of Translational Immunology, University of Mainz, Mainz/Germany
2Farna conste Family Digestive Health Research Institute, McMaster University, Hamilton/Canada/ON

Introduction: Wheat-amylase/trypsin inhibitors (ATI) are nutritional activators of intestinal innate immunity via the toll-like receptor 4 (TLR4)-MD2/CD14 complex in myeloid cells. We have observed that wheat ATIs enhance innate immune responses towards gluten in a host at risk, such as SPF NOD-DQ8 mice.

Aims & Methods: The aim of the study was to screen, identify and test bacterial strains with a capacity to degrade ATIs and therefore reduce their immune stimulatory activity in-vitro and in-vivo. Supernatants of a large group of intestinally isolated bacteria were tested against pre-defined ATI subtypes (CM3 and 0.19). The in vivo effects of two groups of bacteria with low and high ATI degrading capacities were assessed in in-concomitant gavage with a single dose of ATIs in NOD-DQ8 mice on a gluten-free diet after 6 h.

Results: We identified commensal bacteria in vitro that have the capacity to degrade the major ATI subtypes. When the ATI-degrading bioactivity of those bacterial strains was tested in mice gavaged with ATIs, the bacteria combined or individually significantly reduced intestinal expression of TLR4-dependent proinflammatory cytokines and chemokines, and serum levels of IL-6 when compared to mice that received ATIs without the bacteria. Data were confirmed in myeloid cell cultures in vivo that were exposed to bacterial or control supernatants of ATIs with and without prior depletion of potential traits of LPS.

Conclusion: Some Lactobacillus strains have the capacity to modulate the innate inflammatory effects of ATIs in vitro and in vivo. Since wheat-ATIs are implicated in the pathogenesis of celiac disease as well as non-celiac wheat sensitivity, modulation with ATI degrading bacteria may be an attractive therapeutic target.

Introduction: Initiation of a gluten-free diet without proper diagnostic work-up of coeliac disease is a frequent and demanding problem. Recent guidelines suggest a gluten challenge of at least 14 days followed by duodenal biopsy to establish a diagnosis. This approach is associated with a false negative outcome of this approach remains unclear. We aimed to study responses to 14-day gluten challenge in subjects with treated coeliac disease.

Aims & Methods: We challenged 20 subjects with biopsy-verified coeliac disease, 20 healthy volunteers and 8 confirmed mucosal remission, for 14 days with 5.7 g per oral gluten daily. Duodenal biopsies were collected. Blood was analyzed by flow cytometry using HLA-DQ/gluten tetramers, and by multiplex assay for cytokine detection.

Results: Nineteen participants completed the challenge. Villous blunting in blood appeared after 4 days of the gluten challenge but was confirmed mucosal remission, for 14 days with 5.7 g per oral gluten daily. Duodenal biopsies were collected. Blood was analyzed by flow cytometry using HLA-DQ/gluten tetramers, and by multiplex assay for cytokine detection.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP063 RAPID HOME TESTS THAT REVEAL GLUTEN-FREE DIET TRANSGRESSIONS

Introduction: To date, the only effective management of celiac disease is the adherence to a strict, lifelong gluten-free diet (GFD). However, there has been no reliable method to confirm adherence to a GFD or to ascertain whether the origin of acute symptoms in a celiac or gluten-sensitive patient may be related to gluten exposure. There is poor or no correlation of celiac serology and dietary adherence. To address this need, we recently developed laboratory tests to detect gluten immunogenic peptides (GIP) in faeces and urine, excreted after gluten consumption. Our studies demonstrated that 31-60% of adult celiac patients following a GFD have GIP in either faecal or urine samples. Additionally, there was a high correlation between GIP detection and gut mucosal damage (references 1 and 2). To facilitate the self-monitoring of the GFD by consumers, we have adapted the method to be directly used at home.

Aims & Methods: Our goal was to develop and validate a novel, rapid, home test for the monitoring of GFD adherence, which will enable celiac patients and other subjects avoiding gluten to detect GIP in faeces and urine samples by means of a lateral flow immunosassay (LFIA). A total of 233 faecal samples (75 GIP positive (+) and 158 GIP negative (-)) according to the previous laboratory tests were analyzed by the LFIA method. In addition, 290 urine samples from volun- teers under different gluten exposure conditions were analyzed with the LFIA. Faecal and urine samples included positive samples from healthy volunteers who had ingested gluten 16 hours before urine collection (n = 110), and negative samples from celiac patients on a reportedly strict gluten-free diet (n = 180).

Results: For the faecal home test, 74 out of 73 GIP (+) samples were correctly detected as positives with the LFIA. Of the 158 GIP (-) samples, 151 were correctly classified as negative by the LFIA. These results thus indicated a diagnostic sensitivity of 99% and a specificity of 96% for the home test versus the reference laboratory method. The positive predictive value of the home test method for faecal samples was of 91% and the negative predictive value was 99%. In urine, GIP were detected by the LFIA in 100 out of 110 samples of volunteers on a gluten-containing diet. No GIP were detected in 179 out of 180 samples from celiac patients on a GFD. The diagnostic sensitivity and specificity for urine LFIA were therefore 99% and 98% respectively. The positive predictive value for the urine home test was 99% and the negative predictive value was 95%.

Conclusion: The point-of-care/home tests for GIP detection in faeces and urine are highly sensitive and specific to assess adherence to GFD and to detect dietary transgressions, with superior performance over other methods. These tests will enable monitoring of the GFD to subjects avoiding gluten, including celiac patients.

Introduction: The criteria to diagnose patients with lymphocytic enteritis as coeliac disease (CD) are not well established. Increase in gamma delta+ intraepithelial lymphocytes (IEL) has been suggested as a permanent marker of CD (1, 2). The IEL normal cut-off level is not well known, and we have observed that 30% of patients with suspected CD, irrespective of the number of IEL, had increased gammadelta+ IEL.

Aims & Methods: Aim: 1) To assess predictive variables of response to a GFD in patients with lymphocytic enteritis and suspicion of CD; 2) To develop a score for diagnosing CD patients with low-grade enteropathy (coeliac-lite). Methods: From 2010 to 2016 all patients in whom duodenal biopsies were taken to rule out CD were prospectively registered. The inclusion criteria for the present study were: 1) Duodenal biopsies performed on a normal diet; 2) Absence of villous atrophy; 3) Starting with a GFD; 4) Having a follow-up biopsy. Patients were excluded if they were taking NSAI or ARFA drugs, if they had H. pylori or parasitic infection or in case of chronic and non bacterial histological response to GFD (since these patients could not be correctly classified). All included patients had clinical symptoms in the spectrum of CD and HLA-DQ2.5+ or at least one allele of the DQ2-5 haplotype. Standard histological studies and IEL flow cytometry of gamma delta+ and CD3- IEL on duodenal samples were routinely performed. In patients with sustained clinical response to a GFD, a follow-up biopsy was performed after one year. Response to a GFD was considered if there was a clinical and histological (or serological) response. The ‘gold standard’ in diagnosing a patient with CD was applied using the Catassi’s rule of ‘4 of 5’. A logistic regression analysis was performed to assess predictors of GFD response. The ORs were used to derive a new scoring system. ROC was used to define the better cut-off point.

Results: 135 patients fulfilled the inclusion criteria, 42 had normal histology and better cut-off point.

Conclusion: The ‘coeliac-lite score’ allowed to predict response to GFD and thus, to diagnose ‘coeliac-lite’ disease with an acceptable accuracy. In a quarter of patients this score provided a definitive diagnosis of CD at baseline.

Introduction: Gluten may cause gastrointestinal complaints in individuals sensitive to gluten. Aspergillus niger derived prolly endoprotease (AN-PEP) has previously been shown to degrade gluten into non-immunogenic compounds in vivo in settings in healthy subjects in which AN-PEP was added to a liquid, intragastrically infused meal.

Aims & Methods: The aim of the current study was to investigate the efficacy of AN-PEP to degrade gluten in a physiological meal setting in gluten-sensitive subjects. This randomized controlled cross-over study included 18 self-reported gluten-sensitive subjects attended three test days. A multimilen nasoduodenal feeding catheter was placed to collect gastric and duodenal aspirates. Subjects consumed a porridge containing approximately 0.5 g gluten in the form of two crumbled wheat cookies as well as two tablets either containing 160 000 PPI of AN-PEP (high dose), or 80 000 PPI (low dose), or placebo in a double-blinded, randomised manner. Gastric and duodenal content was sampled at several time points over 180 minutes and analysed for gluten epitopes using the Gluten-Tec ELISA. 180-min areas under the curve (AUC) of epitope concentration were calculated using curve fitting. Additionally, participants were asked to fill in questionnaires (GSRS) after each test day. The non-parametric Wilcoxon signed-ranked paired test at a = 0.05 with a Bonferroni correction was used to detect significant differences.

Results: AN-PEP significantly lowered the gluten concentrations in the stomach and in the duodenum compared to the placebo in both the high dose and the low dose. In the stomach, gluten levels were reduced from 218 ± 155 μg/ml (mean ± STD) in the placebo to 31 ± 24 μg/ml in the high dose (p = 0.001) and to 31 ± 22 μg/ml in the low dose (p = 0.001). In the duodenum, gluten levels were reduced from 63 ± 88 μg/ml in the placebo to 12 ± 13 μg/ml in the high dose (p = 0.019) and to 8 ± 5 μg/ml in the low dose (p = 0.015).

Conclusion: Even in a physiological meal setting, AN-PEP significantly degraded most gluten before it entered the duodenum in self-reported gluten-sensitive subjects. In those subjects, the consumption of AN-PEP was well tolerated.

Introduction: Cronh’s disease (CD) is a chronic inflammatory disorder of the gastrointestinal tract characterized by an abnormal immune response against the intestinal microbiota in a genetically predisposed host. The intestinal mucosa of CD patients is abnormally colonized by the adherent-invasive E. coli (AIEC) strains, which are able to adhere to and to invade intestinal epithelial cells (IECs), to survive and replicate within macrophages and induce a strong pro-inflammatoryresponse (1). We recently reported that AIEC infection of IECs induces secretion of epithelial miRNAs which are extracellular vesicles of 30–100 nm having a role in cell-to-cell communication (2). Exosomes secreted by AIEC-infected IECs can activate innate immune response and increase AIEC replication in exosomes-receiving IECs and macrophages (2).

Aims & Methods: This study aimed at investigating the mechanism underlying the exosomes-mediated increased AIEC replication in recipient cells. Exosomes released by uninfected human intestinal epithelial T84 cells (Exo-uninfected) or by T84 cells infected with the AIEC LF82 reference strain (Exo-AIEC), the non pathogenic E. coli K12 MG1655 strain (Exo-K12) or the commensal E. coli HS strain (Exo-HS) were purified using the ExoQuick reagent and used to stimulate T84 cells or human THP-1 macrophages.

Results: We found that stimulation of T84 and THP-1 cells with Exo-AIEC induced an autophagy activation in response to AIEC infection compared to Exo-uninfected, Exo-K12 or Exo-HS. This was due to decreased expression of several autophagy genes. In silico analysis revealed a subset of miRNAs potentially targeting these autophagy genes. Several autophagy gene-targeting miRNAs were found in exosomes with increased levels in Exo-AIEC compared to Exo-uninfected, Exo-K12 or Exo-HS. These exosomal miRNAs were then transferred from exosomes to recipient cells, inhibiting autophagy genes and therefore autophagy response to AIEC infection. This consequently led to increased AIEC replication in cells stimulated with Exo-AIEC compared to that in cells stimulated with Exo-uninfected, Exo-K12 or Exo-HS. Exo-AIEC derived from T84 cells transfected with antisense of the autophagy gene-targeting miRNAs did not carry the corresponding miRNAs and failed to inhibit autophagy activation and to increase bacterial replication in recipient cells.

Conclusion: Our study shows that upon AIEC infection, IECs secrete exosomes that can target specific miRNAs to recipient IECs or macrophages, inhibiting autophagy gene expression and thus autophagy-mediated control of AIEC replication.

**Introduction:** In mice, consumption of dietary emulsifiers, which are detergent-like components of many processed foods, disturbs the intestinal microbiota in a manner that enhances its pro-inflammatory potential and promotes its encroachment into the mucosa [1]. Such disturbance of the microbiota promotes a range of chronic inflammatory diseases, including colitis. We recently demonstrated that such disturbance of the microbiota can be recapitulated, in part, in an in vitro microbiota model, arguing that at least a portion of the effects of emulsifiers in vivo result from direct action of these compounds on the microbiota [2]. Notably, carboxymethylcellulose (CMC), a commonly used synthetic emulsifier, was found to increase the pro-inflammatory potential of the microbiota by inducing expression of flagellar-related genes, without altering species composition. Aims & Methods: We hypothesize that dietary emulsifier may directly impact the pathogenicity of adherent and invasive Enterobacteriaceae (AIEC), which are associated with Crohn’s disease, by promoting their ability to induce intestinal inflammation. AIEC reference strain LF82 was treated with emulsifiers (Carboxymethylcellulose (CMC) or Polysorbate-80 (P80)) in vitro, and the impact on virulence gene expression, whole transcriptome, and adhesion/invasion properties were investigated. Germfree mice were mono-associated with LF82 strain, and the impact of dietary emulsifier consumption on LF82 virulence and intestinal inflammation was investigated.

**Results:** Transcriptomic analysis revealed that, in vitro, CMC altered gene expression of AIEC by favoring expression of genes related to virulence and induction of intestinal inflammation. Moreover, CMC dramatically increased the adhesion ability of AIEC LF82 bacteria to intestinal epithelial cells, while P80 only slightly impacted this process. Moreover, pre-treatment of AIEC LF82 bacteria with CMC significantly increased bacterial motility while using of an isogenic flagellate LF82 strain demonstrated that flagella is playing a central role in AIEC penetration of mucus layer in vivo. AIEC LF82 mono-associated mice are currently being treated with dietary emulsifier in order to investigate the emulsifiers + AIEC combination is sufficient to induce intestinal inflammation.

**Conclusion:** Some dietary emulsifiers have the ability to directly impact micro- biota members including AIEC in a manner that potentiates their ability to promote intestinal inflammation. Our demonstration that some dietary component may directly impact the virulence of Crohn’s disease associated bacteria may explain why only a subset of AIEC positive individual develop Crohn’s disease. Hence, this research may ultimately influence dietary recommendation for AIEC carriers as risk for IBD flares or disease development.

**OP068** GUT DYSBIOSIS CAN LEAD TO VISCERAL HYPERSENSITIVITY AND DEPRESSION IN GERM-FREE RATS

L. Zhang, J. Zhang, S. Zhu, W. Zhang, L. Duan

Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: zhanglu@bjmu.edu.cn

**Introduction:** Gut dysbiosis is implicated in both irritable bowel syndrome (IBS) and depression, which are often comorbid with each other, but the causal relationship is not verified. Our previous study found similar structure but different function of gut microbiota between IBS-D and depression patients.

**Aims & Methods:** Aim: To verify whether shift of gut microbiota function can disturb brain-gut axis function by transplanting fecal microbiota obtained from IBS-D patients and depression patients to germ-free (GF) rats respectively.

**Methods:** Fecal samples from a health control, an IBS-D patient and a depression patient were recruited in our previous study were transplanted to 7 weeks old GF rats by gavage (once/rat, n = 5–6/group). Fourteen days after transplantation, fecal samples of rats were collected for 16S rRNA gene sequencing on Illumina MiSeq and short-chain fatty acids (SCFAs) measurement on UPLC-MS/MS. Open field test, sucrose preference test, forced swimming test (FST) and colorectal barostat were performed for anxiety, depression behavior and visceral sensitivity, respectively.

**Table:** Visceral sensitivity, anxiety, depression behavior and fecal SCFAs levels of recipient rats (Mean ± SE)

<table>
<thead>
<tr>
<th>SCFAs</th>
<th>Health control (n = 5)</th>
<th>IBS-D (n = 6)</th>

</tbody>
</table>

**Results:** The abdominal withdrawal reflex (AWR) is higher in IBS-D recipient (GI) rats than in health control (GH) and depression (GD) recipient rats at colorectal distension of 20 mmHg, 40 mmHg and 60 mmHg, and higher in GI and GD rats than in GH rats at 80 mmHg. The percentage of time in open field center area of GD rats was lower than that of GH and GI rats; the sucrose preference rate is lower in GD rats than in GH and GI rats; the immobile time after strong stress and GI rats in the FST was longer than that of GH rats. Principle component analysis revealed that the fecal microbiota structure of the three groups of rats was significantly different. Fecal formate level was higher in GI rats than in GH and GD rats; fecal acetate and propionate levels were higher in GI rats than in GD and GI rats; fecal valerate level was lower in GD rats than in GH rats (see Table).

**Conclusion:** Gut microbiota from IBS-D patients can lead to visceral hypersensitivity, from depression patients can lead to depression behavior in GI rats. Those suggest an important role of gut microbiota in the pathogenesis of IBS-D and depression; and provide clues for the influence of gut microbiota on brain-gut axis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**OP069** INFLAMMATION MODULATION BY STOMACH MICROBIOTA VIA TLR2/NF-KB SIGNALING PATHWAY IN HP-INDUCED GASTRIC CANCER

Y. Dang, G. Zhang

Department Of Gastroenterology, The First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: yeany_zhi@126.com

**Introduction:** The mechanisms of Helicobacter pylori (HP) initiated cancer have not been well studied. Our previous studies demonstrated that 1) stomach microbiota interacted dynamically within the development from gastritis to gastric cancer; 2) TLR2/NF-KB signaling pathway can be activated by HP infection; the overexpression of TLR2 played an important role in the interaction between HP and non-Hp bacteria; 3) significantly more butyrate was observed after Hp infection, it promoted the proliferation and migration of AGS cell, and up-regulated the expression of TLR2 and NF-KB.

**Aims & Methods:** This study investigated how the stomach microbiota transformed within the development from gastritis to gastric cancer; 2) how the TLR2/NF-KB signaling pathway is activated via the interaction between Hp and non-Hp bacteria. Tissue samples of chronic gastritis, atrophic and IM gastritis, and early gastric cancer were collected through endoscopy. WT and TLR/KO mice were used to build Hp infection animal models. Comprehensive Illumina Miseq microbiota was used to analyze microbiota constructions in clinical samples and animal models. HPLC was used to detect short chain fatty acid (SCFA) in gastric tissue. IHC, Western blot were used to observe TLR2 and NF-KB expression. Inflammatory cytokines such as IL-1β, IL-6, IL-8, TNF-α were tested by real-time PCR. Cell function tests including CCK8 and Transwell were performed in AGS and SGC7901 cells.

**Results:** Bacterial composition analysis in chronic gastritis, atrophic and IM gastritis, and early gastric cancer tissue by Illumina Miseq microbiota demonstrated that 1) Hp was detected in five samples, 2) the total amount of...
Neisseria in the atrophic and IM gastritis sample was nine times more than that in the atrophic and IM gastritis sample. The total amount of *Haemophilus parasuis* in the atrophic and IM gastritis sample was four times more than that in the chronic gastritis. 4) the worse the condition, the more the Pseudomonas, Sphingomonas, Chryseobacterium, Ruminococcus. In addition, it was also found that Hp infection can upregulate TLR2 expression, in turn TLR2-activated RelA/p65 can increase the levels of IL-1/IL-6/IL-8/TNF-α. The total amount of Hp, Clostridium leptum, Clostridium quinshall were increased and Lactobacillus, Enterobacteria, non-Helicobacter were decreased after Hp infection in WT mice. The amount of class Cladostia and class Bacilli showed no significant change after Hp infection in TLR2/KO mice. It was also observed that increased butyrate model can promote proliferation and migration of AGS cells after Hp infection.

Conclusion: Hp infection can induce the alteration of stomach microbiota via the up-regulation of TLR2, in turn leads to the imbalance of stomach microbiota characterized by the increase of butyrate-producing bacteria. Thereafter, TLR2/NF-κB signaling pathway can be activated by the overexpressed butyrate and then promote cytokines at the downstream can also be up-regulated by RelA/p65. All the newly found interactions between bacteria and signaling pathway may finally contribute to the epithelial transformation.

Introduction: In association with innate and adaptive immunity, the microbiota controls the colonization resistance against intestinal pathogens. Caspase recruitment domain 9 (CARD9), an inflammatory bowel disease susceptibility gene, is required to shape a normal gut microbiota. CARD9 mice are more susceptible to the enteric mouse pathogen *Clostridium rodentium* that mimics human infections with enteropathogenic and enterohemorrhagic *Escherichia coli*. Here, we examined how CARD9 controls *C. rodentium* infection susceptibility through microbiota-independent mechanisms.

Aims & Methods: *C. rodentium* infection was assessed in conventional and germ-free (GF) wild-type (WT) and Card9−/− mice. To explore the impact of Card9−/− microbiota in infection susceptibility, GF WT mice were colonized with WT (WT→GF) or Card9−/− (Card9−/−→GF) microbiota before *C. rodentium* infection. Mice were fed a standard diet or a customized version of standard diet in which polysaccharides (PS) or monosaccharides (MS) were used as hydrocarbon source. Microbiota composition was determined by 16S DNA gene sequencing. Inflammation severity was determined by histology score and lipocalin level. Microbiota – host immune system interactions were assessed by qPCR analysis.

Results: The specific intestinal immunoglobulin (Ig) G response against *C. rodentium* was impaired in GF Card9−/− mice compared to GF WT mice. Moreover, heightened *C. rodentium*-induced colitis was observed in Card9−/−→GF mice. Gut microbiota composition of Card9−/−→GF mice was altered and inferred metagenomics revealed that Card9−/−→GF gut bacteria used monosaccharides. MS diet increased *C. rodentium* susceptibility in Card9−/−→GF mice whereas PS diet rescued the phenotype. The specific intestinal IgG response against *C. rodentium* was increased in Card9−/− mice fed the PS diet compared to Card9−/− mice fed the MS diet. Interestingly, the specific intestinal humoral response was also defective in WT mice fed the MS diet compared to WT mice fed the PS diet.

Conclusion: CARD9 controls pathogen virulence in a microbiota-independent manner by supporting a specific humoral response. The microbiota of Card9−/− mice failed to outcompete the monosaccharide-consuming *C. rodentium*, worsening the infection severity. A polysaccharide-enriched diet counteracted the ecological advantage of *C. rodentium* and the defective pathogen-specific antibody response in Card9−/− mice. Thus, CARD9 modulates the susceptibility to intestinopathogenic pathogens virulence independently of the microbiota and by shaping a microbiota competing with pathogens. Genetic susceptibility to intestinal pathogens can be overridden by diet intervention that restores humoral immunity and a competing microbiota.

Introduction: Although gut protection to infections is ensured by innate lymphoid cells (ILCs), how ILCs are regulated remains poorly understood. Here, we show that secretion of the c-type lectin Reg3b downstream of Ripk2 signaling pathway was crucial for immune surveillance by ILCs against *Citrobacter rodentium* that mimics human infection with enteropathogenic and enterohemorrhagic *Escherichia coli*. We aimed to identify crucial factors that impact clearance of *C. rodentium* in mice. Ripk2 KO, Reg3b KO, and wild-type mice were orally inoculated with *C. rodentium* and infection course was monitored for three weeks. Sampling was performed on days 0 (pre-infection), 7, and 14. Microarray analysis was performed on total tissues from cecum. Total tissue was further analyzed by histology, qPCR, Western blot, and flow cytometry. Lamina propria mononuclear cells (LPMCs) from *C. rodentium*-infected Ripk2 KO, Reg3b KO, and wild-type mice were isolated through cell sorting and co-culture experiments were performed with intestine-derived ILCs to assess cytokine secretion.

Results: We found that Ripk2 signaling significantly controls epithelial Reg3b expression, which is required for efficient control of *C. rodentium* infection. Both, Ripk2 KO and Reg3b KO mice displayed an enhanced susceptibility to *C. rodentium*-induced colitis associated with an impaired clearance of the pathogen. Phosphorylation of signal transducer and activator of transcription 3 (STAT3) was decreased in both tumoral and colonic macrophages of *C. rodentium* infected mice. STAT3 phosphorylation downstream of Reg3b secretion was not observed. Cytokine secretion by intestinal phagocytes lowering their propensity to promote IL17A secretion by ILCs early in infection.

Conclusion: These results provide a previously unrecognized mechanism by which intestinal epithelial cells reciprocally regulate production of IL-17A by ILCs promoting immunophagocytic and enterohemorrhagic bacterium.

Contact E-mail Address: szh0722@163.com

Introduction: IBD, a chronic recurrent autoimmune disease, is currently associated with poor prognosis. We need explore new therapeutic strategies for IBD. Intestinal flora is closely related to the pathogenesis of IBD. In order to explore the role of probiotics in the treatment of IBD, we use the family of *Clostridium* enteritidis XVa, which has a strong regulatory effect on the development and differentiation of Treg cells, and its community stability in the intestine determines the homeostasis of intestinal mucosal tolerance [1]. Does *R. intestinalis* have an anti-inflammatory effect in IBD? Receptors which are associated with bacterial identification contain TLR2, TLR4 and TLR5 in the TLRs family [2]. Our early study has found that *R. intestinalis* was able to up-regulate expression of TLR5, whereas it had little effect on TLR2 and TLR4. Does the regulation of intestinal microbial immunity by *R. intestinalis* achieve via TLR5 signaling? *R. intestinalis* in IBD No reports have been reported at home and abroad.

Aims & Methods: To elucidate the anti-inflammatory effect and mechanism of *R. intestinalis* in IBD, we propose to investigate the effects of *R. intestinalis* on Disease Activity Index (DAI) score, intestinal pathologies, the expressions of TLR5, TSLP, TGF-β, and the differentiation of Treg cells by using TNBS colitis models. At the cellular level, we use the human colon epithelial cell line Caco-2, overexpressing and silencing of TLR5 in HEK293 and Caco-2.
cells respectively to conduct inflammatory cell model with LPS and then co-culture with different concentrations of R. intestinalis (Ratio of bacteria and cells were 10:1, 5:1 and 1:1; namely R:I, R:12 and R:13) and detect changes of TSLP and TGF-β.

Results: R. intestinalis significantly decreased DAI scores (the day before mice were killed) in the Control group, TNBS group and TNBS+ R. intestinalis groups were 0.4±0.26, 2.33±0.14 and 1.25±0.3 respectively. Compared with the TNBS group, the DAI score of TNBS+ R. intestinalis group decreased, P < 0.05.

R. intestinalis reduced the degree of shortening of the colon (P < 0.05), and played the anti-inflammatory role by up-regulating the levels of TLR5, TSLP and Caco-2 significantly increased secretion of TSLP and TGF-β levels of the cells (P < 0.05). The co-culture supernatant TSLP of the control group, LPS group, LPS + R:11, LPS + R:12 and LPS + R:13 were (5.88±0.45pg/ml, (3.38±0.19pg/ml, (5.88±0.85pg/ml, (53.1±0.12) pg/ml and (4.97±0.62)pg/ml respectively. The co-culture supernatant TGF-β of the control group, LPS group, LPS + R:11, LPS + R:12 and LPS + R:13 were (394.23+75.935)pg/ml, (249.66±18.50)pg/ml, (415.1±12.58)pg/ml, (385.5±0.70)pg/ml and (412.6±30.54)pg/ml respectively. So it is with the results of Western blot and Real-time PCR. While the silencing of TLR5 cells did not change these cytokines.

Conclusion: R. intestinalis might promote the secretion of TSLP and TGF-β from intestinal epithelial cells via TLR5, thus inducing the differentiation of the Treg cells.

Aims & Methods: We aim to identify sex-related molecular changes in the intestinal barrier in response to acute stress in healthy individuals as an initial step to understand the gender bias in inflammatory disease development. Methods Thirty-six healthy individuals (17 M and 19 F) were recruited. In each participant, two consecutive jejunal biopsies were obtained by Watson's capsule: the first at baseline and the second 90 min after 15 min of intermittent cold pain stress (CPS). Autonomic (blood pressure and heart rate), hormonal (plasma cortisol) and cytokine responses were measured. Stress Ratering Scale (SRS) was completed and measured throughout the study. Total mucosal RNA was isolated and expression levels of epithelial barrier (CLDN2, SLC26A3, TJP1 and TJP3) and mast cell activation-related genes (tryptase: TPASB1, SERPIN1) were analyzed by RT-PCR. Results: CPS induced a significant autonomic response characterized by increased heart rate, blood pressure, and plasma cortisol in association with enhanced stress perception in all participants. CPS increased CLDN2 and SLC26A3 expression (Fold vs. basal: 1.3, p = 0.002), and decreased SLC26A3 gene expression (Fold vs. basal: 0.7, p < 0.001). Interestingly, gene expression studies also uncovered differential responses to acute stress between M and F. Particularly, in the F group CPS induced an increased expression of TPSAB1 (expression Fold vs. basal: [F]: 1.1; [M]: 0.9; p = 0.012) along with a decrease in TJP1 (Fold vs. basal: [F]: 0.9; [M]: 1.1, p = 0.042) and a trend for TJP3 (Fold vs. basal: [F]: 1.0; [M]: 1.1; p = 0.08). Significant positive correlations between CPS-induced changes in TPASB1 and CLDN2 (r = 0.706, p = 0.002), and between TJP1 and TJP3 (r = 0.838, p < 0.001) were found.

Conclusion: Specific and independent gender-related molecular responses in epithelial barrier regulation are unraveled by acute stress exposure in the jejunum of healthy subjects. These molecular differences may explain, in part, female predominance in IBS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims: To identify stress-mediated circadian rhythm changes in the intestinal mucosa, being circadian rhythm regulation the most relevant biological variables were recorded throughout the study. Mucosal RNA was isolated and analyzed by microarray analysis followed by differential gene expression and pathway identification and qPCR validation.

Results: CPS significantly increased heart rate, blood pressure and plasma cortisol, as well as stress perception in all participants. Stress significantly modified the mucosal transcriptome, being circadian rhythm regulation the most relevant biological function (P = 0.00001), with a significant decrease in specific clock genes (NFE2L2, NFIL3, NR1D1, NR2D2, PER1, PER3; P < 0.05).
Moreover, CPS altered epithelial barrier integrity gene expression (increasing CLDN2 and decreasing SLC26A3; P < 0.05). Notably, significant association was found between representative genes of the most significant biological functions altered by stress (Table 1).

Results: We received samples from 119 individuals with IBS, 186 asymptomatic controls and 114 individuals with unspecific GI symptoms. There was no difference in richness between the IBS (117.6 (standard deviation (SD): 16.6)) and control group (115.8 (SD: 16.6), p = 0.36), but richness was higher in samples from individuals with unspecific GI symptoms (126.0 (SD: 21.0), p < 0.01). Diversity was also higher in the IBS group compared with unspecific GI symptoms (0.307 (SD: 0.31), p = 0.06) and did not differ between the IBS (3.00 (SD: 0.29)) and the control group (2.98 (SD: 0.32), p = 0.59). Richness and diversity were significantly higher in parasite-positive samples across all four categories (Tables 1). For asymptomatic controls and those with unspecific GI symptoms, richness was higher for parasite-positive samples in all categories (Table 1). However, this did not apply to those with IBS symptoms. Diversity was higher for all categories of parasite-positive samples from individuals with unspecific GI symptoms and asymptomatic controls (with exception of multiple parasites) (Table 1). For those with IBS, diversity was only higher in relation to presence of Blastocystis or multiple parasites (Table 1). Number of observed operational taxonomic units and Shannons diversity index according to parasite colonization status, specified for symptom group. Difference in mean between positive and negative samples tested by two sided t-test.

Conclusion: Colonization with parasites, including D. fragilis and Blastocystis, was linked to increased microbiome diversity and richness. However, for individuals with IBS, the association to increased richness could not be confirmed and no association to increased diversity was observed for samples positive for any parasite or D. fragilis. This could reflect an altered relationship between bacteria and parasites in IBS. The clinical and public health significance of these findings should be explored in greater detail.

ADVANCES IN ENDOSCOPIC IMAGING: WHAT DOES THE FUTURE HOLD? - ROOM E2

OP077 ENDOSCOPIC MACROSCOPIC TYPE IS A SIGNIFICANT PREDICTOR FOR HISTOLOGICAL TYPES OF EARLY GASTRIC CANCER
T. Kanesaka1, T. Nagahama2, N. Uedo1, H. Doyma3, T. Ueo4, K. Uchita5, H. Ishikawa4, K. Yau6

6Department Of Molecular-targeting Cancer Prevention, Kyoto Prefectural University of Medicine, Kyoto/Japan

Introduction: Gastric cancer is classified into the differentiated and undifferentiated types according to the degree of histological differentiation. The risk of lymph node metastasis of undifferentiated-type early gastric cancer is higher than the differentiated type. 1, 2, 3 therefore these indication criteria for endoscopic resection are different.4

Aims & Methods: This study aimed to clarify the diagnostic abilities of clinical predictors for distinguishing between differentiated-type early gastric cancer and undifferentiated-type early gastric cancer. This was a post hoc study of a multicenter prospective trial in five Japanese hospitals (clinical trial registration number: UMIN000014628). In the trial, 384 patients with eT1 gastric cancer were enrolled and 343 patients were analyzed. According to the protocol, age, gender, and the endoscopic findings of cancer (location, macroscopic type,
diameter, and invasion depth) were evaluated and the final diagnosis using the result was confirmed. All data of the present study were evaluated before the final diagnosis using the resected specimens. In this study, associations between those clinical factors and histological types of cancers were evaluated. Then, those diagnostic abilities for differentiated-type early gastric cancer were calculated. Diagnostic abilities of foresips biopsy were also calculated as a reference.

Results: Multivariate analysis identified older age ($\geq 72$), male, elevated type, and shallower invasion depth ($\leq 10$ mm) as independent significant predictors for differentiating early gastric cancer. Elevated type cancer had the highest sensitivity, specificity, accuracy, positive likelihood ratio, and negative likelihood ratio of it for differentiated-type early gastric cancer were 25.1%, 94.8%, 90.5%, 9.7, and 0.09. Those of the foresips biopsy were 95.6%, 94.8%, 21.1%, 1.0, and 0.09. Conclusion: Elevated type cancer is significant predictors for differentiated-type early gastric cancer and may exclude undifferentiated-type early gastric cancer without a foresips biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP079 THE MOLECULAR BASIS OF 5-AMINOLEVULINIC ACID (ALA)-MEDIATED LASER-BASED PHOTODYNAMIC ENDOSCOPIC DIAGNOSIS (LPDED) FOR DIVERSE EARLY GASTRIC CANCER

1Division Of Medicine And Clinical Science, Tottori University Faculty of Medicine, Yonago, Japan
2Department Of Gastroenterology And Hepatology, Nagasaki University Hospital, Nagasaki, Japan

Contact E-mail Address: kurumi_1022_1107@yahoo.co.jp

Introduction: Laser-based photodynamic endoscopic diagnosis (LPDED) is an emerging technology for the detection and differentiation of early gastric cancer in the excised samples. Its accuracy has already been established in the histopathological diagnosis of early gastric cancer. In this study, we report the accuracy of LPDED in the detection of differentiated-type early gastric cancer.

Methods: The present report is the results of a prospective study conducted in the Division of Medicine and Clinical Science, Tottori University Faculty of Medicine. During the period from January 2015 to December 2017, 120 patients with early gastric cancer were included in this study. The patients were subjected to LPDED and histopathological examination. The results of LPDED and histopathological examination were compared.

Results: The results of LPDED and histopathological examination were compared. The accuracy of LPDED in the detection of differentiated-type early gastric cancer was 94.2%.

Conclusion: LPDED is a reliable tool for the detection of differentiated-type early gastric cancer.

Aims & Methods: In this work we explored different application scenarios of VR in endoscopy to overcome common problems in daily work and improve training experience. The head-mounted display (HMD) HTC VIVE was used to visualize the datasets generated during gastroenterological work-up. Training videos of different endoscopic procedures like advanced polypectomy, closure of a perforating duodenal ulcer, and gastrointestinal bleeding were recorded in high-definition real-time endoscopy and helped during interventions. Still interface problems like acquiring 3D images using standard endoscopes need to be investigated in future work. This work was supported by the German Science Foundation (DFG) under Grant FOR 1321.

Aims & Methods: The electronic patient records were studied of all patients diagnosed in 2016 with UGI cancer within our institution, with a serves a population of 350,000. For those patients who had undergone an UGI endoscopy, in the preceding 3 years, demographics, site and stage of lesion and outcomes were recorded. Endoscopy KPIs were reviewed for the prior examination.

Results: 9187 UGI endoscopies were performed in 2016. UGI cancer identified 95 patients, of which 7 (7.38%) had an endoscopy in the preceding 3 years; however 1 within national guidance for gastric ulcer follow-up (initial histology negative for dysplasia), 85.7% were male. Mean age 68 years. All presented with UGI alarm symptoms: 4 oesophageal and 3 non-junctional gastric cancers. 42.3% have been offered treatment with curative intent, but unfortunately the remainder were offered palliation due to co-morbidity and/or advanced stage at diagnosis. The prior endoscopies were undertaken for investigation of persistent dyspepsia (47%), anemia (27%) and variceal assessment. Mean interval between diagnostic and earlier endoscopy was 20 months (range 1–31 months). All past endoscopies were undertaken by different operators; 3 consultants, 3 nurse endoscopists and a specialist doctor. All but 1 endoscopist had an individual ‘miss’ rate of <1% of their mean annual UGI procedural numbers. 57.1% were done without sedation, all provided evidence of duodenal intubation but the ‘3’ manoeuvre was not recorded.

tumor characteristics, surgical and pathological outcomes are summarized in Table 1. MDPC successfully predicted resection in 64 out of 70 patients (91.4%). Six patients were found to have metastatic disease on surgical exploration. 78.6% (55/70) patients had R0 resections and 12.8 % (9/70) patients had R1 margins. There were no grossly positive margins (R2 resection). Patients went to surgery at a median of 22 days from diagnosis and 15 days from the MDPC decision to resect.

Table 1: The demographic, clinical characteristics, surgical and pathologic outcomes of 70 patients explored for ‘resectable’ pancreatic cancer. Outcomes were analyzed on an intention-to-treat basis as all patients underwent surgery with curative intent.

Conclusion: A MDPC demonstrated a high rate of predicting resectability along with achieving a high percentage of R0 resections at an experienced center. Data from other large centers may help validate the importance of utilizing a MDPC to predict resectability. Moreover, benchmark R0 resection rates are needed and can provide a quality metric for the treatment of resectable pancreatic cancer.

cultured from PLD patients with PRKCSH mutation, patients without mutation and patients with other PBD mutations were grouped in a separate group without a clear expression pattern within their group. PRKCSH mutants shared expression of a subset of genes. The changes indicate endoplasmic reticulum related processes, such as 'protein folding in endoplasmic reticulum' and 'response to endoplasmic reticulum stress'. Mass-spectrometry analysis distinguishes glycopeptide profiles from cyst fluid of PLD patients with (n = 4) and without (n = 8) PRKCSH mutation.

Conclusion: These data strongly suggest a specific defect in protein maturation and localization in the endoplasmic reticulum, and protein glycosylation play a role in the development of hepatic cysts in PLD patients.

OP088 A SYSTEMATIC REVIEW ON THE DEVELOPMENT OF MALIGNANCY AFTER CHOLEDOHAL MALFORMATION
1Department Of Hepato-pancreatico-biliary Surgery And Liver Transplantation, University of Groningen and University Medical Center Groningen, Groningen/Netherlands
2Department Of Pediatric Surgery, University of Groningen and University Medical Center Groningen, Groningen/Netherlands

Contact E-mail Address: anneketenhove@me.com

Introduction: Choledohal malformation (CM) comprises a variety of rare congenital cystic dilatations of the extrahepatic and/or intrahepatic biliary tree, classified according to Todani. Its etiology remains unclear. Although CM is generally considered a premalignant condition, the literature with respect to the risk of malignancy and optimal surgical treatment has not been reviewed systematically. Partly due to its rarity, guidelines for treatment and follow-up are difficult to establish.

Aims & Methods: The aim of this systematic review was to assess the prevalence of malignancy in CM and the differences between its subtypes. Secondary goal was to investigate the risk of malignancy following a cystic drainage procedure versus complete cyst excision.

Methods: This systematic review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement and was registered in PROSPERO, the international prospective register of systematic reviews (ERP2016048392). A systematic search of PubMed and Embase was performed for articles published between January 1995 and June 2016 (cut-off date June 1st, 2016) relevant to malignancy prevalence and/or malignancy in patients with CM. A meta-analysis on the risk of malignancy following cystic drainage procedure versus complete cyst excision was carried out in accordance with the Meta-analysis Of Observational Studies in Epidemiology (MOOSE) guidelines.

Results: We included 18 observational studies with a total of 2904 patients, median age 36 years (range 0-87), 76% female. Overall, 312 (2904 patients developed a malignancy (10.7%). In 212 patients (7.3%) tumors were present during initial surgery, in 100 patients (3.4%) tumors developed during follow-up. The median age at detection of malignancy was 49.5 years (range 12–82 years). Malignancy occurred mainly in CM type IV cysts (in 14%). In CM type I, II, III, and V the malignancy rate was 9%, 3%, 8%, and 6%, respectively (Pearson χ², 17, 986, 4 df, P = 0.001). Of 18 observational studies identified, 9 studies included all CM patients; 9 studies included only CM patients that were subjected to meta-analysis of the different surgical techniques. Compared with patients who underwent complete cyst excision followed by bilo-digestive reconstruction, those who underwent a cystic drainage procedure had a significantly increased risk to develop a biliary malignancy (odds ratio 3.39, 95% confidence interval 2.3% to 10.3% (P = 0.001).

Conclusion: Overall, some 11% of patients with CM may develop a malignancy, especially those with type IV and type I cysts. Patients treated with a cystic drainage procedure had an up to fourfold increased risk to subsequently develop a malignancy following surgery, compared to those who underwent complete cyst excision. Reoperation with complete cyst excision in these patients should be considered. Malignant transformation may occur up to 30 years after initial surgery, therefore careful monitoring of these patients is mandatory, especially those patients who underwent cystic drainage procedures and those with CM types I and IV.

DRUGS, LIVER AND PANCREAS - ROOM B5

OP089 A NOVEL IN VITRO TEST FOR CAUSALITY ASSESSMENT IN POLYMEDICATED PATIENTS WITH DRUG-INDUCED LIVER INJURY: CASES WITH DRUG RECHALLENGE
A. Benesic1, D. Dragon1, I. Rotter2, M. Buchholz3, A. Leitl2, A. L. Gerbes2
1MetaHeps GmbH, Martinsried/Germany
2Internal Medicine 5 Liver Centre Munich, University Hospital Munich (KUM), Munich/Germany
3Laboratory Medicine, University Hospital Munich, Munich/Germany

Contact E-mail Address: abenesic@metaheps.com

Introduction: Idiosyncratic drug-induced liver injury (iDILI) is one of the most challenging diagnoses in hepatology [1]. Drug metabolism, iDILI aetiologies of liver damage in combination with typical drug signatures. Correct causality assessment may be impossible in polymedicated patients. We have investigated a novel in vitro test employing monocyte-derived hepatocyte-like (MH) cells and its possible use to support causality assessment in polymedicated iDILI.

Aims & Methods: This study prospectively included patients with suspected iDILI referred to the University Hospital Munich. Patient data for causality assessment and all drugs and cell generation were collected. Diagnosis by expert review was used as reference standard. Additionally the RUCAM score was calculated. MH cells were generated by a proprietary protocol[2], and were treated with the respective drugs and toxicity response was determined by release of lactate dehydrogenase, Tel-PCR and panel analysis was performed as described in [3]. Performance of MH testing in drug causality was assessed in a subset of patients with data on positive or negative drug rechallenge.

Results: A total of 146 patients were included, 93 adjudicated as iDILI and 53 patients with liver injury unrelated to medication. A majority of the iDILI patients was exposed to at least two drugs (n = 79, 85%). In the subset of 120 polymedicated patients (n = 79 iDILI; 41 non-DILI) the RUCAM test sensitivity was 86% and specificity was 98% for iDILI diagnosis, respectively. In polymedicated cases RUCAM showed a sensitivity of 73% and a specificity of 81%, respectively. In 32 polymedicated iDILI patients re-exposures occurred: of 11 drugs with invalid negative rechallenge results were correctly identified by the MH cell test. All of the 69 drugs that showed negative re-exposure were negative in the MH cell test.

Conclusion: Polymedication is a very frequent issue in iDILI causality assessment. RUCAM has a low sensitivity in polymedicated cases, and as such it lacks sensitivity for iDILI diagnosis and drug causality in polymedicated iDILI patients with rechallenge. Thus, the MH cell test seems to be a valuable tool for causality assessment in complex iDILI cases.

OP090 SCREENING RATE FOR HEPATITIS B VIRUS AMONG CANCER PATIENTS RECEIVING CHEMOTHERAPY IN TAIWAN: A NATIONWIDE POPULATION-BASED STUDY
1Division Of Gastroenterology And Hepatology, Department Of Internal Medicine, Kaohsiung Veterans General Hospital, Kaohsiung City/Taiwan
2Research Center Of Medical Informatics, Kaohsiung Veterans General Hospital, Kaohsiung City/Taiwan

Contact E-mail Address: maudiusin@gmail.com

Aims & Methods: The aim of this study was to evaluate the screening rate for HBV among cancer patients receiving chemotherapy in Taiwan. We collected data from National Health Insurance Research Database in Taiwan on cancer patients receiving chemotherapy from January 1, 2000 to December 31, 2012. The data were collected regarding age, gender, case-loading, department, and specialist of doctor administering chemotherapy, age, gender, and department of patient, type of cancer, and HBV testing (HBsAg, anti-HBc, and anti-HBs) within 2 years prior to chemotherapy. HBV screening was identified based on testing code A108. Overall screening rates were compared between different types of cancer, departments of patient, and time periods before and after the announcement of Taiwanese guideline and the implementation of NIH regulation. Annual percentage change of screening rate and factors associated with screening were also investigated.

Introduction: Many clinical practice guidelines recommend that all cancer patients should be screened for HBV infection before chemotherapy, but the screening rate of 14% - 34% reported from previous studies remains unsatisfactory. In Taiwan, an endemic area of HBV infection, HBV testing (HBsAg, anti-HBc, and anti-HBs) among cancer patients receiving chemotherapy in Taiwan. We collected data from National Health Insurance Research Database in Taiwan on cancer patients receiving chemotherapy from January 1, 2000 to December 31, 2012. The data were collected regarding age, gender, case-loading, department, and specialist of doctor administering chemotherapy, age, gender, and department of patient, type of cancer, and HBV testing (HBsAg, anti-HBc, and anti-HBs) within 2 years prior to chemotherapy. HBV screening was identified based on testing code A108. Overall screening rates were compared between different types of cancer, departments of patient, and time periods before and after the announcement of Taiwanese guideline and the implementation of NIH regulation. Annual percentage change of screening rate and factors associated with screening were also investigated.

Results: Of 379,639 cancer patients, 174,141 (45.9%) received pre-chemotherapy HBV screening. Of patients with screening, 73.2% were tested for HBsAg, 22.1% for HBsAg/anti-HBc, and 4.7% for HBsAg/anti-HBc/anti-HBs. The overall screening rate was 79.5% for hematological cancer and 43.6% for solid cancer; 55.3% for patients from medical departments and 30.9% for those from surgical departments; 38.1% during 2000–2008 and 57.5% during 2009–2012 (p < 0.0001). The annual screening rate for all patients increased from 31.5% in 2000 to 66.3% in 2012, from 64.5% to 90.7% for those with hematological cancer, and from 28.7% to 64.6% for those with solid cancer (p < 0.0001). There was a higher rate of screening rate by 35.9% for solid cancer than by 26.2% for hematological cancer (p < 0.0001). Factors significantly associated with HBV screening were treatment by younger doctor, female doctor, specialist, medical doctor, and doctor with higher-volume case-loading, younger patient, male patient, hematological cancer, and the time period during 2009–2012 (p < 0.0001).

Conclusion: The screening rate for HBV in cancer patients before chemotherapy is still suboptimal. Although the public policy can increase the screening rate, there are some barriers needed to be overcome to improve the awareness about HBV reactivation during chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this nationwide study, we aimed to assess the clinical, biochemical, radiological and histological characteristics of NRH in order to identify risk factors and the clinical course of this disease. We requested the departments of gastroenterology and hepatology from all Dutch hospitals (n = 28) to participate in the study. Questionsnaires were sent in order to collect data on demographics, clinical presentation, blood counts, liver chemistry and abdominal imaging.

Results: In total, 72 hospitals (89%) responded to our primary questionnaire. Based on the completed questionnaires, approximately 22,500 IBD-patients are treated with thiopurines, annually. Out of a total of 85 identified cases of NRH, 54 were thiopurine using IBD-patients (64%); 38 men, mean age at NRH diagnosis 49 years (range: 17–74), mean disease duration 17 years (range: 3–44). Of these, 35 patients were (historically) treated with azathioprine (65%), 18 with mercaptopurine (33%) and 25 with thioguanine (46%). Of the NRH patients exposed to thioguanine, 80% received azathioprine and/or mercaptopurine before. At the time of diagnosis, 58% of the patients had thrombocytopenia, 45% had elevated liver enzymes and 63% had liver-related abdominal pain at abdominal imaging. Furthermore, 20 out of 54 patients (37%) presented with signs of portal hypertension (i.e. esophageal varical bleeding in 45%, thrombocytopenia in 95%, splenomegaly in 55% and ascites in 10%).

Conclusion: In this largest NRH case series to date, the majority of the patients were men (70%) and had an asymptomatic clinical presentation (63%) at time of diagnosis, consistent with earlier literature reports.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
1. Vernier-Massouille G, Cosnes J, Lemann M, et al. Nodular regenerative hyperplasia (NRH) of the liver is a poorly understood condition which has previously been related to, amongst others, the use of thiopurines in patients with inflammatory bowel disease (IBD). The diagnosis and management of NRH are challenging since the natural history of this disease is unknown, and the clinical presentation varies from asymptomatic to severe complications of portal hypertension, such as variceal bleeding or ascites.

Aims & Methods: The aim of this systematic review and meta-analysis was to evaluate the association between the use of statins and the risk of developing AP. The inclusion and exclusion criteria were defined according to the PRISMA statement. Pooled adjusted ORs with corresponding 95% CIs were estimated. Analyses were performed using RevMan 5.3. Studies were sorted by decision of a third author. Eligible studies were selected according to the PRISMA statement. Pooled adjusted ORs with corresponding 95% CIs were calculated using random effects model. Publication bias was assessed through Begg and Mazumdar test. Heterogeneity was assessed by means of the I² value. The latest meta-analysis on this topic evaluated only clinical trials, excluding observational studies and found a reduced risk of AP in statin users.

Conclusion: The results of the first meta-analysis of observational studies for the association between statin use and AP suggest the absence of an increased risk in statin users. Evidence for an increased risk is limited to case-control studies, while cohort studies showed no global effect, similarly to previous data from controlled trials. Further research on the topic is needed to clarify whether statin type, dosage, length of use, or ethnicity of AP might account for this difference.

Introduction: Ozanimod, an oral, once-daily immunomodulator designed to selectively target S1P1R and S1P4R, has demonstrated clinical efficacy in ulcerative colitis (UC) for induction and maintenance therapy in the TOUCHSTONE trial (Sandborn NEJM 2016). The objective of the open-label extension (OLE) of the TOUCHSTONE trial is to evaluate the long-term efficacy and safety of daily 1 mg ozanimod treatment in patients with moderate to severe UC who had initially participated in the TOUCHSTONE trial for up to 32 weeks.

Aims & Methods: A total of 197 patients were randomized (1:1:1) and treated to receive double-blind placebo (PBO) or ozanimod at weeks (wks) 0 and 2 during the 6-wk induction phase (intent-to-treat population). Mayo clinic subscores of SF and RB were evaluated at wks 2, 4, and 6 wks. Mean subscores and mean percent change from baseline (BL) were reported for the overall population and in those who were tumour necrosis factor antagonist (anti-TNF) naïve.

Results: In anti-TNF-naïve patients, greater percentage decreases in mean SF subscores from BL were observed with ozanimod than with PBO, reaching statistical significance at wks 4 and 6 as indicated by the non-overlapping 95% confidence intervals (CIs) (Table). The same trend was observed in the overall population with out reaching statistical significance. Similarly, a numerically greater percentage decrease from BL in RB subscore was observed with ozanimod than with PBO, reaching statistical significance at wk 6 in both anti-TNF-naïve and overall populations. Significantly larger percentages of patients overall achieved SF subscore ≤1 or RB subscore of 0 with ozanimod than with PBO at wk 6 and as early as wk 2 among the anti-TNF-naïve population. A composite of SF subscore ≤1 and RB subscore of 0 was achieved in a significantly greater percentage of patients with VBZ than with PBO at all time points (Table).

Conclusion: Symptomatic improvements were achieved with VBZ as early as wk 2, with greater differences from PBO observed in anti-TNF-naïve patients. Taken together, these results highlight the rapid onset of VDZ in UC, however, assessing clinical efficacy at wk 14 and beyond for those who exhibit a more gradual response should be used to inform clinical practice.

Introduction: By recent advances of immune-biological therapy for UC, the clinical outcomes of UC have been improved. However, intractable cases, in which mucosal regeneration is disturbed, cannot yet be treated well even by the most advanced anti-inflammatory biological therapies. Indigo naturalis (IN), contains highly concentrated aryl hydrocarbon receptor (AhR) ligands, which has the effect for mucosal regeneration via AhR-interleukin-22. Therefore, IN may be effective for inducing mucosal healing in ulcerative colitis (UC). More recently, we reported the efficacy of IN for UC patients who were refractory to conventional treatments in a prospective study, and approximately 70% of patients had clinical response within 8 weeks after the treatment. However, there have been no double-blind trials which demonstrate the efficacy of IN and its appropriate doses are unclear.

Aims & Methods: In this study, we have evaluated the efficacy and safety of IN in terms of the dose dependency. This multicenter, double-blind trial evaluated the safety and efficacy of IN in 86 patients with active UC. An independent centre randomly allocated UC patients (Mayo score of ≥6) to four treatment groups to receive IN (daily dose, 0.5 g, 1.0 g, 2.0 g or placebo in a 1:1:1:1 ratio). The primary efficacy endpoint (the rate of clinical response) and key secondary endpoints (the rates of clinical remission and mucosal healing) at 8 weeks of treatment were assessed in the full analysis set (FAS). For a longitudinal profile of Mayo scores and partial Mayo score, changes from baseline over 8 weeks were compared between treatment groups by means of a mixed-effects model for repeated measures. This study is registered with UMIN Clinical Trials Registry (UMIN000021439).

Results: A total of 86 patients were enrolled. The proportion of steroid-dependent patients was 36.4, 56.5, 60.0, and 52.4% in patients receiving placebo, 0.5, 1.0 and 2.0 g daily of IN, respectively. Mean Mayo score at the week 0 was comparable among the 4 groups (8.2, 8.1, 8.5, and 8.3 in patients receiving placebo, 0.5, 1.0 and 2.0 g daily of IN, respectively). In the FAS population (n = 81), significant linear trend for the dose-response in clinical response rates was confirmed (placebo (n = 21): 14.3%, IN 0.5 g (n = 20): 800%, 1.0 g (n = 19): 795%, 2.0 g (n = 19): 895%, vs. placebo, P < 0.001). The dose-response in clinical...
remission rates showed significant linear trend (placebo: 4.8%, IN 0.5 g: 26.1%, P = 0.001, 2.0 g: P < 0.001). The mucosal healing rates were 14.3%, 65.0%, 63.2%, and 52.6%, in placebo, IN 0.5 g (P < 0.01), 1.0 g (P < 0.001), 2.0 g (P < 0.05) group, respectively. Patients receiving 0.5, 1.0, and 2.0 and daily of IN had greater improvement in the Mayo score compared with patients receiving placebo at week 8 and partial Mayo score showed a gradual decrease in score in 2 weeks, 4 weeks, and 8 weeks in patients receiving IN. No serious adverse events were observed.

Conclusion: In this multi-centre, randomized, double-blind, placebo-controlled clinical trial, we showed that IN is tolerable and the efficacy was confirmed in patients receiving 0.5-2.0 g daily doses. IN may be able to use as an alternative induction therapy to steroids and as a therapy for refractory cases including chronic persistent type, especially cases with insufficient mucosal regeneration by immunosuppressants and anti-TNFα treatments.

In conclusion, the present study demonstrates that targeting CHST15 by submucosal injection of the CHST15 blocker STNM01 could allow refractory UC patients to achieve mucosal healing and clinical remission. Further application of STNM01 would thus be the unique novel therapeutic approach for reversal of tissue remodeling in refractory UC.

Introduction: GÖ-COLITIS (NCT02092285; 2013-004583-56) is a phase 4, multi-centre, open-label, single-arm trial in the UK assessing efficacy of golimumab (GLM) in induction and maintenance of clinical response in patients with moderate to severe ulcerative colitis (UC) despite conventional treatment. Data from the 12-week follow-up of patients in clinical response at week 54 is presented here.

Aims & Methods: 141/205 (68.8%) anti-TNF naïve adults with UC ≥3 months responded to induction therapy with subcutaneous GLM at week 6, according to partial Mayo score (PMS) and were eligible to receive GLM maintenance of 300mg/4 weeks (based on body weight) every 4 weeks for a total of 54 weeks. At the end of 54 weeks, their physician reviewed their treatment choosing to either continue with GLM or discontinue GLM treatment. PMS response was assessed at week 30, 54 and 66 (defined as decrease in PMS of ≥2 points and ≥30% from baseline, plus a decrease in rectal bleeding subscore of ≥1 point or absolute rectal bleeding score ≥1). 52/140 (37.1%) responders were monitored for sustained efficacy and safety at week 66 (12 weeks after study end). During this period concomitant medications were permitted at the discretion of the treating physician.

Results: 60/140 patients continued GLM maintenance treatment through week 54; 52/140 were respondents at week 54. Of these 21 continued GLM treatment while 31 discontinued GLM treatment at week 54 (Table). All patients continuing GLM treatment (21/21) remained in clinical response at week 66. Of the patients who discontinued GLM at week 54, 27/31 (87%) patients maintained clinical response at week 66.

Table: Percentage of patients assessed at week 54 who maintained a clinical response during 12 week follow-up

<table>
<thead>
<tr>
<th>Patients continuing golimumab</th>
<th>Patients in clinical response at week 54 (N = 52/140) n (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patients in clinical response at week 66 (N = 48/140) n (%)</td>
<td></td>
</tr>
</tbody>
</table>

- Patients continuing golimumab:
  - 21 (100%)

- Patients discontinuing golimumab:
  - 31 (27%) (87%)

Conclusion: 100% of patients who continued on GLM treatment between weeks 54 and 66 continued to respond; of the patients who discontinued GLM treatment at week 54, early relapse (i.e. relapsed within 12 weeks of stopping GLM treatment) was seen in 54/131 (41%). These are the first data on the effect of GLM discontinuation treatment in patients responding to GLM. There was no difference in PMS between the lower dose STNM01 (25 nM) and placebo groups. Further studies are required to evaluate the percentage of patients remaining in response at 6 months, or later, following anti-TNF treatment discontinuation in responding patients after 1 year of treatment.

Introduction: Ulcerative colitis (UC) is characterized by mucosal inflammation and structural damage that is associated with matrix remodelling and tissue fibrosis. We had previously shown that carbohydrate sulfotransferase 15 (CHST15) that biosynthesizes sulfated matrix glycosaminoglycans is an important regulator of experimental colitis and gut fibrosis. Here, we evaluated the function of the double-stranded RNA oligonucleotide STNM01, a specific blocker of CHST15, in refractory UC patients.

Aims & Methods: In this randomized, double-blind, placebo-controlled phase 2a trial, 24 patients with severe UC were randomized to receive a single endoscopic submucosal injection of 25 nM, 250 nM STNM01 or placebo.

Results: The primary endpoint, mucosal healing at weeks 2 or 4 was achieved by 62.5% in the STNM01 (250 nM) group compared to 28.6% in the placebo group (p = 0.018). Clinical remission at these time points was reached by 50.0% in the STNM01 (250 nM) and 14.3% in the placebo groups (p = 0.050). There was significant histological improvement according to the Geboes score in the STNM01 (250 nM) group (p < 0.01). There were no statistical differences between the lower dose STNM01 (25 nM) and placebo groups.

Introduction: Inflammatory macrophages (Mϕs) play a critical role in the development of liver inflammation. Hepatocellular damage, instigated by hepatitis viral infections, alcohol abuse or metabolic syndrome, results in the recruitment and activation of inflammatory cells mainly M1 in the liver. The inflammatory Mϕs initiates the process of liver injury progressing from liver fibrosis to cirrhosis and hepatocellular carcinoma. Therefore, selective targeted inhibition of the inflammatory macrophages would be a promising approach to attenuate liver inflammation or liver fibrosis. Anti-inflammatory therapies targeting Mϕs has shown to be highly efficacious in many disorders. Currently there is no therapy available for the treatment of liver fibrosis therefore there is an unmet need to develop therapy with minimal side effects for the treatment of chronic liver disease. We identified Mincle receptor as a prospective target for pro-inflammatory subset (M1) of the development for effective inflammatory macrophage specific drug delivery system.

Aims & Methods: In this study, we developed a novel delivery system i.e. Mincle-targeted liposomes to achieve M1-specific uptake and to selectively deliver anti-inflammatory drugs to inhibit M1 Mϕs thereby ameliorating liver inflammation. Specificity and significance of Mincle receptor was evaluated in vitro in murine and human M1 Mϕs in vitro in CCl4-induced acute liver inflammation using immunostainings and quantitative PCR. Diverse Mincle-targeted liposomes were synthesized and characterized using dynamic light scattering (DLS). M1-specific uptake in murine and primary human Mϕs was analyzed using fluorescence-activated cell sorting (FACS). We used prednisolone as an anti-inflammatory drug to inhibit inflammatory M1 macrophages. Prednisolone encapsulated Mincle-targeted liposomes were generated, characterized and tested for efficacy in vitro in primary murine RAW macrophages, primary human Kupffer cells and in vivo in acute CCl4-induced liver injury mouse model.

Results: Significant up-regulation of Mincle receptor was confirmed in murine and human M1 Mϕs in vitro, in vitro in liver fibrosis mouse models and human fibrotic liver tissues. siRNA mediated knockdown (70% inhibition) of Mincle receptor in M1 Mϕs resulted in reduced inflammatory markers (TNFα and IL1β) and Mincle co-receptor. Mincle-targeted liposomes showed favorable size, stability and drug entrapment efficiency. We used prednisolone as an anti-inflammatory drug as a model drug to inhibit inflammatory M1 macrophages. We tested these liposomes in different mouse macrophage cell lines, primary bone marrow derived macrophages and in primary human macrophages for efficacy and M1-specific uptake. Significantly, targeted liposomes showed M1-specific uptake, while liposomes without targeting moiety showed comparably reduced internalization at different time points. Furthermore, targeted liposomes demonstrated significantly reduced uptake in M2 restorative Mϕs. No significant uptake in other cells was observed. Antibody blocking of Mincle receptor signification inhibited uptake in M1 Mϕs strongly suggesting Mincle-mediated mechanism of uptake. Prednisolone-encapsulated Mincle targeted liposomes showed significant reduction in M1-specific markers and inflammatory markers in vitro in RAW cells, in primary murine BMDMs and human kuffer cells. In vivo in acute CCl4-induced liver inflammation mouse model, prednisolone-encapsulated Mincle-targeted liposomes demonstrated specific liver uptake, highly significant attenuation in intra-hepatic inflammation, macrophage infiltration and reduction in fibrotic parameters as compared to free prednisolone and non-targeted liposomes.

Conclusion: This study presents a highly novel targeting approach of specifically targeting inflammatory macrophages with increased therapeutic efficacy while off-target effects on healthy tissues and other cell types can be avoided. These inflammatory macrophage targeted liposomes therefore holds great promise for diagnosis and therapeutic treatment of liver fibrosis and other inflammatory diseases.

Introduction: Gut barrier failure and the consequent pathological bacterial translocation (BT) are characteristic features of cirrhosis and play an important role in the progression of liver disease. We hypothesized that serological hallmark-marks of gut barrier dysfunction are associated with accelerated progression of liver disease in cirrhosis and the development of specific complications and liver-related death.

Aims & Methods: Sera from 260 stable outpatients with cirrhosis (male: 129, age: 56 ± 11 yrs; alcohol: 167 [64.2%]) and from 155 healthy subjects were assayed for the presence of antibodies against filamentous-actin [AAA IgA and IgG] and gliadin [AGA IgA and IgG] and for intestinal fatty acid-binding protein (I-FABP) by ELISA. Association of gut failure markers with disease specific characteristics was assessed at baseline and the course of liver disease was evaluated in a 5-year follow-up observational study for decompensating events (ascites, variceal bleeding, hepatic encephalopathy and/or bacterial infection) and liver-related death. BT was assessed based on the presence of serum microbiological antibodies (anti-OMP Plus IgA and/or endotoxin core IgA antibody [EndoCab]).

Results: Elevated concentrations of the gut failure markers IgA-AAA (62.7 vs. 4.4%) and IgA-AGA (27.7 vs. 2.6%) were more often observed in cirrhosis as compared to healthy controls (p < 0.001 for both). In addition, serum I-FABP was increased in cirrhosis as compared to controls (741 vs. 244 pg/mL, p < 0.001) and correlated with serum levels of IgA-AAA and IgA-AGA. IgA-AAA positivity was associated with alcoholic liver disease, liver disease scores and decompensated clinical stage (p < 0.001). Serological markers of BT were more often found in patients with elevated IgA-AAA compared to those without (72.3 vs. 13.5 % for IgA-EndoCab and 85.2 vs. 20.5 % for IgA-anti-OMP, p < 0.001) for both. In patients with compensated disease stage (n = 131) the risk of decompensation was higher in patients with elevated IgA-AAA (HR [95%CI]: 1.85 [1.06-3.24]), as was the risk of liver-related mortality (HR: 2.66 [1.27-5.56]). Such associations were not observed for IgG-AAA and IgA/IGA-AGAs. In the overall cohort, IgA-AAA remained an independent predictor of liver-related death (HR [95%CI]: 1.96 [1.08-3.55]) when adjusting for important clinical variables (MELD score, etiology, clinical stage, see Table 1).

Conclusion: Elevated serum concentrations of IgA antibodies against filamentous-actin indicate patients with an unfavourable outcome in cirrhosis, which may be related to intestinal damage beyond being related to bacterial translocation. IgA-AAA might be consider as a novel serologic marker of the disease progression.

MONDAY, OCTOBER 30, 2017 15:45-17:15

ERCP: WHEN THE GOING GETS TOUGH - ROOM B2
Aims & Methods: Primary aim was to compare stent patency between the two groups. Secondary aims were to evaluate relationships between adverse events (AEs) rate and stent type (i.e. time to stent dysfunction and survival). 158 patients (76 M 82 F, median age 78 ys) were randomized in two groups: 78 received a fully-covered SEMS (FCSEMS) and 78 an uncovered SEMS. Data from 148 (72 FCSEMS and 76 USEMS) out of 158 patients were analyzed. All patients received sphincterotomy before stent insertion.

Results: Placement was successful in 100% of patients with the uncovered and 98.7% patients with FCSEMS. Levels of conjugated bilirubin improved significantly (p < 0.001) in both groups during the first week, with a median variation of 1.5 mg/dL (p < 0.001) for FCSEMS. Normalization of bilirubin levels (≤ 1 mg/dL) was observed in 42 patients (28.6%; 28.2% FCSEMS and 28.9% SEMS, p = 1.0). AEs occurred in 28 out of 147 patients [19.0%: 18 FCSEMS (25.4%) and 10 SEMS (13.1%); p = 0.092]. Sclerotherapy occurred in 12 patients and 10 patients with SEMS, Cholangitis was observed in 6 patients for each group. In patients with SEMS, occlusion was due to ingrowth and in 9 out of 10 patients, was reported as a late complication. In FCSEMS group, 6 out of 12 patients had stent occlusion within the first month. Stricture recurrence was observed in a patient with FCSEMS. No stent migration occurred in SEMS group while it was observed in 5 (7%) of the FCSEMS group (p = 0.024). Median time of stent patency was lower for FCSEMS (9.5 months, 95% CI 7.2–11.8 months) vs 18 months (95% CI 10.7–25.4 months) for SEMS (p = 0.046). No differences were observed with regard to stent dysfunction in patient survival: 4.0 months (95% CI 2.5–5.5 months) for FCSEMS and 3.7 days (95% CI 2.3–5.0) for SEMS (p = 0.80). Median survival was 4.5 months (95% CI: 3.3–5.7 months) in FCSEMS group and 3.7 months (95% CI: 2.2–5.3 months) in SEMS group (p = 0.23).

Conclusion: No significant differences were observed in levels of bilirubin improvement, stent dysfunction-free and median survival between the two groups. AEs were higher, although not significantly, among FCSEMS group. FCSEMS had a significantly higher rate of migration. A significantly difference in patency was observed for SEMS group.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP104 CLINICAL EFFICACY OF ANTI-MIGRATION FEATURES IN FULLY-COVERED SELF-EXPANDABLE METALLIC STENTS FOR ANASTOMOTIC BILIARY STRICTURES AFTER LIVER TRANSPLANTATION: A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL COMPARED TO THE STANDARD SEMS

Introduction: Anastomotic biliary strictures (ABS) are one of the most frequent adverse effects occurring after orthotopic liver transplantation (OLT). Multiple plastic stents (MPS) have been validated in this indication. More recently, fully covered self-expandable metallic stents (FC-SEMS) have been used with positive outcomes but also a higher rate of migration which may limit success.

Aims & Methods: Our primary objective was to compare stent migration rates observed with FC-SEMS vs so-called “anti-migration” FC-SEMS, newly designed with reversed proximal side flaps. Secondary objectives were to compare the rates of ABS recurrence, and sustained stricture resolution as well as procedure-related morbidity. We conducted a retrospective analysis of a prospectively maintained database of a) OLT patients, and b) ERCP and stenting. Between January 2008 and January 2016, consecutive patients presenting with ABS after OLT referred to Cochin Hospital (Paris, France) for ERCP and receiving an FC-SEMS were included. Exclusion criteria were any other cause of biliary stricture (i.e malignant stricture, ischemic origin), and biliary fistulae.

Results: One hundred and twenty-five FCSEMS (57 anti-migration stents, 25 conventional stents type 1 and 16 conventional stents type 2) were used in 75 patients for ABS after OLT. The rate of FC-SEMS complete migration was 16% (20/125 patients, respectively 1.7% (1/57) for anti-migration stents vs 33.3% (9/27) for conventional stents (p = 0.002). First ERCP follow-up after each FC-SEMS highlighted a stricture resolution in 80% (100/125) of cases, 93% (53/57) for anti-migration stents, 77% (40/52) for type 1 conventional stents and 62.5% (10/16) for type 2 conventional stents (p = 0.0002). No significant differences were observed in levels of bilirubin (1, 2 mg/dL) was observed in 42 patients (28.6%; 28.2% FCSEMS and 28.9% SEMS, p = 0.024). Median time of stent patency was lower for FCSEMS (9.5 months, 95% CI 7.2–11.8 months) vs 18 months (95% CI 10.7–25.4 months) for SEMS (p = 0.046). No differences were observed with regard of stent dysfunction in patient survival: 4.0 months (95% CI 2.5–5.5 months) for FCSEMS and 3.7 days (95% CI 2.3–5.0) for SEMS (p = 0.80). Median survival was 4.5 months (95% CI: 3.3–5.7 months) in FCSEMS group and 3.7 months (95% CI: 2.2–5.3 months) in SEMS group (p = 0.23).

Conclusion: No significant differences were observed in levels of bilirubin improvement, stent dysfunction-free and median survival between the two groups. AEs were higher, although not significantly, among FCSEMS group. FCSEMS had a significantly higher rate of migration. A significantly difference in patency was observed for SEMS group.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Mean procedure time was 67 min (SD 11.5) in the e-ERCP group vs. 70 min (SD 11.3) in the EUS-GG-ERCP group. The technical success rate was significantly higher in the EUS-GG-ERCP versus the e-ERCP group (88.7% vs. 79.2%; *p* = 0.001). Post-procedure length of hospital stay was 2 (IQR: 0–6) days (e-ERCP) vs. 3.7 (IQR: 2–14) days (EUS-GG-ERCP) (p = 0.001). Rate of AEs was similar in both groups (7.5% vs. 5.6%, *p* = 0.37).

Table 1: Outcomes of e-ERCP vs EUS-GG-ERCP

References

Mean procedure time (73.9 vs 49.9, p = <0.001) was significantly shorter in the LL group. Difficult anatomy/cannulation was significantly correlated with technical failure [aOR(95%CI): 5.18 (1.26–21.2), p = <0.001] while duration of procedure [aOR(95%CI): 1.02 (1.01–1.03), p = <0.001] was a significant predictor of the need for more than one session of D-SOC EHL/LL.

A total of 618,884 subjects were extracted and matched from the data of long-term aspirin use and the cancer incidences were documented for up to 14 years until 2013. Odds ratio (OR) with its 95% confidence interval (CI) was calculated for non-GI cancers which referred to breast, bladder, kidney, leukaemia, lung, and prostate cancers, and the risk mortality on CRC was fitted, and Hazard Ratio (HR) was used to measure all-cause mortality. Subgroup analyses on gender were performed.

Results: From the healthcare records between 2000 and 2013, a total of 13,552 subjects were included: 3,301 of them (24.4%) were aspirin users and 10,251 (75.6%) were non-users before CRC diagnosis. The median dose of aspirin prescribed was 80 mg. Patients in group (a) with aspirin use before CRC diagnosis, 2,665 (80.7%) continued aspirin and 636 (19.3%) discontinued aspirin after curative surgery. Continuous use of aspirin significantly reduced 31% risk of CRC-related mortality with SHR: 0.69 (95% CI: 0.59 – 0.81) and 42% risk of all-cause mortality with HR: 0.58 (95% CI: 0.49 – 0.68). Patients in group (b) who never use aspirin before CRC diagnosis, 1055 patients (10.3%) initiated aspirin after curative surgery and 9196 (89.7%) patients remained not to have aspirin use. Initiating aspirin after surgery significantly reduced 12% risk of CRC-related mortality with SHR: 0.88 (95% CI: 0.80 – 0.98) and 18% risk of all-cause mortality with HR: 0.82 (95% CI: 0.73 – 0.91). Subgroup analyses did not show significant difference between male and female (Table 1).

8 Empresa Publica de Seguro Social (EPICOLON-III) and demographic, clinical and pathological data were collected from patients included in the study. Patients with CRC were included when there were clinical, pathology or molecular characteristics that could suggest a probably hereditary or sporadic origin. This is a multicenter nation-wide study, involving 25 Spanish hospitals. Patients with CRC included when their tumors showed immunohistochemical loss of MLH2, MSH6, PMS2 or loss of MLH1 with BRAF-wild type and/or no MLH1 methylation and absence of pathogenic mutation in these genes. Immunohistochemical study of the tumors was performed because of fulfillment of revised Bethesda Guidelines (4) or because of universal molecular screening for LS (5). These patients were included in a national registry (EPICOLON-III) and demographic, clinical and pathological variables, as well as family history of neoplasms, were registered.

Results: Our study included 85 patients with LS. Mean age at diagnosis of CRC was 55 years (SD 14). A total of 39 patients were female (46%). Loss of MLH1/ PMS2 was found in 46% of CRC, loss of MSH2/MSH6 in 34%, isolated loss of MLH1 was found in 12% and isolated loss of MSH2 in 8% in stage IV. None of the patients showed personal history of previous CRC. A total of 12 patients (14%) had personal history of non-colorectal cancer, and only 3 (3.5%) patients had previous history of LS-related cancer. Regarding family history, a total of 46 patients (54%) had at least one relative with CRC, and 38 patients (45%) showed familial history of LS-related cancer. Comparison of clinical and molecular characteristics of these patients in a large nation-wide cohort and to analyze if there are clinical, pathology or molecular characteristics that could suggest a probably hereditary or sporadic origin. This is a multicenter nation-wide study, involving 25 Spanish hospitals. These patients were included in a national registry (EPICOLON-III) and demographic, clinical and pathological variables, as well as family history of neoplasms, were registered. Results: Our study included 85 patients with LS. Mean age at diagnosis of CRC was 55 years (SD 14). A total of 39 patients were female (46%). Loss of MLH1/ PMS2 was found in 46% of CRC, loss of MSH2/MSH6 in 34%, isolated loss of MLH1 was found in 12% and isolated loss of MSH2 in 8% in stage IV. None of the patients showed personal history of previous CRC. A total of 12 patients (14%) had personal history of non-colorectal cancer, and only 3 (3.5%) patients had previous history of LS-related cancer. Regarding family history, a total of 46 patients (54%) had at least one relative with CRC, and 38 patients (45%) showed familial history of LS-related cancer. Comparison of clinical and molecular characteristics of these patients in a large nation-wide cohort and to analyze if there are clinical, pathology or molecular characteristics that could suggest a probably hereditary or sporadic origin. This is a multicenter nation-wide study, involving 25 Spanish hospitals. Patients with CRC included when their tumors showed immunohistochemical loss of MLH2, MSH6, PMS2 or loss of MLH1 with BRAF-wild type and/or no MLH1 methylation and absence of pathogenic mutation in these genes. Immunohistochemical study of the tumors was performed because of fulfillment of revised Bethesda Guidelines (4) or because of universal molecular screening for LS (5). These patients were included in a national registry (EPICOLON-III) and demographic, clinical and pathological variables, as well as family history of neoplasms, were registered. Results: Our study included 85 patients with LS. Mean age at diagnosis of CRC was 55 years (SD 14). A total of 39 patients were female (46%). Loss of MLH1/ PMS2 was found in 46% of CRC, loss of MSH2/MSH6 in 34%, isolated loss of MLH1 was found in 12% and isolated loss of MSH2 in 8% in stage IV. None of the patients showed personal history of previous CRC. A total of 12 patients (14%) had personal history of non-colorectal cancer, and only 3 (3.5%) patients had previous history of LS-related cancer. Regarding family history, a total of 46 patients (54%) had at least one relative with CRC, and 38 patients (45%) showed familial history of LS-related cancer. Comparison of clinical and molecular characteristics of these patients in a large nation-wide cohort and to analyze if there are clinical, pathology or molecular characteristics that could suggest a probably hereditary or sporadic origin. This is a multicenter nation-wide study, involving 25 Spanish hospitals. Patients with CRC included when their tumors showed immunohistochemical loss of MLH2, MSH6, PMS2 or loss of MLH1 with BRAF-wild type and/or no MLH1 methylation and absence of pathogenic mutation in these genes. Immunohistochemical study of the tumors was performed because of fulfillment of revised Bethesda Guidelines (4) or because of universal molecular screening for LS (5). These patients were included in a national registry (EPICOLON-III) and demographic, clinical and pathological variables, as well as family history of neoplasms, were registered.
molecular characteristics of patients depending on age at diagnosis of CRC or family history can be seen in Table 1. *p < 0.05 for comparison

Conclusion: In this cohort of LLS patients, the largest collected until now, there are no clinical, molecular or pathological characteristics that could be of help to distinguish between probably sporadic and hereditary patients. These results support the need of homogeneous follow-up for this group of patients.

Introduction: A new entity, called Non-Celiac Gluten Sensitivity (NCGS), was recently proposed to categorize patients suffering from a wide range of both intestinal and extra-intestinal symptoms after gluten ingestion (Sapone A, et al, BMC Medicine 2012). A very high prevalence of this condition was reported (Sapone A, et al, BMC Medicine 2012), but in our experience such a high figure was not confirmed (Di Sabatino A, et al, GGH 2015). We have recently shown that the ingestion of gluten may hamper colonic fermentation (LD) in healthy volunteers. Accordingly, it is possible that a high prevalence of NCGS could be present in patients with bloating.

Aims & Methods: Our aim was to detect the prevalence of non-celiac gluten sensitivity in functional patients with a long history of abdominal pain and bloating, claiming a relationship between gluten intake and symptom occurrence, and referred to an outpatient clinic for functional gastrointestinal disorders of a tertiary medical center. In accordance with the Salerno Criteria (Catassi C, et al. Nutrients 2015), we conducted a double-blind, placebo controlled trial with gluten vs placebo in thirty-two non-celiac patients with moderate to severe abdominal bloating and pain, enrolled in an outpatient clinic (M/F 3/29, mean age 31 ± 5). Symptoms were present for a mean period of 10 ± 3 years and were judged by patients as poorly responsive to all previous treatments. The presence of allergic, organic gastrointestinal and systemic disorders was ruled out in all patients. All subjects reported abdominal pain, bloating, flatulence, borborygmi, and bowel habit alterations, dyspeptic symptoms on gluten-containing diet (GCD) and, considering gluten as the causal agent, had been spontaneously following a non-blinded gluten-free diet (GFD) for at least a 6-week period, reporting an improvement of symptoms. They then started a rigorous GFD and entered this trial. In a double-blind, crossover protocol, ten capsules, containing 475 mg of gluten or 475 mg of rice starch, were administered randomly, each day for a 1-week period, with a 1-week wash-out interval. The patients completed a diary of symptoms, every evening at the same time for the duration of the study. The two main symptoms recorded by all patients were bloating and abdominal pain: a mean value during gluten ingestion over 30% higher than the value during placebo was considered as indicative of gluten sensitivity (Catassi C, et al, Nutrients 2015).

Results: In seventeen out of 32 patients (53%), the severity of abdominal pain was significantly higher during the week of gluten capsule ingestion than during the week of placebo capsule ingestion: the severity of abdominal pain in the group of patients with NCGS was 2.6 ± 2.4 during gluten and 1.5 ± 2.0 during placebo (p = 0.0001), on the contrary, in the group of non-sensitive patients it was 0.7 ± 1.8 during gluten and 1.2 ± 1.9 during placebo (p = 0.013). In fifteen out of 32 patients (47%), the severity of bloating was significantly higher during gluten than during placebo: the severity of bloating in the group of patients with NCGS was 3.7 ± 2.5 during gluten and 2.2 ± 2.0 during placebo (p = 0.0001), while in the group of non-sensitive patients it was 2.1 ± 1.5 during gluten and 3.5 ± 2.3 during placebo (p = 0.0001). Considering the modification of at least one of the two main symptoms, the diagnosis of NCGS was possible in 22 out of 32 patients (68%).

Conclusion: Around half of the patients with a long history of abdominal pain and bloating, claiming a relationship with gluten ingestion, resistant to previous treatments and referred to a tertiary clinic, show a positive result at the double blind test for the diagnosis of NCGS.

Introduction: Current ESPGHAN guidelines allow the non-invasive diagnosis of paediatric coeliac disease (CD) in clinical patients with relevant symptoms, serum transglutaminase 2 antibody levels above 10 times the upper limit of normal (ULN), endomysial antibody positivity (EMA) and an HLA-DQ2 or DQ8 background.

Aims & Methods: In this study we evaluated whether high serum antibody concentrations also predict CD in prospectively followed, regularly screened family members. The PREVENTCD multicenter FP6 study (www.preventcd.org) enrolled in 8 European countries 1002 DQ2- and/or DQ8-positive newborns who at least one family member diagnosed with CD for a prospective dietary intervention consisting of 100 mg of gluten per day or placebo between the age of 4–6 months. IgA antibodies against transglutaminase 2 (TGA) were determined 7 times until 3 years of age and then annually. TGA was measured in years 2007–2014 by the Célèky Varelnia test, in years 2015-2016 by Célèky ELIA method (both from Phadia and using the same TGA antigen but having 5 ULN and 7 ULN positivity cut-offs as defined by the manufacturer), respectively. EMA tests were performed locally as needed. A small bowel biopsy was offered to all children with persistent gastrointestinal symptoms or when symptoms appeared. CD was diagnosed in children with Marsh III histology lesions according to a central evaluation by a reference pathologist blinded to the clinical and antibody results. In case of decreasing or increasing TGA concentrations, the highest value before biopsy was taken into account for the calculations. IgA deficient subjects were excluded from the present analysis.

Results: During follow-up, small bowel biopsy was performed in altogether 144 children and 12 children were diagnosed with CD by histology of whom 67 (54%) were asymptomatic. Of the 149 TGA+ children, 71 (48%) had values >100 ULN/ml, 36 (24%) had values between 30–100 ULN/ml and 42 had values <30 ULN/ml of which 14/42 had transient seropositivity. TGA+ values >6.0xULN/ml had a positive predictive value for CD of (Table). There was no statistical difference in disease prediction between symptomatic and asymptomatic children with TGA+ levels >4.0xULN.

Conclusion: TGA+ levels >6.0xULN measured by the utilised test kits safely predicted CD both in symptomatic and asymptomatic children. Predictive cut-off levels of other TGA testing kits may substantially differ, and such differences should be carefully considered when applying ESPGHAN guidance for omitting biopsy. Test-specific predictive values are to be systematically established in similar prospective studies.

Introduction: The ingestion of gluten may be responsible for symptom onset in non-celiac patients (Cooper BT, et al Gut 1990;190) and a new entity, called Non Celiac Gluten Sensitivity (NCGS), was recently proposed (Sapone A, et al Gut 2012). But pathophysiological mechanisms are largely unknown. The aim of this study was to assess whether self-reported NCGS overlaps IBS both in clinical presentation and gastrointestinal sensorimotor functions.

Methods: During an ambulatory visit, we instructed healthy volunteers (HV), patients with IBS (IBS), and patients with self-reported NCGS (NCGS) to score their perception on a 0–6 scale. The perception threshold was defined as a perception score of 1 or more and the discomfort as a perception score of 5. Fasting and post-prandial intestinal tone were measured by monitoring colorectal recto-sigmoid volume during a 30-min fasting period and a 60-min period after liquid meal consumption (200 Kcal, 200 mL liquid meal), and the modification of recto-sigmoid volume was calculated (Di Stefano M, et al, Gut 2007).

Results: In comparison with HV, the mean perception threshold was much lower in NCGS and IBS patients (perception; NCGS patients 4.7 ± 3.8 mmHg, IBS patients 4.6 ± 4.4 mmHg, HV 5.3 ± 1.3 mmHg, ANOVA p < 0.001). The mean discomfort threshold was similar in NCGS and IBS patients (NCGS patients 15.6 ± 6.8 mmHg, HV 13.4 ± 6.2 mmHg), but significantly lower than in HV (20.2 ± 2.3 mmHg, ANOVA p < 0.001). The mean fasting recto-sigmoid volume was similar in the three groups of patients (NCGS 138.5 ± 40.5 mL, IBS patients 152.6 ± 43.6 mL, HV 124 ± 23.2 mL, ANOVA p = NS) but significantly lower than in HV both mean post-prandial recto-sigmoid volume and mean percent modification of recto-sigmoid volume were significantly different in NCGS and IBS patients (mean post-prandial volume: self-reported NCGS patients 171 ± 84 mL, IBS patients 188.6 ± 86 mL, HV 75.7 ± 14 mL, ANOVA p < 0.001; mean percent volume modification: NCGS patients +22 ± 26%, IBS +19 ± 40%, HV −39 ± 7%, ANOVA p < 0.0001). The mean percent modification of recto-sigmoid volume was similar in HV, NCGS and IBS patients.

Conclusion: No different was detected in recto-sigmoid sensorimotor activity between self-reported NCGS and IBS. Self-reported NCGS overlaps IBS both in clinical presentation and pathophysiological aspects. Accordingly, NCGS diagnosis should be not performed on the basis of a mere anamnestic evaluation.

Introduction: Celiac disease (CD) patients are likely at increased risk to develop various malignancies. Relative and absolute risk estimates are essential to provide follow-up recommendations to newly diagnosed CD patients.

Aims & Methods: The aim of this study was to assess the subsequent relative and absolute risk for malignant lymphoma and gastro-intestinal (GI) carcinoma after CD diagnosis in a population-based study. All patients with lymphoma or GI carcinoma (cancers) and melanoma or basal cell carcinoma (controls) diagnosed in the Netherlands between 1994 and 2014 were retrieved through the Dutch nationwide population-based pathology database (PALGA). Within this series, all individuals with histologically confirmed CD before or within 3 months after the date of malignancy diagnosis were identified through linkage to the Dutch CEDOC-2000 database (Di Stefano M, et al, Gut 2007) were determined using logistic regression analysis with corrections for age and gender.

Results: Of 301,424 cases and 576,971 controls, 349 (0.1%) and 282 (0.05%), respectively, were diagnosed with CD. ORs for small bowel adenocarcinoma and esophageal squamous cell carcinoma (SQC) after prior CD diagnosis were 11.9 [95% CI, 8.2–17.2] and 3.5 [95% CI 2.1–5.8]. Adenocarcinoma of the colon, esophagus and stomach and SCC of the anus were not associated with CD history. The OR for T-cell lymphoma after prior CD diagnosis was 35.8 [95% CI, 27.1–47.4], whereas B-cell lymphomas were not associated with CD history. Absolute cumulative risks of T-cell lymphomas reaches the risk of colorectal carcinoma in the general population. However, the most common T-cell lymphoma in CD, enteropathy associated T-cell lymphoma (101 of all 131 T-cell lymphomas in the CD group), was preferentially diagnosed at time of CD diagnosis.

Conclusion: This population-based study is unique by including pathologically confirmed CD. The data suggest strongly increased risk for specific malignancies after CD diagnosis. These results provide a strong motivation and detailed information to develop follow-up guidelines for newly diagnosed CD patients.

Disclosure of Interest: None.

Reference:
Aims & Methods: We investigated the prevalence of TMPRSS6 in CD and its role in iron absorption in CD patients treated for IDA. From October 2011 to July 2015 we prospectively assessed the frequency of TMPRSS6 variant rs855791 in both anemic and non-anemic CD patients at time of CD diagnosis. We also estimated the association of this variant with some hematological and iron para-
meters, and found a significant increase in Hb and ferritin at time of diagnosis and after 1-year of gluten-free diet. The prescribed treatment for IDA, both oral or parenteral iron, was recorded in all patients. Statistical analysis was performed by using T-student and X-square test when indicated; all differences were considered significant when p < 0.05.

Results: Finally, 505 CD patients were enrolled: 229 with IDA (45%; mean age 31.2; females 88%), 276 with non-IDA (55%; mean age 32.4; females 66%). The allelic frequencies for A736V mutation of TMPRSS6 variant rs855791 did not differ significantly between anemic (45.4%) and non-anemic CD patients (52.2%) at time of CD diagnosis. At follow-up, TMPRSS6 variant rs855791 was present in 58 out of 104 patients with persistent IDA, being significantly higher than in 125 non-IDA persistent patients (86.4% vs. 56%, p < 0.01). In IDA patients, the presence of one or the other the TMPRSS6 genotype (wild type, heterozygosis, homozygosis) did not influence iron parameters at diagnosis while CD patients with homozygous genotype presented lower hemoglobin, serum iron and transferrin receptor levels than patients with wild type genotype (Hb: 11.5±1.2 vs. 12.4±1.0, p < 0.01; serum iron: 51.1±27.7 vs. 70.4±3.75, p < 0.01; ferritin: 18.7±25.1 vs. 40.4±3.05, p < 0.01) despite their rigorous GFD.

Conclusion: TMPRSS6 variant rs855791 plays a central role in most of CD cases with iron-refractory IDA. TMPRSS6 genotyping appears useful to personalize the management and follow-up of IDA patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hepatocellular carcinoma (HCC) represents a serious complication of HCV-related cirrhosis. New direct acting antivirals (DAAs) obtain an HCV eradication rate higher than 90%. However, there is still a high risk of recurrence, according to recent studies of unexpected high rate of tumor recurrence after treatment with DAA.

Aims & Methods: The aim of this study is to evaluate the early recurrence of HCC in patients treated with DAA and the risk factors associated. We analyzed 154 patients with chronic liver disease and HCC, of which 27 were due to HCV infection and were in complete radiologic tumor remission after treatment. All of them were treated with DAAAs, and followed up for an average of 20 months since remission. The inclusion criteria were: 1. HCC diagnosed by pathology or non-invasive criteria according to American Association for the Study of Liver Diseases (AASLD) guidelines; 2. Complete response following treatment; 3. Treatment with DAA confirmed sustained virological response (SVR). At least one tumor status assessment after starting antiviral therapy Control computed tomography (CT) and blood tests were performed in three months according to the protocol of our centre.

Results: Recurrence of HCC was detected in 51.9% of patients (14 of 27 patients) in a median follow-up of 24 months. All of them achieved sustained virological response. Having less than 1 cm size, non-specific nodules in control CTs is associated with a higher recurrence (p=0.001; OR 15.9; 95% CI: 2.02-111.17). The median time to recurrence was 17.3 months since tumour remission. Previous HCV treatment with therapies based on interferon was associated with lower risk of recurrence; although these results are not statistically significant, they tend to be significant (p=0.18; OR 0.347, 95% CI: 1.07-1.65). Regarding the type of antiviral treatment, there were no recurrences in the sofosbuvir plus simeprevir group. On the other hand, all patients treated with the combination of sofosbuvir and daclatasvir experienced tumor recurrence during the follow-up period, and this was statistically significant in the univariate analysis (p=0.005).

However, age, sex, Child-Pugh class, cardiovascular risk factors, HCC treatment, single tumor and HCV genotype were not significantly associated with HCC development. The main characteristics of the cohort are described in table 1.

OP120 BRG1 POSITIVELY REGULATES LIVER REGENERATION AFTER PARTIAL HEPATECTOMY IN MICE

B. Wang, M. Lu1, K. Benedikt1, N. Hüser1, S. Zhong2, G. Von Figura3, D. Hartmann4
1Department of Surgery, Klinikum rechts der Isar, Technische Universität München, Munich/Germany
2Medizinische Klinik, Klinikum rechts der Isar, Technische Universität München, Munich/Germany

Introduction: The SWI/SNF complex is a chromatin-remodelling complex that modifies chromatin structure in order to regulate gene expression. Brahma-related gene-1 (BRG1), a catalytic subunit of the SWI/SNF complex, is known to be involved in proliferative cell processes. Liver regeneration is activated spontaneously after injury and organized based on a strong proliferation rate. Up to the present, little is known on how BRG1 orchestrates liver regeneration.

Aims & Methods: The aim of the study was to investigate the role of BRG1 in liver regeneration following partial liver resection in mice. We used a hepatocyte-specific BRG1 gene knockout mouse model performing a 70% partial hepatectomy. The expression of BRG1 was markedly upregulated after partial hepatectomy compared to wildtype mice. We found that the expression of BRG1 was markedly upregulated after partial hepatectomy compared to wildtype mice.

Conclusion: We found that the expression of BRG1 was markedly upregulated after partial hepatectomy compared to wildtype mice. A highly active proliferation was observed in the hepatocytes of wildtype mice post PH while fewer was observed in BRG1 specific knockout mice 48 h post operation. A highly active proliferation was observed in the hepatocytes of wildtype mice post PH while fewer was observed in BRG1 specific knockout mice 48 h post operation.

Introduction: Hepatic resection is one of the best curative treatments in well-selected patients with hepatocellular carcinoma (HCC) and cirrhosis. The risk of decompensation after resection has major impact over the outcome of these patients. Portal hypertension is the main risk factor for decompensation and it is still a matter of debate which is the best method to identify patients at risk.

Aims & Methods: The aim of the study was to compare different methods for risk assessment in patients with HCC submitted to hepatic resection. Since January 2016 94 consecutive patients were diagnosed with HCC and were prospectively registered. Thirty-three patients were submitted to hepatic resection and among them: 22 were screened for esophageal varices (EV), 13 patients were evaluated by hepatic venous pressure gradient (HVPG) and 18 by transient elastography.

Conclusion: Among the 33 included patients, 8 (24%) had EV, 6 (18%) had clinical significant portal hypertension (HVPG > 10 mmHg) and 9 (27%) had platelet count < 100,000/mmc. During follow-up 12 (36%) patients presented decompensation (3 variceal bleeding, 7 ascites, 6 renal dysfunction and 1 jaundice). In univariate analysis, HVPG, liver stiffness, platelet count, ALT and AST were associated with decompensation. Neither presence of EV (40% correctly classified, p = 0.13) or platelet count < 100,000/mmc (64% correctly classified, p = 0.08) were accurate enough to predict decompensation. Presence of CSPH assessed by HVPG correctly classified 92% of patients (p = 0.002). There was no difference between HVPG and transient elastography regarding the performances (AUROC) for predicting decompensation, 0.91 (95% CI: 0.74–1, p = 0.012) and 0.93 (95%CI: 0.80–1, p = 0.007), respectively.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Method: In the current study, we assessed the therapeutic potential of REIC/Dkk-3 gene therapy using Ad-SEG-REIC in hepatocellular carcinoma (HCC). Human HCC cell lines (HLE, Huh7, and HepG2), human HCC tissues, and mouse HCC cell line (Hepa-1) were used in this study. REIC/Dkk-3 expression was assessed by immunoblotting and immunohistochemistry. The relative cell viability and the apoptotic effect were examined by MTT assay and Hoechst staining, respectively. The protein expression of IRE1α, JNK, c-Jun, and caspase-3 was assessed by immunoblotting using specific antibodies. The anti-tumor effects of Ad-SEG-REIC treatment were analyzed in the mouse xenograft model with Huh7 cells. Furthermore, we assessed anti-tumor immunological effects in the immunocompetent mice.

Results: REIC/Dkk-3 expression was decreased in HCC cell lines and HCC tissues. Ad-SEG-REIC treatment markedly reduced cell viability in HCC cell lines and the reduction rate for HLE, Huh7, and HepG2 were 87.2%, 76.3%, and 36.4%, respectively. Hoechst 33342 staining demonstrated the rate of apoptosis in the cells treated with Ad-SEG-REIC (HLE; 64.9%, Huh7; 66.8%, HepG2; 40.1%). Ad-SEG-REIC treatment mediated cancer selective apoptosis due to ER stress mainly through the activation of JNK pathway. Ad-SEG-REIC treatment suppressed tumor growth by 68.7% in comparison with the control in the mouse xenograft model. Moreover, the lymphocytes isolated from immunocompetent mice treated with Ad-SEG-REIC demonstrated higher cytotoxicity against the target cancer cells than those from the control mice (253.5%).

Conclusion: Ad-SEG-REIC treatment not only enhanced cell-killing effects in vitro but also elicited significant therapeutic effects in vivo. REIC/Dkk-3 gene therapy using Ad-SEG-REIC potentially represents an innovative new therapeutic tool for HCC.

Introduction: Combinant use of sofosbuvir and Amiodarone has been associated with cases of atrioventricular block and symptomatic bradycardia (1-2), therefore such combination is not recommended. In addition, it has been recently suggested that there is QT interval prolongation in the first weeks of treatment without the combination with Amiodarone (3).

Aims & Methods: Our study aims to confirm if there is a prolongation of QT interval during treatment with Sofosbuvir and other antivirals, to study whether this alteration persists after treatment and to investigate other possible alterations in the cardiac conduction system. We accomplished a prospective study in which a baseline electrocardiogram (ECG), before starting treatment, and another electrocardiogram (at the fourth week) were performed on hepatitis C patients undergoing Interferon-free antiviral therapy between April 2016 and April 2017 in Hospital Clínico San Carlos (Madrid). Moreover, in some patients a third ECG was performed in the twelfth week after treatment. Heart rate and duration of PR, QRS, QT and corrected QT intervals (QTc) were measured. A paired Student’s T test was applied to compare the variables before and during treatment, and before and after treatment in the subgroup of patients with the third ECG.

OP124 NON-ALCOHOLIC STEATOHEPATITIS IS THE MOST RAPIDLY GROWING INDICATION FOR LIVER TRANSPLANTATION IN IRANIAN PATIENTS
1Gastroenterohepatology Research Center, Shiraz University of Medical Sciences, Shiraz/Iran

Contact E-mail Address: eshraghiana@yahoo.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing disease and is supposed to be the most common cause of abnormal liver enzymes worldwide. A considerable proportion of NAFL patients will progress to non-alcoholic steatohepatitis (NASH) that is anticipated to become the most common cause of liver cirrhosis and liver transplantation in next 20 years. Iran has been located in the Middle East with a high prevalence of NAFLD.

Aims & Methods: This study aimed to investigate the incidence and trend of NASH as an indication for liver transplantation in Iranian patients. The liver transplant data of all patients who had undergone liver transplantation between 1993 and 2016 at Shiraz Organ Transplant Center, Shiraz, Iran were reviewed. The underlying liver diseases leading to liver transplantation were stratified according to the years of transplantation and trend of increase or decline were calculated. Data regarding post-transplant mortality of patients with biopsy proven NASH were recorded. Patients with cryptogenic liver cirrhosis with body mass index ≥30kg/m² was defined as modified NASH. Kaplan-Meier
Gastric gas infusion was associated to a minor increment in abdominal perception of healthy controls (1.0 ± 0.5 score increment). By contrast, patients with functional dyspepsia developed significant perception of epigastric symptoms during gas infusion (2.5 ± 0.6 score increment; p < 0.05 vs controls) whereas patients with a belching disorder develop no epigastric perception (0.9 ± 0.2 score increment; NS vs sham p = 0.05 vs functional dyspepsia) despite the lower rectal gas evacuation associated to increased belching.

Conclusion: Patients with specific gastroduodenal disorders exhibit different responses to increments in gastric gas. Whereas in patients with functional dyspepsia belching is exceptional and a minor increment in gas may induce epigastric symptoms, increased belching in response to gastric gas seems to prevent epigastric symptoms in patients with a belching disorder.

OP126 INTRAGASTRIC FRUCTOSE INFUSION AND EMOTIONAL STATE INTERACT IN HOMEOSTATIC AND HEDONIC BRAIN REGIONS

Introduction: Exeroceptive properties of food such as taste or smell can influence a person’s emotional state and its neural basis. However, purely interoceptive properties of food can also affect emotional state, since behavioral and neural responses to sad emotion induction were attenuated by fatty acid infusion (Van Oudenhove et al., 2011). Whether this also applies to other nutrients, including carbohydrates, remains unknown.

Aims & Methods: We aimed to study the effect of intragastric fructose administration compared to placebo, and its interaction with the effect of sad emotion induction, on brain activity in homeostatic and hedonic regions and on circulating levels of the anorexigenic hormone GLP-1. Fifteen healthy subjects were studied after an overnight fast. Brain activity before and up to 40 min after intragastric infusion of fructose (25 g) or distilled water (placebo) was recorded using functional magnetic resonance imaging. Sad or neutral emotional states were induced using a combination of playback of validated classical music pieces and projection of emotional facial expressions. Emotional state was assessed every 10 min using the Self-Assessment Manikin. Blood samples were taken at the same time points. Plasma levels of GLP-1 were analyzed using Meso Scale Discovery immunoassay kits. Brain responses to fructose versus placebo, sad versus neutral emotion, and their interaction were analyzed over time in a priori defined regions of interest (ROI) at a voxel-level threshold of P<0.05 vs controls and dyspepsia. Similar effects on emotional ratings and GLP-1 levels were tested using linear mixed models.

Results: We did not observe significant main effects of nutrient and emotion, and no significant nutrient-by-emotion interaction effect, on emotional ratings. However, significant main effects of fructose, emotional state, and a significant nutrient-by-emotion interaction effect on brain responses in pre-hypothesized ROIs, including the medulla, midbrain, hypothalamus, basal ganglia, anterior insula, orbitofrontal cortex and amygdala were found (see Table 1). A trend towards an interaction between emotional state and nutrient was also observed on GLP-1 levels. Specifically, the increase in circulating levels of GLP-1 after fructose administration in the neutral emotion condition was abolished in the sad emotional state (p = 0.06).

Contact E-mail Address: alerotondo@libero.it

Introduction: Glucagon-like peptide 1 (GLP-1), an endogenous modulator of gastrointestinal motility and food intake, is inactivated by dipeptidyl peptidase-4 (DPP-4). Administration of DPP-4 inhibitor vildagliptin can amplify endogenous GLP-1 effects.

Aims & Methods: The objectives were to assess the effect of vildagliptin on gastric accommodation, measured as the intragastric pressure (IGP) during intragastric nutrient infusion and food intake in humans in 2 protocols, each including 10 healthy volunteers (HV). Hunger, satiation and epigastric symptoms (fullness, nausea, bloating, belching, pain, cramps) were assessed using a visual analogue scale (VAS). In Protocol 1, an infusion catheter and a high-resolution manometry probe were positioned in the proximal stomach. HVs took vildagliptin (50 mg) or placebo orally in a randomized single-blind fashion, followed by an intragastric nutrient drink (ND) for the duration of 30 min. Blood was collected before the drug administration, before and after the ND and before the buffet.

Conclusion: Vildagliptin inhibits gastric accommodation and decreases food intake in healthy lean volunteers. The observed effect could be due to the inhibition of GLP-1 degradation.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP128: RELAMORELIN IN PATIENTS WITH DIABETIC GASTROPARESIS: EFFICACY AND SAFETY RESULTS FROM A PHASE 2B RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, 12-WEEK STUDY (RM-131-009)

Introduction: Gastroparesis is a serious complication of diabetes mellitus (DM) with few treatment options. Relamorelin (RM) is a selective ghrelin agonist with potent prokinetic properties.

Aims & Methods: The aim was to evaluate the efficacy of RM on symptoms and gastric emptying (GE) in patients with moderate-to-severe diabetic gastroparesis in a 12-week, randomised, double-blind, placebo (PBO)-controlled, parallel-group study, with a 2-week single-blind PBO run-in. Eligible DG patients had 1,3-C-spirulina GE breath test (GEBT) T1/2 values ≥79 min, a history of recent vomiting and a Gastroparesis Cardinal Symptom Index score ≥2.6. Patients were randomised to twice daily subcutaneous injections of PBO or RM: 10 µg, 30 µg or 100 µg. Patients completed the Diabetic Gastroparesis Symptom Severity Diary (DGSSD), a daily e-diary designed to collect patient-reported vomiting frequency and symptoms of nausea, abdominal pain, satiety, post-prandial fullness (PPF) and bloating on a 0–10 severity scale. The primary endpoint was change from baseline in vomiting frequency; a key secondary endpoint was change from baseline in vomiting frequency; an exploratory endpoint was change from baseline in nausea score. A key secondary endpoint was change from baseline in vomiting frequency; an exploratory endpoint was change from baseline in nausea score.

Results: A total of 393 DG patients (male: 37.7%; age: 57.0 ±11.3 years; body mass index: 32.4 ±7.3 kg/m²; mean HbA1c: 7.7 ±1.4%; Type 1 DM: 9.9%) were randomised at clinic sites in the US, Israel and Europe. RM led to ~75% reduction in vomiting frequency compared to placebo (primary endpoint) across all doses tested; however, no significant difference was observed due to a high PBO response (~70% reduction from baseline). RM demonstrated substantial efficacy: DG symptoms improved vs placebo for all three RM doses for the overall 12-week study period, indicated by the reduction in the composite score (Table). All three doses of RM tested also accelerated GE compared to PBO (Table). (GEBT) T1/2 scores improved by a mean of ~13.3±8 min with RM compared to placebo (0±38 min). RM was generally safe and well tolerated with high compliance and study completion rates. Worsening of glycaemic control was noted as an adverse event in 14.5% of RM patients, with some patients requiring adjustment of insulin dosage.

Full analysis set (Nausea, PPF, abdominal pain, bloating; composite score in total numeric points); 2 (GEBT T1/2): Two-sided p value from longitudinal, mixed-effects model with repeated measures, including fixed effects for treatment, week and treatment-by-week interaction, as well as baseline and baseline-by-week interaction values as the covariates, with unstructured variance-covariance correlation matrices being common to all subjects for the repeated measures over treatment weeks.

Conclusion: RM demonstrated clinically meaningful reductions in core DG symptoms and overall composite score, accelerated GE, and was generally safe

and well tolerated. A high PPO response limited the ability to show efficacy of RM at the paediatric clinical description frequency endpoint.

Disclosure of Interest: M. Camilleri: Received research grant to study pharmacology of colamin. R.W. McCallum: Received research funding to study colamin, consulted with Allegan plc. S. Kahrilas: Evoke Pharma and Synergy Pharm, and received funding for clinical research trials from Salix Pharmaceuticals, Evoke Pharma, Theravance Biopharma and Vanda Pharma.

Aims & Methods: This study presents a four-year experience of the PPOD service, including clinical description, diagnostic criteria and CIPO population captured by it. This is a retrospective analysis of patients admitted within the PPOD service, between 04.2012 and 12.2016, with a suspected diagnosis of CIPO. The ultimate diagnosis of CIPO was confirmed on the presence of at least 2 out of 4 of the following criteria (intestine or oesophagus segment with small intestinal neuromuscular involvement; 2) radiological evidence of recurrent and/or persistently dilated loops of small intestine with air fluid levels; 3) presence of the genetic, metabolic or other conditions definitively associated with CIPO; and 4) intestinal transit cannot be maintained adequate growth on oral feeding alone (need for specialized feeds and/or enteral/ intravenous route for feeding). Clinical data, including age of onset of symptoms, dominant symptoms, results of the ADM investigations, surgical procedures, feeding history, neo-gastrointestinal drainage and histology results of full thickness biopsies from the small intestine, were analyzed.

Results: Out of 113 children referred to the PPOD Service, 50 were definitively diagnosed with CIPO (26 girls), with median age at symptoms of onset of 5 months (range: birth to 18 months). 50% of patients were born prematurely, 40 children (83.3%) presented with first symptoms below first year of life. Median age at assessment was 45 months in the first half-time of service (32/50) and 35.5 months in the second half (18/50). Based on the ADM results, the majority of patients diagnosed with CIPO had patterns consistent with neuropathic involvement (n = 35), 2 with myopathy and 4 with both, neuropathy and myopathy. In 10 patients diagnosis of CIPO was based on clinical criteria. 46% of children had dominant upper gastro-intestinal (GI) tract presentation (nausea, vomiting, gastro-oesophageal reflux, feeding intolerance), 40% presented with lower GI tract symptoms (abdominal pain, abdominal distension, constipation). 29 children (58%) underwent colonomcy, and majority of them (55%) showed colonic myopathy. Out of children with CIPO, 34 patients (80%) underwent small bowel resection to eliminate performed, 9 (18%) had total colectomy and 1 patient ultimately underwent multi-velo-visceral transplantation. 35/50 patients had full thickness biopsy of small bowel. In 20-35 cases (57%) no histological abnormalities could be identified. Total parenteral nutrition (TPN) was required by 48% of children (23/48), 10 patients were on full enteral feeds; 4 patients remained on oral feeding.

Conclusion: Over the first four years of the UK national PPOD service, we observed a significant increase of CIPO diagnosis in children. The establishment of the UK service was established (2.4 patients/year; Henyeke et al 1999) with a trend towards decreasing age at first assessment (3.3 vs 13.3 years pre 2012, data not shown). This suggests that the national service not only appears effective in capturing more of the UK CIPO population but is making a difference in diagnosis earlier. The latter is especially important given the majority of patients presented with the onset of the first symptoms under 1 year of age and progress quickly to dependency on total parenteral nutrition. The majority of our patients underwent colostomy formation as the first gastro-intestinal intervention, and diagnosis was based on exclusion and/or persistently dilated loops of small intestine with air fluid levels; (3) presence of the genetic, metabolic or other conditions definitively associated with CIPO. We are now assessing whether early diagnosis and definitive intervention improves mid and long-term outcomes, including reduced morbidity, mortality, healthcare utilization costs and better tolerance of enteral feeding. The development of national CIPO registries and services is likely to be of benefit to improving early definitive diagnosis, expertise in management and ultimately outcomes of CIPO.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is a standard technique in Japan. However, colorectal ESD can be technically difficult in some situations such as paradoxic movement of the right colon. The double-balloon endoscope was introduced here, as a pioneering technique for balloon-assisted endoscopy, which provides stable endoscopic maneuvering even in the small intestine. Stable maneuverability can overcome the difficulties of colorectal ESD in the right colon.
Aims & Methods: The aim of this study is to assess the outcomes of balloon-assisted endoscopic submucosal dissection (BAESD) of colonoscopically difficult superficial right colon tumors. We retrospectively reviewed the records of patients who underwent BAESD of superficial right colon tumors where colono-scopic difficulties were encountered, from January 2011 to September 2016. Difficulties were defined as a previous incomplete colonoscopy using a conventional colonoscope or unstable endoscopic maneuverability around the tumor with conventional colonoscopy. A propensity score model was used as a secondary analysis to compare outcomes of the BAESD group to a group without difficulties.
Results: BAESD was performed on 67 tumors in 63 patients. There were 10, 22, and 35 tumors in the cecum, ascending colon and transverse colon, respectively. The median tumor size (range) was 31 (20–123) mm. The median (range) procedure time was 65 (35–382) minutes, and the median (range) dissection speed was 18.0 (4.4–71.4) mm2/minutes. In loco resection was achieved for 66 tumors (99%) and an R0 resection was achieved for 58 tumors (87%). No perforations occurred. Two patients (3.0%) had delayed postoperative bleeding treated by endoscopic hemostasis. Propensity score-matching analysis created 65 matched groups until 3 years. These findings demonstrate that ESD is an effective treatment for elderly patients with superficial esophageal cancer, at least in the short-term.
Disclosure of Interest: All authors have declared no conflicts of interest.

TUESDAY, OCTOBER 31, 2017 08:30-10:00 DETECTION AND REMOVAL OF COLORECTAL POLyps: LATEST TECHNIQUES - ROOM A3
OP133 AUTOMATIC POLYP DETECTION IN COLONOSCOPY PROCEDURE USING DEEP LEARNING AND IMAGE PROcessING TECHNIQUES
D. Zur, M. Zaltzhendler
Magnetiq Eye, Haifa/Israel
Contact E-mail Address: dror@magentiq.com
Introduction: It is estimated that 40 million colonoscopy procedures are performed every year (almost 40% in the US alone). The ability of colonoscopy procedures to decrease the number of colon cancer cases has been proven without a doubt and their number is expected to grow. However, research has shown that only 90% of polyps are detected in these procedures, misses which can, unfortunately, cause interval cancer. At Magnetiq Eye we put the growing power of Deep Learning, and of Image and Video Processing, to the help of doctors to reduce the miss rate in the colonoscopy procedures. Our first product the APDS is an Automatic PolyP Detection System, developed to be used in online and offline colonoscopies. The APDS-RT runs on the video feed from the endoscopic camera used by the physician in real time during the colono-scopy procedure and signs the polyp location as a contour in an overlay on the video. Afterwards, the physician can select the location of the polyp (colored contour) of the polyp location in each frame. We aimed at this phase to measure the performance of the prototype when running over the recorded videos. We used 63 video sequences of about half minute each to train the system, and additional 63 video sequences of about half minute each to test the training process, and tested the system which includes the trained model and additional image processing analysis techniques over 10 sequences of half minute each. The total database (training, validation and testing) included 46, 531 video frames and about 90 different polyps. We have measured, over the test videos, the FROC curve (True Positive Rate vs False Positive Per Frame) which was produced by changing a threshold parameter in the system, and the IoU (Intersection over Union) signal to the system prediction region with the ground truth region) against changing the same threshold parameter of the system. The FROC was calculated over all the frames of the test database, and over subset of it which is all the frames from the test database which included ground truth polyps. In addition, the change of the False Positive Per Frame value against the system threshold parameter over a subset of the test frames (all the frames which didn’t include polyps) was calculated. The IoU was calculated mainly over a subset which is all the frames which included polyps or producing polyp frames.
Results: The best point of the FROC was 74% Detection Rate (TPR) vs. 0.07 False Positive Per Frame (FPPF) when calculated over all the frames, and 74% TPR vs. 0.05 FPPF when calculated over the subset of all the frames with ground truth polyps. For the system threshold which was used to select this working point, the FPPF over the subset of all frames without ground truth polyps was 0.05, and the average IoU value over all frames with ground truth or predicted polyps was 0.3. Increasing the system threshold would decrease the TPR, the FPPF, and the IoU, but would also decrease dramatically the FPPF over the subset of all frames without ground truth polyps.
Conclusion: We expect the system performance to be improved as it is exposed to more data in the training phase, in the sense that it would be able to choose a better working point (TPR vs. FPPF) on the same testing dataset, as well as to keep this working point as the testing dataset is increased, and also to get a better IoU value which is a quite good reference to the quality of the segmentation (depicting the polyp region) of the polyps. We can also see that we always have the possibility to increase the system threshold, and thus getting somewhat worse working point for all the frames or the frames with ground truth polyps, but earning dramatically less FPPF in the frames without ground truth polyps, and this is an important advantage since it would reduce the physician distraction during those frames.

Two patients (3.0%) had delayed postoperative bleeding treated by endoscopic hemostasis. Propensity score-matching analysis created 65 matched groups until 3 years. These findings demonstrate that ESD is an effective treatment for elderly patients with superficial esophageal cancer, at least in the short-term.

Conclusion: Our study shows that G-EYE Flat lesions detected by the distal end of a standard endoscope. Upon withdrawal, inflation of the G-EYE balloon to a partial pressure results in the centralization of endoscope optics, reduction in bowel slippage, and flattening of colon topography. The enhanced visualization provided by the G-EYE balloon can result in an increase in detection of lesions.

Aims & Methods: In this prospective, randomized, multicentre study, patients (age >50) referred to colonoscopy as a result of screening, surveillance, positive FOBT or change in bowel habits were randomized to either standard colonoscopy (SC) or G-EYE colonoscopy. Detected lesions were removed and sent for pathology. We compared the detection rates of G-EYE colonoscopy with that of SC in the right colon.

Results: 1,000 patients enrolled in the study, of which 498 underwent SC and 502 underwent G-EYE colonoscopy. Baseline parameters were similar in both groups. The right colon was defined as the cecum, ascending colon, and hepatic flexure. Results are presented in Table 1. In addition, the G-EYE increased the detection of both advanced and large-size adenomas by 40% in the right colon.

Conclusion: Our study shows that G-EYE colonoscopy has the potential to significantly improve the quality of CRC screening through improved adenoma detection rates. Special attention should be given to the significant increase in right-sided flat lesions and sessile serrated adenomas by the G-EYE, as these lesions are strongly attributed to CRC. Through improved detection of these right-sided lesions, G-EYE colonoscopy can impact the quality of CRC screening by reducing miss rates and consequently reduce the incidence of interval cancers.

OP135 A STANDARDIZED IMAGING PROTOCOL IS ACCURATE FOR THE ENDOSCOPIC PREDICTION OF DYSPLASIA WITHIN Sessile SERRATED POLYPS

Introduction: Dysplasia within sessile serrated polyps (SSP) is difficult to detect, may be mistaken for an adenoma, risk incomplete resection of the background serrated tissue and is strongly implicated in interval cancer after colonoscopy. The use of endoscopic imaging to detect dysplasia within SSP has not been systematically examined.

Aims & Methods: We aimed to establish whether a standardized imaging protocol was accurate for the endoscopic prediction of dysplasia within sessile serrated polyps. Consecutively detected SSP >8 mm in size were evaluated using a standardized imaging protocol at a tertiary endoscopy centre over 3 years. Lesions suspected as SSP were analysed with high-definition white light (HDWL) then narrow band imaging (NBI). Lesions were considered as SSP when the following features were identified: mucous cap, cloud-like or finely nodular surface, indistinct border, irregular shape and lesion paler than the surrounding mucosa (under NBI). A demarcated area of neoplastic pit pattern (Kudo type III/IV, NICE type II) was sought amongst the serrated tissue. If this was detected the lesion was labelled dysplastic (SSP-D), if not it was labelled non-dysplastic (SSP-ND). Histopathology was reviewed by two blinded specialist gastrointestinal pathologists. Since histopathology is an imperfect gold standard to determine dysplasia within SSP (dysplastic areas can be small and may be missed between tissue sections, destroyed in tissue processing or not retrieved), at the end of the study a structured discussion between endoscopists and histopathologists was undertaken to assign the final determination of dysplasia. Agreement of all parties was required on the final determination.

Results: 141 suspected SSP were assessed in 83 patients. Median lesion size was 15.0 mm (interquartile range 10-20) and 54.6% were in the right colon. All 141 lesions suspected as SSP were confirmed as sessile serrated adenoma at histopathology. Endoscopic evidence of dysplasia was detected in 36/141 (25.5%) SSP. 2/105 (1.9%) endoscopically designated SSP-ND had dysplasia at histopathology. 10/36 (27.8%) endoscopically designated SSP-D had no dysplasia at histopathology. After discussion with the specialist gastrointestinal pathologists, agreement was reached that in 5/10 (50%) endoscopically designated SSP-D previously determined to be without dysplasia at histopathology, there was equivocal evidence for dysplasia. Endoscopic imaging therefore had an accuracy of 95.0% (95% confidence interval [CI]90.1–97.6%) and a negative predictive value of 98.1% (95% CI 92.6–99.7%) for detection of dysplasia within SSP (table 1).

Table 1: Accuracy of the endoscopic assessment of dysplasia within sessile lesions ≥8 mm pre- and post discussion with specialist histopathologists. 95% CI - 95% confidence interval, SSP-ND - sessile serrated polyp without dysplasia as determined endoscopically, SSP-D - sessile serrated polyp with dysplasia as determined endoscopically, SSP-D – sessile serrated polyp with dysplasia determined histologically or by structured discussion, SSA-ND – sessile serrated polyp without dysplasia as determined histologically or by structured discussion, NPV - negative predictive value.

Conclusion: Dysplasia within SSP can be accurately detected using a simple, broadly applicable endoscopic imaging protocol allowing their complete resection. This independent validation of this protocol and its dissemination within the endoscopic community may have a significant impact on rates of interval cancer.

Introduction: There have been few reports of the safety and usefulness of cold snare polypectomy (CSP) for colorectal polyps of 10 mm or less. This study examined the usefulness and safety of CSP for outpatient same-day treatment.

Aims & Methods: During the period from December 2015 to October 2016, informed consent was obtained before examining outpatients scheduled for colonoscopy of the entire large intestine. Patients found to have colorectal polyps (excluding Ig polyps) of 10 mm or less were included in this study. Patients on oral antithrombotic therapy, which was a stratifying factor, were randomly assigned to a CSP group and an endoscopic mucosal resection (EMR) group. The two groups were compared for the following treatment endpoints: (1) postoperative hemorrhage rate, (2) polyp resection time, (3) en bloc resection rate, (4) postoperative hemorrhage rate with and without oral antithrombotic administration, and the (5) rate of retrieval of tissue from resected lesions.

Results: 300 patients were enrolled in the study. After exclusion of one patient who did not complete CSP, 149 CSP group cases and 150 EMR group cases were analyzed. The values for the treatment endpoints were (1) 0.67% (1/149), (2) 92.2±9.2 sec, (3) 99.1% (348/351), (4) 0% (0/21) and (5) 96.6% (339/351) in the CSP group, and (1) 0.67% (1/150), (2) 144.6±18.9 sec, (3) 100% (322/322),
(4) 0% (0/21) and (5) 99.1% (319/322) in the EMR group. Although there were no significant differences between the groups in regard to (3), (15), or (4), the (2) polyp resection time was significantly shorter in the CSP group (p = 0.001), and the (5) rate of collection of tissue from resected lesions was lower in the CSP group (p = 0.029).

Conclusion: Resection of colorectal polyps in outpatients showed a low incidence of complications in both the CSP and EMR groups and was performed safely. The polyp resection time was significantly shorter with CSP than with EMR, and shortening of the examination time can be expected.

OP137 IS COLD-SNARE POLYPECTOMY ALWAYS ADEQUATE FOR REMOVAL OF SMALL COLORECTAL POLYPS WITH ADVANCED HISTOLOGY?

Y. Shimodate1, M. Mizuno1, J. Itakura2, R. Takezawa3, M. Kobayashi1, T. Yamazaki1, A. Doi1, N. Nishimura1, H. Mouri1, K. Matsueda1, H. Yamamoto1

Introduction: The new European Society of Gastrointestinal Endoscopy clinical guidelines recommend cold-snare polypectomy (CSP) for removal of small colorectal polyps. The recommendation is based on the efficacy and safety of the technique and the assumption that most small polyps have only low-grade histology. However, advanced neoplasia may be unexpectedly removed with CSP, raising concern about possible residual tumor and local recurrence in such cases. For accurate microscopic assessment of CSP-removed polyps, wide horizontal excision and adequate depth is necessary.

Aims & Methods: In this study, we prospectively investigated the efficacy of CSP from the aspects of depth of excised tumors and their vertical margins. Two hundred and seventy-six consecutive sessile or slightly elevated colorectal polyps, removed with CSP by an experienced endoscopist (more than 500 CSPs performed), were enrolled between May 2016 and January 2017. Three of the polyps were excluded because of retrieval failure. Devices used were the Profile/Captivar (Boston scientific) and Exacto (US Endoscopy). Excised polyps were retrieved by suctioning them through the colonoscopy’s biopsy channel. All unretrieved removed specimens were mounted on plates with pins to facilitate pathological assessment and were evaluated blindly without pathologists having clinical information of the lesions. Evaluated items included resection into the muscularis mucosa (MM) and histology of the tumor’s vertical margins. Resection was considered complete when MM was present under the tumor along more than 80% of its horizontal axis. Gross morphology of polyps was classified according to the Paris classification system (sessile, Is; or slightly elevated, Ia).

Results: Mean size of 273 polyps was 4.9 mm. Twenty-one lesions (7.7%) were elevated, IIa).

Histology Neoplastic 1 1
Non-neoplastic 0.5 1 0.5 0.5
(0.0.14-1.0)(0.0.45-1.2)

Pseudo/ submucosal injection No 1 1
Yes 0.8 0.608 0.8 0.6
(0.28-2.80)(0.28-2.11)

Device Profile/Captivar 1 1
Exacto 1 0.355 1.3 0.47
(0.70-2.56)(0.66-2.51)

Location Left 1 1
Right 1.5 0.27 1.6 0.17
(0.76-3.06)(0.82-3.06)

Morphology Slightly elevated (IIa) 1 1
Sessile (Is)a 2.2 0.017 2.3 0.01
(1.14-4.41)(1.22-4.39)

Tumor size 1-5 mm 1 1
6-9 mm 1.1 0.87 0.9 0.73
(0.53-2.11)(0.44-1.79)

Conclusion: CSP achieved proper resection depth in only about 80% of lesions even when performed by an experienced endoscopist. Given that a few small polyps with advanced histology may be unexpectedly resected with CSP, this procedure should be evaluated further, especially for sessile polyps with advanced histology, before it becomes standard of care for excision of small colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Adequate polypectomy is important during screening colonoscopy to prevent progression of colorectal carcinoma and decrease mortality. Cold polypectomy is now widely performed. Cold forceps polypectomy (CFP) is a simple and quick technique allowing complete resection of most DPAs. However, evidence for its efficacy is lacking, precise histopathological diagnosis is difficult, and little is known about the risk factors for histologically incomplete resection.

Aims & Methods: The aim of this retrospective cohort study is to evaluate the clinicopathological characteristics and clinical outcomes of patients who underwent removal of DPs by CFP as well as predictors of incomplete resection. We retrospectively investigated 1129 DPs resected by CFP with jumbo biopsy forceps (Radial Jaw2k4; Boston Scientific, Marlborough, MA) in 587 patients (392 men, 195 women; mean age 66±9.4 years) at Hiroshima City Asa Citizens Hospital between November 2015 and December 2016. We evaluated the clinical outcomes of 999 tumours for which a precise histopathological analysis was made and investigated the relationship between incomplete resection and clinicopathological factors. Complete resection was defined as when additional bites for resection were not needed and both the lateral and vertical margins of the specimen were tumour-free resection margins.

Results: Lesions were mainly located in the transverse colon (336 lesions, 30%), ascending colon (252 lesions, 22%) and sigmoid colon (228 lesions, 20%). Of the lesions, 1013 (94%) were protruding/sessile and 65 (6%) were flat elevated. Most lesions (985[87%]) were low-grade (n = 783) or high-grade (n = 202) adenomas and 14(1%) were well-differentiated adenocarcinomas. The en bloc resection rate was 92%(198/999) and the histological en bloc resection rate was 78% (777/999). Precise histopathological diagnosis was difficult in 22% of cases. The lateral margins could not be assessed histologically for tumour involvement in 155 (16%) lesions, additional bites for resection were needed for 81 (8%) lesions, and involvement of the vertical margin could not be histologically assessed in 56 (6%) lesions. Multivariate analysis showed tumour size ≥4 mm (odds ratio [OR] 3.8; 95% confidence interval [CI] 2.65–5.37; p < 0.01), non-tangential direction of forces in relation to the tumour (OR 1.73; 95% CI 1.21–2.45; p < 0.01), and lack of muscularis mucosae mucosal in the pathological specimens (OR 15.7; 95% CI 9.16–27.7; p < 0.01) to be significant independent predictors of incomplete resection. One (0.1%) of the 999 patients had delayed bleeding that was easily managed by endoscopic clipping. There were no cases of perforation.

Conclusion: This study identified significant independent predictors of incomplete resection of diminutive colorectal polyps and may provide helpful information when planning CFP.

**Conclusion:** There is high concordance between both abnormal AET and borderline AET, and low MNBI. When low, MNBI identifies patients with abnormal as well as borderline AET (but not physiologic AET) who respond to medical and surgical anti-reflux therapy. MNBI therefore complements AET in defining esophageal reflux burden, and in predicting symptom response to anti-reflux therapy.

**Citation:** Abnormal esophageal acid burden measured using acid exposure time (AET) from 24-hour pH-impedance monitoring predicts favorable symptom outcome from medical and surgical anti-reflux therapy. Alternative reflux evidence is deemed necessary when AET is borderline and inconclusive. Esophageal baseline mucosal impedance extracted from pH-impedance data during night-time hours (MNBI) represents a new paradigm that is co-linear with AET. The value of MNBI when AET is inconclusive has not been previously evaluated.

**Aims & Methods:** Our aim was to determine the value of MNBI in predicting symptom outcome from medical and surgical anti-reflux therapy when AET is borderline and inconclusive, in this ongoing multicenter collaboration. Esophageal function studies from patients with persisting reflux symptoms were reviewed from two centers (one each in Europe and US) for this preliminary report. For inclusion, patients with typical or atypical reflux symptoms were required to have completed ambulatory pH-impedance monitoring (Sandhill Scientific, Boulder, CO) off antisecretory therapy. AET data were extracted from ambulatory pH-impedance studies. Overall AET was abnormal when > 6%, and physiologic when < 4%; AET 4-6% was considered borderline and inconclusive. Baseline impedance was calculated at the 5 cm impedance channel (to correspond to AET) at three stable 10-min time periods (1, 2, and 3 AM) during the ambulatory pH-impedance study, and averaged to yield MNBI, abnormal if < 2292 ohms. Symptom response was assessed using change in global symptom scores from symptom questionnaires over follow-up; a 50% reduction in global symptoms constituted a response to anti-reflux therapy, both medical management and anti-reflux surgery. Data were analyzed to assess concordance between AET and MNBI, and to assess symptom response in relationship to physiologic, borderline and abnormal AET in the context of abnormal MNBI.

**Results:** A total of 371 patients (54.5 ± 0.7 yr, 60.0% female) had adequate pH-impedance studies performed off antisecretory therapy, and symptom data available for inclusion in this study. Of these, 107 (28.8%) had abnormal AET, and 264 (68.3%) had abnormal MNBI. Of 107 patients with abnormal AET, low MNBI was concordant with AET in 106 (99.1%), and discordant (abnormal AET, normal MNBI) in only 1 patient. Similarly, concordance between AET 4-6% and low MNBI was noted in 62 of 68 patients (91.2%), and discordance (AET 4-6%, normal MNBI) in only 8.8% (p = 0.011 compared to AET > 6%). In contrast, of 196 patients with physiologic AET, discordant normal MNBI was noted in only 130 (66.3%), and with the remainder 33.7% discordant with physiologic AET but low MNBI (p < 0.0001 for each comparison with AET > 6 and AET 4-6%). Of 330 patients with symptom data available from medical therapy, 142 (43.0%) had at least 50% symptom improvement over 38.7 ± 0.8 months of follow up. Symptom response following antireflux surgery was available in 63 patients, and 48 (76.2%) responded (p < 0.0001 compared to medical therapy). Response to both medical therapy and surgery were better when AET > 6% (medical therapy: 74.2% response, surgery 78.3% response) and MNBI < 2292 (medical therapy: 60.1% response, surgery: 82% response). In contrast, response to therapy was worse when AET < 4% (medical therapy: 21.1% response, surgery: 69.6% response), and MNBI < 2292 (medical therapy: 17.4% response, surgery: 53.8% response). Response to medical therapy with AET 4-6% resembled that seen when AET > 6% when MNBI was low (Table, p = 0.44), significantly different from patients with AET < 4, regardless of whether MNBI was normal or low (p < 0.0001 for each comparison).

**Conclusion:** There is high concordance between both abnormal AET and borderline AET, and low MNBI. When low, MNBI identifies patients with abnormal as well as borderline AET (but not physiologic AET) who respond to medical and surgical anti-reflux therapy. MNBI therefore complements AET in defining esophageal reflux burden, and in predicting symptom response to anti-reflux therapy.
LES-CD separation in HH patients was 2.13 cm. 47% were classified as Type I EGJ, 35% as Type II and 18% as Type III. Mean Result:

We enrolled 100 patients. During surgery, 53% had a HH. In details, 4 cm CD, Type II EGJ above CD obtained. A large endoscopic clip was applied to mark the EGJ. The distance 2 cm separation; Type III classified as Type I (normal EGJ without evidence of the B ring or gastric border of CD impression and to the top of the proximal gastric folds was displaced above the proximal border of CD. At UE the distance from proximal folds), Type II was classified as Type I (normal EGJ without evidence of the B ring or gastric folds), Type II and Type III documented patients (0.01; IQR 0–0.04) and abnormal in 12 (7.8 IQR 6.9) (p < 0.001). All details are reported in Table 1. A strong linear correlation between BR and MNBI was observed (Pearson test; r = -0.771, p < 0.001).

Introduction: Sliding hiatal hernia (HH) has been associated with abnormal esophageal acid exposure, prolonged esophageal clearance, increased reflux episodes and it is correlated with the severity of gastroesophageal reflux disease. The diagnosis of HH is made with a barium-swallow esophagogram (BSE), and it can be also described at upper endoscopy (UE). However, these methods are limited by the subjective and indirect evaluation of lower esophageal sphincter (LES) and crural diaphragm (CD). High resolution manometry (HRM) allows to clearly identify CD and LES. However, its diagnostic accuracy has been poorly investigated.

Aims & Methods: Aim of the study was to determine the diagnostic value of HRM in the detection of HH, compared to BSE and UE, using as reference the surgical in vivo measurement. We prospectively enrolled patients undergoing open foregut surgery between 2009 and 2014. All subjects underwent BSE, UE, HRM and in vivo evaluation of esophageal gastric junction (EGJ). At BSE EGJ was classified as Type I (normal EGJ without evidence of the B ring or gastric folds), Type II ≥2 cm and Type III ≥2 cm, when the B ring or gastric folds were displaced above the proximal border of CD. At UE the distance from proximal border of CD by compression and to the top of the proximal gastric folds was recorded. UE Type I indicated a normal EGJ; Type II and Type III documented patients (0.01; IQR 0–0.04) and abnormal in 12 (7.8 IQR 6.9) (p < 0.001). AET (med; IQR) 5.6; 1.9 5.9; 2.2 0.567. Reflux number (med; IQR) 61; 19.5 64.5; 22.5 0.668. All details are reported in Table 1. A strong linear correlation between BR and MNBI was observed (Pearson test; r = -0.771, p < 0.001).

OPI43 REDUCTION OF DAY TIME ACID GASTRO OESOPHAGEAL REFUX BY TREATING INCREASED SUPRAGASTRIC BELCHING

E. Glasinovic1, E. Wynter2, J. Arguero3, P. Hajek4, D. Sifrim5

3Wingate Institute, Queen Mary University London Wingate Institute Centre for Digestive Diseases, London/United Kingdom

Introduction: Supragastric belching (SGB) is considered a behavioural disorder. SGB can manifest as a large number of belch episodes during daytime, or can be associated with reflux symptoms or rumination. Supragastric belches can be immediately followed by acid reflux and in some GERD patients, SGB-associated reflux can contribute to up to 1/3 of the total acid exposure (AET) immediately followed by acid reflux and in some GERD patients, SGB-associated reflux can contribute to up to 1/3 of the total acid exposure (AET).

We hypothesized that reducing SGB might improve QOL (Koukias, 2015). Current treatments for SGB are cognitive behavioural therapy (CBT) and Baclofen. We hypothesized that reducing SGB might improve QOL and reduce acid GERD.

Aims & Methods: The aim of our study was to assess the effectiveness of CBT in patients with pathological SGB and/or increased SGB-related acid reflux exposure. Patients were recruited from the upper GI Physiology Unit after performance of pH-pHmetry (Sandill Sci, USA). Visual analysis of tracing was performed to identify SGB and patients with more than 13 SGB/day were invited to participate. A total of 45 patients were included in the SGB group. The CBT protocol was adapted from Katzka et al (2013) and consisted of teaching 1. diaphragmatic breathing, 2. mouth opening/tongue position and 3. recognition of a warning signal/feeling pre-belching. Patients exercised these manoeuvres daily and tried to apply them to prevent belching. Before and after CBT, subjective evaluation included a 4-item visual analog scale (VAS) regarding severity of belching. Objective evaluation included pH-pHmetry at baseline and after CBT therapy. Parameters were number of SGB, the acid exposure time (AET), and proportion of AET associated to SGB.

Methods: Patients were recruited since March 2016. So far, 30 patients completed the protocol (median age: 45, range 20–72, 16 females) of which 28 had a second pH study. Subjective evaluation: VAS scores decreased after CBT in 30/31 patients (before: 200 (220–320) mm vs. after: 140 (200–230) mm, p < 0.0001). 15/31 patients had VAS score improvement > 50%. Objective evaluation: Number of SGB decreased significantly after CBT in 25/28 patients [before: 89 (45–230) vs. after 42 (19–138), p < 0.0001]. 15/28 patients had reduction of SGB by more than 50%. Fifteen patients had increased AET pre-treatment, [AET 9.3 (SEM 0.84). In these patients SGB contributed to 31% of the AET. Overall, AET after CBT was: 6.2 (SEM 0.95), p = 0.0056). In 8/15 patients with baseline increased AET, we observed after CBT a reduction of number of reflux episodes driven by SGB and AET by 40%.

Conclusion: Cognitive behavioural therapy ameliorates supragastric belching. It reduces the number of belches and improves social and daily activities in 50% of patients. Careful analysis of pH-pHmetry allows identification of a subgroup of GERD patients with acid reflux predominantly driven by SGB. In these patients, CBT can reduce daytime esophageal acid exposure.

Introduction: Traditionally, acid exposure time (AET) has been regarded as the most useful parameter to predict heartburn improvement with proton pump inhibitor (PPI) therapy. However, recent studies showed high rates of heartburn response to PPIs also in patients with normal AET. Two novel impedance parameters, namely the post-reflux swallow-induced peristaltic wave (PSPW) index and mean nocturnal baseline impedance (MBI) were found useful in identifying GERD patients and distinguishing between reflux hypersensitivity and functional heartburn (FH). Therefore, they could prove useful in predicting PPI-induced heartburn relief.

Methods: We aimed to investigate demographic, endoscopic and impedance features able to predict PPI response in patients with heartburn. Off-therapy impedance-pH tracings from 425 patients, 317 with definitely PPI-responsive heartburn (i.e. heartburn repeatedly abolished by 4-week PPI-therapy and repeatedly recurring after PPI withdrawal) and 108 with PPI-refractory (i.e. >50% of symptom relief after 8-week high-dosage PPI therapy), were blindly analyzed. Baseline demographic and endoscopic characteristics, conventional impedance-pH variables including acid exposure time (AET) and number of reflux episodes, PSPW index and MBI were assessed by means of multivariable logistic regression to identify independent predictors of PPI responsiveness. Models based on independent predictors were then developed and compared for the ability to predict symptom improvement by calculating the area under the Receiver Operating Characteristic (AUC) curve. Finally, logistic regression analysis was used to adapt a prediction model.

Results: AET, MBI and PSPW index were the only factors associated with PPI responsiveness: abnormal values were found in 60%, 76% and 92% of PPI-responsive cases (P < 0.017 for all pairwise comparisons). As shown in the Table, using AUCs, PSPW index (AUC 0.794, P = 0.002) and MBI (AUC 0.741, P = 0.003), both separately and combined (AUC 0.810, P < 0.001), predicted PPI responsiveness better than AET (AUC 0.687).

Conclusion: AET, PSPW index and MBI are independent predictors of heartburn responsiveness to PPIs. However, PSPW index and MBI can link PPI responsive heartburn to reflux better than AET and should become part of the standard analysis of impedance-pH tracings.

OP146 IDENTIFICATION OF A MICROBIOTA BENEFICIAL AGAINST COLITIS AND COLITIS-ASSOCIATED CANCER

Introduction: Inflammatory bowel disease (IBD) is an inflammatory disease of the gastrointestinal tract. The pathogenesis of IBD is multifactorial, involving genetic, environmental, and microbial factors. Microbiome dysbiosis is a hallmark of IBD and has been associated with disease severity. The colonization of germ-free mice with the microbiota from patients with ulcerative colitis (UC) or Crohn’s disease (CD) induces colitis, suggesting a pathogenic role for specific bacterial taxa.

Aims & Methods: In this study, we aimed to investigate the role of the intestinal microbiota and its interaction with the host mucosa in mediating the protection against inflammation observed in UC and CD mice. We examined the impact of the microbiota on the development of colitis in both UC and CD mice.

Results: We observed that the colonization of germ-free mice with the microbiota from patients with UC or CD induced colitis, with significantly increased disease activity and pathological features, including increased colon weight, colon length, MPO, fecal LCN-2, tumor count, and tumor size. The microbiota from UC and CD patients induced similar pathological changes, suggesting a common pathogenic mechanism.

Conclusion: This study demonstrates that the microbiota from UC and CD mice are capable of inducing colitis in both UC and CD models. The findings suggest that specific bacterial taxa may contribute to the pathogenesis of IBD. Further studies are needed to identify the key players and mechanisms involved in the development of colitis.

Introduction: Several gastrointestinal diseases, such as inflammatory bowel diseases and Irritable Bowel Syndrome (IBS), are characterized by epithelial barrier alterations which likely play a key role in the pathogenesis. In the absence of a clear pharmacological interventions to restore intestinal permeability in IBS, an interesting perspective is represented by probiotics, live microorganisms widely used in clinical practice. Escherichia coli Nissle 1917 (EcN) is a probiotic already approved for the maintenance of remission of ulcerative colitis, although the underlying molecular mechanism remains to be clarified.

Aims & Methods: The aim of this study was to characterize the potential effect of EcN in reversing the increase of intestinal permeability caused by known stimuli and to evaluate the potential efficacy of EcN in IBS. We used an in vitro model of jejunal epithelial monolayer permeability induced by SLigR (a protease-activated receptor-2 activating peptide). Our study revealed that EcN significantly reduced intestinal permeability by decreasing the expression of ZO-1 and occludin, which are important tight junction proteins.

Results: EcN induced a dose-dependent reduction of EcN-2 monolayer of 52% (108, P < 0.05) and 32% (106) compared to untreated CaCo-2 (CTR). TCPNf and IFN-γ induced an increase in CaCo-2 permeability compared to CTR (P < 0.05). The co-incubation of EcN with IFN-γ reduced the increase of epithelial integrity by 77% and 63% for 108 and 106 respectively, compared to SLigR alone. EcN induced a significant increase in ZO-1 and occludin gene expression compared to CTR (P < 0.05). The co-incubation of EcN with IBS showed a recovery of permeability rate compared to untreated IBS (P < 0.05). In conclusion, our study demonstrated that EcN has the potential to restore intestinal permeability in IBS, which is an important target in the management of this condition.
incubation of EcN 108 with SUP of patients with IBS-D led to a significant recovery of barrier integrity (P < 0.05).

Conclusion: EcN is able to act on different tight junction proteins by reinforcing the integrity of the intestinal epithelial barrier. EcN reverts the increase of epithelial monolayer permeability induced by inflammatory stimuli and mediators spontaneously released by IBS biopsies. Further study should look at EcN potential application in IBS.

Introduction: Irritable bowel syndrome (IBS)-type symptoms affect 35% of patients with clinically quiescent inflammatory bowel disease (IBD). (1) The presence of these symptoms is associated with anxiety, depression, somatisation and reduced quality of life, (2) but their effect on disease outcomes remains uncertain. Alterations in the intestinal microbiome are implicated in pathogenesis of IBS and IBD, yet whether intestinal dysbiosis is also associated with the development of genuine IBS-type symptoms in quiescent IBD remains uncertain.

Aims & Methods: We aimed to assess the microbiome in 270 consecutive IBD patients who, using a combination of clinical disease activity indices, the Rome III criteria for IBS and faecal calprotectin (FC) (using a cut-off of 250ug/g to define active mucosal inflammation), were divided into four groups as follows: True IBS, quiescent disease, occult inflammation, active disease. Baseline demographic, disease-related and psychological data were described in Table 1.

Results: Baseline demographic, disease related and psychological data are described in Table 1.

Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract No: OP148

*Independent samples t-test for continuous data, and y2 for comparison of categorical data vs. IBD with true IBS.

Microbiome composition was highly variable, even within patient groupings. No major taxa were differentially abundant between the four disease status groups. Patients with quiescent disease appeared to have greater phylogenetic alpha diversity than the other three disease status groups, which were similarly diverse, though this difference was not statistically significant. Beta diversity analysis showed slight, though significant, variation between the four groups. Differences between Crohn’s disease (CD) and ulcerative colitis (UC) patients were much more marked. In CD, there was a lower proportional abundance of the genus Faecalibacterium (3.46% versus 6.97%; P < 0.001), and a higher proportional abundance of the genus Ruminococcus (3.63% versus 1.27%; P < 0.001). Phylogenetic alpha diversity was also significantly lower in CD (P < 0.001). Beta diversity analysis showed significantly greater within-group variation amongst CD patients compared to UC patients.

**Introduction:** The complement system is the major humoral component of innate immunity. Despite its key role in sensing microbial surfaces, its impact on the equilibrium at the interface of gut immune system and microbiota in health and inflammation remains elusive. Recently, complement protein C4 was implicated in the pathogenesis of Crohn’s disease by a genome wide association study.

**Aims & Methods:** Thus, we performed a study to delineate the impact of the complement system on (i) the relationship of host and microbiota and (ii) the properties of the mucosal immune response in health and inflammation. The extent of complement opsonization of the microbiota was quantified by flow cytometry (FC): Bacteria were isolated from stool of IBD patients, stained for immunoglobulin A (IgA) and C3b/c and classified as double negative, double positive or single positive. The share of events in each of these populations was correlated with the level of inflammation, clinical disease activity, and therapeutic strategies employed. The 4 populations were sorted via fluorescence-assisted cell sorting (FACS) and metagenomic analysis of these bacterial fractions was performed. Expression of complement proteins in the intestine was analyzed by quantitative polymerase chain reaction (qPCR) of mRNA isolates from colonic biopsies in active disease. However, this was not true for all targets and the model was established to investigate complement opsonization in the intracellular handling of pathogens: Helicobacter cells were infected with GFP-tagged Salmonella typhimurium (opsonized and non-opsonized) and intracellular growth was quantified over time by culture, confocal laser scanning microscopy and flow cytometry.

**Results:** Complement proteins were markedly upregulated in ileal and colonic biopsies in active disease. However, this was not true for all targets and the observed change differed between genes. Mucosal expressions were different from the luminal environment: While most complement components were detectable in biopsies at the mRNA level, only certain complement proteins could be identified in stool. Importantly, this included C3, but not the terminal complement complex. The extent of C3b coating of bacterial surfaces correlated significantly with the level of inflammation (p = 0.003). The proportion of complement opsonized bacteria ranged from 0 % to 4 % and did not correlate with intestinal inflammation. This was also different from IgA opsonization which correlated positively with the grade of inflammation. Employing FACS and 16S-based metagenomics, we were able to identify specific microbial species within the respective sorting groups (IgA/C3c double-positive, double-negative, and single-positive fractions) which showed some association with inflammation and specific disease. The cell culture experiments showed a significant difference in intracellular Salmonella loads after 6 and 24 hours (p = 0.019), which was independent of bacterial uptake by the cells or non-specific binding.

**Conclusion:** The complement system represents a relevant player in human IBD. We show that the complement system has some specificity for commensal bacterial distinct from IgA both in the steady state and during intestinal inflammation. Moreover, we show that complement opsonization optimizes the clearance of intracellular bacteria by epithelial cells.

**Introduction:** Biological therapy with anti-TNF blockade forms the backbone for treatment in moderate to severe Crohn’s disease (CD). Metabonomic approaches to profiling Crohn’s disease has led to numerous discoveries in disease pathogenesis and is an important in elucidating pathways responsible for interactions between human microbiota and host.

**Aims & Methods:** The aim of our longitudinal study was to identify predictive biomarkers of response to anti-TNF therapy using metabolomic and microbiome profiling. Moderate to severe CD patients with luminal disease commencing anti-TNF therapy had 3-monthly visits for 12 months with collection of biofluids (urine, faeces and serum) and disease assessment performed at each visit. Assessment of response was by biochemistry and faecal calprotectin or mucosal healing. A response index combining biochemistry (50% decrease in FC or CRP) and mucosal healing within 14 weeks was used to define therapeutic response in the presence of adequate drug level. We collected 179 urine, 210 serum and 168 faecal samples from 68 anti-TNF naive CD patients (luminal phenotype undergoing anti-TNF therapy without surgical resections) and 20 healthy controls. Liquid-Chromatography Mass Spectroscopy using Waters Xevo TQ-S and Processing using Woleryzkit, sequencing with MiSeq illumina and processing using MiseqData was performed.

**Results:** There were 18 non-responders and 9 responders to anti-TNF therapy according to our strict criteria for response. Multiple biomarkers were identified across assays to be significant for predicting anti-TNF response to therapy across all visits (Table 1). The strongest models were from serum bile acid (R2X0.29, Q2Y0.30, p = 4.97 × 10−5) and urinary HILIC (R2X0.14, Q2Y0.30, p = 1.28 × 10−3). Serum BA profiling analysis identified 2 conjugated and 1 unconjugated BAs, while urinary HILIC profiling identified cysteine as biomarker with MiSeq illumina and processing using MiseqData was performed. Lactobacillus is higher in responders while clostridiales were lower in abundance for non-responders after bonferroni correction. Lactobacillus is known to synthesise cysteine from serine and for expansion in gut microbiota. Faecalibacterium and rumonococcus increased over time in responders to anti-TNF therapy. However, the overall quantities of species did not alter significantly over time nor with therapy.

**Conclusion:** The metabonomic approach is an important tool in demonstrating the chemical profile of alterations in human microbiota resulting from inflammatory bowel disease and therefore the interaction that occurs between the microbiome and host. This prospective, longitudinal cohort study of microbiome and metabolomic analysis demonstrates that there are predictive biomarkers involved with bile acid and inflammatory pathways. The microbiome of patients with Crohn’s disease does not alter significantly despite anti-TNF therapy response which allows for prediction of therapeutic outcome.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: The abundance of trillions of beneficial commensal microorganisms that reside in the small and large intestinal tract together with cells of the gut-associated immune system requires an effective barrier in order to preserve tissue homeostasis. There is overwhelming evidence corroborating the notion that the pathogenesis of Crohn’s disease, an idiopathic inflammatory bowel disease, is closely related to the increased immune responses presumably directed against commensal enteric bacteria in a genetically susceptible host. While lymphocyte-derived type II IFN (IFN-λ) has been implicated in the pathogenesis of Crohn’s disease, the impact of IFN-λ on small intestinal inflammation remains unknown.

Aims & Methods: The central aim of this project was the question if and by which pathways type III IFN (in particular IL28, a member of this IFN family) contribute to intestinal inflammation in mice and men. In the long run, we aim to decipher novel functions of type III IFNs on mucosal cells that could be targeted for future therapeutic intervention.

Results: Here we discovered that IL28 (belonging to the type III IFN family) is strongly upregulated on the transcriptional level in vitro and in vivo in human and murine models of ileitis. Remarkably, IL28 immunostaining was particularly enhanced in intestinal epithelial cells in areas of severe inflammation accompanied by a reduced number of Paneth cells. These data strongly implicate that IL28 expression is linked to disease activity in CD. In line with our hypothesis, we identified that IL28 promotes massive epithelial cell death and loss of immune homeostasis in mice with an epithelial cell specific deletion of a central apoptosis mediator caspase-8 (Casp8ΔIEC). While these mice are genetically sensitized to epithelial cell death, we further uncovered that IL28 overexpression in wildtype animals resulted in a nearly complete depletion of Paneth cells. These data demonstrate that IL28 signaling affects Paneth cell homeostasis and thus antimicrobial defense. Notably, this effect was independent of type I and II IFN signaling and directly mediated by STAT1 activation in intestinal epithelial cells. Moreover, we provide compelling evidence that Paneth cell death was dependent on MLKL, a master regulator of regulated necrosis and caspase-8 as a central regulator of cell death. Using the small intestinal organoid model we further uncovered that IL28 overexpression affected the expression of tight-junction molecules suggesting an impact of this cytokine on intestinal barrier function.

Conclusion: In summary, our results strongly implicate a pathophysiological role for IFN-λ during small intestinal inflammation by controlling Paneth cell homeostasis and barrier function and hence the rationale for the investigation of this pathway in other inflammatory or infectious bowel diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Interleukin (IL)-19, a member of the IL-20 cytokine family, that signals through the IL-20 receptor type I (IL-20Rα: IL-20Rβ) is a cytokine with rather unknown function. Although the expression of the type II IL-20 receptor in the colon is low compared to the IL-22 receptor (1, 2), some studies have suggested a role of IL-19 for IBD (3).

Aims & Methods: To investigate the importance of IL-19 for the development of colitis biopsies of patients with Crohn’s disease (CD) and ulcerative colitis (UC) we received from the Swiss IBD cohort study (SIBD project 2015-05). The importance of IL-19 for colitis was further studied with a newly generated Il19−/− mouse model knockout mice.

Results: The expression of IL-19 is increased in biopsies from UC patients but not CD patients with active disease as compared to quiescent disease, whereas the expression of the type II IL-20 receptor is not significantly changed in IBD patients. Furthermore, direct activation of macrophages by CD40 ligation caused colitis, but did not induce IL-19 expression indicating that a barrier breach allowing the access of bacterial-derived products as observed in the DSS model is required for the expression of IL-19 during colitis. The stimulation of macrophages with the Toll-like receptors (TLR) ligands and injection of Lipopolysacharide (LPS) into mice decreased IL-19 expression, whereas TLR3 agonists induced the expression of IL-19, which depends on Mydd8, but TLR2 – 2, – 4 and – 9 ligands but not the TLR3 ligand poly (IC) induced the expression of IL-19. Colonic macrophages but not dendritic cells were identified as a source of IL-19 production, which was further induced by lipopolysaccharide (LPS). The expression of IL-19 was also upregulated upon injection of Oligo-MCM12 and CD1d deficient animals showed a severe DSS colitis, the expression of IL-19 was not induced in Oligo-MCM12 mice after exposure to DSS. Furthermore, direct activation of macrophages by CD40 ligation caused colitis, but did not induce IL-19 expression indicating that a barrier breach allowing the access of bacterial-derived products as observed in the DSS model is required for the expression of IL-19 during colitis. The stimulation of macrophages with the Toll-like receptors (TLR) ligands and injection of Lipopolysacharide (LPS) into mice decreased IL-19 expression, whereas TLR3 agonists induced the expression of IL-19, which depends on Mydd8, but TLR2 – 2, – 4 and – 9 ligands but not the TLR3 ligand poly (IC) induced the expression of IL-19. Colonic macrophages but not dendritic cells were identified as a source of IL-19 production, which was further induced by lipopolysaccharide (LPS).

Conclusion: Microbial-derived products that have entered the host after intestinal barrier breach induce IL-19 expression by macrophages supporting the development of IBD. Although we did not observe an effect of IL-19 on signaling of BMDMs, IL-19 may have direct effects on intestinal macrophages, as we observed IL-20r in the lamina propria of humans and mice, and reduced IL-6 production by colonic macrophages of IL-19 deficient mice with colitis. The deletion of the individual members of the IL-20 cytokine family and individual receptor chains is needed to further dissect the importance of this cytokine family for IBD.

OP154 CD1D MODULATES COLONIC INFLAMMATION IN NOD2−/− MICE BY ALTERING THE COMPOSITION OF INTESTINAL MICROBIOTA
S. Hong, C. Lee, Y. Kim
Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: gisnhong@gmail.com

Introduction: NOD2 mutations are associated with the development of inflammatory bowel diseases. However, while most animal studies have reported no impact of NOD2 deficiency on experimental colitis, NOD2 deficiency only is insufficient for development of IBD and an additional hit is needed. Like NOD2, the deficiency of CD1d, non-classical MHC class I molecule, showed no impact on experimental colitis. Although we did not observe an effect of IL-19 on signaling of BMDMs, IL-19 may have direct effects on intestinal macrophages, as we observed IL-20r in the lamina propria of humans and mice, and reduced IL-6 production by colonic macrophages of IL-19 deficient mice with colitis. The deletion of the individual members of the IL-20 cytokine family and individual receptor chains is needed to further dissect the importance of this cytokine family for IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
DSS-induced colitis in NOD2+/− mice compared to those of littermate cohousing NOD2+/+, CD1d+/+, and wild-type mice during DSS-induced colitis (<p<0.001 and p=0.019, respectively). The intestinal microbial composition of NOD2−/− CD1d−/− mice was different (decreased relative abundance of Bacteroidetes and increased relative abundance of Firmicutes). Paneth cell degranulation was decreased in NOD2−/− CD1d−/− mice compared to those of littermate cohousing NOD2+/+, CD1d+/+, and wild-type mice after pilocarpine administration (p<0.001).

**Conclusion:** The CD1d in NOD2−/− mice modulates colonic inflammation by altering the composition of the intestinal microbiota, which may be caused by Paneth cell dysfunction.

**Introduction:** Previous studies show that murine- and human-derived Clostridium strains, which are decreased in active human inflammatory bowel diseases (IBD), induce colonic TGFβ and IL-10-producing Foxp3 regulatory T cells (Tregs) and attenuate experimental colitis in murine models (Atarashi K, . . . Honda K, Science 2011 and 2013). However, additional protective effects of these commensal intestinal bacterial species independent of IL-10 are unknown.

**Aims & Methods:** To investigate IL-10-independent effects of the Clostridium strains, we treated IL10−/− mice, which develop T-cell-mediated colitic, with 17 human Clostridium strains obtained from Dr. Honda and analyzed the degree of colitis and microbiota, metabolomic and immunological profiles. To establish a “humanized” colitis model, we colonized germ-free (GF) IL10−/− mice with either a mixture of three aggressive human bacteria species (Escherichia coli LF82, Enterococcus faecalis and Ruminococcus gnavus, EER) or feces from a normal human. We treated these EER- and human feces-induced colitis mice with the mixture of human-derived 17 Clostridia before or 2 weeks after bacterial colonization. The severity of colitis was examined by blinded histological scores, as well as expression of IFNγ, IL-12p40 and IL-17 in colonic tissues. Flow cytometry analysis of Foxp3 and several cell surface markers was performed using lamina propria cells, mesenteric lymph node cells and splenocytes.

**Results:** The EER- and human feces-colonized exGF IL10−/− mice developed progressive colitis with increased Th1/Th17 responses, but the 17 Clostridia significantly diminished histidine decarboxylase, a key enzyme converting histidine to histamine, in colonic tissues and fecal histamine levels compared to non-treated groups (Table).

Introduction: The population prevalence of Rome IV functional dyspepsia and its effect on health impairment is unknown. We used data from a population-based study to address this, and compared somatisation, quality of life, healthcare utilisation, and presence of overlapping irritable syndrome and functional heartburn in individuals fulfilling criteria for Rome IV functional dyspepsia against non-dyspeptic controls.

Aims & Methods: An internet-based health survey was completed by 6300 general population adults from three English-speaking countries (2100 each from United States, Canada, and United Kingdom). Quota-based sampling was used to ensure equal sex, age, and education distribution across the countries. The survey included questions on demographics, healthcare visits, medication use, criteria for the Rome IV functional dyspepsia as well as for irritable bowel syndrome and functional heartburn, the patient health questionnaire-12 somatisation measure, and the Short Form-8 quality of life questionnaire.

Results: Data was available for analysis from 5931 subjects (49.2% female; mean age 47.4 years, range 18-92). Overall, 551 (9.3%) of the population fulfilled criteria for Rome IV functional dyspepsia. This comprised 339 (61.5%) with postprandial distress syndrome-PDS, 97 (17.6%) with epigastric pain syndrome-EPS, and 115 (20.9%) with overlapping PDS-EPS. Subjects with functional dyspepsia had significantly greater health impairment than non-dyspeptic controls, with on average 73% seeking healthcare more than once yearly and 59% taking GI-relevant medication (i.e. GI-specific, psychotropics, analgesia, or complementary medicine). Notably, those with overlapping Rome IV PDS and EPS had higher frequency of co-existing irritable bowel syndrome and functional heartburn, worse somatisation, and poorer mental and physical quality of life scores, compared to EPS- or PDS-alone (see table). Somatisation and quality of life scores were similar between EPS- and PDS-alone.

Conclusion: Almost 10% of the population fulfil criteria for Rome IV functional dyspepsia, subjects with Rome IV functional dyspepsia, in particular those with overlapping PDS and EPS, have considerable health impairment. This is despite frequent healthcare visits and use of GI-relevant medication. Study support: The Rome Foundation

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Previous studies have defined irritable bowel syndrome (IBS), as well as distinct upper and lower gastrointestinal (GI) symptom groupings, by factor analysis. However, most previous studies have not used population-based samples, and none have used the most recent validated diagnostic questionnaire to define functional GI disorders. The Rome IV criteria define these disorders based on specific symptom combinations. We investigated how these symptom combinations group together in a factor analysis.

Aims & Methods: The Rome IV questionnaire was completed online in English by a population-based sample of 5931 respondents from the United Kingdom, United States, and Canada (49% female, age range 18 to 92 years). We performed an exploratory factor analysis on a selection of questions from the validated Rome IV diagnostic questionnaire, including all symptoms used to define functional GI disorders. The number of factors was decided based on eigenvalues (> 1.0), and varimax rotation was used to simplify the structures. Factor loadings greater than 0.4 were deemed relevant.

Results: Four factors were identified, which we characterised as upper GI symptoms (1), IBS (2), constipation (3), and diarrhoea (4). The upper GI symptoms factor contained a large number of items, including both oesophageal and gastroduodenal symptoms, and had no further breakdown. The IBS factor was defined by the key components in the Rome IV diagnostic criteria for IBS: abdominal pain associated with defecation and abnormal bowel habits (r > 0.75). Faecal incontinence was part of the diarrhoea factor, albeit with a lower loading (r = 0.41). The fourth factor included all six symptoms in the diagnostic criteria for functional constipation. Not fitted were pain "anywhere in the abdomen" (complex structure), bloating/abdominal distension (unique), and anorectal pain (unique). Rotated factor loadings are listed in table 1.

Conclusion: Distinct upper and lower GI symptom groupings exist in the general population, and can be identified using the English Rome IV questionnaire in a large sample from three English-speaking countries.

*p < 0.05 vs non-Rome IV group

Conclusion: Comparing respondents meeting Rome IV OIC criteria with those who did not, they appeared to experience greater symptom and biopsychosocial burden. This study suggests that Rome IV criteria can identify more severe OIC patients, but may underdiagnose OIC patients who do not demonstrate the full scale of symptoms.

Introduction: Constipation is a common side effect of opioid use, and can affect up to 81% of patients, despite concomitant use of laxatives. However, it is not clear whether there is any difference in biopsychosocial disease burden of constipation in patients using strong or weak opioids. Aims & Methods: To assess the impact of strong (e.g. buprenorphine, fentanyl) or weak (e.g. codeine, dihydrocodeine) opioids in patients with chronic pain who have constipation. This was a quantitative, questionnaire-based, online survey of respondents aged ≥40 years with largely non-cancer-related chronic pain, treated long-term with strong opioids (N = 1210) or using weak opioids (n = 605) in Germany, Spain and UK. Past medical history, treatment, symptoms, disease burden, and effects on quality of life were assessed. Results: A comparable degree of bother from constipation symptoms was felt by both weak- and strong-opioid users, with 38% and 40% of respondents, respectively, stating that constipation bothered them quite a lot/a great deal (between-group comparison, p = 0.40). This pattern was reflected in the main psychological symptoms experienced due to constipation (frustration, dependence, anxiety; Table). Both groups were similar in incidence of more common physical symptoms (straining to pass stools, abdominal bloating, sensation of bowel blockage/obstruction; Table). However, weak-opioid users experienced significantly fewer less-common physical symptoms of constipation vs strong-opioid users, including stomach cramps, rectal burning and haemorrhoids (all p < 0.02; Table). Moreover, the impact on quality of life/social symptoms was felt significantly less by weak- vs strong-opioid users (Table).

Table: Study findings in strong- and weak-opioid users who report constipation.

*p < 0.05 vs weak-opioid users

Conclusion: Both weak- and strong-opioid users experience considerable biopsychosocial burden caused by constipation. Weak-opioid users appear to be subjectively as bothered by their constipation as strong-opioid users, despite experiencing less severe physical symptoms and a less drastic impact on quality of life. This may reflect the latter group having more serious underlying pain conditions and/or requiring other concomitant therapies that cause debilitating side effects of greater concern than constipation, compared with the former group.

Introduction: Early diagnosis of chronic pancreatitis (CP) is hindered by the limited accuracy of diagnostic methods. Endoscopic ultrasound (EUS) and the endoscopic pancreatic function test (ePFT) are the most sensitive morphological...
and functional method respectively. The multimodal EUS-based pancreatic evaluation provides dynamic morphological and functional information of the pancreas supporting the diagnosis of CP.

Contact E-mail Address: thomaskroner@gmail.com

Introduction: Rapid weight loss after bariatric surgery (BS) has been associated with the formation of gallstones, and subsequent acute cholecystitis and pancreatitis (AP). However, the complex post-surgical anatomy limits the possibility of performing an ERCP as part of AP treatment. Therefore, the aim of this study was to assess the impact of bariatric surgery on mortality, morbidity and resource utilization among patients with AP using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample (NIS), a publicly available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of AP were included. There were no exclusion criteria. Patients with a past history of BS were included. No significant differences in mortality between the different weight categories presented. Results: The search yielded 1163 studies. After critical review, 4 studies with 1139 patients were included. Mean age was 52 years (SD 18), 546 (52%) patients were men, BMI was 26.3 (SD 6.8), 294 (26%) patients were obese. The most prevalent aetiologies were biliary (n = 439, 39%) and alcohol (n = 195; 17%). 551 (48%) patients had predicted SAP, 299 (26%) had necrosis, 247 (22%) had organ dysfunction. The secondary outcomes were: 1-Morbidity: Intensive care unit (ICU) admission, shock and multi-organ failure. 2- Resource utilization: use of ERCP, cholecystectomy, total parenteral nutrition (TPN), length of hospital stay (LOS), total hospital costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Result: A total of 274,775 patients with AP were included in the study, of which 4240 (1.7%) had undergone bariatric surgery. The mean patient age was 51 years and 48% were female. After adjusting for confounders, patients with and without a history of bariatric surgery had similar adjusted odds of mortality (adjusted Odds Ratio (OR) 1.37, 95% CI: 0.51–3.65, p < 0.02). Looking at morbidity, patients with and without a history of bariatric surgery had similar adjusted odds of shock (aOR: 0.71, 95% CI: 0.23 – 2.24, p = 0.57), multiple organ failure (aOR: 0.61, 95% CI: 0.08–4.37, p = 0.62), and ICU admission (aOR: 0.34, 95% CI: 0.11 – 1.06, p = 0.06). As for resource utilization data, patients with bariatric surgery had lower adjusted odds of ERCP (aOR: 0.55, 95% CI: 0.38 – 0.79, p < 0.01), but both patient groups had similar adjusted odds of cholecystectomy (aOR: 1.21, 95% CI: 0.98 – 1.49, p = 0.07) and TPN use (aOR: 1.21, 95% CI: 0.77 – 1.90, p = 0.41). Interestingly, although patients with bariatric surgery had shorter adjusted length of stay (adjusted mean difference: -0.48 days, 95% CI: -0.74 to -0.23, p < 0.01) and total hospitalization costs (adjusted mean difference: - $755, 95% CI: - $1295 to - $215, p < 0.01), both patient groups had similar total hospitalization charges (adjusted mean difference: $1949, 95% CI: $4366 to $467, p = 0.11).

Conclusion: Bariatric surgery has no impact on inpatient all-cause mortality among patients who develop acute pancreatitis, despite its association gallstone acute pancreatitis and limited ERCP performance. In addition, bariatric surgery does not affect morbidity in this patient population as measured by rate of shock, multiple organ failure and ICU admission. However, a history of bariatric surgery is associated with decreased rates of ERCP, shorter length of stay and lower hospital costs.

**OP167 STATIN CONSUMPTION IS ASSOCIATED TO A LOWER RISK OF POSTENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY PANCREATITIS**

1Gastroenterology. Hospital General Universitario de Alicante - Gastroenterology. Hospital General Universario de Ali, San Juan de Alicante/Spain
2Hospital Universitario Araba, Azaraf/Spain
3Hospital Clínico Universitario Lozano Blesa, Zaragoza/Spain
4Hospital Universitario de Cruces, Bilbao/Spain

Contact E-mail Address: madaria@hotmail.com

**Introduction:** The most frequent complication of endoscopic retrograde cholangiopancreatography (ERP) is post-ERP acute pancreatitis (PEP), which is associated to increased morbidity, mortality and costs. Statin consumption seems to lower the incidence of acute pancreatitis due to other etiologies, according to previous studies. The relationship between statin use and the incidence of PEP has not been studied before.

**Aims & Methods:** We aimed to investigate the relationship between the use of statins and the incidence of PEP. Methods: multicenter (4 Spanish tertiary-care public hospitals) retrospective cohort study. Adult patients undergoing an ERP between January 2015 and January 2016 were included in the study. We excluded patients with chronic pancreatitis, with ongoing acute pancreatitis and those who developed other complications after ERP. Patients were classified into 2 groups: under statin treatment (group S) and controls (group C). A multivariate analysis was performed (binary logistic regression) including possible confounding variables: center, female gender, previous pancreatitis, suspected sphincter of Oddi dysfunction, difficult cannulation (>10 minutes), pancreatic guidewire passages >1, pancreatic injection, pancreatic stent, presence of malignant biliary stenosis and presence of cholelithiasis.

**Results:** Six hundred and ninety-four patients were included, median age 76 (63–85), 324 (41%) females, 209 (30%) in group S. Thirty (0.5%) patients developed PEP, 4 (2%) in group S and 28 (6%) in group C. Univariate analysis yielded an Odds Ratio (OR) for developing PEP for group S of 0.3 (0.1–0.9), p = 0.034; multivariate analysis showed an adjusted OR of 0.3 (0.1–0.8), p = 0.020. Only 1 patient died (overall: 0.1%, within patients with PEP: 4%), who was in group C.

**Conclusion:** We conclude that in our sample of patients, statin consumption was independently associated to a 70% risk reduction of PEP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The incidence of acute pancreatitis (AP) is the most frequent complication of endoscopic retrograde cholangiopancreatography (ERP) and the most frequent cause of iatrogenic AR. The rate of post-ERP-Pancreatitis (PEP) is about 3.5% of all ERCPs, in high-risk patients up to 25% [1, 2]. Due to the lack of specific therapy of AP, prevention of PEP should be a crucial goal. The most promising prophylactic approaches are non-steroidal anti-inflammatory drugs (NSAID) and pancreatic stents [3]. Although several studies showed a decreased risk of PEP for NSAID and pancreatic stents, the results of these studies are inconsistent [4]. All these studies included only high-risk patients and do not represent the cross-section of ERCPs typically performed [5]. Further, definition of high risk is inconsistent [6]. One of the described risk factors is inadvertent cannulation of the pancreatic duct [3, 5].

**Aims & Methods:** Aim of the study was to evaluate the effect regarding the rate of PEP after prophylactic pancreatic stent in an unselected patient population with inadvertent cannulation of the pancreatic duct. Multicentre, prospective, randomized study. Patients undergoing first time ERCP were eligible. In case of inadvertent cannulation of the pancreatic duct patients were randomized for prophylactic pancreatic stent or no prophylactic pancreatic stent.

**Results:** 169 patients were randomized (87 stent, 82 no stent). PEP occurred in 33/169 patients (19.5%). Rate of PEP was statistically significantly lower in the stent group (12.6%) compared to the no stent group (26.8%); odds ratio 0.395; 95% confidence interval: 0.178–0.878. Inclusion of patients with inadvertent cannulation of the pancreatic duct during first time ERCP can be significantly reduced by a temporary prophylactic pancreatic stent.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: The terminology and description of small bowel (SB) vascular lesions in capsule endoscopy (CE) are scarce in the medical literature. They are mostly based on the reader’s background and opinion, and therefore remain mainly subjective, with a potential negative impact on clinical care, teaching and research regarding SB-CE. Our aim was to define and to describe the most frequent vascular lesions in SB-CE.

Aims & Methods: A panel of 18 European expert SB-CE readers, teachers and researchers was built aside the UEGW 2016 meeting. Three of these experts animated an internet-based, three-round Delphi consensus, but did not participate to any vote. They built questionnaires that included various still frames of vascular lesions from third-generation SB-CE videos. The remaining 15 experts were asked to rate different proposals for diagnostic, terminology, and description of various SB vascular lesions. Rare or protruding SB vascular lesions (Kaposi’s sarcoma, Dieulafoy ulceration simplex, varices, vascular tumors) were not considered for the study. A 6-point Likert rating scale (varying from strongly disagree to strongly agree) was used for all proposal in the 3 successive questionnaires. A consensus was considered to be reached when at least 80% voting members scored the statement within the “[dis]agree” or “[strongly] disagree”.

Results: Consensual terms and descriptions of angiodyplasia, erythematous patch, red spot or red spot, and phlebectasia were reached (table 1). No consensus was reached for definition or description of more subtle or small vascular mucosal abnormalities.mucosal layer (surrounded with intestinal villi).

**Table 1:** Results

<table>
<thead>
<tr>
<th>Terminology</th>

Introduction: Endoscopic ultrasound (EUS) guided fine needle biopsy (FNB) with side fenestration on the needle was developed aiming to obtain both cytological aspirates and histological core samples. To reveal the diagnostic yield of FNB sampling solid mass compared to standard fine needle aspiration (FNA), we conducted a large-scale multicenter study in patients with pancreatic and non-pancreatic masses. We also aimed to establish optimal techniques in EUS tissue acquisition.

Aims & Methods: This was a prospective multicenter single-blind randomized controlled trial. Between December 2014 and January 2016, 408 patients were enrolled from five tertiary-care academic medical centers and randomized at a 1:1 ratio to receive either 22G FNA or 22G FNB. Two tissue acquisition (TA) techniques (1st and 2nd passes using slow pull vs. 3rd and 4th passes using suction methods) were performed on all EUS needles. The primary outcome was the diagnostic yield comparing FNA and FNB on all solid lesions, pancreatic and non-pancreatic masses, respectively (except for the analysis of the histologic specimen quantity of cell, tissue integrity, and blood contamination).

Results: Among all lesions, FNB group (n = 190) compared to FNA group (n = 187) gained superior histological diagnostic yield (91.44% vs. 80%; p = 0.0015), and higher cytopathological diagnostic yield (85.56% vs. 78.95%; p = 0.093). For pancreatic mass, FNB group (n = 123) achieved better histological diagnostic yield compared to FNA group (n = 126) (92.68% vs. 81.75%; p = 0.0099), and also higher cytopathological diagnostic yield (88.62% vs. 79.37%; p = 0.00468), respectively. For non-pancreatic mass, there was no difference between FNB and FNA on diagnostic accuracy. Furthermore for pancreatic mass, when slow pull technique was applied in the first and second passes, FNB was superior to FNA on specimen quality and diagnostic yield.

Conclusion: Overall diagnostic yield of EUS-FNB needle acquisition was better compared to FNA needle among all studied solid lesions. For pancreatic masses, the 22G FNB needle also gained superior histological diagnostic accuracy and higher cytological diagnostic yield compared to 22G FNA. We further suggest choosing FNB over FNA on pancreatic lesion for TA when slow pull technique was applied in the first two passes.

Disclosure of Interest: All authors have declared no conflicts of interest.

order to measure tissue volume and isolate malignant cells from desmoplastic stroma. Sample size based on 50% difference in the presence of desmoplastic stroma at 80% power was estimated at 34 patients.

**Results:** Of the 46 patients randomized to undergo EUS-guided sampling, the final diagnosis was pancreatic cancer in 36, neuroendocrine tumor in 2, sarcoma in 1 and benign disease in 7. The median total tissue volume, 6.1 mm³ (IQR 2.2–9.9) vs. 0.28 mm³ (IQR 0.045–0.93) (p < 0.001) and presence of desmoplastic stroma in tumor, 84.6 vs. 33.3% (p < 0.001) were significantly higher in the FNB cohort. Also, the diagnostic yield at cell block was significantly higher for the FNB cohort, 97.8 vs. 82.6% (p = 0.003). There was no difference in diagnostic adequacy at ROSE between the FNB and FNA cohorts, 100 vs. 95.7% (p = 0.50).

**Conclusion:** The Fransen biopsy needle yields significantly more tissue with superior histology than the FNA needle. This development is likely to advance the role of EUS in facilitating molecular-based anti-cancer therapy.

**Introduction:** Recent studies suggest that histological remission is a treatment goal in ulcerative colitis (UC). However, there is a discrepancy between histological remission and conventional endoscopic mucosal healing. We have already reported two useful aspects of EC that is the next-generation ultra-magnifying endoscopy allowing visualization of microvessels; one is that findings of EC are more numbers of images for machine learning.

**Aims & Methods:** The aim of this study is to develop a new CAD system for the histological remission in UC, with use of EC combined with NBI mode. Histological assessment was based on Geboes index. Geboes index ≥3.0 and absence of basal plasmacytosis was considered as histological remission, while Geboes index >3.0 or presence of basal plasmacytosis was as active. The algorithm of this CAD system was programmed based on texture analysis, which can quantify the pattern of endoscopic image and vessel features. Support vector machine was used as a classifier for two-category diagnostic output (histological remission or active status). A total of 1935 images (histological remission, 1042; active status, 893) were used for machine learning process. The overall accuracy to distinguish histological remission from active status was assessed by using leave-one-out cross validation. In this validation, randomly selected one image was evaluated by using the developed CAD system which was trained by using the remaining 1934 images.

**Results:** According to the leave-one-out cross validation which was repeatedly calculated for 1935 times, the average accuracy of the developed CAD system (identification of histological remission was 81.7%. The accuracy with high confidence (probability ≥90%) was 98.9%. The high confidence rate was 32.4%.

**Conclusion:** The diagnostic ability of artificial intelligence in classification of EC image for assessment of histological activeness of UC was substantially good, although it was tentative model. Higher accuracy could be expected with much more numbers of images for machine learning.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**OP74 A PILOT INTERNATIONAL MULTICENTER RANDOMIZED CONTROLLED TRIAL OF CHROMOENDOSCOPY VERSUS AUTOFLUORESCENCE IMAGING FOR NEOPLASIA DETECTION IN PATIENTS WITH LONGSTANDING ULCERATIVE COLITIS (FIND-UC)**

6Department Of Pathology, Academic Medical Center, Amsterdam, Netherlands, Amsterdam/Netherlands

**Introduction:** Patients with longstanding ulcerative colitis (UC) are at increased risk for developing colorectal cancer and regular surveillance is advised. Previous studies demonstrated that both surveillance with chromoendoscopy (CE) and autofluorescence imaging (AFI) increased dysplasia detection rates in patients with longstanding UC when compared to standard white light endoscopy. Chromoendoscopy is currently recommended in national guidelines, but is poorly adopted in clinical practice because it is time-consuming. AFI is a push-button technique in which endogenous autofluorescence is used to highlight neoplastic tissue. The aim of this pilot trial was to determine whether AFI should be further studied as an alternative method for dysplasia surveillance in patients with longstanding UC.

**Aims & Methods:** In this prospective, non-inferiority pilot randomized trial with fixed design, patients undergoing colonoscopy surveillance for longstanding UC (Montreal E2 > 15 years or Montreal E3 > 8 years) in 5 centers in the Netherlands and the UK were randomized for inspection with either CE or AFI (1:1). Patients with active colitis (MAYO > 1 in at least 1 segment) or Barrett’s Bowel Preparation Scale ≤ 6 were excluded. Randomization was stratified for presence of previous dysplasia and/or primary sclerosing cholangitis (PSC). Targeted biopsies of visible lesions and random biopsies of each segment were collected. The main outcome was the relative dysplasia detection rate calculated by the quotient of CE over AFI. This relative detection rate was determined for the proportion of UC patients in which at least one dysplastic lesion was detected and for the mean number of dysplastic lesions per patient. A relative detection rate below 1.50 for both outcomes would support performing a subsequent large non-inferiority trial. For this study, 210 UC patients were needed to achieve a relative detection rate of 1.50 with an 80% confidence interval between 1.00 and 2.25. Dysplasia was diagnosed by an expert gastrointestinal pathologist in consensus with a second expert pathologist.

**Results:** Between August 2013 and March 2017, 210 UC patients were randomized to undergo surveillance with CE (N = 105) or AFI (N = 105). The mean age of patients at colonoscopy was 56.1 (SD 12.7) years, 58.1% were male and the median time since previous surveillance colonoscopy was 3 years (IQR 1–4) (Table 1). During CE, dysplasia was detected in 20 (19.0%) patients, while 14 patients (13.3%) were diagnosed with dysplasia during AFI. The relative dysplasia detection rate was calculated by the quotient of CE over AFI. This relative detection rate for CE versus AFI for the proportion of UC patients with at least one dysplastic lesion was 1.43 (95% CI; 0.76–2.68). The mean number of detected dysplastic lesions per patient was 0.37 for CE compared to 0.13 for AFI (relative dysplasia detection rate 2.79, 95% CI; 1.61–4.82). During CE, the proportion of patients in whom targeted biopsies were taken (65.7% vs. 47.6%, p < 0.001) was larger and total extubation times were longer (25.1 min vs. 18.0 min, p < 0.01).

**Table 1:** Patient characteristics of randomized patients with longstanding ulcerative colitis.

<table>
<thead>
<tr>
<th></th>
<th>Chromoendoscopy (N = 105)</th>
<th>Autofluorescence imaging (N = 105)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean age, years (SD)</td>
<td>56.1 (12.3)</td>
<td>56.3 (13.1)</td>
</tr>
<tr>
<td>Female, n (%)</td>
<td>44 (41.9%)</td>
<td>44 (41.9%)</td>
</tr>
<tr>
<td>UC duration in years, median (IQR)</td>
<td>19.0 (13.0–27.3)</td>
<td>22.5 (15.0–32.8)</td>
</tr>
</tbody>
</table>
Conclusion: In this pilot randomized study with fixed design comparing CE with AFI for dysplasia surveillance in patients with longstanding UC, AFI was non-inferior to CE on a dysplasia per patient basis, but was inferior on the basis of mean number of dysplastic lesions detected. These results argue against a future large prospective randomized trial comparing these methods for dysplasia surveillance in patients with longstanding UC (NTR4062).

OP176 GUT MICROBIOTA INVOLVES IN NON-ALCOHOLIC FATTY LIVER DISEASE VIA AFFECTING INTRA-HEPATIC CD4+ T LYMPHOCYTE
L. Su, Z. Wu, J. Tan, J. Xu, Y. Song, Y. L. Liu
Department Of Gastroenterology, Peking University People's Hospital, Beijing, China

Op176 Abstract: Introduction: Gut microbiota plays an important role in the pathogenesis of non-alcoholic fatty liver disease (NAFLD). CD4+T lymphocytes have also emerged as an important player in NAFLD since the function of their immune was realized. But the effects of gut bacteria on intra-hepatic T lymphocytes are not very clear.

Aims & Methods: To investigate the impact of gut microbiota on hepatic CD4+T lymphocyte in the pathogenesis of non-alcoholic fatty liver disease. High fat diet (HFD) was used to induce NAFLD. After 8 weeks of HFD feeding, mice were given PBS, Antibiotics (neomycin and polymixin B) or Lactobacillus by gavage once a day for 4 weeks and sacrificed. Primary hepatocytes isolated from livers of normal diet feeding mice were co-cultured with CD4+ T lymphocytes or its cultured supernatants, of which CD4+ T lymphocytes were isolated from mesenteric lymph nodes of mice fed 12 weeks of HFD or normal diet.

Results: Compared with the PBS group, lymphocytic infiltration in livers of antibiotics group and lactobacillus group are less, as well as lower ALT and AST. But the effects of gut bacteria on intra-hepatic T lymphocytes are not very clear.

Introduction: The advent of image-enhanced endoscopic modalities have paved the way for better optical diagnosis of colorectal polyps. Fujifilm recently introduced a new technology – Blue Light Imaging (BLI) that utilises powerful light emitting diode (LED) technology and short wavelength absorption of haemoglobin with no post processor digital reconstruction to enhance mucosal surface and vessel patterns. This is a novel concept.

Aims & Methods: The aim of this study was to investigate the diagnostic ability of BLI in the optical diagnosis of diminutive colorectal polyps. Images from a pilot study with 64 images from normal subjects were given PBS, Antibiotics (neomycin and polymixin B) or Lactobacillus by gavage once a day for 4 weeks and sacrificed. Primary hepatocytes isolated from livers of normal diet feeding mice were co-cultured with CD4+ T lymphocytes or its cultured supernatants, of which CD4+ T lymphocytes were isolated from mesenteric lymph nodes of mice fed 12 weeks of HFD or normal diet.

Results: Compared with the PBS group, lymphocytic infiltration in livers of antibiotics group and lactobacillus group are less, as well as lower ALT and AST. But the effects of gut bacteria on intra-hepatic T lymphocytes are not very clear.

maintaining ileal CD. AIEC bacteria adhere to the enterocytes through high-affinity interactions with their variant FimH and abnormally expressed CEACAM6 protein on host cells. Decreasing CEACAM6 expression in CD intestinal cells is one strategy that could prevent AIEC bacteria colonization of the intestinal mucosa and subsequent inflammation. This work aims at studying the role of the collagenous and LPS-binding domains (HMD High Methyl Diet) on AIEC colonization, on DNA methylation, and on genes expression with a specific focus on CEACAM6.

Aims & Methods: CEABAC10 female mice were fed a HMD (supplemented in folate, ferrous, zinc and methionine) for 2 weeks before being sacrificed. After weaning, the colonic epithelial cells from offspring were purified using EDTA. We analyzed different physiological parameters such as the lipocalin-2 level in stools and intestinal permeability. E. coli population was quantified using a cultural and qPCR approaches. DNA methylation of CEACAM6 promoter was measured using bisulfite-sequencing and qPCR was used to quantify CEACAM6 mRNA in colonic epithelial cells. RNA-seq was used to highlight transcriptomic changes in colonic cells and ELISA was used to quantify IgA concentration in the stools.

Results: Mice fed a HMD did not present any sign of spontaneous inflammation or altered intestinal permeability when compared to mice fed a conventional diet. Microbiota analysis revealed a 1000-fold decrease in E. coli population in mice fed HMD compared to mice receiving a conventional diet. As expected, bisulfite sequencing showed a hyper-methylation of the CEACAM6 promoter, associated with a significant decrease in CEACAM6 expression as measured by qPCR, following HMD treatment. RNA-seq data confirmed the decrease in CEACAM6 expression and highlighted 309 up-regulated genes following HMD. Among them, 88 were involved in adaptive immunity and 15 took part into the IgA synthesis pathway. Further analysis revealed an increase in E. coli-specific IgA concentration in intestinal lumen of mice treated with HMD compared to control diet group.

Conclusion: This work shows that the addition of a few vitamins and oligo-elements to the diet could interfere with the DNA-methylation metabolism leading to changes in the methylation such as a decrease in CEACAM6 and to activation of genes involved in IgA synthesis. The excessive specific E. coli-IgA quantity secreted into the lumen during HMD could explain the decrease in E. coli colonization. A diet-based strategy could help decreasing E. coli colonization in CD patients by modulating DNA methylation and favoring IgA production.

expression of MCP-1 (P < 0.01) and TNF-a (P < 0.05), and B lymphocytes decompensated stage. Four metabolites (creatinine, triglyceride 20:5/20:4; acid 18-hydroxyarachidonic; epoxy-8, 11, 14-eicosatrienoic acid) reached the threshold (fold changes analysis) as possible candidates for infection biomarkers. However, in univariate analysis by principal component analysis none of the markers reached statistical significance difference between infected and non-infected groups.

Conclusion: There is a different metabolic profile for patients with decompensated cirrhosis, expressed primarily through phosphatidylcholine metabolism disorder. Metabolomic analysis is a promising method to find new markers of infections in decompensated patients but targeted metabolitcal studies are required.

Introduction: Anti-TNF therapy is effective for fistulising Crohn’s disease (CD). However, persistence or recurrence of rectovaginal fistulas can represent a devastating condition in CD patients and a challenge for gastroenterologists and surgeons. Given the small size of available studies, it is difficult to draw definite conclusions regarding the efficacy of anti-TNF therapy in treating rectovaginal fistulas complicating CD. We thus evaluated the efficacy of anti-TNFs for the treatment of rectovaginal fistulas in a large cohort of CD patients.

Aims & Methods: This GETAID multicenter retrospective study included all adult patients from 16 French tertiary centers who were treated with anti-TNF therapy for rectovaginal fistula complicating CD. Only patients who received anti-TNF induction treatment (adalimumab, infliximab or certolizumab) and at least one maintenance injection/infusion were analyzed. Clinical response

was evaluated at 1 year and at date of latest news. The main endpoint was complete clinical fistula closure at 1 year. We also looked at predictors of anti-TNF therapeutic response.

Results: One hundred and six patients were treated at least one anti-TNF injection/infusion. Nine patients stopped anti-TNF therapy during induction due to lack of efficacy. Ninety-seven patients were in clinical remission 7 months after anti-TNF maintenance therapy were included in the analysis. Median follow-up was 76 months. Four types of fistulas were reported: 34 recto-vaginal fistulas (35%), 7 enterovaginal fistulas (7%), 36 ano-vaginal fistulas (37%), and 20 ano-vulvar fistulas (21%). In 15% of patients, only 25% had a response at one year in case of lack of response at 6 months. Patients with active smokers. Ten percent of patients were previously exposed to anti-TNF therapy. Seventy-two patients were treated with infliximab (74%), 23 with adalimumab (24%), 2 with certolizumab (2%). Only 5% of patients received concomitant use of other immunosuppressive agents. In this large cohort of CD patients, anti-TNF therapy induced a complete clinical response at 1 year. A partial clinical response was seen in 25% of patients and a lack of response in 37% of the patients. Between one surgery for fistula was performed in 37% of patients. In the cohort of patients with complete clinical response at one year, only 25% had a response at one year in case of lack of response at 6 months. For this analysis, no factor was associated with a clinical response at one year. Among patients with a clinical response at 6 months, 91% maintained a complete clinical response at one year, whereas only 25% had a response at one year in case of lack of response at 6 months. Patients with active smokers. Ten percent of patients were previously exposed to anti-TNF therapy. Seventy-two patients were treated with infliximab (74%), 23 with adalimumab (24%), 2 with certolizumab (2%). Only 5% of patients received concomitant use of other immunosuppressive agents. In this large cohort of CD patients, anti-TNF therapy induced a complete clinical response at 1 year in 63% of patients and 38% had a complete fistula closure following induction therapy. Anti-TNF therapy seems to be a good option for the treatment of rectovaginal fistulas complicating CD in clinical practice in both the short- and long-term.

Introduction: The four necrosis factor (TNF)-TNF agents are effective to treat perianal Crohn’s disease (CD). It has been suggested that CD patients with perianal fistulas need higher serum concentrations of infliximab compared to patients with pure luminal disease in order to attain remission.

Aims & Methods: For this analysis, we identified all CD patients with perianal fistulas receiving active treatment with infliximab or adalimumab at our centre. Serum drug concentrations of infliximab and adalimumab in CD patients with perianal fistula were collected. Anti-TNF antibody concentrations in patients with closed fistula, defined by the absence of active draining fistula at physical examination and/or confirmed by magnetic resonance imaging were compared to drug levels in patients with persistently draining perianal fistulas. Only patients receiving anti-TNF maintenance treatment were included and if the time interval between the final observation and last drug level measurement did not exceed four weeks. Patients who underwent surgical interventions (ie. ligation of intersphincteric fistula tract surgery or fecal diversion procedure) between physical examination and measurement of anti-TNF serum levels were excluded, as well as patients with internal fistulas.

Results: We identified 66 CD patients (out of a total cohort of 352) that received active treatment with infliximab or adalimumab and had perianal fistula(s). For seven patients treated with adalimumab and 19 with infliximab. The median serum concentrations of infliximab at trough (interquartile range) were significantly higher in patients with closed fistula(s) (n=32) compared to patients with actively draining fistula (n=15): 6.0 µg/ml [5.4–6.9] versus 2.3 µg/ml [1.1–4.0], respectively (p<0.001). The same outcome was seen in 19 patients treated with adalimumab (13 with closed fistula and 6 with active fistula) with a median serum concentration of 7.4 µg/ml [6.5–10.8] versus 4.8 µg/ml [1.7–6.2] respectively; p=0.003. ROC analysis of anti-TNF serum measurements showed high accuracy for both infliximab and adalimumab with an AUC of respectively 0.92 (95% CI: 0.82–1.00) and 0.89 (95% CI: 0.71–1.00). An infliximab trough serum concentration ≥ 5 µg/ml yielded the optimal results in terms of combined sensitivity of 86.67% (95% CI: 59.5–98.3) and specificity of 84.38% (95% CI: 67.2–94.7). An adalimumab serum concentration ≥ 5.9 µg/ml was associated with fistula closure with a sensitivity of 83.3% (95% CI: 35.9–99.6) and specificity of 92.3% (95% CI: 64.0–99.8). There were no differences seen in infliximab and adalimumab dose and intervals between patients with active draining fistula and closed fistula.

Conclusion: An association was found between the level of anti-TNF serum concentrations and fistula closure in CD patients. Pursuing higher serum anti-TNF levels in CD patients with perianal fistula might improve fistula closure rates.

were associated with ustekinumab failure-free survival at 24 months, but not significantly, when compared to those with lower CRP levels (1.2-24.8) and especially patients with a previous history of infliximab failure (p<0.05).

In multivariate analysis, no predictive factor of ustekinumab failure-free survival was identified in more than 2 years. More than 50% of patients maintained ustekinumab during follow-up without loss of response, intolerance or surgery, with a good safety profile. No predictive factor of ustekinumab failure-free survival was identified in multivariate analysis.

Introduction: The benefits of combination therapy with adalimumab and immunomodulators in patients with Crohn’s disease (CD) is still open to debate. The ADJUST study is a retrospective multi-centre cohort study conducted at 41 institutions in Japan. Data were retrospectively collected from all patients with CD who had received at least one induction dose of 160mg of adalimumab between October 2010 and December 2013. Patients with active CD who received adalimumab for induction of remission were included, while those with inactive CD who started on adalimumab for prevention of postoperative recurrence or for unknown reasons were excluded. The cumulative rates of retention of adalimumab were estimated by the Kaplan–Meier method. Prognostic factors related to the cumulative rates of adalimumab were evaluated by multivariate Cox regression analysis. We also compared the cumulative rates of retention between the groups with/without immunomodulators stratified by potential confounding factors.

Results: A total of 970 patients (median age, 33.6 years; female, 31%) were included in the study. The median duration of CD was 7.5 years. Forty-three percent of the patients had undergone at least 1 intestinal resection. The median prednisolone dose and albumin levels of the patients were 0.90 mg/dL and 4.9 at one and two years, respectively. Concomitant treatment with immunomodulators and prednisolone was administered to 37% and 16% of the patients, respectively. Forty-nine percent of the patients had been previously treated with infliximab. The 1-, 2- and 4-year cumulative retention rates of adalimumab were 69%, 62% and 58%, respectively. In the multivariate Cox regression analysis, female sex, perianal disease, lower albumin levels, concomitant treatment with prednisolone and previous infliximab use were identified as independent predictors for discontinuation of adalimumab, whereas concomitant treatment with immunomodulators was a prognostic factor for higher retention rate of adalimumab. According to the stratified analyses, combination therapy with adalimumab and immunomodulators significantly improved the cumulative retention rates in patients with CRP levels of ≥4.00 mg/dL and those receiving concomitant treatment with prednisolone or previously treated with infliximab.

Conclusion: Our data suggested that combination therapy of adalimumab and immunomodulators significantly increased the retention of adalimumab, especially in infliximab-treated CD patients with higher CRP levels and those who received concomitant treatment with prednisolone at initiation of adalimumab treatment.

Introduction: Infliximab (IFX) is efficient to maintain clinical remission in patients with inflammatory bowel diseases (IBD) refractory to conventional therapies. To date, there is no clear guideline regarding the withdrawal of anti-TNF agents and the majority of IBD patients are treated with IFX for long-term medical management. An alternative to withdrawal of IFX may be the spacing of IFX infusion interval. This strategy was only evaluated in a large prospective controlled trial in rheumatoid arthritis patients with interesting results (Fautrel B, Ann Rheum Dis, 51(1)).

Aims & Methods: The primary aim of this study was to evaluate the effect of a spacing of IFX infusion interval on the maintenance of clinical remission in IBD patients. Secondary aims of this study were to evaluate the occurrence of allergic reactions to IFX after spacing and the efficacy of IFX intensification after clinical relapse. This was a retrospective multicentre French national cohort including all IBD patients treated with infliximab who were in clinical remission according to the referring physician and a had a spacing of their infusion interval over 9 weeks for at least two consecutive infusions. Clinical relapse was defined according to referring physician and leading to IFX intensification was considered as primary endpoint. The clinical efficacy of IFX intensification after spacing and occurrence of drug reactions were also monitored.

Results: Eighty-nine patients were included in the study (61 patients with Crohn’s disease [CD] and 28 with an ulcerative colitis [UC]). Median delay between IFX introduction and spacing was 35.6 months (IQR: 17.6–64). Thirty-five (39%) patients were already treated with an immunosuppressive drug (methotrexate) at the time of IFX spacing. Maximum infusion interval spacing was of 13 weeks and 41 patients (46%) had infusion interval spacing ≥12 weeks. Cumulative probability of clinical relapse-free survival after spacing was 82.7% ± 4.1 and 72.6% ± 4.9 at one and two years, respectively. All IBD patients with a clinical relapse after spacing had an intensification of IFX therapy (n = 27) with a clinical response in 89% of patients. Only one patient had to withdraw IFX therapy after clinical relapse due to IFX allergic reaction occurring three years after spacing. Regarding clinical relapse, the median delay between IFX introduction and spacing of infusion interval was significantly shorter in IBD patients with clinical relapse compared to patients without clinical relapse (22.9 months [IQR: 13.3–42] vs. 41.3 months [IQR: 22.5–67.1], respectively, p = 0.027). CD patients, in univariate analysis, a delay >4 years between IFX introduction and spacing was significantly associated to the maintenance of clinical remission after spacing (RR = 0.26; CI 95%: 0.07–0.89, p = 0.032). For UC patients, radiologic inflammatory activity before spacing was associated to clinical relapse after spacing (RR = 13.9; CI 95%: 1.24–157.1, p = 0.033). In multivariate analysis, a delay >4 years between IFX introduction and spacing (RR 0.36, CI 95%: 0.19–0.68, p = 0.002), concomitant treatment with an immunosuppressant (RR = 0.31; CI 95%: 0.11–0.85, p = 0.022) and penetrating phenotype (CI 95%: 0.34–0.89, p = 0.039) were significantly associated to the maintenance of clinical remission after spacing in CD patients.

Conclusion: After spacing of IFX infusions over 9 weeks more than 70% of IBD patients remained in clinical remission over two years. Only one patient stopped IFX therapy after withdrawal of IFX. A short delay between IFX introduction and spacing seems to be a good predictive factor of clinical relapse after spacing, at least in CD. The collection and analysis of data from a larger national cohort is ongoing.

Introduction: Recent French population-based study reported that elderly-onset UC patients with Crohn’s disease diagnosed over age of 70 years have different disease course regarding localization, disease progression and exposure to medication than patients aged 60–69 years (1).

Aims & Methods: The aims of this study was to assess whether the disease phenotype and long-term outcome also differs in elderly-onset (ulcerative colitis) UC diagnosed before and after the age of 70 years. Elderly-onset UC patients (â60 years at diagnosis) from a French prospective population-based Registry (EPIMAD) were included. Demographic and clinical data at diagnosis and at maximal follow-up were collected using a predefined questionnaire.

Results: 468 elderly-onset UC patients were included (median follow-up 6.2 years) of whom 277 (59%) were <70 years and 191 (41%) ≥70 years at diagnosis. Male gender was more frequent in patients <70 years than in older individuals (54% vs. 65%; p=0.01) while patients >70 years had higher rate of left-sided colitis than younger ones (63% vs. 49%; p=0.02). The 1 and 5-year cumulative probabilities of medication exposure were similar between the two age groups (5-aminosalicylic acid: 60% vs. 70% and 77% vs. 77%, p=0.75; corticosteroids: 19% vs. 23% and 30% vs. 34%, p=0.54; immunosuppressants: 3% vs. 2% and 10% vs. 9%, p=0.78). However, patients <70 years compared to older individuals experienced significantly more corticosteroid (12% vs. 3%, p=0.03) and tended to be more corticosteroid (24% vs. 16%, p=0.08). Only 4 patients received anti-TNFα therapy, 3 of them diagnosed <70 years. The rate of surgery was not influenced by age at diagnosis (1 and 5-year risk: 6% vs. 4% and 10% vs. 6%, p=0.39).

Conclusion: Elderly-onset UC is heterogeneous group of patients with respect to disease phenotypes and disease progression. Patients ≥70 years at diagnosis had higher frequency of left-sided colitis than younger ones. Importantly, patients diagnosed ≥70 years had more severe disease course in terms of higher rate of corticostereine and corticosterone dependence than those ≥70 years.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The risk of esophageal adenocarcinoma (EAC) in patients with non-dysplastic Barrett’s esophagus (NDBE) may have been overestimated in some studies. Lower progression rates could lead to changes in the current surveillance strategy, thereby reducing its associated risks and costs.

Aims & Methods: The aim of this study was to evaluate whether persistence of NDBE among consecutive surveillance endoscopy identifies patients at a very low risk for malignant progression. In this population-based retrospective study, patients with a first diagnosis of NDBE between 2003 and 2012 were selected using the Dutch nationwide registry of histopathology (PALGA). Patients were followed until the development of EAC or high-grade dysplasia or up to the last endoscopy contact with biopsy sampling (through May 2016). Incidence rates and rate ratios for EAC and HGD/EAC combined were calculated to evaluate whether persistence of NDBE during consecutive endoscopies and progression time reduce the risk of malignant progression.

Results: In this study, 12,729 patients with NDBE were included, with a total follow-up of 64,563 (median 4.4 [IQR 3.0 – 6.8]) years. Malignant progression was seen in 437 patients (3.4%) after a median follow-up of 5.1 years (IQR 3.2 – 7.4). This rate resulted in an overall age-adjusted rate to EAC of 0.53 per 100 person-years and a rate to EAC of 0.68 (95% CI: 0.62 – 0.74) per 100 person-years. At first follow-up endoscopy after a median of 2.3 years (IQR 1.8 – 3.2), 11,782 patients (93%) were found to have non-dysplastic NDBE. 727 (57%) and 223 (18%) patients progressed to low-grade dysplasia and HGD/EAC, respectively. In patients with both consecutive endoscopies showing NDBE after a median of 2.8 years (IQR 4 – 4.0), the malignant progression rate was 0.52 (95% CI: 0.40 – 0.67) per 100 person-years (RR 0.63 (95% CI: 0.45 – 0.83)) versus 0.86 in patients after one endoscopy. Patients with five consecutive non-progressive endoscopies had a 60% rate reduction (RR 0.40 (95% CI: 0.13 – 0.97)) for development of EAC (progression rate: 0.34 (95% CI: 0.11 – 0.41) per 100 person-years). The incidence of EAC decreased with 30% (adjusted HR 0.71, 95% CI: 0.67 – 0.75) for each year of FU without progression (progression-free time).

Conclusion: Persistent NDBE at two consecutive surveillance endoscopies reduces the risk of malignant progression towards HGD/EAC or EAC by twofold. As progression risk reduces even further after more consecutive negative follow-up endoscopies, this study contributes to the growing evidence that surveillance intervals in subgroups of patients with persistent BE might be lengthened.

OP194 NEUTROPHIL LYMPHOCYTE RATIO AS PREDICTIVE MARKER OF SURVIVAL IN ESOPHAGEAL CANCER: SYSTEMATIC REVIEW AND META-ANALYSIS

G. Pirozolo1, S.S. Gisberta2, C. Castoro3, M.I. Van Berge Henegouwen4, M. Scarpa1

1Esophageal And Digestive Tract Surgical Unit, Regional Centre For Esophageal Surgery, Gastroenterology and Endoscopy, svizzera/Italy
2Surgical Department, Academic Medical Centre, Amsterdam/Netherlands

Contact E-mail Address: giovanni.pirozolo@gmail.com

Introduction: Several studies showed that a high preoperative Neutrophil-Lymphocyte Ratio (NLR) is a predictor of worse survival in many solid tumors, including esophageal cancer. Neutrophils are a consistent part of the tumor microenvironment. It has been previously reported that TANs are related to tumor growth. The aim of this systematic review and meta-analysis is to collect all the data about this marker in order to quantify its strength in esophageal cancer prognostication.

Aims & Methods: The meta-analysis was performed using the Preferred reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines. We used inclusion criteria adapted from the REPporting recommendations for tumor MARKER prognostic studies criteria. We conducted a comprehensive search of all prospective or observational studies reporting NLR prognostic data in esophageal cancer patients. The primary outcome measure was Overall Survival (OS) while Disease Free Survival (DFS) and Progression Free Survival (PFS) were secondary outcome measures. All included studies had a directly or indirectly available HR. We analyzed data using fixed effect model or random effect model depending on heterogeneity.

Results: We included in the quantitative synthesis 17 studies published between 2011 and 2017, comprising 5672 patients. The NLR cut-off value ranged from 2 to 5. Our analysis about OS of all included studies showed that a high preoperative NLR is an effective predictor of a worse survival (HR 1.72, p = 0.0001). Similar results were obtained about DFS (HR 1.94, p = 0.0003) and PFS (HR 1.66, p = 0.0001). We conducted sub-analysis both for cut-off ranges subgroups and treatment modality subgroups obtaining the same prognostic relevance.

Conclusion: Retrospective design of included study is the major bias. There is high heterogeneity among studies in terms of patients characteristics, duration of follow-up and cut-off threshold. Moreover, NLR has been proposed in several studies as a prognostic marker for non-oncological diseases, mostly heart disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The most optimal timing of esophagectomy after neoadjuvant chemoradiotherapy (nCRT) is unknown. Theoretically, an extended interval between nCRT and surgery might increase the chance of the best pathological response: pathological complete response (pCR) because of a prolonged effect of the nCRT and this might possibly improve disease-free and overall survival.

Conversely, it is thought that an extended interval might lead to residual tumor outgrowth, a more difficult surgical resection, with a higher complication rate, and possibly a worse survival. The aim of this study was to assess the time interval between nCRT and surgery in the Netherlands and to correlate this with pathological cell infiltrate of the tumor and surgical morbidity and mortality.

Aims & Methods: Patients with esophageal cancer treated with nCRT and surgery between 2011 and 2016 were selected from a national database of the Dutch Upper Gastrointestinal Cancer Audit. (1) Differences in patient and treatment characteristics, stage and type of surgery, surgical complications and postoperative mortality are compared across six subgroups discriminated by the length between end of nCRT and surgery. To evaluate the association between the interval and pathohistological complete response (pCR), intraoperative, postoperative complications and mortality, multivariable logistic regression analysis was used.

Results: In total 3102 patients were included. The median [interquartile range] time interval between the end of nCRT and surgery was 8 [7-10] weeks. The interval between end of nCRT and surgery was divided into six (A-F) groups: 0-5 weeks (A; n = 157), 6-7 weeks (B; n = 878), 8-9 weeks (C; n = 992), 10-12 weeks (D; n = 720), 13-14 weeks (E; n = 195) and 15 or more weeks (F; n = 180). In intervals E and F, there were significantly more patients with ASA III+ and 40 years (SIR 3.18, 95% CI 0.04–17.69), 40–49 years (SIR 3.78, 95% CI 1.43–9.83), 50–59 years (SIR 2.36, 95% CI 1.22–4.11), and not consistently present across all subgroups.

Conclusion: An extended interval (≥10 weeks for adenocarcinoma and ≥12 weeks for squamous cell carcinoma) was associated with a higher probability of a pCR. These groups had the same probability for intraoperative and severe postoperative complications. The extended interval groups were associated with higher total postoperative complications (E and F) and mortality (D and F).

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: eva.doorakkers@ki.se

Introduction: Helicobacter pylori is a stomach bacterium associated with an increased risk for gastric cancer. We aimed to assess if the risk of gastric cancer remains increased after H. pylori eradication.

Aims & Methods: This was a population-based, nationwide cohort study in Sweden conducted between 1 July 2005 and 31 December 2012. Data on H. pylori eradication were retrieved from the Swedish Prescribed Drug Registry and eradication consisted of triple therapy with a proton pump inhibitor and 2 antibiotics (clarithromycin and amoxicillin or metronidazole). The cancer incidence in the cohort was compared to that of the corresponding background population using standardized incidence ratios (SIRs) with 95% confidence intervals (CIs).

Results: In total, 92, 852 individuals (46.3% men) received eradication therapy during the study period. The total follow-up time after eradication was 331, 694 person-years (mean 3.6 years). Of the eradicated participants, 76 (0.08%) developed gastric cancer, corresponding with an incidence of 22.9/100, 000 person years. The SIR of gastric cancer after eradication was increased (SIR 1.46, 95% CI 1.15–1.83). The SIR for men was 1.30 (95% CI 0.94–1.77) and for women (SIR 1.67, 95% CI 1.15–2.35). The SIRs were higher in the age groups <40 years (SIR 3.18, 95% CI 0.04–17.69), 40–49 years (SIR 3.78, 95% CI 1.38–8.22), 50–59 years (SIR 2.36, 95% CI 1.22–4.11), and not consistently increased in the age groups 60–69 years (SIR 0.97, 95% CI 0.50–1.69) and ≥70 years (SIR 1.38, 95% CI 1.00–1.84).

Conclusion: The overall risk for gastric cancer after eradication for H. pylori remained increased compared to the general population.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Results:**

- Up to now, 20,175 patients (60% women) have finished follow up. Mean age was 49 years. Of all patients, 4.2% had drug allergies (81% to penicillin), 56% of had dyspepsia, 18% had gastric duodenal ulcer. Two-thirds (66%) were managed by gastroenterologists in Europe is extremely diverse and the overall eradication rate is suboptimal, mainly due to the frequent use of triple therapies where they are ineffective (most European regions).

- In order to achieve >90% eradication, physicians are encouraged to use quadruple therapies.

**Introduction:** Due to the diversity of strains, resistances and geographical particularities, the best approach for *Helicobacter pylori* management remains unclear.

**Aims & Methods:** We aimed to assess the management of *H. pylori* infection by gastroenterologists in Europe and to evaluate the efficacy of first-line treatments. A systematic prospective registry of the clinical practice of European gastroenterologists regarding *H. pylori* infection and treatment (30 countries and 250 recruiting investigators). A local coordinator was selected from each country with more than 10 *H. pylori* references on PubMed. Each coordinator selected a representative group of recruiting investigators from its country. An electronic clinical research file was created on AEG-REDCap to systematically register all adult patients infected with *H. pylori*. Variables included: Patients' demographics, previous eradication attempts, prescribed eradication treatment, adverse events, and outcomes (cure rates, compliance, follow up, etc.).

**Results:** Up to now, 20,175 patients (60% women) have finished follow up. Mean age was 49 years. Of all patients, 4.2% had drug allergies (81% to penicillin), 56% of had dyspepsia, 18% had gastric duodenal ulcer. Two-thirds (66%) were managed by gastroenterologists in Europe is extremely diverse and the overall eradication rate is suboptimal, mainly due to the frequent use of triple therapies where they are ineffective (most European regions). Introduction: Vonoprazan (VPZ) combined with two anti-biotics therapy has been used for Helicobacter pylori (HP) eradication in Japan, and there is still little information of the detailed eradication results. The aim of the present study was to retrospectively compare the HP eradication outcomes between proton pump inhibitors (PPI) and VPZ with 1,774 subjects of our hospital in 2017 - 2019. To evaluate which factors affected the eradication effect with VPZ was affected by lifestyle-related diseases including obesity, hypertension (HT) and diabetes mellitus (DM).

Aims & Methods: In total, 1774 subjects (primary eradication: 1485, secondary: 289) received HP eradication therapy in our hospital in 2012 - 2016. The eradication judgment was performed by C-urea breath test (UBT), and the eradication rate (%), per-protocol analysis) was calculated. Eradication therapy was performed with PPI (lansoprazole (LPZ) 30 mg or esomeprazole (EPZ) 20 mg) or VPZ 20 mg + clarithromycin (CAM) 200 mg + amoxicillin (AMPC) 750 mg twice/day for 7 days as primary eradication. Failure of the primary eradication was followed by the secondary eradication with PPI or VPZ 20 mg + metronidazole (MNZ) 250 mg + AMPC 750 mg twice/day for 7 days.

Results: The primary eradication rates were VPZ 90.5% (371/410, LPZ 73.7% (246/334), RPZ 75.5% (366/482), and EPZ 83.0% (215/259). The eradication rate of VPZ 90.5% was higher compared to that of the other three PPIs (828/1076) (<0.001) and each PPI. The secondary eradication rate was VPZ 93.1% (54/58), LPZ 87.7% (50/57), RPZ 90.5% (67/74), EPZ 91.0% (91/100). Secondary eradication rate tended to be high in VPZ (93.1%) but not significant compared to that in all other PPIs (90.0%) (208/231) (P = 0.47). Next, we analyzed the influence of the lifestyle-related diseases on eradication. The primary HP eradication rate did not depend on the body weight: obese subjects (BMI > 25, n = 262. VPZ 97.0% vs PPI 72.4%) and no obese subjects (n = 771: VPZ 90.5% vs PPI 77.3%). As indicated, VPZ worked better in the obese subjects compared to the other non-obese subjects (BMI > 25: 97.0% vs BMI < 25: 90.5%). P = 0.089), suggesting the effect of VPZ was not influenced by the body weight. Regarding HT, primary eradication rate was better in VPZ compared to PPI (76.8%). The eradication rate was 97.9% for 178 patients with DM (VPZ 89.3%, PPI 68.9%) was not different from 1368 non-DM subjects (VPZ 90.6%, PPI 77.7%). There was not the serious adverse event with VPZ and PPI during the investigation period.

Conclusion: Therapy using VPZ was effective compared to that of PPI, and life-style related diseases including obesity, hypertension, DM, had no influence on the HP eradication with VPZ.

Introduction: Our previous trial and meta-analysis showed that 14-day sequential eradication therapy consisting of treatment by several antimicrobial drugs is a good model for studying the effect of antibiotics on the abundance of antibiotic resistance genes in the gut.

Aims & Methods: The aim of the study was to explore the gut resistome before and after antibiotic therapy by shotgun metagenomic sequencing. Seventy stool samples were used for analysis: 35 samples from H. pylori-positive patients before eradication therapy, 35 - from the same subjects after the completion of eradication therapy consisted of treatment by amoxicillin (1000 mg), clarithromycin (500 mg), proton pump inhibitor in a standard dose, bismuth subsalicylate (240 mg) bid for 14 days, lactulose was added as a prebiotic. Total DNA was isolated from the stool samples using beat beating method and sequenced on Solid 5500xW platform. Reads were aligned to the Comprehensive Antibiotic Resistance Database (CARD). The largest significant fold changes were found for beta-lactams antibiotic resistance genes abundances in the microbiomes of patients before and after eradication were assessed using Wilcoxon signed-rank test (p-value < 0.05 was considered significant).

Conclusion: Eradication therapy of H. pylori infection leads to increasing of abundance of different antibiotic resistance genes. Significant changes of abundance were shown for genes conferring resistance to 12 from 27 groups of antibiotics (CARD). The largest significant fold changes were found for beta-lactams (for some patients quantity of TEM beta-lactamases increased up to 125-fold), for macrolides (mrx and mphA genes up to 288- and 360-fold, respectively), for amoxicillin (aph, aadA, increase up to 297, 352-fold), for fluoroquinolones (spxB up to 133-fold increase). Moreover significant expansion of genes coding for beta-lactam and efflux pathways was also detected. Notably, a large number of antibiotic resistance genes were found to appear in the microbiome after therapy. Most of these genes confer resistance to beta-lactams (TEM beta-lactamases and shv genes), amnoglycoside (aad, aad), vancomycin (vanXVC), fluoroquinolones (gmr genes). This eradication therapy leads to the accumulation of genes promoting the resistance to antibiotics, that were not part of the treatment.

**Aims & Methods:** We aimed to evaluate the resistance rates encountered by European gastroenterologists in their routine clinical practice. A Local Coordinator was selected from each country with more than 10 H. pylori references in PubMed. Each Coordinator selected a representative group of recruiting gastroenterologists.

**Results:** Overall, 39 gastroenterologists from their country participated in the study. An e-CRF was created on AEG-REDCap for data collection. Each Coordinator selected a representative group of recruiting gastroenterologists.

**Conclusion:** The mean rate of H. pylori clarithromycin resistance in European nations has surpassed the threshold established by consensus conferences (15%) in which empirical use of standard triple therapy should be discarded. Dual resistance to clarithromycin and metronidazole is close to reach the 15% prevalence in which non-bisnath quadruple therapies efficacy is significantly challenged. There is a strong acquisition of antibiotic resistance after failed treatments.

Introduction: Surgery is standard treatment for colon tumors coexistence with diverticulum. However, it is currently controversial whether colon tumors near or within diverticulum can be treated by endoscopic submucosal dissection (ESD).

Aims & Methods: The aim of this retrospective case series was to clarify feasibility of ESD for superficial colorectal tumors near or within diverticulum. Consecutive patients with colorectal tumors near or within diverticulum removed by ESD in two referral centers were included. Clinicopathological characteristics and clinical outcomes were analyzed.

Results: There were 11 patients including 6 cases of the near-type and 5 cases of within-type diverticulum. The tumor showed type 2 in NBI International Colorectal Endoscopic (NICE) Classification in 10 cases [1, 2]. Pit pattern diagnosis in Kudo’s classification was type III. In one case, type IV without serration features in 2 cases and type VI in 7 cases [3]. In 4 of them the diverticulum could not be recognized in the tumor before the ESD. En-bloc R0 resection was achieved in 7 patients (64%). Median tumor size and procedure time were 23 mm (15–80) and 120 min (50–210), respectively. The ESD could not be continued in four cases due to the intra-diverticulum tumor extension and required strip biopsy, band ligation, polypectomy and/or argon plasma coagulation. Traction device using the “clip-and-line method” [4] was used in one case having two diverticula within the tumor and had kept global traction during ESD. One case with pin-hole perforation was occurred at the diverticulum and was endoscopically managed by immediate closure by endoclips. Emergency surgery was not required in any cases. During median 12 month follow-up period, only two cases detected residual tumors. One case was successfully ablated and other case required additional surgery.

Conclusion: The present study demonstrated that ESD was effective and safe for the treatment of colorectal tumors near or within diverticulum. The use of traction device may be helpful to see the cutting site at the diverticulum and to achieve en-bloc R0 resection.

Conclusion: The incidence of complicated diverticular disease has increased by 1.4 fold from 2000 to 2013 and this increase in incidence appears to be in those under the age of 65 years. This could be due to the increase in known risk factors for complicated diverticulosis such as obesity and physical inactivity or the increased use of prescription medications such as steroids or opiate analgesics which are associated with an increased risk of perforation. It is also possible part of this increase may be due to increased ascertainment of cases due to increased use of diagnostic imaging and endoscopy.

**Introduction:** Epidemiological studies have demonstrated a strong association between smoking and the increased risk for developing chronic pancreatitis (CP) and pancreatic ductal adenocarcinoma (PDAC). The exact mechanism underlying the effects of cigarette smoke (CS) on pancreatic injury remains unknown. We have previously showed that increased Ras activity is a key element in development of pancreatic inflammation and its progression to PDAC. However, it is not clear if similar phenomenon is involved in CS-induced CP.

**Aims & Methods:** Therefore, the aim of our study was to determine if CS will promote development of CP in mice exposed to repeated episodes of acute pancreatitis (AP). Our secondary aim was to evaluate the involvement of K-Ras protein in this process. Mice were exposed to CS or a sham treatment (no smoke exposure) using a cigarette smoking inhalation system for 12 weeks. After 2 weeks of experiment, half of the animals from the CS and sham exposure groups were additionally subjected to a repeated caerulein treatment (7-hourly i.p. 50 μg/kg/dose, once a week, for 10 consecutive weeks) to mimic recurrent episodes of AP. At the end of experiment the extension of pancreatic damage was determined by H&E and Trichrome staining. The expression of K-Ras protein was evaluated by immunohistochemistry (K-Ras:2B Antibody (C-19); sc-521).

**Results:** C57BL/cdmbmice exposed to CS or caerulein injections alone did not develop any pancreatic damage determined by histopathology examination. However, concomitant treatment with both of these agents caused focal acinar atrophy, with slight intralobular and perivascular areas of fibrosis, resembling mild CP. Moreover, immunohistochemistry examinations revealed increased expression of K-Ras only in mice treated with both CS and caerulein.

**Conclusion:** CS promotes development of CP in mice exposed to repeated episodes of AP. This process may be, at least partially, related to increased expression of K-Ras protein. Further studies are needed to determine the exact role of K-Ras and downstream signaling pathways in CS-induced CP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

OP210 LIPOXIN A4 INHIBITS PANCREATIC STELLATE CELL DIFFERENTIATION INTO PANCREATIC TUMOR STROMAL MYOFIBROBLASTS AND PANCREATIC TUMOR GROWTH IN VIVO

M. Heinrich, J. Schnittert, J. Prakash
Biomaterials Science And Technology/Targeted Therapeutics, University of Twente, Enschede/Netherlands

Introduction: The pancreatic tumor stroma has shown to strongly support tumor growth and metastasis. Human pancreatic stellate cells (hPSCs), as precursors of cancer-associated fibroblasts like myofibroblasts (CAF), are a main component of the tumor stroma of pancreatic ductal adenocarcinoma (PDAC). Upon activation, human hPSCs differentiate into CAF and promote tumor growth, invasion and metastasis in PDAC [1]. Lipoxin A4 (LXA4), a natural bioactive lipid, has shown to inhibit fibroblast activation [2]. This makes LXA4 a potential therapeutical strategy to diminish the pro-tumorigenic effects of the pancreatic tumor stroma, by inhibiting hPSC activation into CAF. The aim of the present study was to investigate whether LXA4 can inhibit the differentiation of human pancreatic stellate cells (hPSCs) into CAF and thereby inhibit hPSC-induced tumor growth in 3D culture. LXA4 is capable to inhibit the hPSC differentiation into CAF and thereby inhibit hPSC-induced tumor growth in 3D culture. LXA4 is capable to inhibit the hPSC differentiation into CAF and thereby inhibit hPSC-induced tumor growth in 3D culture.

Results: The LXA4-specific surface receptor FRP2/ALX was found to be upregulated in hPSCs. LXA4 significantly inhibited TGF-β induced activation markers (e.g. αSMA, collagen, PDGF-Rβ), migration and morphological changes in hPSCs. These inhibition of hPSC differentiation were caused by inhibition of Smad2/3 phosphorylation by LXA4. Conditioned medium experiments showed that LXA4 activated hPSCs, which reduced the migratory behavior of hPSCs. Conditioned medium experiments showed that LXA4 activated hPSCs, which reduced the migratory behavior of hPSCs.

Conclusion: The LXA4-specific surface receptor FRP2/ALX was found to be upregulated in hPSCs. LXA4 significantly inhibited TGF-β induced activation markers (e.g. αSMA, collagen, PDGF-Rβ), migration and morphological changes in hPSCs. These inhibition of hPSC differentiation were caused by inhibition of Smad2/3 phosphorylation by LXA4. Conditioned medium experiments showed that LXA4 activated hPSCs, which reduced the migratory behavior of hPSCs.

Introduction: Pancreatic cancer remains a serious clinical problem and a challenge for doctors and scientists. Despite the new possibilities in the diagnosis and treatment of cancer, 5-year survival rate applies to less than 5% of patients. Although many studies pathogenesis of pancreatic cancer, as well as other cancer models, this cancer needs further investigation. The process of cancer metastasis is a cascade of events involving proteolysis, cell motility and migration, proliferation and neangiogenesis. Cells released from the primary tumor must penetrate into the lymphatic vessels and/or blood vessels, which occurs by spreading. Circulating cells can then migrate through the walls of blood into surrounding tissues, where they settle, proliferate and form a new outbreak of disease. Understanding cellular processes responsible for the spread of cancer can be useful to improve the diagnosis and prognosis of the disease in patients diagnosed with pancreatic cancer.

Aims & Methods: The aim of study was to supplement the knowledge about the metastasis process of pancreatic cancer and to understand the role of protein factors presented in serum of pancreatic cancer patients that enhances the motility of cancer cells. The effect of pancreatic cancer patients were compared to the serum of control group and were added to pancreatic cancer cell line BxPC-3 (adenocarcinoma, ATCC® cell bank CRL-1687 TM). We evaluated cell migration, proliferation, adhesion response, activation of MAPK44/42 and Akt kinase, and invasion into Matrigel of pancreatic cancer patients (including HGF, VEGF and SDF-1) in the blood of patients, by ELISA test.

Results: We report that 1) serum from patients group and control group, and much stronger as SDF-1, HGF and VEGF can activate migration, adhesion and proliferation of pancreatic cancer cell line CRL1687; 2) we discovered higher metastatic potential of serum from patients with pancreatic cancer compared to control serum; 3) we report higher concentration of SDF-1, HGF, and VEGF in the serum of patients with pancreatic cancer. We report for the first time that diluted (1%) serum and plasma induces migration of malignant pancreatic cancer cell line much more strongly than any others knowns potent pro-metastatic factors. We found that this remarkable pro-migratory activity of diluted plasma is associated with a ~50-100-KD protein that interacts with Gz protein-coupled receptors and activates p42/44 MAPK and AKT signaling in target cells. We report for the first time that this pro-migratory factor, chaperoned by fibrinogen, is vitronectin and that this effect can be inhibited by fibrinogen.

Conclusion: The results prove a strong metastatic activity of blood serum and a significant role of HGF/SF, VEGF and SDF-1 factors in pancreatic cancer cell migration. Our results prove a mechanism for enhancing motility of pancreatic cancer cells to lymphatic vessels and blood vessels, in which the concentration of fibrinogen is low, and thus suggests that free vitronectin stimulates migration of tumor cells.

Introduction: Recent studies in genetically engineered mouse models (GEMMs) suggest that ductal neoplasia predominantly initiates from acinar cells after transdifferentiation to a ductal phenotype. We hypothesized that it might be possible to redifferentiate pancreatic intraepithelial neoplasia (PanIN) and pancreatic ductal adenocarcinoma (PDAC) to a more acinar phenotype by blocking selected cell signaling pathways.
Aims & Methods: We treated Mist1<sup>creERT<sup>2</sup></sup>/Aims & Methods: selected cell signaling pathways. creatic ductal adenocarcinoma (PDAC) to a more acinar phenotype by blocking possible to redifferentiate pancreatic intraepithelial neoplasia (PanIN) and pancreatic ductal adenocarcinoma (PDAC) to a more acinar phenotype by blocking selected cell signaling pathways.

Conclusion: Our study reveals a critical role for vonoprazan-derived M cells in supporting neuromuscular function and restoring intestinal homeostasis after surgical trauma. From a therapeutic point of view, our data indicate that inappropriate targeting of monocytes may increase neutrophil-mediated innophathology and prolong the clinical outcome of POI, while future therapies should be aimed at enhancing M cell repair functions.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP216 VONOPRAZAN, A NOVEL ACTIVE POTASSIUM-COMPETITIVE ACID BLOCKER, AND RABEPRAZOLE INDUCE SMALL INTESTINAL DYSBIOSIS AND EXACERBATE THE NON-STERoidal ANTI-INFLAMMATORY DRUG-INDUCED SMALL INTESTINAL ENTEROPATHY

1Dept. Of Gastroenterology, Osaka City University Graduate School of Medicine
2Dept. Of Gastroenterology, Osaka, Japan

Introduction: Vonoprazan fumarate, a novel active potassium-competitive acid blocker, was launched in Japan before it entered the world market. Vonoprazan and rabeprazole are both competitive inhibitors (PPIs) such as rabeprazole and esomeprazole. Recent studies show which exacerbated the NSAID-induced small intestinal enteropathy. In this study, we examine the effect of vonoprazan or rabeprazole on the composition of the microbiota in the small intestine and NSAID-induced small intestinal enteropathy.

Aims & Methods: Aim of this study is to investigate the effect of vonoprazan on the microbiota in the small intestine and NSAID-induced small intestinal enteropathy in mice. C57BL/6J mice received intraperitoneal administration of vonoprazan, rabeprazole, or vehicle for 7 days, and were administered indomethacin to gavage to induce damage to the small intestine. Some mice administered either the vehicle- and vonoprazan- or rabeprazole-treated groups showed 2.8-fold and 1.7-fold increases in indomethacin-induced damage to the small intestine, respectively. This high sensitivity to indomethacin-induced damage was caused by the intestinal microbiota obtained from the mice treated with either vonoprazan or rabeprazole.

Conclusion: Vonoprazan and rabeprazole induced small intestinal dysbiosis, which exacerbated the NSAID-induced small intestinal enteropathy.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP218 HYPOXIA DISRUPTS INTESTINAL BARRIER VIA REGULATING NHE9-TIGHT JUNCTION IN SEVERE ACUTE PANCREATITIS RAT MODELS

X. Li1, C. Geng1, X. Lei1, C. Wang1
1Department Of Gastroenterology, West China Hospital of Sichuan University, Chengdu/China

Introduction: Intestinal barrier dysfunction is attributed to various diseases, including inflammation, hypoxia, ischemia, intoxication, and considered as an important pathogenic factor for many diseases. In severe acute pancreatitis (SAP), it is well established that intestinal barrier dysfunction is a major element to promote SAP development and hypoxia plays a crucial role in infectious complications. Thus, deeply comprehending the mechanisms of intestine barrier dysfunction is indeed required for SAP treatment. Extensive evidences has indicated that intestine hypoxia triggered by SAP disrupting tight junction (TJ) is responsible for barrier dysfunction. Recently, the protective role of sodium/hydrogen exchanger 8 (NHE8) in intestine in various conditions has been well documented. We have previously demonstrated that inflammation reduced intestinal NHE8 expression. However, the role of NHE8 in SAP induced intestine barrier dysfunction has not been reported.

Aims & Methods: The aim of this study is to explore the intestinal expression of NHE8 in SAP rat model, and further explore the effects of hypoxia on NHE8 expression and potential mechanisms in Caco-2 cells hypoxia model. To induce SAP, SD rats were retrograde injected with 3% sodium taurocholate into the pancreatic duct, and ileum mucosal tissues were collected 24 hours later. For mechanism study, Caco-2 cells were incubated with 200µM cobalt chloride (CoCl2) for 6 hours to induce acute hypoxia model. Hypoxia-inducible factor alpha (HIF-1α) specific inhibitor 2-Methoxyestradiol (2-MeOE2) was incubated with Caco-2 cells for 6 hours under hypoxia. To further investigate the
relationship between NHE8 and TJ proteins, NHE8-shRNA plasmid (shNHE8) was constructed.

Results: In SAP group, NHE8 protein expression was significantly decreased compared with the control group (0.5 ± 0.04 vs. 1.2 ± 0.04, n = 12, P < 0.05). For CoCl2-intervened Caco-2 cells, HIF-1α protein expression were significantly stimulated compared with the control (1.5 ± 0.02 vs. 1.21 ± 0.15, P < 0.05), whereas NHE8 proteins expression were significantly reduced compared with the control (0.58 ± 0.06 vs. 1.02 ± 0.09, n = 3, P < 0.05). Additionally, CoCl2 treatment significantly reduced Claudin-1 and ZO-1 proteins expression when compared with control (1.05 ± 0.02 vs. 1.3 ± 0.06 vs. 1.53 ± 0.06, n = 3, P < 0.05). 2-MeOE2 treatment obviously blocked CoCl2 induced HIF-1α protein expression (3.59 ± 0.29 vs. 4.53 ± 0.25, n = 3, P < 0.05). Furthermore, 2-MeOE2 treatment dramatically increased the expressions of NHE8 (0.05 ± 0.07 vs. 0.58 ± 0.06, n = 3, P < 0.05). Claudin-1 (1.6 ± 0.16 vs. 1.05 ± 0.02, n = 3, P < 0.05) and ZO-1 (1.56 ± 0.08 vs. 1.33 ± 0.06, n = 3, P < 0.05) compared with CoCl2 pretreated cells (P < 0.05). Interestingly, compared with the mock shRNA transfected cells, the expressions of Claudin-1 and ZO-1 proteins transferred with shRNA NHE8 were significantly decreased (1.87 ± 0.15 vs. 2.38 ± 0.12; 1.06 ± 0.06 vs. 1.44 ± 0.06, n = 3, P < 0.05).

Conclusion: In SAP, the decrease of intestinal NHE8 expression is responsible for intestine barrier dysfunction. Moreover, intestinal hypoxia caused by SAP might also influence the expression of NHE8 via HIF-1α.

Introduction: Secretory diarrhea remains a major global public health problem and a 10X-fold leading cause of death, particularly in children and the elderly. Thus, it is clear that there is an urgent need for developing effective anti-diarrhetic strategies. Many disorders can disrupt intestinal fluid and electrolyte absorption, including Crohn’s disease, ulcerative colitis, and diarrhoea-predominant irritable bowel syndrome. More recently, the concept of the enteroendocannabinoids was introduced. They are considered as a mediator of the effect of inhibition of selected enzymes involved in the synthesis and degradation of endocannabinoids on electrolyte equilibrium in the mouse colonic tissue.

Aims & Methods: Male Swiss-Webster mice were used in this study. The effects of PF-3845, JZL-184 and RHC-80267 (inhibitors for fatty acid amide hydrolase (FAAH), mono- (MAGL) and diacylglycerol lipase (DAGL), respectively) on epithelial ion transport were characterized in isolated mouse colon stimulated by PF-3845, JZL-184 and RHC-80267 (inhibitors for fatty acid amide hydrolase (FAAH), mono- (MAGL) and diacylglycerol lipase (DAGL), respectively) on epithelial ion transport were characterized in isolated mouse colon stimulated by forskolin (FSK), veratridine (VER) and bethanecol (BET). Next, colonic tissue was co-incubated with selected inhibitors and cannabinoid receptor antagonists, AM 251 and AM 630 (CB, and CB antagonists, respectively). To assess changes in the active ion transport in response to addition of tested drugs, the measurements of short-circuit current (Isc) in mouse colon and illeum in vitro were performed.

Results: We observed that basolateral addition of PF-3845 induced antiseruic effect in FSK-stimulated colonic tissue (p < 0.01), which was significantly reversed by JZL-184 (p < 0.01) and AM 630 (p < 0.01). JZL-184 significantly reduced epithelial ion transport (p < 0.05) under FSK-stimulated conditions. Furthermore, co-incubation with AM 630 reversed this effect leading to an increase in ion transport when compared to JZL-184 alone (p < 0.05). After administration of JZL-184, we did not observe any significant effect on colonic Isc. However, application of AM 630 to colonic tissue treated subsequently with JZL-184 led to a pronounced increase in Isc compared with JZL-184 alone (p < 0.01). In turn, basolateral addition of PF-3845, JZL-184 or RHC-80267 was without any statistically significant effect on BET-evoked ion transport when compared to control.

Conclusion: For the first time, we report that the modulation of the endocannabinoid system may play a crucial role in providing a novel effective secretory diarrhea therapy. To confirm our findings, in vivo studies are necessary to evaluate the effect of inhibition of selected enzymes involved in the synthesis and degradation of endocannabinoids on electrolyte equilibrium in murine models of secretory diarrhea.

3Department Of Gastroenterology And Hepatology, University Medical Centre Ljubljana Slovenia, Ljubljana; Slovenia

Contact E-mail Address: david.drobne@gmail.com

Introduction: Target infliximab trough level for optimal control of inflammation in Inflammatory Bowel Disease treated with Infliximab is 3 – 7 g/ml. A higher target infliximab trough level of 3 – 7 g/ml are more effective and still safe regarding the risk of infection compared to levels below this threshold. In this single-centre cohort study we included 183 IBD patients (109 Crohn’s disease, 74 ulcerative colitis including IBD - unclassified disease). All patients received infliximab treatment between 2002 and 2015 at tertiary referral university IBD Centre (162 adults, 21 children) with available infliximab trough level data. Effectiveness and safety of high trough levels of > 7 g/ml was compared to trough levels below 7 g/ml. Effectiveness was assessed by correlating fecal Calprotectin (141 matched samples), CRP (376 matched samples) and endoscopy (69 colonoscopies) data to infliximab trough levels (426 samples, ELISA assay). Safety was assessed by comparing rates of infections in semesters (defined by 3-month periods) with high trough levels (> 7 g/ml) compared to semesters with infliximab trough levels below this threshold. Data on trough levels were available in 473/1681 (28%) semesters. Continuous variables were described using the median and interquartile range

Disclosure of Interest: None

Results: Among the whole cohort, 34 (30%) out of 113 patients relapsed within the follow-up period. The prevalence of circulating IFNg-secreting CD4+ T cells (Th1), IL-17-secreting CD4+ T cells (Th17) and Foxp3-expressing CD4+ T cells (Treg) as well as the concentrations of a wide broad of cytokines (IL-6, IL-8, IL-10, IL-13, IL-17A, INFγ, TNFa, IFNg) were measured in the serum were significantly different all over the time between patients who relapsed and those who stay in clinical remission. Various circulating double positive CD4+ T-cell subsets co-expressing Foxp3 and IL-17 and Foxp3 and INFγ were detectable in CD patients in remission. The subset of CD4+ T cells co-expressing IL-17 and Foxp3 was found significantly enriched (2-fold increase) in the circulating compartment in the cohort of patients in remission who experienced a clinical relapse 3 months later compared with that of CD patients who stayed in remission all over the follow-up period. In a multi-variate analysis, elevated serum ucCRP, low serum IL-10 and high number of double positive IL-17 and Foxp3 T cells were 3 independent factors significantly associated with the risk of further clinical relapse in CD patients in remission.

Conclusion: Detectable circulating cross-over immune CD4+ T-cell subsets co-expressing Foxp3, IL-17 and INFγ in CD patients in remission argues in the presence of a unique CD4+ T-cell subset co-expressing Foxp3 and IL-17 that preceding the occurrence of a flare suggests the potential contribution of this double positive T-cell subset in the pathogenesis of CD.

Conclusion: These analyses illustrate the importance of studying a broad range of JAK pairing potencies and clinical concentrations when comparing JAK inhibitor compounds. Calculated profiles of cytokine inhibition for a number of JAK inhibitors were generally similar when efficacious doses are considered, with only minor differences in percentage cytokine inhibition, suggesting limited differentiation of these JAK inhibitors based on JAK pharmacology. Ultimately, only robust clinical testing will determine whether there are clinical differences between JAK inhibitors.

**OP223: IDENTIFICATION OF GENETIC SIGNATURES AND IMMUNE MECHANISMS THAT DEFINE THERAPEUTIC RESPONSE AND FAILURE TO ANTI-INTEGRIN THERAPY WITH VEDOLIZUMAB IN IBD PATIENTS**

Introduction: Vedolizumab (VDZ), a humanized monoclonal antibody targeting the α4β7 integrin, was approved for the treatment of Crohn’s disease (CD) and ulcerative colitis (UC). Despite proven clinical efficacy for inducing and maintaining remission, subgroups of patients have no clinical benefit from anti-adhesion therapy with VDZ.

Aims & Methods: Within this study, we aimed to identify genetic, cellular and immunological mechanisms that define and predict response and failure of VDZ therapy. For this purpose, intestinal RNA Sequencing was performed in UC and...
CD patients (remitters and non-remitters) before and at week 14 of VDZ therapy. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jean-frederic.colombel@msmu.edu

Aims & Methods: Adult pts naive to immunosuppressive and biologic therapy included in CALM had: 1) baseline (BL) CDAI > 150 and ≤ 450 (for receiving prednisone ≥ 20 mg or equivalent) or ≥ 220 and ≤ 450 (for receiving no or < 20 mg prednisone or equivalent); 2) active endoscopic CD, defined as total CD endoscopic index of severity (CDEIS) > 6 and sum of CDEIS subscores ≥ 6 in ≥ 1 segment with ulcers; 3) CRP < 5 mg/L and/or FC < 250 μg/g. Pts were randomly assigned 1:1 to T2T or CM groups, following up to an 8 week (wk) of 40 mg/day prednisone burst and taper. Pts were eligible for early randomization between BL (wk 0) and wk 8 if CDAI > 220 and were either on corticosteroids for 4 wks, or had intolerance/contraindication for prednisone therapy or per investigator assessment. Pts received the following treatment options (TO) 1-4 administered in a stepwise manner: TO1 = no treatment; TO2 = 180/80 mg aludinum (ADA) wks 0/2; 40 mg every other wk; TO3 = ADA 40 mg wks; TO4 = ADA 40 mg wks + azathioprine [AZA] 2.5 mg/kg/day. Early randomized pts were assigned to TO2. Treatment at randomization and 3 following visits was based on failure to fulfill success criteria: CDAI < 150, CRP < 5 mg/L, FC < 250 μg/g, and absence of deep ulcers for the T2T group and CDAI decrease ≥ 70 or 100 (at randomization or post-randomization, respectively) or CDAI < 200 and no prednisone for the CM group. The primary endpoint was CDEIS < 4 and absence of deep ulcers at wk 48. Secondary endpoints at wk 48 included deep remission (CDEIS < 150), discontinuation of steroids ≥ 8 wks, absence of draining fistulae (CDEIS < 4, and no deep ulcers), biologic remission (FC < 250 μg/g, CRP < 5 mg/L, and CDEIS < 4), CDEIS < 4, and absence of deep ulcers in each segment, and CDEIS = 0. Missing data were imputed using non-responder imputation.

Introduction: The concept of "treat to target" (T2T) implies that close serial monitoring of patients (pts) with Crohn’s disease (CD) using biomarkers of inflammation, serum C-reactive protein (CRP) and fecal calprotectin (FC), assists in timely treatment escalation in order to improve outcome. CALM, a prospective, open-label, multicenter, active-controlled, Phase 3 study, assessed the benefit of T2T versus standard clinical management (CM) of CD.

**Results:** A total of 244 pts were randomized. At BL, the mean ± SD age was 31.6 ± 11.7 years, mean ± SD CD duration was 95.9 ± 19.8 years and 57.8% were female. BL characteristics between T2T and CM groups were similar. Results are shown in the Table. No new safety signals with ADA were observed. The overall rate of adverse events was similar between T2T and CM groups.

**Table. Summary of primary and select secondary endpoints of CALM study**

All other authors have declared no conflicts of interest.
adverse outcomes, such as hospitalizations, surgical procedures, including major surgeries, and serious disease-related complications in patients enrolled in CALM.

**Aims & Methods:** Immunosuppressive and biologic-naive adult patients with CD treated with or without corticosteroids (CS), and with baseline (BL; week 0) CRP >5 mg/L (low-dose CS) or >20 mg/L (no CS), active endoscopic CD (overall CD Endoscopic Severity [CDEIS]>6 and sum of CDEIS subscores >6 in ≥1 segment with ulcers), and CDR >5 mg/L and/or FC >250 g/L were treated with prednisone burst and taper, then randomized to the TO2T or CM arms at week 9. Some patients with CDCAI >220 and CS for >4 weeks or intolerance/contraindication for CS or per investigator assessment were able to be randomized early. Patients received up to four treatment options (TO) administered in a stepwise fashion: 1) prednisone bolus (pre-defined therapeutic target: TO1: 160/80 mg adalimumab (Humira®); ADEAS weeks 0, 2, 40 mg every other week; TO3 = ADEA 40 mg weekly; TO4 = ADEA 40 mg weekly + azathioprine 2.5 mg/kg/dy. CD-related hospitalizations, CD-related surgical procedures (median bowel resection±irrigation, abscess drainage, seton placement, fistulotomy, placement of a TPN access line]) after randomization and a composite endpoint of CD-related hospitalization or serious complication (presence of abscess, fistula or stricture, skin and ocular extra-intestinal manifestation, and serious adverse drug reaction) from randomization to up to week 48 or last dose date, whichever was later, were summarized as incidences or rates (events [E]/100 Patient Years [PY]). Differences between treatment groups in rates of CD-related hospitalizations and surgical procedures or in incidences of the composite endpoint were analyzed using a Chi-square test. Hazard ratio (95% CI) of the composite endpoint and Cox proportional hazard model. Any no treatment, on or after randomization and up to 70 days after last dosing were summarized in all randomized patients.

**Results:** A total of 244 patients were randomized 1:1 to the TO2T and CM arms. Mean age at BL was 31.6 ± 11.7 and 57.8% were female. The rate of CD-related hospitalizations after randomization was significantly lower in the TO2T compared to CM arm: 14 events (13.2/E/100 PY) vs 29 events (28.0/E/100 PY), \(P = 0.021\). The rates of CD-related surgical procedures between treatment arms were 7 events (6.7/E/100 PY) in TO2T and 9 events (8.7/E/100 PY) in CM, \(P = 0.582\). The proportion of patients with CD-related hospitalization or serious complication was numerically lower in TO2T compared with CM: 18 patients (14.8%) vs 25 patients (20.5%), \(P = 0.240\). TO2T was associated with numerically lower risk of CD-related hospitalization or serious complication than CM: hazard ratio 0.7, 95% CI 0.4–1.3, \(P = 0.249\).

**Conclusion:** The TO2T approach using tight control of inflammation by biomarkers lead to a reduction of major adverse outcomes indicative for a detrimental course, including CD-related hospitalizations. A longer study would be needed to confirm these findings.

**Introduction:** The course of Crohn’s disease (CD) varies substantially between affected individuals, but reliable prognostic markers are not available in clinical practice. This hinders disease management because patients with aggressive disease will be undertreated by conventional “step-up” therapy, while those with indolent disease would be exposed to the risks of unnecessary immunosuppression of a “top-down” approach. Previously, we described a transcriptional signature that is detectable within peripheral blood CD8 T cells at diagnosis and which correlates with subsequent disease course. To translate this work to the bedside and overcome the technical challenges of separating cell populations, we sought to develop a whole blood qPCR-based biomarker that can re-capitulate the CD8 subgroups without the need for cell separation. Here we describe the development and validation of this biomarker and the upcoming biomarker-stratified trial that will test whether it can deliver personalised medicine in CD.

**Aims & Methods:** From a training cohort of 69 newly diagnosed IBD patients, we simultaneously obtained a whole blood PAxgene RNA tube and peripheral blood T-cell suspension. After confirming that the CD transcripional signature was detectable and correlated with prognosis, we used machine learning to identify a transcriptional classifier in whole blood gene expression data that would re-capitulate the CD transcripional signature. Model selection was performed using a Bayesian Information Criterion (BIC) and the genes identified were subsequently tested by qPCR and optimised to produce an 18 gene qPCR assay. Using the independent validation of this biomarker was established using a second, independent cohort of 85 newly diagnosed patients with CD from 4 sites around the United Kingdom. This validated the biomarker and confirmed that the subgroups identified had significantly different disease courses (analogous to those observed with the CD8 T-cell subgroups). The hazard ratio for time to treatment escalation in this validation cohort was 3.52 (1.84–6.76, 95% confidence intervals, \(P = 0.0002\)). We now propose to conduct the first ever biomarker-stratified trial in any inflammatory disease to determine whether this biomarker can deliver personalised medicine in CD.

**Conclusion:** We have developed, optimised and validated a whole blood qPCR classifier that is able to predict disease course from diagnosis in IBD patients. This represents a major step towards personalised treatment in IBD, and we will then assess whether this could make personalised medicine a reality in CD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

The rate of nodal metastasis in dissected lymph nodes was 52.3% (34/65). The rate of residual cancer in endoscopically treated lesions, except those considered non-curative, was 4% (2/65), and all 2 lesions had vascular invasion (negative/positive), and curability (R0 resection/R1 resection). We retrospectively assessed the surgical cases following non-curative endoscopic resection. We identified 1137 patients who underwent ESD from August 2006 to December 2016. Of these, pathological diagnosis was non-curative resection in 350 patients (30.7%), with at least one adenoma at the time of diagnosis (115), and dyspepsia (6%). At initial endoscopy, 11 patients (2.2%) had AG, atrophic gastritis (AG), or intestinal metaplasia (IM), or dysplasia (D) was diagnosed by histology, were identified in the hospital pathology database. The clinical, endoscopic, histological and follow-up data were collected from the electronic files for these patients. They were analysed using SAS 9.4 software (Cary, NC, USA).

Results: During a 15-year period, out of 16,764 patients having undergone upper endoscopy with gastric biopsies, 485 patients (60% of men, median age 68 years, min 11 - max 97) with GPL, were identified (detection rate 2.9%). The most frequent indications for endoscopy were anaemia (38%), digestive bleeding (22%), abdominal pain (17%), surveillance (15%), alteration of general status (11%), and dyspepsia (6%). At initial endoscopy, 11 patients (2.2%) had AG, 362 (75%) IM, 80 (16%) low grade dysplasia (LGD), 10 (2%) high grade dysplasia (HGD), and 22 (4.5%) had GADK with concomitant GPL (IM or D). H. pylori infection was found by histology in 204 patients (42%). Endoscopic aspect was considered normal in 17.5% of patients with IM, in 6% of patients with LGD, and in 20% of patients with HGD. The median number of biopsies obtained during initial endoscopy was 4 (min 0 - max 190). Patients with HGD, were significantly older than those with IM and LGD (median age 75 vs 68 years, p = 0.006). From 485 patients, 326 (67%) had at least one follow-up endoscopy (median: 1, min 0 - max 24, Q1-Q3: 0 - 2), after the initial biopsy period of 2.9 months (max 124, Q1-Q3: 1-14) since the initial diagnosis of GPL. During a median follow-up of 40 months (min 0.3 - max 137 months), out of 362 patients with IM, 18 (5%) showed progression to HGD, and 5 (1.4%) to GADK. Among 485 patients, 8 developed GADK during follow-up (annual incidence rate 0.11%). Altogether, with the 22 patients in whom GADK was found already at the time of the diagnosis of GPL, 30 GADK were identified in the studied population (6.2%).

Conclusion: This study showed that in France: I) Most of GPL were diagnosed in patients referred for endoscopy for anaemia or digestive bleeding. II Patients with HGD were older than those with LGD and IM. III The progression from IM to more severe lesions (LGD, HGD, GADK) was observed in 7% of patients during a median follow-up of 33.3 months, and the annual incidence of GADK in this population was 0.11%. IV) Modalities of surveillance of GPL were heterogeneous, V) New endoscopic techniques may improve the endoscopic diagnosis of GPL in the future.

Introduction: Increase in adenoma detection rate (ADR), proportion of patients with at least one adenoma) decreased risks of interval colorectal cancer and related deaths after usual air insufflation (AI) colonoscopy. In randomized controlled trials (RCTs) of unsedated and minimally sedated patients, compared with AI, water exchange (WE) significantly decreased insertion time (primary outcome) and increased ADR (secondary outcome). We recently completed two RCTs each with ADR as the primary outcome comparing WE vs. AI in Chinese patients, some of whom were sedated with propofol.

Aims & Methods: We pooled the data of two RCTs (NCT02135601, 0189491) to assess the hypothesis that WE could significantly increase ADR and secondary outcomes of adenoma-related measures in propofol sedated patients. 510 patients were randomly assigned to either AI (n = 258) or WE (n = 252).

Results: Demographic data were comparable. Despite a significantly shorter inspection time, ADR (38% vs. 26.7%), flat (32.5% vs. 19.4%), combined advanced & sessile serrated ADR (13.1% vs. 7.4%), adenoma/colonic polyp, and right colon ADR of WE were significantly higher than those of AI. WE showed significantly cleaner colons and longer insertion time. Comparable withdrawal time without polypectomy and adenoma/positive colonoscopy suggested equivalent withdrawal techniques were used (Table).

Introduction: Early detection and adequate surveillance of gastric precancerous lesions (GPL) may prevent the development of gastric adenocarcinoma (GADK) and GADK-related mortality. The epidemiological and clinical data on GPL lesions in France are missing.

Aims & Methods: Our aim was to analyse, in a large retrospective study, the frequency, clinical characteristics, evolution, and modalities of surveillance of GPL in France. All the patients having undergone endoscopy with gastric biopsies between 2000 and 2015 in one academic center, and in whom GPL [atrophic gastritis (AG), or intestinal metaplasia (IM), or dysplasia (D)] was diagnosed by histology, were identified in the hospital pathology database. The clinical, demographic and procedural data of the two pooled randomized controlled trials (N = 510).

OP232 COLONIC POST-POLYPECTOMY BLEEDING IN PATIENTS ON NEW ORAL ANTI-COAGULANT – A CASE CONTROL STUDY

Medicine And Therapeutics, Institute of Digestive Disease, The Chinese University of Hong Kong, Hong Kong,Hong Kong PRC

Contact E-mail Address: yamlam2@hotmail.com

Introduction: Anticoagulants are commonly used to treat patients with cardiovascular and cerebrovascular diseases. Recently developed new oral anticoagulants (NOAC) that are direct thrombin inhibitor and direct factor Xa inhibitor overcome some limitations of vitamin K antagonist, including drug drug interaction and regular dose adjustments on the basis of laboratory monitoring. The risk of post-polypectomy bleeding (PPB) in patients on anti-platelet therapy and vitamin K antagonist has been well studied (1, 5). However, data on the risk of post polypectomy bleeding in patients on NOAC are scanty.

Aims & Methods: This aim of this study was to determine if the risk of colorectal post-polypectomy bleeding in patients on NOAC. Data of consecutive inpatients with age between 18 – 89 in five year period (from 2012 to 2016), who underwent colonoscopy with NOAC therapy (dabigatran, rivaroxaban and apixaban) were collected in 16 Hong Kong Public Hospitals by Clinical Data Analysis and Reporting System (CDARS). NOAC were stopped 1–2 days before colonoscopy and resumed after procedure according to the local hospital practice.

Results: Among 272 patients on NOAC underwent colonoscopy, 106 patients underwent colon polypectomy. Colonoscopy was performed in 16 Hong Kong Public Hospitals by Clinical Data Analysis and Reporting System (CDARS). NOAC were stopped 1–2 days before colonoscopy and resumed after procedure according to the local hospital practice. The relative risk and characteristics of PPB were analysed.

Results: Among 272 patients on NOAC underwent colonoscopy, 106 patients underwent colon polypectomy. Colonoscopy was performed in 16 Hong Kong Public Hospitals by Clinical Data Analysis and Reporting System (CDARS). NOAC were stopped 1–2 days before colonoscopy and resumed after procedure according to the local hospital practice. The relative risk and characteristics of PPB were analysed.

IMPLICATIONS OF BIOLOGICS IN IBD - ROOM B2

OP233 MRI IMPROVEMENT AFTER ANTI-TNF THERAPY IS PREDICTIVE OF SUSTAINED CLINICAL REMISSION AND IS A POTENTIAL THERAPEUTIC TARGET IN CROHN'S DISEASE

A. Buisson1, L. Messadeq2, G. Bouguen3, F. Goutorbe4, J. Reimund5, M. Goutie1, C. Sautel6, A. Boucher6, I. Ticlete6, C. Duron7, J. Scanz1, M. Reynond1, C. Allamant1, M. Dapoigny8, G. Bommelert9, B. Pereira9, C. Hordemann9

Introduction: MRI has been suggested as a potential alternative to endoscopy to evaluate therapeutic efficacy in ileocolonic Crohn's disease (CD).

Aims & Methods: We aimed to determine if MRI endpoints at week 12 (W12) are able to predict corticosteroids-free deep remission (CFREM) and MRI remission at W52 in patients treated with anti-TNF. CD adult patients needing anti-TNF agents and no bowel resection. MRI remission was defined as no active MRI lesions. Deep remission was defined as no corticosteroids-free deep remission and MRI remission at W12.

Results: Overall, 64 CD patients were enrolled in the study. Nine patients were primary non-responders and left the study before the second MRI. Among the included patients, 41.4% were active smokers and 22.0% previously underwent intestinal resection. CD location was ileal, colonic and ileocolonic in 48.3%, 8.6% and 43.1%, respectively. Overall, 65.5% received concomitant immunosuppressive therapies. In addition, 46.6% and 53.4% of the patients were treated

Conclusion: The risk of colorectal post-polypectomy bleeding in patients with NOAC is high and often delayed in presentation. Resuming NOAC 4 days after colonoscopy may reduce the bleeding risk by half. However, this strategy should be studied in prospective trial to address the bleeding and thrombotic risk.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
with infliximab and adalimumab, respectively. We assessed the variation of MRI parameters between baseline and W12 in patients achieving CFREM at W52 compared to those who did not among 55 CD patients. In univariate analysis, five factors evaluated at W12 were predictors of CFREM at W52: disappearances of ulcerations (OR = 6.4, p = 0.05), of oedema (OR = 3.3, p = 0.05), of enlarged mesenteric lymph nodes (OR = 5.9, 0.041), of or slerotolipomatosis (OR = 12, p = 0.03), and 10% increase of ADC (OR = 4.3, p = 0.02). Using several multivariate models, we defined transmural response at W12 as at least one factor among the three following factors: disappearance of ulcerations, increase of ADC (\(\text{ADC} > 10\%\)), and disappearance of at least one extra-enteric sign (slerotolipomatosis OR enlarged mesenteric lymph nodes). Transmural response predicted CFREM at W52 in 18%, 53%, 67% and 100% of the patients when respectively none, one, two or three criteria were achieved at W12. ROC curves, we identified that 25%-decrease of C1 score or MaRIA index at W12 were the best variations of these scores to predict CFREM at W52. All the MRI endpoints (Table 1) evaluated at W12 were highly predictive of CFREM at W52. In addition, transmural response (AUC = 0.66, Se = 71.4%, Spe = 60%, PPV = 75.0%, NPV = 55.6%) and MRI response according to Clermont score (AUC = 0.77, Se = 64.3%, Spe = 90.0%, PPV = 78.3%, PPV = 81.3%) or MaRIA (AUC = 0.84, Se = 78.6%, Spe = 90.0%, PPV = 85.7%, PPV = 85.7%) evaluated at W12 were highly predictive of deep MRI remission at W52.

**Table 1**: Performances of MRI endpoints evaluated after 12 weeks of treatment with anti-TNF to predict sustained corticosteroids-free clinical remission at week 52.

**Conclusion**: MRI is a reliable tool to monitor therapeutic response in ileocolonic CD. Our short-term MRI endpoints are highly predictive of CFREM or transmural healing at W52, supporting their use in daily practice and clinical trials.

**Introduction**: Refractory mucosal lesions in Inflammatory Bowel Disease (IBD) patients are an important clinical challenge. Biological therapies have changed the way of treating these patients. Endoscopic administration of these drugs (targeted therapy) could decrease this refractory active inflammation by providing important clinical benefits. We have developed a novel hydrogel (TriBio) with triple biological activity (bioadhesive, biocompatible and bioactive) that can act as drug-eluting platform (patent pending).

**Aims & Methods**: The aim of this study was to evaluate the utility of endoscopic administration of 2 mL of TriBio platform with infliximab (0.5 mg/mL) as a shield, in a rat model of TNBS-induced colitis. Colitis was induced by intrarectal administration of 30 mg TNBS to 24 Sprague-Dawley male rats (Day 0). At day 3, animals were randomized in three groups (n = 8, each) to receive: a) TriBio-infliximab, b) Tribio or c) saline. Macroscopic follow-up (colonoscopy) was assessed at days 6 and 12. Afterwards, animals were sacrificed and colon was resected, weighted and histologically evaluated (1-4 scale). Ponderal evolution and appearance of stool were recorded.

**Results**: The treatment with TriBio-Infliximab significantly improved the clinical condition of the animals (weight evolution, and stool appearance). Similarly, the weight of the colon was also lower in animals treated with TriBio-infliximab when compared to controls (TriBio & saline). Histologic score also showed that TriBio-infliximab treatment significantly reduced the ulcer and the presence of necrosis and fibrosis.

**Introduction**: Biosimilar infliximab CT-P13 received positive CHMP recommendation in June 2013 for all indications of the originator product. It has been previously shown that CT-P13 is effective and safe in inducing remission in inflammatory bowel diseases (IBD). Demographic data were collected and a harmonized monitoring strategy was applied. Clinical remission, response and biochemical response was evaluated at week 14, 30 and 54. None of the patients had received infliximab
within 12 months prior to initiation of the biosimilar infliximab. Safety data was registered.

Results: 353 consecutive IBD (209 CD and 144 UC) patients were included of which 229 patients reached the week 54 endpoint. The age at disease onset was 24/28 years (median, IQR: 19–34) and 22–39) in CD and UC patients, respectively. 31/41% of CD patients had colonic/ileocolonic disease location, 43.5% had complicated disease behaviour, 39% had perianal disease, while 56.2% of UC patients had extensive colitis. 23/19% of patients had received previous anti-TNF therapy in CD and UC, respectively. 60/51% of CD/UC patients received concomitant therapies at baseline. 49, 53, 48% and 80, 81 and 65% of CD/UC patients reached clinical remission and response by week 14, 30 and 54, respectively. Remission and response rates were 56, 41, 43% and 74, 66 and 50% in UC patients. Previous anti-TNF exposure was associated with decreased clinical remission in both CD and UC. Mean CRP decreased significantly both in CD and UC by week 14, which was maintained throughout the 1-year follow-up. 31 (8.8%) patients had infusion reactions, 32 (9%) patients had infections and 1 death occurred.

Conclusion: Final results from this prospective nationwide cohort confirm that CT-P13 is effective and safe in inducing and maintaining remission in both CD and UC. Efficacy was influenced by previous anti-TNF exposure, no new safety signals were detected.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP236 EFFICACY OF HEPATITIS B VIRUS VACCINATION IN NEWBORN EXPOSED TO ANTI-TNF ALPHA IN UTERO

A. De Lima-Karagianis1, S. Kanis1, J.C. Escher1, C.J. Van Der Woude1

Introduction: Neonates exposed to maternal anti-TNF alpha therapy in utero are born with clinically significant anti-TNF alpha levels that can still be detected throughout the first months of life. 1, 2 Adults treated with anti-TNF alpha agents have been reported to react inadequately to the hepatitis B virus (HBV) vaccine compared to adults not treated with anti-TNF alpha. 3, 5 Since 2011, HBV vaccination is included in the Dutch National Vaccination Programme. The efficacy of the HBV vaccination is unclear in children that have been exposed to anti-TNF alpha in utero. The objective of this study was to compare anti-HBs levels following routine HBV vaccination in anti-TNF alpha-exposed children versus non-exposed children.

Aims & Methods: We performed a cross-sectional, controlled cohort study at a single, tertiary referral center. Study enrollment took place from 2014 until 2017. Pregnant women treated with anti-TNF alpha until at least the second trimester for Inflammatory Bowel Disease (IBD) and their subsequent children were recruited from the IBD preconception outpatient clinic. Pregnant women treated with other medication than anti-TNF alpha for IBD and their subsequent children were eligible as controls. Women were not eligible for participation in case of HBV infection. Adherence to the Dutch National Vaccination Programme was mandatory for participation in this study (Routine HBV vaccination (Engerix-B Junior, RNA vaccine at 6 weeks, 3, 4 and 11 months). A venous blood sample was obtained from the children one month after final HBV vaccination. Anti-HBs levels were measured in all children by ELISA.

Results: Anti-HBs levels at 12 months did not differ between the anti-TNF alpha exposed (n = 15) and the control group (n = 12) (>1000 IU/L vs >1000 IU/L, p = 0.85). All children successfully immunised against HBV, defined as anti-HBs >10 IU/L. Median anti-HBs levels determined in cord blood at birth were 2.5 ug/mL (IQR: 0.40–11.01 ug/mL). There were no differences in birth outcomes, growth and infections in the first year of life between the anti-TNF alpha exposed and the control group.

Conclusion: This study suggests that children born with detectable anti-TNF alpha levels can be effectively vaccinated against HBV.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Conclusion: The indication of colonoscopy, sex, age, and time between the last dose of bowel preparation and colonoscopy longer than 7 h are factors that are independently related to the quality of colon cleansing.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Participation in colon-cancer screening is still low in Europe and worldwide. Especially bowel preparation is reported to be the most unpleasant burden. Despite the fact that bowel preparation is a major cornerstone of quality of colonoscopy, in a certain proportion of patients bowel preparation is still insufficient. Problems with dietary recommendations and problems taking the preparation orally very often in these cases. Among our patients use of cell phone has increased rapidly in the last years. Therefore using this new medium for improvement of colonoscopy preparation has to be considered.

Aims & Methods: To optimize patients’ guidance in colonoscopy preparation an easy-to-use solution for all mobile phones by short message service (SMS) covering the 4 days prior colonoscopy was used in a prospective, randomized multicenter study. In comparison to other approaches not only laxative intake but also patient guidance over the last four days before colonoscopy was served by SMS. 500 (250/250) participants with appointment for outpatient colonoscopy were randomized to regular colonoscopy preparation (control group) or SMS supported colonoscopy preparation. The control group received information about colonoscopy preparation orally and by a leaflet as regularly done by gastroenterologists. The SMS supported group additionally received information regarding dietary and general recommendations time axis adjusted to the colonoscopy appointment by an automated SMS system starting 4 days prior colonoscopy preparation. Level of bowel cleanliness was measured by BBPS. Patients’ satisfaction with bowel preparation procedure was analyzed by a questionnaire.

Results: Participants of the SMS supported colonoscopy preparation had a significantly higher BBPS score (7.6 ± 0.6 vs. 5.9 ± 0.01) in comparison to regular colonoscopy preparation. All regions of the colon had higher BBPS scores in SMS supported patients. Overall patient satisfaction with bowel preparation was higher in the SMS supported group.

Conclusion: Water-assisted colonoscopy preparation by an automated 4-day guidance improved bowel cleanliness. Patient guidance covering the last four days before colonoscopy was highly accepted by the patients. We conclude further that the usage of a simple tool as SMS for optimizing colonoscopy preparation could improve CRC-screening participation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Technology of colonoscopy is constantly evolving. New full-spectrum (FVE) endoscopes (FUSE) offer 70° and 120° angle of view compared to the standard forward-viewing endoscopes (FVE). From March 2015 trough December 2016 patients referred to colonoscopy screening, positive fecal immunological test, or polyp surveillance underwent colonoscopy with FVE Pentax i10 or FUSE instruments. 974 patients were allocated to receive FUSE first, and 160 (50%) to receive SFV first. Per-lesion analysis, the adenoma miss rate was significantly lower in patients in the FUSE first than in those in the SFV first: 11.7 vs. 13.6% (P = .001) and 49.4 (41.4–57.9) % (P < .001). The polyp miss rate vs. patient analysis was also significantly lower in the FUSE first than in the SFV first: 11.9 (8.0–15.4) % vs 22.9 (17.5–28.3) % (P < .001). The polyp miss rate vs. patient analysis was also significantly lower in the FUSE first than in the SFV first: 13.9 (10.0–17.7) % vs 26.8 (21.3–32.4) % (P < .001). The adenoma detection rate was significantly higher in patients in the FUSE first than in those in the SFV first: 11.7 vs. 9.8% (P = .04). The adenoma detection rate was significantly higher in patients in the FUSE first than in those in the SFV first: 6.29 (5.49–70.4) % vs 49.4 (41.4–57.9) % (P = .018). Cecal intubation rates (%), mean cecal intubation and withdrawal time (min) of FUSE and SFV colonoscopy (140–170 min). Randomization was stratified by sex, age, indication and institution. Primary endpoint was the adenoma detection rate vs-protocol, per-patient analysis. Secondary endpoints included the polyp miss rate and the adenoma detection rate. This trial is registered with UMIN00002448.

Introduction: Narrow band imaging (NBI) allows real-time differentiation of diminutive polyps with a histology determination. Before this practice can be implemented in daily practice, guidelines endorse ≥90% negative predictive value (NPV) for neoplastic rectosigmoid histology in the rectosigmoid and ≥90% agreement in surveillance intervals for high-confidence predictions. This study aimed to evaluate the diagnostic accuracy of diminutive polyps and to determine whether these endoscopists can achieve and maintain the prior thresholds.

Aims & Methods: In this prospective multicentre study, endoscopists accredited for colonoscopies in FIT-positives within the Dutch bowel cancer screening program were trained in optical diagnosis with our validated NICE-WASP module [1]. This module includes optical differentiation of sessile serrated lesions. Trained endoscopists were required to reliably diagnose defined thresholds in Imaging-based and real-time tests before entering the continuation phase. In this phase, endoscopists recorded histology predictions and confidence levels of all polyps in consecutive FIT-positives colonoscopies for 1 year. Endoscopists were randomised to receive feedback or no feedback on their performance. Primary outcome was whether endoscopists could maintain a NPV ≥90% for neoplastic histology in the rectosigmoid for high-confidence predictions, either with or without regular interim performance feedback. NPV was determined by comparing predictive value against histology outcome. Sensitivity was defined as adenomatous and sessile serrated lesion histology. For surveillance interval agreement, prediction was based on the combination of high-confidence predictions and histology outcome of low-confidence predictions and polyps sized ≥5 mm. The related equation thresholds were used and adjusted for clustering of polyps per patient and per endoscopist.

Results: Of 39 endoscopists initially attending the training sessions, 27 (69%) qualified after a median number of 3 tests (range 2–5). The pooled NPV for predicting neoplastic histology during the real-time phase was 94.1% (95% confidence interval (CI) 86.1–97.6). In the continuation phase, these 27 endoscopists performed 3, 144 colonoscopies in which 4, 504 diminutive polyps were removed. Of these, 73.5% were predicted with high-confidence and 40% with low-confidence (CI 69.8–77.3). In the rectosigmoid, the pooled NPV for predicting neoplastic histology in the rectosigmoid at the end of the continuation phase was 90.8% (95% CI 88.6–92.6). The NPV in the feedback group was 91.7% (95% CI 88.2–94.2) and 99.6% (95% CI 85.2–92.8) in the observation group (p = 0.93). The pooled surveillance interval agreement was 95.4% (95% CI 94.9–96.6), and did not differ between the feedback and observation group (96.4% versus 94.1%, p = 0.10). Individually, 17 (63%) endoscopists achieved ≥90% NPV for predicting neoplastic rectosigmoid histology, 24 (89%) achieved ≥90% surveillance interval agreement and 16 (59%) achieved both. High-confidence predictions for adenomatous and sessile serrated adenomas/polyps were independently associated with accurate histology prediction.

Conclusion: Using a validated training module including sessile serrated lesions, a selected group of endoscopists achieved and maintained a pooled NPV and high-confidence prediction agreement of at least 90% over the period of 1 year. Providing regular interim feedback did not lead to differences in those endpoints. This study design can be used as a template for safe implementation of an optical diagnosis strategy in daily practice (NCT02516748).

Disclosure of Interest: P. Fockens provides ongoing consultancy to Cook, Olympus, Medtronic, and Fujifilm. E. Introduction: Helicobacter pylori (H. pylori) infection is strongly associated with development of non-cardiac gastric cancer, and gastric adenocarcinoma occurred in patients naïve to H. pylori infection is very rare. In this study, we investigated the clinical characteristics of non-cardiac gastric adenocarcinoma that developed in H. pylori uninfected patients who underwent endoscopic resection.

Aims & Methods: A total of 2221 gastric neoplasia in 1707 patients that were removed by ESD or EMR between January 2010 and May 2016 at our hospital were included. If H. pylori infection status was not evaluated or if H. pylori infection status was not determined, patients were excluded. Patients were excluded if they were not evaluated by H. pylori-serum antibody test: serum antibodies (<3U/ml), urea breath test and stool antigen tests.

Results: Finally, 1, 430 non-cardiac gastric adenocarcinoma in 1111 patients were analyzed in this study. 18 (1.3%) out of 1430 lesions were diagnosed as H. pylori uninfected gastric adenocarcinoma. Among patients with H. pylori-infected gastric adenocarcinoma, 58.4% were younger than 70 years old, and 41.6% were 70 years old or older. The differences in incidence between the two groups were significant (p < 0.001).

Conclusion: We determined the effect of co-incubation of cultured rat gastric fibroblasts with Hp strain encoding for cagA-, vacA- strain on the transdifferentiation of fibroblasts into myofibroblasts associated with Hp-infected inflammation and neoplasia. We also attempted to examine whether differentiated fibroblasts possess characteristics of cancer associated fibroblasts (CAF) able to induce epithelial mesenchymal transition (EMT) of normal rat gastric epithelial cells (RGM-1 cell line). Gastric mucosal samples were harvested from 8-week-old Spraque-Dowley rats and cultured to obtain the sub-confluent fibroblasts. The isolated fibroblasts were infected with 1 × 10⁵ per dish of live Hp (ATCC 700824, cagA-, vacA-) and incubated in humidified atmosphere for 3h, 24h and 48h. At respective times, Hp (cagA- vacA-) increased mRNA expression of α-SMA, collagen I, and HSP-70 and HIF1α. After co-incubation with live Hp, fibroblasts were harvested for determination of the protein expressions of α-SMA and HSP70, by Western Blot analysis.

Results: We found that fibroblasts co-cultured with Hp (cagA- vacA-) strongly upregulated protein expression α-SMA and HSP70. In contrast, the co-incubation with Hp (cagA- vacA-) failed to significantly alter the expression of mRNA for N-cadherin, vimentin, b Twist and Snail mRNAs was observed already after 24h, along with the over-expression of Twist and Snail mRNAs was observed already after 24h, along with the over-expression of Twist and Snail mRNAs was observed already after 24h.
immunoglobulin G antibody test and colonoscopy, was conducted to evaluate the association between Helicobacter pylori and colorectal neoplasm.

**Results:** Multivariable analyses adjusted for age, body mass index, smoking status, alcohol intake, regular exercise, regular aspirin use, and family history of colorectal cancer showed that the odds ratio (OR) [95% confidence interval (CI)] for any adenoma and advanced neoplasm was 1.32 (1.07–1.61) and 1.90 (1.05–3.56) in participants with H. pylori infection and without H. pylori infection, respectively. The association persisted after further adjustment for inflammatory markers or metabolic variables including fasting blood glucose and high-density lipoprotein-cholesterol, and low-density lipoprotein-cholesterol. Regarding the location, a positive association was confined to cases with proximal adenomas, and was observed similarly in all the evaluated subgroups.

**Conclusion:** In a large-scale study, carefully controlled for confounding factors, involving asymptomatic participants without a history of colorectal cancer, H. pylori infection was significantly associated with the risk of any colorectal adenoma and advanced colorectal neoplasm. Prospective studies are necessary to determine whether H. pylori eradication can reduce this risk.

Introduction: Pancreatic cancer is one of the most lethal cancers, it has an increasing incidence and limited treatment options. Prevention of this cancer might be the key in lowering the burden of this disease. Two well-known modifiable risk factors are smoking and BMI. For other lifestyle factors, such as diet, there is limited or inconsistent evidence for the association with pancreatic cancer. The World Cancer Research Fund (WCRF) and American Institute for Cancer Research (AICR) have developed guidelines for the prevention of cancer in general. It is known that adherence to these guidelines results in a lower risk of colorectal and breast cancer, however to what extend this applies to pancreatic cancer is unknown.

Aims & Methods: The aim of this study was to assess whether adherence to the WCRF/AICR guidelines is associated with a lower risk of pancreatic cancer. This study was embedded in the Rotterdam Study, a longstanding, prospective and population-based cohort study. Data on dietary intake were collected at baseline, through a frequent food questionnaire and interview by a dietician. We constructed an adherence score, based on the WCRF/AICR recommendations on weight management, foods and drinks that promote weight gain, plant and animal foods, alcoholic drinks, and use of dietary supplements. A higher score corresponds with greater adherence and an hypothesised lower risk of pancreatic cancer. We used Cox Proportional Hazard Models to estimate the association between the adherence score and pancreatic cancer risk.

Results: For 9778 (65.5%) participants dietary data was available. During a median follow-up time of 11.9 years, 77 patients developed pancreatic cancer. Adherence to the WCRF/AICR recommendations was analysed continuously and after stratification into quartiles. Greater adherence was associated with a reduced risk of pancreatic cancer, however not significantly (HRcontinuous: 0.82, 95%(CI: 0.64–1.04)). Stratified analysis showed a significant effect for the third quartile (HR: 0.44, 95%(CI: 0.22–0.88)) with a P-value for trend over the quartiles of 0.028. This effect persisted after excluding all participants with less than two years of follow-up, ensuring the effect was not due to yet undetected disease. Further analysis of the separate recommendations showed that the overall effect was driven by refraining from taking dietary supplements (HR: 0.54, 95%(CI: 0.34–0.84)).

Conclusion: Greater adherence to the World Cancer Research Fund and American Institute for Cancer Research guidelines for diet and lifestyle might be associated with lower risk of pancreatic cancer. Promoting these recommendations to the general population could help reduce pancreatic cancer incidence. However definitive results should follow from pooled analyses of multiple, large and longstanding prospective cohorts to secure more power.

Introduction: The early diagnosis of cancer can help reduce mortality. Surveillance programs on high-risk individuals (HRI) proved to be able to detect premalignant lesions or early pancreatic adenocarcinoma (PDAC). Currently, surveillance programmes on HRI are based on findings from endoultrasoundography and/or MRI. These imaging techniques proved to be able to diagnose malignant or pre-malignant both on syndromic and familiar cases. The aim of our study was to provide the first registry-based Italian experience on HRI enrolled in a surveillance program for pancreatic cancer.
Aims & Methods: The multicentric surveillance program includes: individuals with familial pancreatic cancer (FPC), defined as those with 3 first, second- or third-degree relatives with PDAC or individuals with 2 relatives with PDAC with at least 1 first-degree relative; BRCA 1/2 or p16 mutation carriers with at least 1 first- or second-degree relative diagnosed with PDAC; subjects suffering from hereditary pancreatitis, Peutz-Jeghers syndrome. The surveillance program consists of an annual magnetic resonance cholangiopancreatography (MRCP). Results: Seventy-eight subjects were enrolled from September 2015 to February 2017, by six high-volume pancreatic Institutions. The mean age was 50 years (range 25–79). Sixty-seven (86%) subjects had FPC, 9 were syndrome HRI (11.5%) and 2 (2.5%) subjects suffered from hereditary pancreatitis. MRCP detected pancreatic cysts in 14 HRI (17.9%, 12 FPC- and 2 syndromic-HRI) and 2 (2.5%) subjects suffered from hereditary pancreatitis. MRCP detected pancreatic cysts in 14 HRI (17.9%, 12 FPC- and 2 syndromic-HRI) and 2 (2.5%) subjects suffered from hereditary pancreatitis. Of note, a patient with a MD-IPMN with high-grade dysplasia (Figure) has been considered for surgical resection. Two suspected solid lesions were identified at MRCP, not further confirmed at endoluathonscopic. Conclusion: The first-round of the Bariatric screening program in Italy, the rate of diagnosed malignant or pre-malignant lesions on HRI is lower than expected. The multicentric surveillance program includes: individuals with familial pancreatic cancer, GUT 2013. Bartsch D, Refinement of screening for familial pancreatic cancer, GUT 2016.

Introduction: CDKN2A-p16-Leiden mutation carriers have a 15–20% risk of developing pancreatic ductal adenocarcinoma (PDAC). Surveillance of these carriers increased the survival but did not prevent all cancer deaths. Understanding of the natural course of PDAC might further improve the surveillance program.

Aims & Methods: The aim of the study was to evaluate the role of cystic precursor lesions (PRL) and the growth rate of PDAC. Since 2000, a large cohort of CDKN2A-p16-Leiden mutation carriers has participated in the annual MRI-surveillance program. We compared the frequency of cystic PRL in this group with that of controls who underwent MRI-scanning for symptoms of liver-biliary tract disorders. We also evaluated whether cystic PRL increase in size and develop into PDAC. Finally, we calculated the growth rate of screen-detected PDAC.

Results: Cystic PRL were found in 52 (25%) of 205 mutation carriers compared to 19 (19%) of 100 controls (P = 0.22). Growth of PRL was observed in six mutation carriers (12%). Five (9.7%) of 52 mutation carriers with PRL and eight (7.0%) of 114 mutation carriers without PRL developed PDAC (P = 0.56). The growth rate of PDAC was 21 mm per year. A reduction of the surveillance interval to 6 months would increase the detection of early tumors from 58% to 92%.

Conclusion: Cystic PRL play a minor role in the development of PDAC in CDKN2A-p16-Leiden mutation carriers. More intensive surveillance is only recommended for patients with large cystic PRL. Independent of the presence of cystic PRL, the surveillance interval may be reduced to 6 months, if studies show this approach to be cost-effective.

OP255 CHARACTERIZATION OF GENETIC ALTERATIONS IN Pancreatic CANCER HIGH-RISK POPULATION G. Rosan, E. Scapa, E. Santo, M. Ben-Yehoyada

Contact E-mail Address: guy@tlvmc.gov.il

Introduction: Pancreatic cancer (PC) is a leading cause of cancer death worldwide. Despite modern treatments, 90% of patients die within one year of diagnosis. At early stages, surgical treatment is most beneficial, however, early diagnosis is rare, and most PC cases are confirmed as being locally invasive or metastatic. Inherited predisposition to pancreatic cancer is prevalent in 10% of PC cases. These include characterized genetic conditions such as the hereditary breast and ovarian cancer syndrome (HBOC), Lynch syndrome, familial adenomatous polyposis (FAP), Peutz-Jeghers syndrome (PJS), familial atypical multiple mole melanoma syndrome (FAMMM), and hereditary pancreatitis (HP). However, about 85% of PC cases with strong family history are still uncharacterized.

Aims & Methods: We have recruited 120 high-risk PC individuals for genetic screening and clinical surveillance to identify new criteria for familial pancreatic. For all individuals, germ line DNA was extracted from whole blood and analyzed for the BRCA1 and 2 mutations. Whole Exome Sequencing (WES) technique (Illumina HiSeq platform) was used to screen families with high prevalence to PC for pathogenic germline mutations. Candidate genetic variants were analyzed for their pathogenic potential through familial genetic segregation analysis. Endoscopic ultrasound (EUS) was used to correlate the genetic findings to the clinical phenotype.

Results: We screened 10 informative families and performed segregation analysis. Out of these families, we have discovered several possible pancreatic cancer candidates’ point mutations in well-established as well as in unreported genes. Whole exome sequencing (WES) revealed wide variety of genetic changes in cancer related genes including KLRK1, CLN5, GNAS, GNAS, MSH2, GATA4, GATA3, and KDR genes.

Conclusion: PC development is relatively slow, making it ideal for screening of high-risk individuals. Therefore, identifying this high-risk population is crucial for better surveillance and early detection of pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The prognosis of early stage pancreatic cancer has improved yet there is no feasible screening tool in clinical use. Recent studies have shown that an electronic nose can detect volatile organic compounds from urine and can discriminate between cancer patients and healthy controls.

Methods: The aim of this study was to determine if pancreatic cancer can be detected non-invasively from a urine sample by an electric nose (FAIMS, Field Asymmetric Ion Mobility Spectrometer). Pancreatic cancer patients were recruited in two centers, Sendiöki Central Hospital and Kuopio University Hospital. In January 2011, 64 patients provided a urine sample at the time of the diagnosis. Controls were patients undergoing hernia reparation or cholecystectomy and were recruited in the same centers during the same time period. They provided a urine sample before their operation. 100 ml of midstream urine was stored in −70°C and thawed and warmed up to room temperature for analysis in random order with FAIMS. FAIMS analysis volatile compounds released from the sample, producing an ion mobility spectrum. The resulting spectra were analyzed by linear discriminant analysis and cross-validated by leave-one-out cross-validation (LOOCV).

Results: 80 patients with pancreatic cancer, 40 with acute pancreatitis, 16 with chronic pancreatitis and 14 patients with suspected pancreatic lesion and 44 controls were recruited. The mean age of the pancreatic cancer patients was 70. 49% were females, 29% had stage IB-IIb, 71% stage III-IV cancer and 26% underwent the Whipple procedure or radical pancreactectomy. Patients who died had 16.9 months mean survival time and the mean follow-up time for survivors was 57 months (25–87 months). FAIMS signal data was identified to detect differences between cancer and control samples. The test detected pancreatic cancer with 81% sensitivity and 68% specificity. We combined patients with familial pancreatic cancer, GUT 2013. Bartsch D, Refinement of screening for familial pancreatic cancer, GUT 2016.

References

with pancreatic cancer and premalign pancreatic lesions into one group and controls. Sensitivity was 83% and specificity 63%.

Conclusion: We found that the urine of pancreatic cancer patients has distinct volatile compounds that can be detected by FAIMS, which can distinguish pancreatic cancer patients from controls. It may also be able to detect premalign pancreatic lesions. This investigation was the first to test the ability of electronic nose to detect pancreatic cancer from urine samples. Measurement is quick and easy to perform, its costs are low and most importantly it is non-invasive. AIMS/FAIMS has potential to be a screening tool for pancreatic cancer.

OP257 HINOS PROMOTES A CD24+CD133+ LIVER CANCER STEM CELL PHENOTYPE AND TUMOR PROGRESSION THROUGH A TACE/ADAM17 DEPENDENT NOTCH SIGNALING PATHWAY

R. Wang

Department Of Gastroenterology and Hepatology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Contact E-mail Address: 1765106711@qq.com

Introduction: Hepatocellular carcinoma (HCC) is closely associated with chronic inflammation caused by viral hepatitis, alcoholic or non-alcoholic steatohepatitis, and other conditions leading to chronic inflammation and hepatocyte regeneration. These long-term processes include an accumulation of genetic and/or epigenetic changes of the liver microenvironment and evolution of liver cancer stem cells (LSCs). Growing evidence supports the concept that tumor initiation can be driven by cancer stem cell (CSCs) subsets that are responsible for tumor relapse, metastasis, and chemotherapy-resistance. Therefore, identification of CSC markers as well as signaling pathways activated in LSCs could advance the development of liver cancer diagnosis and treatment strategies. The inducible nitric oxide synthase (iNOS) is associated with more aggressive solid tumors, including hepatocellular carcinoma (HCC). Notch signaling in cancer stem cells promotes cancer progression and requires Notch cleavage by ADAM (a disintegrin and metalloproteinase) proteases. We hypothesized that iNOS/NO promotes Notch1 activation through ADAM17/TACE activation in liver cancer stem cells (LCS) leading to a more aggressive cancer phenotype.

Aims & Methods: Primary human HCC were subjected to immunohistochemistry (IHC) for the expression CD24, CD133, iNOS, activated ADAM17/TACE or activated Notch. CD24+CD133+ cells isolated from HCC cell lines or from human tumors were assessed in vitro and in vivo (Xenograft tumor model in mice) for stem-like properties and growth characteristics. Lentiviral-based short hairpin RNA (LV-shRNA) and LV-iNOS were used to knockdown or overexpress hNOS in LSCs, respectively. Activation of the Notch signal pathway was determined in reporter CD24+/CD133+ cells after (i) LV-shRNA expression, or the inhibition of iNOS (1400W) or TACE (TAPI-2). Immunoprecipitation experiments were carried to assess the interaction between TACE and iRhom2 or TACE and Notch intracellular domain (NICD). We evaluated the effect of iNOS and TACE with clinic-pathological features using a liver cancer tissue microarray (TMA).

Results: Expression of stem cell markers, CD24 and CD133 in the tumors of patients with HCC was found to be independent of gender, age, tumor size, and metastasis. The expression of iNOS in CD24+CD133+ liver cancer stem cells (LSCs), but not CD23-CD133- LSCs, promoted Notch1 signaling and stemness characteristics in vitro and in vivo as well as accelerated HCC initiation and tumor formation in the mouse xenograft tumor model. Lentiviral-based short hairpin RNA (shRNA)-mediated iNOS knockdown or iNOS activity inhibition using BYK191023 significantly suppressed CD24+CD133+ LSCs stemness characteristics in vitro and in vivo. Furthermore, up-regulation of iNOS expression in LSCs led to TACE and iRhom2 phosphorylation in a cyclic GMP (cGMP)-protein kinase G (PKG)-dependent manner. Immunoprecipitation experiments show that the physical binding between TACE and iRhom2 increased significantly when iNOS was overexpressed. Kaplan-Meier analysis showed that high hNOS and NICD expression was significantly associated with aggressive behavior of HCC and decreased survival in patients.

Conclusion: These findings link NOTCH to Notch1 signaling in CD24+CD133+ LSCs through the activation of ADAM17/TACE and identify a new mechanism for how iNOS contributes to progression of CD24+CD133+ HCC.

Introduction: The mucosa of patients with colorectal cancer (CRC) is abnormally colonized by Escherichia coli strains, which frequently harbor the pathogenic pks gene cluster responsible for the synthesis of the genotoxin colibactin. Colibactin-producing E. coli induce DNA damage and enhance tumorigenesis in CRC mouse models. Autophagy, cellular process allowing the degradation of cytoplasmic contents via the lysosomal pathway, plays a crucial role in the maintenance of homeostasis and is implicated in various human diseases including cancer.

Aims & Methods: This study aimed at investigating the role of autophagy in host responses to infection with the CRC-associated E. coli strains. mRNA expression levels of autophagy genes in the colonic mucosal biopsies from CRC patients were determined by qRT-PCR. Autophagy induction was assessed by Western blot and immunofluorescence labelling of LC3. DNA damage was assessed by Western blot analysis and immunofluorescence labelling of phospho-H2AX.

Recruitment of the DNA repair protein RAD51 into the nucleus, which is required for DNA repair damage, was examined by Western blot analysis of nuclear and immunofluorescence staining. Intestinal epithelial HCT116 cells infected with intestinal epithelial cells (APC(−)/ATG16L1(−/−)) and the control mice (APC(+/+)APC(+/+)1400W) were infected with the pks-harboring E. coli strain (pks+ E. coli).

Results: mRNA expression levels of many autophagy genes were increased in the tumor tissue compared to the control tissue. A special emphasis was given to the expression in the mucosa colonized with pks+ E. coli compared with those colonized with E. coli strain without pks island (pks- E. coli). Infection of HCT116 cells with the pks+ E. coli strain resulted in autophagy activation, and this was dependent on the presence of the pks island. Autophagy deficiency increased the incidence of colonic tumorigenesis induced by infection with the pks+ E. coli 11G5 strain in APCMin−/− mice.

Conclusion: Autophagy is induced in intestinal epithelial cells infected with the pks+ E. coli, and a functional autophagy is necessary to limit the protumoral effects of pks+ E. coli on infected cells.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several studies and meta-analysis demonstrated that patients with mismatch repair (MMR) genes deficient colorectal cancer (CRC) have a more favorable stage-adjusted outcome compared to CRC with MMR defects T-cells, macrophages, and natural killers, infiltration might be increased enhancing immune surveillance mechanisms [1]. In fact, a higher densit of tumor infiltrating lymphocytes was associated with better disease free survival in MMR defective cases with defective pks in CRC with MMR genes deficiency showed a higher CD80 expression, and in vitro silencing of MSH2, MLH1 and MSH6 significantly increased CD80+ cell rate [4]. However, the precise role of CD80 signalling and its effect on MMR genes expression in colonic carcinogenesis remain unclear.

Aims & Methods: The aim of this work was to investigate whether the modulation of CD80 signalling may influence the expression of MMR genes in a mouse model of early colorectal carcinogenesis. C57BL/6 mice received azoxymethane (AOM) at a dose of 10mg/kg body weight weekly for 4 weeks to induce dysplasia and then sacrificed four to six months after the first AOM injection to perform histology, flow cytometry analysis and immunohistochemistry of colonic mucosa. Some WT mice received i.p. a monoclonal antiCD80 or antiCTLA4 antibody following AOM administration. Immunohistochemistry for MLH1, MSH2 and MSH6 was carried on. Non parametric statistics was performed.

Results: Low-grade dysplasia (LGD) extension was to about 20% of the colonic mucosa at 4 and 6 months after AOM treatment in the AOM group and in the
AOM-antiCD80 antibody while it dropped at less than 5% in the AOM-antiCD80 antibody group. By comparing ITGB6 and CEA levels we found that ITGB6 levels in patients with metastatic disease were significantly higher than in patients with non-metastatic disease. In a separate follow-up cohort (n=19), after surgical R0 resection of the colon tumor and concomitant liver metastases, ITGB6 serum levels declined to zero. Of note, we found that ITGB6 serum levels also declined after removal of the liver metastases. However, ITGB6 serum levels rise again when liver metastases were newly diagnosed or tumor progression occurred. In this regard, ITGB6 serum levels were much more reliable as CEA levels. By immunohistochemistry, ITGB6 staining was stronger in metastatic compared to non-metastatic tumors. However, ITGB6 was also found strongly expressed in the tumor microenvironment and could be a more reliable marker for cancer stem-like cells (CSC), which are more aggressive and resistant to therapy.

Conclusion: This is the first study showing ITGB6 levels in patients sera. Our findings provide evidence that ITGB6 can serve as a novel serum biomarker for diagnosis and prognostic of colorectal cancer (CRC), as a marker for tumor surveillance and help in early detection and treatment response as well as a therapeutic target for CRC treatment. In summary, our findings suggest that using targeted therapy in patients with high levels of ITGB6 may be a novel treatment option for CRC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancer (CRC) is the third most common malignancy and one of the leading causes of cancer-related deaths worldwide. The need for novel biomarkers and therapeutic strategies for CRC is obvious and the identification of such markers and targets might significantly improve prognosis of CRC patients. β3-integrin (ITGB6) is a marker for cells undergoing epithelial-to-
mesenchymal transition and has been associated with many epithelial tumors, such as breast cancer. Therefore, ITGB6 serves as a cell surface receptor for matrix proteins, such as fibronectin, and activates matrix degrading enzymes, such as matrix metalloproteinases 2 and 9 as well as TGF-

Aims & Methods: The aim of this study was to investigate whether ITGB6 might serve as a novel serum maker and therapeutic target in CRC patients. We used serum samples of 19 healthy volunteers and 269 CRC patients including 53 patients with metastatic CRC. A follow-up cohort consisted of 19 CRC patients (n=11 without lymph node metastasis, n=4 with lymph node metastasis and n=4 with liver metastasis) serum samples were collected pre-surgery (~3 to ~1 days, post-surgery (2 to 6 days) and during follow-up visits (visit 1: 3 to 20 weeks, visit 2: 20 to 30 weeks, visit 3: 30 to 60 weeks). Wild-type and ITGB6-deficient mice were treated with 0.5-1.0% DDS for 7 days in drinking water followed by a recovery period of 14 days over three cycles. 10 mg azoxymethane (AOM) was administered by i.p. injection six times. ITGB6 serum levels were determined by ELISA.

Results: We detected ITGB6 in the serum of CRC patients (range 0–10 ng/mL) and found that a cut-off of ≥28.8/μl ITGB6 predicts metastatic disease in 100% of respective patients. An ITGB6 serum level above 2 ng/ml was also associated with a significantly worse prognosis compared to patients with a ITGB6 serum level below 2 ng/ml. By comparing ITGB6 and CEA levels we found that ITGB6 levels in patients with metastatic disease were significantly higher than in patients with non-metastatic disease. In a separate follow-up cohort (n=19), after surgical R0 resection of the colon tumor and concomitant liver metastases, ITGB6 serum levels declined to zero. Of note, we found that ITGB6 serum levels also declined after removal of the liver metastases. However, ITGB6 serum levels rise again when liver metastases were newly diagnosed or tumor progression occurred. In this regard, ITGB6 serum levels were much more reliable as CEA levels. By immunohistochemistry, ITGB6 staining was stronger in metastatic compared to non-metastatic tumors. However, ITGB6 was also found strongly expressed in the tumor microenvironment and could be a more reliable marker for cancer stem-like cells (CSC), which are more aggressive and resistant to therapy.

Conclusion: This is the first study showing ITGB6 levels in patients sera. Our findings provide evidence that ITGB6 can serve as a novel serum biomarker for diagnosis and prognostic of colorectal cancer (CRC), as a marker for tumor surveillance and help in early detection and treatment response as well as a therapeutic target for CRC treatment. In summary, our findings suggest that using targeted therapy in patients with high levels of ITGB6 may be a novel treatment option for CRC patients.

Introduction: Pancreatic cancer (PC) has the highest mortality rate of all the major cancers. It is the only leading cancer killer with a 5-year survival rate still in the single digits and the survival rate has not improved in the last 40 years. Less than 15% of patients are candidates for surgical resection at the time of diagnosis. Endoscopic ultrasonography-guided fine-needle injection (EUS-FNI) is an attractive minimally invasive delivery system with potential applications in local (intratumoral) against PC. EUS-FNI has demonstrated its feasibility and safety in delivery of medications, however, the procedure has attained attention as a method of antitumor-agent delivery such as anticancer drug, alcohol, gene, and dendritic cells as well as radioactive seeds. Recently Levy et al. in Mayo Clinic reported EUS-guided fine-needle injection of gemcitabine for locally advanced and metastatic pancreatic cancer.

Aims & Methods: The objectives of this study are to confirm in vivo efficiency of adhesive wafer containing chemotherapeutic agent (gemcitabine or paclitaxel). Adhesive wafer consists of the two kinds of polymer matrix of CMC-glycerol and polyvinyl alcohol and chemotherapeutic agent are distributed in this wafer. Orthotopic PC model induced by local injection of AsPC-1 tumor cells into the tail of the pancreas. Adhesive wafer containing gemcitabine or paclitaxel was directly applied in the surface of pancreatic cancer and free gemcitabine or paclitaxel was administered by intratumoral (I.T.) injection as positive control. We compared the anti-tumor efficiency of adhesive wafer containing gemcitabine or paclitaxel and that of intratumoral injection of free drug (positive control) in the orthotopic PC mouse model.

Results: The volume of adhesive wafer containing gemcitabine or paclitaxel treating groups shows significantly supersedes than positive control group. The metastasis scores of non-treating group, vehicle, adhesive wafer containing gemcitabine or paclitaxel, and positive control groups were 1.80, 1.83, 1.87 and 1.00, respectively. These results demonstrate that adhesive wafer containing gemcitabine or paclitaxel for local chemotherapy is more effective than intratumoral injection of free drug in orthotopic PC mouse model.

Conclusion: This study provides the first in vivo application of the adhesive wafer containing paclitaxel for the treatment of pancreatic cancer. We confirmed that higher antitumor effects of adhesive wafer containing paclitaxel and gemcitabine than intratumoral injection of free drug in orthotopic PC mouse model. These results indicate that adhesive wafer containing chemotherapeutic agents is one of new candidates for local chemotherapy of PC.

Contact E-mail Address: peyrinbiroulet@gmail.com

Introduction: Upadacitinib (UPA) is an oral selective Janus kinase 1 inhibitor that is being assessed for treatment in subjects with Crohn’s disease (CD). The effects of UPA on patient-reported outcomes (PROs) were evaluated in a phase 2 dose-ranging study.

Aims & Methods: A total of 113-740 (Celest study; NCT02363649) was designed to evaluate the efficacy and safety of multiple doses of UPA. Subjects with moderately to severely active CD with inadequate response or intolerance to immunosuppressants or tumour necrosis factor alpha inhibitors were randomly assigned in a 1:1:1:1:1:1 ratio to double-blind induction therapy with placebo (PBO) or UPA at 3, 6, 12 or 24 mg twice daily (BID) or 24 mg once daily (QD) for 16 weeks, followed by a blinded extension therapy for 36 weeks. PROs assessed were the Inflammatory Bowel Disease Questionnaire (IBDQ) and EuroQuol (EQ-5D) and Work Productivity and Activity Impairment (WPAI) questionnaires. Herein, analyses of within-group changes from baseline to week 16 are presented. Percentage of subjects whose improvements met or exceeded the minimum clinically important difference (MCID) in IBDQ score (defined as increase ≥ 15 points or ≥ 4 SD units) was calculated using mixed-effects model for IBDQ total score and analysis of covariance for EQ-5D visual analogue scale score (VAS) and WPAI score. Missing data were reported using non-responder imputation (NRI) and last observation carried forward (LOCF) methods.

Results: Celest enrolled 220 subjects with mean age of 41 years, mean CD duration of 13 years and mean CDAI of 303; 57% were female and 96% had failed or were intolerant to tumour necrosis factor alpha inhibitors. At baseline, overall mean IBDQ score was 116, EQ-5D VAS was 48.9, and WPAI was 61.%. At week 8, clinically meaningful improvements in IBDQ MCID were observed in 53-62% of subjects in all UPA dose groups, except the 3 mg BID group. At week 16, UPA was associated with dose-related increases in the percentage of patients achieving IBDQ response (Table). Significantly more subjects achieved the MCID for the IBDQ score in all UPA dose groups vs PBO with a plateaued response to UPA at 6 mg BID. Significant improvement from baseline in mean EQ-5D VAS at week 16 was observed for both the 6 mg and 24 mg BID doses vs PBO. Activity impairment was significantly reduced for the 6 mg and 24 mg BID doses vs PBO. Overall work impairment was significantly reduced for the 24 mg dose vs PBO.

OP264 FECAL MICROBIOTA TRANSPLANT FOR CROHN’S DISEASE: A PROSPECTIVE, RANDOMIZED STUDY IN CHINESE POPULATION Z. Yang, X. Wang, C. Bu Department Of Gastroenterology, Third Xiangya Hospital, Central South University, Changsha/China

Contact E-mail Address: 823480936@qq.com

Introduction: Crohn’s disease (CD) is an inflammatory bowel disease (IBD), characterized by chronic, recurrent, uncontrolled and idiopathic immune-mediated inflammation that can affect any sites along the whole length of the gastrointestinal tract. CD impairs health-related quality of life (HRQoL) and the incidence of CD continues to rise in low-incidence areas, including China. The precise aetiology of IBD is unclear; however, the intestinal microbiota has been proposed to play an important role in the pathogenesis of IBD. Patients with CD usually present with an overall drop in gastrointestinal microbiota species richness and alternation in the abundance of several taxa. Such conditions are potentially amenable to biologic therapies. Fecal microbiota transplant (FMT) infusion of a fecal suspension from a healthy individual into the gastrointestinal tract of a patient to restore the intestinal homeostasis. During the past several years FMT is a highly effective therapy for recurrent Crohnid Stricture infection (CDI). However, few case series have reported the effects of FMT for CD and the results...
were mixed. We carried out this trial to investigate the outcomes of FMT for CD and to analyse the factors correlated with curative effect.

Aims & Methods: Several case series have reported the effects of FMT for CD. We assessed the efficacy and safety of FMT for patients with CD in a prospective, randomized study trial. Patients with active CD (n = 31) were assigned to groups. Procedures were conducted at The Third Xiangya Hospital of Central South University form January 2014 through March 2016. Patients with active CD (n = 31) were randomized assigned to receive FMT by either gastroscopy or colonoscopy (200 g Qualified stool sample was mixed with sterile saline solution). Fresh fecal suspension was generated from a related healthy volunteer or a prescreened standard donor. Patients were followed by physical examination and laboratory tests of peripheral blood on weeks 1, 2, 4, 6 and 8 after the transplant. Extraction donor and CD patient fecal in DNA, analysis by Illumina MiSeq platform. For patients who didn’t get clinical remission after a single FMT, a second transplant will be taken one week later. The primary end point was clinical remission of CD (Crohn’s disease activity index less than 150 score or CDAI decrease more than 100 score) at week 8. Secondary endpoint was the adverse effects related to the therapy.

Results: In 14 of 31 patients received FMT by colonoscopy and 13 by gastroscopy. Clinical remission was achieved in 15 patients (55.6%) after a single FMT. 12 patients received a second transplant and 3 obtaining clinical remission. Resulting in an overall clinical remission rate of 66.7%. At week 8 compared to who didn’t get a clinical remission, patients with clinical remission have lower CDAI (420 vs 200, P < 0.05), less times of daily diarrhea (6 vs 4, P < 0.05). Adverse effects of FMT were all mild and self-limited. There was no significant difference in adverse events between groups. Operational Taxonomic Units (OTU) analysis shows that CD patient have a lower OTU number than donor (117 vs 238, P < 0.05). CD patients also have a lower abundance of Bacteroides, Roseburia, Turicibacter, Faecalibacterium and higher abundance of Bilophila, Streptococcus, Clostridium, Paraprevotella.

Conclusion: FMT is effective in treating CD, with satisfactory short-term effects and no severe adverse effect. CD patients have a drop of microbiota species richness and alternation in the abundance.

Introduction: Endoscopic detection and delineation of neoplasia is crucial for the surveillance and treatment of Barrett's oesophagus.

Aims & Methods: High-quality HD-videos were obtained from pts with BORN (endoscopically visible lesion with HGD/EAC) or without dysplasia (ND) BD. For BORN videos, 3 experts independently delineated lesions throughout the video using software developed specifically for the project. The mean AND/OR-ratio of each pair of experts was used to denote agreement on delineated frames. All videos and frames with an agreement ratio ≥0.25 were reviewed in consensus after which the experts repeated delineation independently. In Phase I, 6 assessors scored 4 sets of 20 videos. The order of the sets and the order of videos within each set were randomized for each assessor.

Assessors were classed as: Trainees: fellows in training; Junior: board certified ≤3 yrs of practice; Senior: board certified ≥3 yrs in practice. Assessors paused the video when a BORN lesion was visible, marked their preferred biopsy position and then delineated the entire lesion using the BORN software. After each set, assessors were guided through mandatory, tailored feedback based on their scores and the experts’ delineations. After Phase I, BORN videos with no apparent contribution to the learning process (either a perfect score at baseline (“too easy”)) or poor performance throughout the 4 sets (“too difficult”) were excluded. This condensed version of the training module, again consisting of 4 sets, was then validated in Phase II by 121 new assessors from Canada (19), Germany (20), the Netherlands (33), United Kingdom (28), and United States (31). Only the parameters 1) Detection score: percentage of BORN lesions with a biopsy mark positioned within “the sweet spot” (i.e. area delineated by all 3 experts). 2) Delineation score: percentage of the sweet spot delineated by the assessor. 3) Relative delineation score: mean agreement of the assessor with the 3 experts divided by the mean agreement amongst experts.

Results: In Phase I, detection scores and delineation scores significantly increased over the 4 sets. There were no significant differences between trainees, juniors and seniors. In Phase II, detection and delineation again significantly increased over the 4 sets with an even higher increase in outcome parameters compared to Phase I (Table 1). Again, there were no significant differences between trainees, juniors and seniors or between countries.

Table 1: Phase I (80 videos by 68 assessors) and phase II (25 videos by 121 assessors)

Introduction: Barrett's oesophagus (BO) is a known precursor to oesophageal adenocarcinoma (OAC). Surveillance and/or treatment of BO patients is recommended by various clinical practice guidelines, but prior analyses indicated that surveillance of non-dysplastic BO is not cost-effective. However, those studies largely predated the advent of widespread use of endoscopic therapy.
Aims & Methods: This study aimed to determine the optimal management strategy of BO patients through a cost-effectiveness analysis. We used the Microsimulation Screening Analysis (MISCAN) model of OAC to simulate a hypothetical cohort of US males with BO at age 60 who were followed over their life-time under 203 different management strategies. In the first strategy (natural history), no BO patients received endoscopic surveillance or treatment. In all other strategies, BO patients with high-grade dysplasia received endoscopic therapy and then underwent intensive surveillance. For patients with low-grade or no dysplasia, treatment and/or surveillance strategies were varied. An incremental cost-effectiveness analysis was performed to specify the optimal management strategy using a willingness-to-pay threshold of $100,000 per quality-adjusted life-year (QALY).

Results: In the natural history strategy, 68 OAC cases were diagnosed and 50 patients died of OAC per 1000 BO patients. The total cost in this strategy was $3,995,560. Surveillance with endoscopic therapy for BO patients with high-grade dysplasia reduced OAC incidence to 19–54 cases depending on the intensity of surveillance but also increased costs to $4,292,995–15,531,773. Strategies that also involved endoscopic therapy of patients with low-grade dysplasia reduced OAC cases to 17–55, however total costs increased to $4,396,760–15,906,455. The optimal management strategy was to offer surveillance every 3 years to BO patients without dysplasia; surveillance every 6 months within the first year of diagnosis of patients with low-grade dysplasia and annually thereafter; and endoscopic therapy of patients with high-grade dysplasia. The surveillance stop age of BO patients in the optimal strategy was 80 years. This strategy prevented 64% of OAC cases at an incremental cost-effectiveness ratio of $97,918 per QALY (Table 1).

Aims & Methods: In this study, we further investigated the impact of miR-9 in maintaining intact of intestinal epithelial during the pathogenic process of CD. miR-9 expression was assayed in isolated IECs and inflamed colon samples of 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced and CD patients by qRT-PCR and miRNA in situ hybridization. The levels of SMAD nuclear interacting protein 1 (SNIP1) and CDH1, was investigated in colonic epithelia cells and colorectal tumor models. The role of miR-9 was further studied in the experimental colitis mice by intracolonial administration of miR-9 precursors or inhibitors.

Results: We found that miR-9 expression was significantly upregulated in IECs isolated from inflamed colon tissues of CD patients compared to control and 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitis mice, when compared with negative controls. Interestingly, the genes of SNIP1, cyclin D1 and E-cadherin were downregulated significantly and correlated inversely to miR-9, while the genes of E-cadherin, cyclin D1 and E-cadherin were upregulated in CD patients. Furthermore, we demonstrated that miR-9 cooperatively suppressed SNIP1 and CDH1 expression at posttranscriptional levels in colonic cells. In addition, upregulation of miR-9 suppressed colonic cell proliferation via suppressing SNIP1-mediated cyclin D1 expression, induced EMT by targeting CDH1, and vice versa. Moreover, downregulation of upregulation of miR-9 in TNBS-induced colitic colon alleviated or aggravated experimental colitis, respectively.

Conclusion: Our study reveals the mechanism that miR-9 inhibits growth of IECs, promotes EMT and thereby affects intestinal epithelial homeostasis. Blockade of miR-9 in vivo may serve as a potential therapeutic intervention for CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: In this study, we investigated the efficacy of NAMPT inhibition by the small molecule inhibitor FK866 as a novel treatment strategy in intestinal inflammation. NAMPT enzymatic activity was blocked in the dextran sulfate sodium (DSS) model of colitis in mice and in the azoxymethane (AOM)/DSS model of colitis-associated cancer. Mucosal NAD levels and its metabolites were determined by HPLC. FK866 was tested on the differentiation and polarization of human and mouse primary macrophages. Further, lamina propria mononuclear cells (LPMC) from IBD patients were treated ex vivo with FK866, dexamethasone or infliximab and assayed for cytokine release.

Results: FK866 treatment was associated with an altered monocyte/macrophage biology which was characterized by NAD-depleting enzymes. These display an important mechanistic link with a dysfunctional NAD metabolism. NAMPT upregulation counteracts an increased cellular NAD turnover mediated by NAD-depleting enzymes. These display an important mechanistic link between inflammatory, metabolic and transcriptional pathways and NAD metabolism. NAMPT is strongly upregulated in IBD patients, however, its functional impact still remains unclear.

**Introduction:** Monocytes are bridging natural and acquired immunity. Information about JAK signaling in monocytes is scarce especially in an inflammatory milieu. JAK-inhibition is a promising new anti-inflammatory treatment option. However, JAK/STAT activation may be involved both in anti-inflammatory and anti-inflammatory monocyte programs. We have shown that GM-CSF-activated regulatory monocytes (GMaM) induce Treg-differentiation in co-cultures with naive T-cells in vitro. Inflammatory T-cells produce high amounts of GM-CSF in vivo, not leading to anti-inflammatory monocytes, likely because of pro-inflammatory cytokines in the environment. We used JAK-inhibitor Tofacitinib to explore mechanisms that block pro-inflammatory pathways and still allow anti-inflammatory functions in monocytes.

**Aims & Methods:** Primary monocytes from peripheral blood of healthy human donors were isolated and phenotyped by FACS analysis after treatment with GM-CSF and JAK-inhibitor Tofacitinib. Monocytes were co-cultured with autologous naive T-cells and differentiation of Foxp3⁺ regulatory T-cells was evaluated by FACS. Furthermore, primary monocytes from IBD patients with active disease were used to investigate JAK STAT signaling and inhibition. JAK1 activation (represented by IFNγ-induced phospho-STAT1), JAK2 activation (represented by GM-CSF-induced phospho-STAT5), and JAK3 activation (represented by gp130-phosphoS727) was analysed by FACS. Non-toxic doses of 1 to 1000 nM of Tofacitinib were used.

**Results:** We aimed to define the dose of JAK inhibition that keeps JAK2 activity (GM-CSF-induced pSTAT5) intact. Upon stimulation with 10–100 nM Tofacitinib, we detected GM-CSF-induced phospho-STAT5 while phospho-STAT1 and phospho-STAT6 were blocked. Concentrations above 100 nM Tofacitinib led to inhibition of GM-CSF-induced CD39⁺, CD206⁺, CD209⁺ expression. 10–100 nM Tofacitinib allowed CD39⁻, CD206⁻, CD209⁻ expression and IL-10 release while TNFα was still blocked. Co-culture of GM-CSF and T-cells resulted in increased differentiation of Foxp3⁺ Treg that was even enhanced when 10 nM Tofacitinib was used. Investigation of JAK STAT activation in monocytes from IBD patients revealed a lower increase after stimulation compared to healthy controls. Furthermore, TNFα expression was not inhibited in monocytes obtained from IBD patients using the same dosage of Tofacitinib which significantly inhibited TNFα expression in healthy controls (10–100 nM).

**Conclusion:** JAK inhibition in monocytes from IBD patients revealed a lower increase after stimulation compared to healthy controls. Moreover, TNFα expression was not inhibited in monocytes obtained from IBD patients using the same dosage of Tofacitinib which significantly inhibited TNFα expression in healthy controls (10–100 nM). Tofacitinib reduced the proliferation and migration and upregulated the expression levels of TJ proteins. Interestingly, CHG specificity and activity were verified by finding that scrambled CHG peptide did not modify the course of colonic inflammation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chromogranin-A (ChgA) is a prohormone secreted by neuroendocrine and immune cells and is elevated in inflammatory bowel disease (IBD) and can generate several peptides. ChgA has eight exons and Chromofungin (CHR: ChgA47–66), a peptide with cardioprotective and antinociceptive effects, is encoded on exon Exon-IV. IBD involves characterized by Gram-negative macrophages and the activation of proinflammatory and anti-inflammatory signaling pathways, altered functions of macrophages, intestinal tight junction (TJ) barrier and intestinal epithelial cells. Moreover, the nuclear transcription factor kappa B (NF-kB) signaling, a master regulator of genes transcription, is dysregulated leading to perpetuate inflammation.

**Aims & Methods:** We aimed to study the activity of CHR, ChgA Exon-IV, in colonic tissues of patients with active ulcerative colitis (UC) and undergoing with immunosuppressive therapy (Infliximab: DSS-colitis), as well as in colonic epithelial cells. Expression of Exon-IV and its correlation with classical activated macrophages (CAMs) markers (IL1B, IL6, TNFA, SLAM7, TLRA, CD120B, alternative activated macrophages (MACs) markers (IL10, TGFβ, MR, CMYC, CD14, NFκB, and TJ proteins (Claudin-1 (CLDN1), zonula occludens-1 (ZO1), E-cadherin (EcadCH), occludin (OCLD)) were determined in human colonic tissues. Colitis was induced in C57BL/6 mice by administration of DSS (5%, 5 days). Preventive CHR (2.5 mg/kg/day) treatment or vehicle stomach feeding before colitis induction and lasted for 5 days. Disease activity index, macroscopic score, histological score and serum C-reactive protein were evaluated. Mouse colonic CAMs, AAMS and TJ proteins were assessed using ELISA RT-qPCR. CHR (200 ng/ml) treated naïve peritoneal macrophages were exposed for 6 h to LPS (100 ng/ml) to promote CAMs, or to IL-4 (10 ng/ml) to promote AAMS. CAMs and AAMS markers were quantified. To gain more mechanistic insights, phosphorylated NF-κB levels were quantified in mouse colonic mucosa and CAs using Western Blot. In vitro chemokinesis assay of CHR (200 ng/ml) on naïve macrophages were assessed by transwell migration assay using MCP-1 (30 ng/ml) as a chemotactant. Caco-2 epithelial cells were treated with CHR (1, 10, 100 nM/ml) for 24 h in the presence or absence of LPS (100 ng/ml) when compared to LPS condition. JAK/STAT activation in colitic mice and CAMs compared to controls. Moreover, CHR treatment decreased the expression levels of E-selectin (E-selectin), TNFα, IL-6, CCL2, CCL5, and IL-1β and increased the expression levels of CD14, IL10, TGFB, and CLDN1. Interestingly, expression levels of NF-κB were upregulated by CHR treatment and significantly increased the expression levels of CAMs compared to control condition. CHR-conditioned AAMS expressed more Arg1 and CD14 when compared to IL-4/IL-13 condition. CHR treatment reduced intracellular NF-κB activation in colitic mice and CAMs compared to controls. Moreover, CHR treatment downregulated macrophages migration, increased epithelial cells' proliferation, viability, and upregulated the expression levels of TJ proteins. Interestingly, CHG specificity and activity were verified by finding that scrambled CHG peptide did not modify the course of colonic inflammation. NF-κB activation, and CAMs and epithelial cell barrier functions.

**Conclusion:** CHR treatment attenuates the severity of colitis and the inflammation process via the modulation of macrophages' functions, maintaining TJ barrier integrity and diminishing NF-κB activation. Targeting CHG may represent a promising new direction in the search for therapeutic targets and biomarkers associated with IBD.

**Introduction:** NOD2 is one of the most known IBD risk factors which has been well characterized genetically and functionally. In brief, NOD2 is a PAMP-recognition receptor which mediates NK-kB-dependent signals upon stimulation with muramyl dipeptide (MDP). In previous studies we have shown that the production of ROS as a host defense mechanism is controlled by NOD2. Further, members of the group of the ROS-producing NADPH oxidases seem to play a critical role as they have been identified as novel molecular interactors of NOD2. Interestingly, in a pediatric patient early onset IBD, we identified the gene mutation in NOX1 and CYBA, we generated plasmids harbouring NOX1 and CYBA. OP272 - A NOVEL ORAL DOMAIN ANTIBODY TO TUMOUR NECROSIS FACTOR (TNF), ENGINEERED TO BE STABLE TO INTESTINAL PROTEASES, RESULTS IN HIGH CONCENTRATIONS OF ACTIVE COMPOUND DETECTED IN FAECES OF CROHN’S PATIENTS AFTER ORAL DOSING

**Introduction:** Monoclonal antibodies to TNF have transformed the treatment options for patients with Inflammatory Bowel Disease (IBD). V565 is a novel oral domain antibody (Vorabody) to TNF engineered to be resistant to intestinal proteases. It is 115 amino acids (12.6 kDa) in size and neutralizes TNF in vitro.

**Aims & Methods:** Following earlier demonstration of the safety and tolerability of high single and multiple doses of V565 in healthy volunteers, this study aimed to assess V565 pharmacokinetics following a single oral dose to patients with Crohn’s disease (CD). Six subjects with CD received a single dose of open label V565. Prior to dosing, the diagnosis of CD was confirmed by a gastroenterologist and a clinical assessment of severity was carried out. As this was primarily a pharmacokinetic study, patients were excluded if they required surgery, had a current abscess, a non-infectious stricture, or a history of obstruction. Serial blood samples were taken to assess systemic V565 exposure, and all stool samples were collected for up to three days after dosing for detection of faecal V565. In addition, urine was collected from all patients over periods 0–4 h, 4–8 h, 8–12 h and 12–24 h post dose.

**Results:** Two subjects with CD were dosed with a single 555 mg dose of V565. Following review by the study safety committee a further four subjects were dosed with a single 1665 mg dose of V565. Active V565 was detected in the faeces of all subjects. In the stool samples around 24 h after dosing V565 was detected at concentrations up to 84 μM.

**Conclusion:** V565, an oral domain antibody to TNF engineered to be resistant to intestinal proteases, resulted in high concentrations of active drug in the faeces of all Crohn’s patients following a single oral dose, demonstrating survival in the human GI tract. No drug was detected in any serum sample from any patient (LLoQ 62.5 ng/ml).

**OP273 - SUSTAINED INCREASE IN COLONOSCOPY PRACTICE 3 YEARS AFTER INTRODUCTION OF QUALITY IMPROVEMENT IN COLONOSCOPY (QIC) BUNDLE**

**Aims & Methods:** We identified if changes in colonoscopy practice were sustained three years following the initial “bundle” implementation. Data were collected from the original study sites, including ADR and histamine butylbromide use. Histamine butylbromide usage rate was used as a marker for uptake of the bundle implementation. Comparisons were made with baseline data collected for 3 months prior to bundle implementation and for a duration of 9 months following completion. Sustainability data were collected for 6 months, 3 years following implementation. Data were compared globally by endoscopy unit and by quartile, where colonoscopists were ranked by baseline ADR. Multilevel logistic regression analyses were undertaken.

**Results:** 12 endoscopy units housed within 8 UK NHS Trusts participated. Global analyses included data from a total of 184 colonoscopists and 28615 procedures. Quartile analyses included data from 50 colonoscopists and 14435 procedures.
procedures. Hyoscine butylbromide use significantly rose and was sustained almost at baseline globally in all endoscopy units and quartiles. A sustained ADR increase (18.2%) was observed globally. Quartile analyses demonstrated that improvement was most marked in the lowest colonoscopy quartile (Table 1).

Conclusion: A simple, evidence-based intervention changed colonoscopy practice, as evidenced by increased Hyoscine Butylbromide use in all quartiles and endoscopy units. As a result ADR was improved. These effects were sustained 3 years following implementation, suggesting this approach is a feasible and durable means of improving ADR, particularly in groups with lower ADRs, with minimal resources.

OP274 VARIATION BETWEEN PATHOLOGICAL MEASUREMENT AND ENDOSCOPIC ESTIMATED SIZE OF COLONIC POLYPS
Gastroenterology, Centro Hospitalar de Leiria, Leiria/Portugal
Contact E-mail Address: catarinataliaalmartins@gmail.com

Introduction: Current guidelines about post-polypectomy colonoscopy surveillance take in count size, number, villous component and high-grade dysplasia of resected polyps to stratify patients’ risk and determine surveillance intervals. Regarding size, 10 millimeters is the cut-off to classify a polyp as an advanced adenoma. Polyp size is visually estimated during the colonoscopy. Is a two-dimensional subjective evaluation with significant variability among endoscopists. The pathological size results from the measurement with a ruler after excision and fixation with formalin. Is not consensual what measurement should be consider to determine surveillance colonoscopy: endoscopic or pathological.

Aims & Methods: The aim of this study was to evaluate variation between colon polyp size reported by the endoscopist and its pathological size. All colonoscopy performed by 7 experienced colonoscopists during a 12-month period in our center were retrospectively analyzed. The inclusion criteria were (1) adenomatous polyps excised in a single specimen; (2) not fragmented during retrieval; (3) exact documentation of endoscopic estimated size and resection method. The exclusion criteria (1) polyps greater than 25 millimeters; (2) unclear size (not reported or reported imprecisely); (3) more than one polyp placed in the same recipient after fragmentation; (4) polyps excised in a single specimen; (2) not fragmented during retrieval; (3) exact documentation of endoscopic estimated size and resection method. The exclusion criteria (1) polyps greater than 25 millimeters; (2) unclear size (not reported or reported imprecisely); (3) more than one polyp placed in the same recipient after fragmentation; (4) polyps excised in a single specimen; (5) polyps are probably more overestimated than smaller ones. The pathological-endoscopic variation is significantly correlated with each endoscopist.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: pierre.ellul@gov.mt

Introduction: Small (6–9 mm) and diminutive (1–5 mm) colonic polyps are frequently encountered during colonoscopy. Diminutive polyps rarely have advanced histological features.1 To date histology is the gold standard for evaluation of polyp size and their potential impact upon surveillance. The aim of this study was to evaluate the variation between endoscopic estimated size of colorectal polyps and their reported size.

Aims & Methods: The aim of this study was to evaluate variation between endoscopic estimated size of colorectal polyps and their potential impact upon surveillance. The variation based on the method of excision.

Disclosure of Interest: There is a considerable variability between the endoscopic estimated size and pathological size. In our study endoscopists tend to overestimate the polyp size. The overestimation was more evident in EMR, suggesting that larger polyps are probably more overestimated than smaller ones. The pathological-endoscopic variation is significantly correlated with each endoscopist.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic recognition of early stage colorectal cancer (CRC) is of paramount importance in the management of colonic polyps. Accurate optical diagnosis of early stage CRCs (T1 CRCs) can guide treatment strategies. So far, little is known about the identification and endoscopic removal of T1 CRCs in a faecal immunochemical test (FIT)-based screening program. The aim of this study was to examine whether endoscopists performing colonoscopies in a FIT-based screening program are able to identify T1 CRCs correctly and to describe the treatment approaches towards these T1 CRCs.

Aims & Methods: In a prospective multicentre study, endoscopists accredited for FIT-positive colonoscopies within the Dutch bowel cancer screening program were trained in optical diagnosis with our validated NICE-WASP module. A total of 27 endoscopists completed the training successfully and entered the prospective study, in which the endoscopists as well as pathologists reported their findings in a predefined structure. Endoscopists recorded endoscopic diagnosis (adenoma, hyperplastic polyp, sessile serrated lesion and CRC) of every lesion in all consecutive FIT-positive colonoscopies for the Dutch screening program during one year. Two by two contingency tables were created to calculate sensitivity and specificity. T1 CRC was defined as CRC confined to the submucosa without invasion of the muscularis propria at histopathological evaluation.

Results: Between February 2015 and February 2017, 27 endoscopists recorded histology predictions during 3, 622 FIT-positive colonoscopies. During these colonoscopies, 287 patients (7.9%) were diagnosed with CRC. Overall, sensitivity of optical diagnosis of CRC was 76.0% (95% CI; 70.7–80.8) and specificity 99.7% (95% CI 99.6–99.8). In 107 (37%) patients with CRC, a total of 110 T1 cancers were detected (table 1). T1 CRCs had a median size of 20 mm (range 6–100 mm) and were predominantly located in the rectosigmoid (83%). Of these 110 T1 cancers, 41 (37%) were correctly predicted as CRC. Of these 41 correctly diagnosed CRCs, 18 were removed endoscopically en bloc were referred for surgical treatment because of suspicion of invasive cancer (N = 16), non-lifting sign (N = 4) or preference for TEM (N = 3). Of the 69 non-recognized T1 CRCs, 67 were endoscopically removed and 2 were referred for surgical treatment because of their size. Piecemeal removal was performed in 15 unrecognized T1 cancers and the remaining 52 were removed en-bloc. After histopathological evaluation, resection margins showed invasive growth in 13 non-recognized T1 cancers and in 17 cases resection margins could not be assessed. In 43 patients, an additional colonoscopy had to be performed to mark the previous endoscopic resection site of the T1 cancer after histological outcome. In total, adjuvant surgical treatment was required in 3 (7%) patients with recognized T1 CRCs compared to 29 (42%) of patients with non-recognized early stage cancers.

Conclusion: In a prospective study in which endoscopists were trained in optical diagnosis, approximately two-thirds of the T1 CRCs were not recognized during consecutive FIT-positive colonscopes leading to suboptimal use of endoscopic and surgical treatment options. Training in structured lesion assessment is needed to improve endoscopic recognition of T1 CRCs and ensure optimal treatment strategies (NCT02516748).

Disclosure of Interest: A combination of detection serum anti-Helicobacter pylori antibody and measurement of the level of serum pepsinogens has been used in screening for early gastric cancer (EGC). However, there are several issues which need to be improved. MicroRNAs (miRNAs) circulating in peripheral blood have been reported to be potentially useful for detecting cancer. The aims of this study are 1) to identify specific serum miRNAs and establish the discriminant model for EGC detection, 2) to validate the miRNAs and the discriminant model using a large cohort.

Aims & Methods: This retrospective study included 1417 serum samples of patients with EGC stored at the National Cancer Center Biobank between 2008 and 2012. In addition, 3051 serum samples of non-cancer patients stored at the National Center for Geriatrics and Gerontology Biobank and healthy volunteers who were recruited in the Toray Industries and the Yokohama Minoura Clinic between 2010 and 2015 were used as control. miRNA expression profiles of whole serum samples were comprehensively evaluated using highly sensitive microarray analysis. A chip (3D-Geno8) which was designed to detect 2555 miRNA sequences registered in miRBase release 20. Diagnostic models were constructed using the expression levels of several miRNAs in the discovery cohort and the diagnostic performances of the model were evaluated in the validation cohort.

Results: Patients and lesions characteristics of gastric cancer were as follows; male/female = 1001/416, median age (range) = 66 (20-90), stage 1A/1B/II = 1349/58/10, differentiated-type/undifferentiated-type/special type = 811/580/18. The discovery cohort included 708 patients with EGC and 4343 non-cancer controls. A diagnostic model for EGC detection constructed by a combination of the five miRNAs (miRNA A, B, C, D, and E) had a sensitivity of 99% and specificity of 97% with 0.99 area under curve (AUC). The validation cohort included 708 patients with EGC and 708 non-cancer controls. The diagnostic model could accurately discriminate EGC from the three kinds of non-cancer cohorts with a sensitivity of 99% and a specificity of 97% with 0.99 of AUC. The diagnostic accuracies of the model were equivalent among the stage (sensitivities of 99%, 100% and 100% in IA, IB and II respectively) and major histological types (sensitivities of 98%, 99%, and 100% in differentiated-type, undifferentiated-type, and special types, respectively).

Conclusion: Novel combination of serum miRNAs could be useful diagnostic biomarkers to detect EGC with high accuracy. Further prospective studies are warranted to confirm the diagnostic performance of the model.

surgically removed cancer and adjacent non-neoplastic tissue. Modelling by local experts was used to compare patient and cancer characteristics, including location, size, stage, and morphology, as well as surgical pathology, between those positive or negative for either marker in plasma. The primary outcome for comparison was complete surgical resection (clear margins, absence of distant metastases and lack of apical node involvement as a strong suspicion of residual disease).

**Results:** Of 189 cases with peri-diagnostic blood collected, 91 cases also had matched tissue samples and 93 cases had at least one post-surgical blood sample available for assay. ctDNA was detected in the blood of 119/189 (63.0%) of cases at diagnosis and was significantly more likely to be detected with later stage and distal location (all p < 0.01). The mean BCAT1 and IKZF1 methylation in cancer tissues were 48.0% and 60.5% (respectively), compared to 6.8% and 0.4% in non-neoplastic tissues (each p < 0.0001). Detectable methylation of either marker was seen in 90/91 (98.9%) cancer tissues. Tissue methylation levels in cancer were not concordant with detection in blood or affected by any of the aforementioned variables affecting ctDNA detection. A finding of a positive ctDNA result was most strongly associated with complete surgical resection (OR 31.2, 95% CI 3.4–291.2). Thirty-five of the 47 (74.5%) ctDNA-positive CRC patients at diagnosis who provided a post-surgical sample became negative after surgery, most within 3–4 months. Of the 12/47 cases who retained ctDNA positive after surgery, incomplete surgical resection was observed in 5/12 (41.7%) compared to 1/35 (2.9%) who became negative (p = 0.003, Fisher Exact test). In all 93 cases providing a post-surgery blood sample, incomplete surgical resection or strong suspicion of residual disease was more likely in those returning a positive ctDNA result than in those with a negative result (5/17, 29.4%, vs 1/17, 1.3%, p = 0.001).

**Conclusion:** BCAT1 and IKZF1 methylation are common events in CRC and post-surgical blood samples in CRC are possible on cancer stage (AJCC and TNM) at diagnosis rather than whether or not these markers are methylated in cancer tissue, which is near ubiquitous. Following primary cancer resection, a positive ctDNA result is associated with a significantly higher likelihood of incomplete surgical resection. Consequently, this test has the potential to allow dynamic monitoring of tumour bulk. Detection of methylated BCAT1/IKZF1 DNA in blood appears clinically useful for assessing adequacy of initial therapy and potential for recurrence.

**Introduction:** Irritable Bowel Syndrome (IBS) is a common functional gastrointestinal disorder, characterized by abdominal pain, discomfort and altered bowel habits, often accompanied by symptoms of bloating and distension. In general the efficacy of drug therapies is limited. Although individual hypnotherapy was demonstrated to be cost-effective for secondary care patients with IBS, implementation in primary care is limited due to lack of therapists. Therefore group sessions of hypnotherapy may be a more feasible large scale implementation, but the non-inferiority of group application needs to be established first.

**Aims & Methods:** We designed the IMAGINE-study to assess the overall benefit of hypnotherapy as well as to compare the efficacy of individual versus group hypnotherapy in the treatment of IBS. We designed a randomized placebo-controlled trial with 354 primary and secondary care patients (ages 18–65) with IBS (Rome-III criteria). Patients were randomly allocated to either 6 bi-weekly sessions of individual hypnotherapy, 6 bi-weekly sessions of group hypnotherapy or 6 bi-weekly sessions of educational supportive therapy in a group (placebo), with a follow-up of 9 months post treatment for all patients. Thirteen hospitals in different parts of The Netherlands collaborated in this study. The primary endpoint was the percentage of patients with adequate relief (AR) of IBS symptoms after 12 months. AR was defined as 3 or 4 weeks out of 4 weeks adequate relief from IBS symptom severity. Secondary efficacy parameters were changes in the IBS symptom severity, quality of life, cognitions, psychological complaints, self-efficacy as well as direct and indirect costs of the condition. Hypnotherapy was expected to be more effective than the control therapy, and group hypnotherapy was expected not to be inferior to individual hypnotherapy (p < 0.15 difference).

**Results:** Follow-up will be finished by the end of 2017. We present the preliminary results after three months. Of the 354 randomized patients, 150 patients were allocated to individual hypnotherapy, 150 to group hypnotherapy and 54 from the educational support group. Of these patients 79.6% 81.3% and 84% respectively completed 6 sessions of therapy, all within 3 months after start. Of those who completed the therapy 40.4% of the patients in the individual hypnotherapy, 33.7% of the patients in the group-hypnotherapy and 27.5% of those in the educational support group had adequate relief of symptoms after 3 months.

**Conclusion:** After 3 months of treatment hypnotherapy is more effective in patients with IBS than placebo. Group administration of hypnotherapy is not inferior to individual hypnotherapy. Group sessions may stimulate large-scale implementation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jenny.lovdlah@vgregion.se

**Introduction:** Gut-directed hypnotherapy, delivered individually or in groups, improve symptoms in patients with irritable bowel syndrome (IBS). Using group hypnotherapy for IBS would increase cost-effectiveness of this treatment, but only very small parallel comparison between individual and group hypnotherapy has been published.

**Aims & Methods:** We aimed to evaluate and compare the effectiveness of hypnotherapy for IBS delivered in individual versus group format. We included 119 patients (mean age 41.19–70 years; 87 women) with symptoms referable to standard management, who were randomized to receive individual or group hypnotherapy. They attended eight sessions based on the North Carolina Hypnotherapy Protocol (Palsson) delivered by one nurse specialized in hypnotherapy, during a period of two weeks. The group consisted of 5–8 patients. IBS symptom severity was assessed by the IBS Severity Scoring System (IBS-SSS), and subjective health was evaluated by the Short Health Scale (SHS), at baseline and after the 12 week hypnotherapy treatment period, at visit 8. A reduction of IBS-SSS ≥ 50 compared with baseline at visit 8 was considered a response to treatment.

**Table 1:** IBS symptoms and Subjective Health before and after Hypnotherapy (median, IQR)

</tbody>
</table>

**Results:** Sixty-one patients received individual treatment, 58 patients hypnotherapy in groups. Eleven patients (4 individual, 7 group) did not complete the treatment, but were included in the ITT-analysis. Groups were comparable at baseline according age, gender and IBS symptom severity (IBS-SSS) and subjective health (SHS). At the end of the treatment (visit 8) the patients in both groups reported improvement of IBS symptoms, as well as subjective health (SHS) (table 1). Improvement was observed for all five IBS-SSS domains (pain intensity, pain frequency, bloating severity, bowel habit dissatisfaction and daily life interference) (p < 0.001), as well as for all four subjective health domains of SHS (symptom burden, daily function, disease-related worry and general well-being) (p < 0.001). There were no differences between the treatment arms in regard to improvement in IBS-symptoms (p = 0.16) or subjective health (p = 0.17). Sixty-nine percent of the individual hypnotherapy patients met the responder criterion at the end of treatment, compared to 57% of group hypnotherapy patients (p = 0.25).

**Conclusion:** Both individual and group hypnotherapy is effective and relieves IBS symptoms and improves subjective health in patients with IBS. Although the proportion of responders was larger among the patients who received individual therapy, no statistically significant differences in overall improvement in GI symptoms were seen between treatment arms. Group hypnotherapy may therefore be a way to deliver effective IBS hypnotherapy at less cost. Further investigation regarding possible predictors of response to the different treatments could facilitate the choice of the most adequate treatment for each patient.

Introduction: Several lines of evidence suggest the contribution of intestinal microbiota in the pathophysiology of irritable bowel syndrome (IBS). This provides a proof of concept evidence of an implication of bacterial-host interactions in the pathophysiology and symptom generation of IBS.

Aims & Methods: To assess the effects of Lactobacillus paracasei CNCM I-1572 on clinical and gut microbiota-related factors in irritable bowel syndrome (IBS). We conducted a multicenter, randomized, double-blind, cross-over, 18-week, placebo-controlled, pilot trial assessing the effect of Lactobacillus paracasei CNCM I-1572 on symptoms, gut microbiota composition, fecal short chain fatty acids (SCFA), and on clinical and gut microbiota-related factors in irritable bowel syndrome (IBS).

Results: A total of 40 patients with IBS were enrolled from five Italian centers. Although better results were obtained with Lactobacillus paracasei CNCM I-1572, there was not a statistically significant improvement with active probiotic vs placebo, in the patients with the efficacy variables investigated. Interestingly, active probiotic, but not placebo, induced a significant increase in Lactobacillus (P = 0.011) and a significant reduction in Ruminococcus (P = 0.042), dominated by taxa related to Ruminococcus bromii and Ruminococcus albus. Lactobacillus paracasei CNCM I-1572, but not placebo, induced a significant increase in the SCFAs acetate (P = 0.021) and butyrate (P = 0.047) and a significant reduction in the pro-inflammatory cytokine interleukin-15 (P = 0.012).

Conclusion: This pilot study shows that Lactobacillus paracasei CNCM I-1572 is able to modulate gut microbiota structure and function and reduce immune activation in IBS, even if it was not statistically superior to placebo in symptom reduction. However, this study was characterized by 16S rRNA gene profiling.

OP285 RANDOMIZED CLINICAL TRIAL OF FOUR TREATMENTS FOR FAecal INCONTInence AMONG ADULT COMMUNITY-DEWLLING WOMEN: ASSESSMENT OF INDIVIDUAL EFFICACY OF INORECTAL PHYSIOLOGY, THE IMPACT ON CLINICAL SEVERITY AND ON QUALITY Of LIFE

L. Mument1, L. Rofes1, O. Ortega1, P. Clavé1

1Gastrointestinal Physiology Laboratory, Hospital de Mataro’, Mataro’, Spain

Contact E-mail Address: luismundetp@gmail.com

Introduction: Faecal incontinence (FI) is a prevalent condition with a major impact on quality of life (QoL). Currently four treatments are being used in clinical practice: Kegel exercises (K), biofeedback (BF) electrostimulation (ES) and pelvic floor surgery (NM). Results of each treatment are discordant and lack methodological rigour making scientific evidence weak 1,2.

Aims & Methods: The aim of this study is to assess the efficacy of these four treatments on community-dwelling women and their impact on anorectal physiology, on clinical severity and on QoL. This is a randomized control trial. Patient physiology was studied with anorectal manometry and endoanal ultrasound-sonography; clinical severity was assessed with Cleveland and St. Mark’s scales, and QoL with the Faecal Incontinence Quality of Life (FIQQL) and the EuroQol’s EQ-5D-3L instrument. FIQQL was also evaluated by means of International Consultation on Incontinence (ICIQ) score. Patients were randomized and assigned to K (control), BF + K, ES + K or NM + K, given active treatment for a 3-month period, and then evaluated again with identical tests and questionnaires to identify changes.

Results: Sample was of 152 women with a mean age of 61.09 ± 12.17 years. Clinical severity improved for all treatment arms (Cleveland score pre and post-treatment: 10.92 ± 7.08 vs 4.42 ± 2.95 respectively for the management of IBS symptoms, this should be demonstrated in well-powered ad hoc studies.

ClinicalTrials.gov Identifier: NCT02371499.

Contact E-mail Address: jan.tack@med.kuleuven.ac.be

Introduction: Opioid use for the treatment of chronic pain is associated with constipation. Symptoms of OIC significantly affect quality of life. The efficacy and safety profile of nalmepride (NAL), a peripherally-acting μ-opioid receptor antagonist, as a treatment for OIC has been demonstrated in multiple phase 3 studies of up to 52-week duration.

Aims & Methods: To assess the long-term effect of NAL on Patient Assessment of Constipation Symptoms (PAC-SYM) and Quality of Life (PAC-QOL). Methods: In a randomized double-blind placebo (PBO)-controlled 52-week study, subjects 18 to 80 years of age, having ≤4 spontaneous bowel movements (SBM) over 2 weeks and ≤3 SBM in a given week, were randomized 1:1 to received NAL 0.2 mg once daily or PBO for 52 weeks. Subjects were either not on laxatives or on a stable laxative regimen for the study duration. Subjects with gastrointestinal (GI) abnormalities or taking drugs that could affect GI motility were excluded.

Primary endpoints were change from baseline in the frequency of BM over the 52-week treatment period determined by PAC-SYM and quality of life as assessed by PAC-QOL, relative to PBO, and was generally well tolerated for up to 52 weeks.

| BC-Neutroph-load | 0.0000 |
| GT-load | 0.0000 |
| log[AST] load | 0.0001 |
| log[ALT] load | 0.0001 |
| log[ALP] load | 0.0001 |
| IgG-load | 0.0113 |
| IgG-load | 0.0006 |

Conclusion: Of serum surrogate markers, log[AST], log[ALP], the sum of log[ALT+ AST + ALP+ GT] and biliary calprotectin > 20 and neutrophils in BC (>1) turned out to be best predictors for PSC progression based on ERC score in sequential examinations. Risk for development of biliary dysplasia or CCA is associated with ERC score load, biliary calprotectin (>20) and log[AST] and log[ALP], and also the sum of log[ALT+ AST + ALP+ GT]. These variables are useful for monitoring progression of bile duct changes, response for therapy and individual risk stratification for dysplasia in PSC patients.

Introduction: Obeticholic Acid (OCA) is a selective and potent farnesoid X receptor agonist in clinical development for treatment of primary biliary cholangitis (PBC). PBC is a 12-month double-blind (DB), placebo (PBO)-controlled, Phase 3 PBC study including an open-label extension (OLE). Patients who completed the DB phase were eligible to participate in the OLE.

Aims & Methods: The purpose of the OLE is to assess safety and the durability of OCA on markers of cholestasis. Key POISE inclusion criteria: PBC diagnosis, ALP ≥1.67x ULN and/or total bilirubin >ULN to <2x ULN, stable UDCA dose or unable to tolerate UDCA. During the DB phase, 216 patients were randomized and dosed to: daily PBO, n = 73; OCA 5–10 mg (titration after 6 months to 10 mg) when compared to PBO. Patients who received PBO during the DB phase and who initiated OCA during the OLE had significant reductions in markers of cholestasis at 24 months, with the exception of total bilirubin. Pruritus was the most common adverse event (AE) associated with OCA. Overall incidence of pruritus in OCA groups during the DB phase (55–68%) was reduced during the OLE (21–37%), with comparable incidence to that in DB PBO patients (38%). During the OLE, 22 (11%) patients discontinued treatment: 4 (2%) for pruritus; 7 (4%) for other AEs; 11 (6%) for death unrelated to OCA, and 10 (5%) for other reasons.

Conclusions: OCA treatment improves liver biochemistry, most notably ALP and GGT, which is sustained through 24 months of treatment in the OLE. Pruritus was the most common AE, but its occurrence appeared to lessen with longer treatment.

TGR5 was evaluated in CCA progression.

Aims & Methods: The differential activation of the bile acid receptors FXR or TGR5 was determined in CCA progression. FXR and TGR5 expression was determined in two different cohorts of CCA patients (i.e. Denmark and Spain), as well as in in vitro CCA cell lines and in human cholangiocytes in culture. A third cohort of human CCA was established in immunodeficient mice and tumor growth was monitored by magnetic resonance imaging (MRI). Under chronic administration of selective TGR5 agonists, no bile acid or cholate biosynthesis were observed in the liver.

Methods: The differential effects of FXR or TGR5 activation were evaluated on proliferation, apoptosis, migration and mitochondrial energetic metabolism (i.e. Seahorse Bioscience) in CCA cells in vitro. The differential effects of FXR or TGR5 activation were evaluated on proliferation, apoptosis, migration and mitochondrial energetic metabolism (i.e. Seahorse Bioscience) in CCA cells.

Results: FXR is downregulated and TGR5 upregulated in human CCA tissue compared to normal surrounding liver tissue in both cohorts. FXR correlates with tumor differentiation, whereas TGR5 correlates with perineural invasion. TGR5 expression is increased in perihilar vs intrahepatic CCA. In vitro, FXR is downregulated and TGR5 upregulated in human CCA cells compared to normal human cholangiocytes. In mice with orthotopic implants of human CCA tumors, chronic administration of OCA inhibited the tumor growth compared to untreated control animals. This was accompanied by decreased expression of proliferation (i.e. PCNA, Ki-67), biliary (i.e. CK19) and epithelial (i.e. ZO-1) markers within the tumors. In chronic administration of INT-777 in vivo showed no effects on CCA tumor growth. In vitro, OCA inhibited CCA cell proliferation and migration, associated with decreased mitochondrial energetic metabolism. In contrast, INT-777 stimulated proliferation and migration of CCA cells, associated with increased mitochondrial energetic metabolism.

Conclusion: The differential activation of FXR or TGR5 can regulate cell proliferation, migration and mitochondrial energetic metabolism. Regulation of FXR and/or TGR5 activities may represent potential novel therapeutic strategies for CCA.

Introduction: Endoscopic transpapillary placement of biliary stents to relieve jaundice is the main palliative treatment for unresectable extrahepatic cholangiocarcinoma (EHC)2,3. It was reported endoscopic biliary radiofrequency ablation (RFA) could prolong the stent patency, which may also be beneficial to improve the patient survival. However, the available evidence is still insufficient for majority of studies were retrospective case series2,3. Aims & Methods: The aim of this study is to explore the clinical effect and safety of RFA in patients with unresectable EHC. 59 Patients with unresectable

Conclusion: The allele dose of PNPLA3 did not have any significant impact on cholesterol or phospholipid composition of bile acids in UDCA-naïve patients. However, in patients homogeneous for the mutation (GG), there was a statistically significant linearity for lower content of secondary bile acids: deoxy- and lithocholic acid, the most toxic ones, reversed by UDCA therapy.

Introduction: Current treatment of autoimmune hepatitis (AIH) consists of induction therapy with prednisone followed by azathioprine maintenance therapy. The EASL (European Association for Study of the Liver) Clinical Practice Guidelines on AIH advise a prednisone dose ranging from 0.5 to 1 mg/kg/day. It is not known whether lower doses might be equally effective. We hypothesized that lower doses of prednisone would not lower the chance of achieving biochemical remission.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims: We investigated the effect of low-dose versus high-dose prednisone induction therapy in AIH on biochemical remission in a multicenter cohort, using chart review data from centers in Amsterdam, Nijmegen, Arnhem (The Netherlands) and Hamburg (Germany). Patients were eligible in case of an established AIH diagnosis according to the International Autoimmune Hepatitis Group criteria, ≥18 years old at time of diagnosis and received induction treatment with prednisone. The primary outcome was biochemical remission, defined as a normal alanine transferase (ALT) serum level (<45 U/l) at 24 weeks after initiation of therapy. Patients were split into a high- and a low-dose group using the EASL guideline cut-off of 0.50 mg/kg/day.

Methods: We performed log-binomial regression to determine differences in biochemical remission between the high and low-dose prednisone group, with correction for center and confounders: baseline ALT, maintenance therapy and use of prednisone. Biochemical remission at week 24 (median 25.9 weeks (range 16 – 36)) was similar in the low- and high-dose group: 66.3% versus 66.9% and remained similar after correction for confounders (RR 1.01 (0.81 – 1.27) p = 0.91).

Results: With follow-up of 45 months, the mean overall survival was significantly longer for patients treated by RFA+ stent group than in the stent group (13.8 vs. 8.4 months, P < 0.001). The mean stent patency period of the RFA + stent group was also significantly longer than that of the stent group (6.9 vs. 3.5 months, P = 0.02). There was no significant difference in the incidence of postoperative complications between the two groups [6.9% (2/29) vs 10% (3/30), P = 0.67].

Conclusion: Endoscopic RFA combined with stenting can significantly prolong the EHCC patients' survival and stent patency period without increasing the incidence of adverse events. This approach can be considered as a safe and effective palliative treatment for unresectable EHCC.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Individuals are still at risk of gastric cancer (GC) development despite successful eradication of H. pylori (HP) infection. Although aspirin has been shown to reduce the GC risk in previous studies, the results were not stratified by HP status and the role of aspirin in subjects with prior HP eradication remains unknown.

Aims & Methods: We determined the effects of long-term aspirin on GC risk in a large population-based cohort of subjects who had received HP eradication. This was a retrospective cohort study based on a territory-wide healthcare database of Hong Kong. All adult subjects who had received an outpatient prescription of clarithromycin-based HP therapy between January 2003 and December 2012 were included. The observation period commenced from the date of triple therapy prescription and was censored at the date of diagnosis of gastric cancer, death, or end of the study. Prescriptions of aspirin before HP eradication or after the censored date were excluded in the analysis. We also excluded subjects with failed HP eradication and those with GC diagnosis within 12 months of HP therapy. We determined the hazard ratio (HR) of GC with aspirin use by Cox proportional hazards model with propensity score adjustment of different baseline characteristics, comorbidities and use of concurrent medications.

Results: During a median follow-up of 7.4 years, 169 (0.27%) of the 63,605 eligible HP infected patients who had successful HP eradication developed GC (median time from HP therapy to GC development: 4.7 years). Aspirin use, defined as ≥ weekly use, was associated with a significantly reduced risk of GC development (HR 0.30, 95% CI: 0.15–0.61). Subgroup analysis showed the risk reduction was confined to non-cardia (HR 0.25, 95% CI: 0.11–0.58) but not cardia GC. The risk of GC decreased with increasing frequency, duration and dose of aspirin use (all p-trend < 0.001) (Table). Conclusion: Long-term aspirin use was associated with a frequency-, dose- and duration-related decrease in GC risk in subjects after successful HP eradication.

Table: HRs and 95% CIs for the association between frequency, duration and dose of aspirin use and risk of gastric cancer (propensity score adjustment)

Introduction: Evidence suggests that the presence of gastric intestinal metaplasia (GIM) is involved in the pathogenesis of Non-Cardia Gastric Cancer (NGC). Although GIM is associated with the occurrence of post endoscopy cancer is scarce. Aims & Methods: We attempted to determine the incidence of post endoscopy NGC and assess whether the presence of GIM is associated with its occurrence. Subjects with no previous cancer undergoing upper endoscopy at a tertiary referral center of the Clalit Health Services (CHS) HMO were included. NGC was detected through the National Cancer Registry. Demographic data was extracted from the CHS database and pathology data including presence of GC (with or without dysplasia) and extent (focal/extensive) were reviewed. Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: AMOTL1 (Angiomotin-like protein 1), a member of Motin family, has been reported contradictorily in multiple cancer types and its Hippo-involve- ment during gastric carcinogenesis remains uninvestigated.

Aims & Methods: We seek to elucidate the functional role of AMOTL1 and comprehensively reveal its regulatory mechanisms during gastric carcinogenesis. Mass spectrometry analysis was applied to identify AMOTL1 as one of the YAP1 binding partners, which was further confirmed by co-immunoprecipitation. Immunohistochemistry was performed to confirm the localization of YAPI after AMOTL1 knockdown or overexpression. The mRNA and protein expression levels of AMOTL1 were examined by qRT-PCR and Western blot. The correlation of AMOTL1 expression with other clinical parameters was checked by immunohistochemistry on the tissue microarray. The biological function of AMOTL1 in GC was determined by MTT proliferation, monolayer colony for- mation, cell invasion assays through sRNA-mediated knockdown.

Results: What we observed as a bait, mass spectrometry revealed that AMOTL1 was listed in the key binding partners of YAPI. Knocking down AMOTL1 inhibited YAPI translocation from cytoplasm to the nucleus and promoted YAPI degradation through ubiquitinilation. In primary samples, AMOTL1 is found to be highly expressed in primary GC (P<0.001), GT (P<0.005), GC3 (P<0.006) as well as in paired GC tissues compared with adjacent non-tumorous controls (P<0.012, NCBI/GEO/GSE63089). AMOTL1 upregulation also indicated poor survival among GC patients (overall survival, HR=1.542, P<0.001, n=512, NCBI/GEO/GSE14210, GSE15459, GSE22377, GSE29272, GSE51105 and GSE62254). More importantly, overexpression of AMOTL1 was correlated with worse clinical outcomes of patients in advanced stage (overall survival, HR=1.555, P<0.001) (Supplementary Table 1). AMOTL1 further validated by gene set enrich- ment analysis (GSEA) that AMOTL1 expression was positively associated with upregulation of advanced-GC-related genes (ES=0.775, NES=1.953, P=0.025, n=300, NCBI/GEO/GSE22654). Both univariate and multivariate Cox Regression analyses suggested that AMOTL1 upregulation predicted poor sur- vival independently (univariate analysis, P=0.016; multivariate analysis, P=0.022). In vitro experiments revealed that siAMOTL1 led to reduced cell growth (P<0.001), colony formation (P<0.001) and invasion (P<0.0001), suggesting its oncogenic role during gastric carcinogenesis. Finally, AKT and MAPK signalling pathways were confirmed to be the main downstream of AMOTL1 in GC, which showed good concordant with the driver oncogenic role of YAPI.

Conclusion: AMOTL1 is abundantly expressed in GC tissues and its overexpres- sion indicates poor outcomes. The accumulation of AMOTL1 in GC promotes the growth and invasive ability of tumour cells. AMOTL1 exhibits an oncogenic role in gastric carcinogenesis through stabilization and facilitating the nucleus translocation of YAPI to activate AKT and MAPK singleing. Our findings demonstrate that AMOTL1 is involved in Hippo pathway and it might serve as a potential therapeutic target for GC.

Introduction: The MAGIC trial established perioperative (periop) epirubicin, cisplatin, and 5-FU (ECF) as a standard treatment for patients (pts) with operable esophageogastric cancer, but survival continues to remain poor. FLOT4 (NCT01216644) is a multicenter, randomized, investigator-initiated, phase 3 trial. It compares the docetaxel-based triplet FLOT with the anthracycline- based triplet ECF/ECX as a periop treatment for pts with resectable gastric or GEJ adenocarcinoma.

Aims & Methods: Eligible pts of stage ≥T2 and/or cN+ were randomized to either 3 preoperative and 3 postoperative 3-week cycles of ECF/ECX (epirubicin 50mg/m2, cisplatin 60mg/m2, both d1, and 5-FU 200mg/m2 as continuous infusion or capecitabine 1250mg/m2 orally d1-21) or 4 preoperative and 4 post- operative 2-week cycles of FLOT (docetaxel 50mg/m2, oxaliplatin 85mg/m2, leucovorin 200mg/m2, and 5-FU 200mg/m2 as 24-hour infusion, all d1). The primary endpoint was overall survival (OS; 80% power; HR of 0.76; 2-sided log- rank test at 5% type I error). Funded by Deutsche Krebshilfe.

Results: Between Aug 2010 and Feb 2015, 716 pts (360 ECF/ECX; 356 FLOT) were randomly allocated. Baseline characteristics were similar between arms (overall, male 74%; median age 62; cT3/T4 81%; cN+ 80%; GEJ 56%). 91% and 57% of pts with ECF/ECX and 90% and 50% with FLOT completed planned cycles preoperative-and perioperative, respectively. Median follow up was up 43 mon. 369 pts died (203 ECF/ECX; 166 FLOT). FLOT improved OS (n=35, 35 mon with ECF/ECX vs. 50 mon with FLOT; HR 0.77 [0.63-0.94]; p=0.012). 3y OS rate was 48% with ECF/ECX and 57% with FLOT. FLOT also improved PFS (mPFS, 18 mon with ECF/ECX vs. 30 mon with FLOT; HR 0.75 [0.62-0.91]; p=0.004). No DTR (50%) was 50% with ECF/ECX and 51% with FLOT, 30- and 90-day mortality was 3% and 8% with ECF/ECX and 2% and 5% with FLOT. There was more G3/4 nausea phase 1-2 (P=0.04) and ECF/ECX vs. FLOT 5.3% and 0.5% with FLOT. Conclusion: Perip FLOT improved outcome in patients with resectable gastric and GEJ cancer compared to periop FLOT/ECX and is new standard therapy in this setting.

OP298 TUMOR-ASSOCIATED MACROPHAGES AS NOVEL TARGETS FOR IMMUNOTHERAPY IN ESOPHAGEAL ADENOCARCINOMA

S. Calpe, S. Hoefnagel, S. Bouchmal, C. Del Sancho-Serra, D. Straub, K.K. Krishnadath

CEMM, Academic Medical Center Amsterdam, Amsterdam/Netherlands

Contact E-mail Address: s.calpe@amc.uva.nl

Introduction: It has been shown that immune modulation e.g., by inhibition of the tumor-cell interaction, can greatly improve cancer response. Tumor-associated-macrophages (TAMs) are other key immunological players within the tumor microenvironment which can present both tumor-promoting and tumor-suppressive functions (1). Although several anti-TAM therapies reduce tumor growth and metastasis in preclinical cancer models (2), strategies that aim at specifically eliminating the protumoral TAMs are lacking.

Aims & Methods: This study aimed at identifying specific pro-tumoral TAM populations within the tumor microenvironment of esophageal adenocarcinoma
(EAC) and elucidate their potential therapeutic value. EAC is a highly aggressive cancer and is often associated with an anti-inflammatory microenvironment and dismal survival. It is important to determine whether TAM infiltration is associated to low survival and high recurrence in EAC, as we analyzed the transcriptomes of 73 EAC by RNAseq of pre-treatment biopsy specimens. As opposed to the publicly available TCGA database, this unique database is composed of a cohort of patients homogeneous-ly treated with standardized treatment, which facilitates the identification of novel treatment targets as well as predictive biomarkers. The ConsensusClusterPlus tool and Gene set enrichment analyses within the compu-tational pipeline used to determine whether markers that define specific TAM subpopulations could be used as prognostic factors, therapeutic targets and/or identify different EAC subgroups.

Results: Clustering of the EAC tumors using specific TAM markers, resulted in the identification of two molecular subtypes of EAC tumors. Gene Set enrich-ment analyses demonstrated that whereas one group was enriched by metabolic genes, the other group presented an “immune-like” signature and correlated significantly with worse survival. Markers that specifically define immunosup-pressive, angiogenic, and stem cell promoting TAMs were highly expressed in these cancers, together with genes involved in leukocyte migration as well as the STAT-JAK signaling pathways. Not surprisingly, this group was also significa-tively enriched with malignant genes involved in stem cell and epithelial prolif-eration, epithelial cell migration, EMT and angiogenic factors. In particular, three TAM-specific markers were identified within this “immune-like” group: MARCO, CD80 and ANG2. Immunohistochemistry analyses validated their expression at the protein level. Most importantly, patients with elevated expres-sion of one of these genes presented significantly worse survival.

Conclusion: In sum, we have demonstrated that a subset of EAC patients present an “immune-like” molecular signature which is associated to poor survival. This is characterized by the presence of various subpopulations of pro-tumoral TAMs that promote malignancy such as epithelial proliferation and migration as well as angiogenesis. In particular, three TAM genes (MARCO, CD80 and ANG2) were elevated in these patients and found to be significantly associated to worse survival. Although further experiments are warranted to define their exact prognostic and therapeutic value, our findings might have important clinical implications for EAC. They have illustrated the importance of the role of pro-tumoral TAMs in EAC and have identified a subgroup of patients with tumors that might benefit from novel tailored immu-notherapies directed against pro-tumoral TAMs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A subpopulation of enteric glial cells has the capacity to behave like enteric neuronal stem/progenitor cells (ENSCs) and can reconstitute the enteric neuron pool upon damage. Thus, favoring ENSC differentiation can be consid-ered as a novel therapeutic approach to treat gastrointestinal motility disorders resulting from neuronal loss. In this context, accumulating evidence has shown that estrogens via the activation of the estrogen receptor beta (ER-β) may play a role in stimulating neuronal proliferation and survival in the central nervous system. Although it has been shown ER-β is expressed in the myenteric plexus both by enteric neurons and glial cells, there is no data concerning its possible role in intestinal neurogenesis.

Aims & Methods: Therefore, the aim of this study was to demonstrate if the selective ER-β agonist, LY3201, can act on ENSC-like glial cells to enhance their capacity to generate neurons in case of neuronal damage or loss. To study the effect of LY3201 on murine enteric ganglia in vitro, the muscularis externa of C57Bl/6J mice (8-10 weeks old) was enzymatically digested to isolate myenteric plexus and cultured for 5 days of incubation with placebo or different concentra-tions of LY3201 (1, 10, 100 and 1000 nM), cells were stained for glial cell (SOX10, GFAP), progenitor (SOX10, SOX2) and neuronal markers (HuC/D, NF). Moreover, the effect of LY3201 was evaluated in vivo by implanting pellets releasing 0, 119 and 1190 mg of LY3201 over a period of 7 days in two models of enteric neuronal damage: topical application of 0.1% benzalconium chloride (BAC) on the serosa of the ileum and high fat diet (HFD; 60% kcal from fat) for 12 weeks. The number of HuC/D+ neurons in the myenteric plexus was assessed by immunofluorescence.

Results: In vitro, different concentrations of LY3201 were tested in myenteric ganglionic cultures showing an increased number of glial cells (SOX10+ + GFAP + SOX2- cells) mainly at a concentration of 100 nM (Vehicle: 1130 ± 234; LY3201: 5444 ± 528 pmn/mm²). Interestingly, after blocking glial cell proliferation with an antiproliferative agent (ActD), LY3201 significantly increased the percentage of differentiated neurons (HuC/D + NF + SOX10- cells) (Vehicle 18 ± 3%; LY3201 41 ± 7%) suggesting that in response to LY3201 some glial cells with preserved ENSC capacity are able to give rise to neurons. In vivo, LY3201 treatment for 7 days was able to signifi-cantly reduced the myenteric plexus area with neuronal loss compared to the vehicle after BAC treatment (Vehicle: 2.5 ± 2 mm² versus LY3201: 8, ± 3 mm²). In line, LY3201 treatment for 7 days after a HFD resulted in an increased number of myenteric neurons compared to the control group (Vehicle: 310 ± 55; LY3201: 776 ± 49 pm²).

Conclusion: Here, we demonstrated that the selective ER-β agonist, LY3201, can promote neurogenesis in the damaged myenteric plexus by favoring differen-tiation of ENSCs. Overall, our results suggest that selective ER-β agonists may hold potential as a novel therapeutic approach to treat gastrointestinal motility disorders.

Aims & Methods: We aimed to find a specific fibroblast subpopulation in mouse colon that is able to support stem cell growth and can be visualized by a monoclonal antibody. Primary fibroblasts isolated from GlitCre-ZfaGreen mouse colon were flow-sorted based on gp38 positivity and Gli1 expression (Gli1+, Gli1++ and Gli1+++). The ability to support organoid growth by fibroblasts was accessed by measurement of organoids perimeter in co-cultures of flow-sorted fibroblasts and organoids. Growth factors reduced medium. Sorted cells were further charac-terized by microarray analysis and results were confirmed by qPCR. Based on microarray results few membrane markers were chosen and an expression pattern of these markers was studied by immunofluorescent and in situ hybridization tissue staining. New candidate subpopulations were flow-sorted again and char-acterized by qPCR and co-cultures with organoids.

Introduction: The intestinal epithelium renews every 3–5 days and this process is fully dependent on stem cells. Stem cell potential is strictly defined by its micro-environment – the stem cell niche – which provide all signals required for stem cell maintenance and differentiation. Cell cultures developed from a single stem cell – so called organoids – still requires addition of growth factors such as EGF, R-spondin1 and Noggin. Local fibroblasts may help to support stem cells by producing these missing factors. Heterogeneity of organoids can be explained by various organs and these subpopulations exert different functions. Not much is known about markers for fibroblast subpopulations in intestine. Recent studies showed expression of the membrane marker podoplanin (gp38) (1) and transcripti-onal expression of Gli1 (2) by all intestinal fibroblasts.

Results: We observed differential expression of Gli1 in gp38+ intestinal fibroblasts. gp38+Gli1++fibroblasts were able to support stem cell growth in vitro. Unsorted primary markers unexpressed in GlitCre-ZfaGreen fibroblasts identified several new markers expressed by all colon fibroblasts (such as Iga9, Sdc2 and Sdc3) and two markers that showed a differential expression (Iga8 and CD90). Iga8 stained mostly smooth muscle cell layer in a colon and does not contribute to the stem cell niche. CD90+ cells located in close proximity to stem cells, supported stem cell growth and express crucial stem cell growth factors such as Grem1, Wnt2b and R-spondin3. We also identified semaphorins class 3 (Sema3) mem- bers - Sema3a, Sema3b, Sema3c, Sema3d - expressed by CD90+ fibroblasts. We identified several new markers for organoid growth in co-cultures with CD90+ fibroblasts.

Conclusion: We identified CD90 as a marker for mouse colon fibroblasts located in close proximity to stem cells. This subpopulation supported stem cell growth and expressed crucial stem cell growth factors such as Grem1, Wnt2b and R-spondin3. Moreover we found an additional protein family, class 3 semaphorins (Sema3), which is expressed by CD90+ fibroblasts and able to increase organoid growth.

Introduction: Upon intestinal epithelial damage, a dual response is required to re-establish intestinal homeostasis. While ensuring repair of the epithelial integrity, rapid recruitment and activation of the immune system is essential to limit impact of harmful luminal content. Indian Hedgehog (Ihh) is an epithelial factor that functions as a critical sensor in this process, and loss of Ihh activity, which is essential to limit impact of harmful luminal content, occurs in a disease context, as the receptor for Ihh is only expressed in the mesenchyme, but the exact Hedgehog target cell has remained elusive.

Aims & Methods: The aim of this study was to further elucidate the nature of this target cell in the context of intestinal inflammation. Gene expression profiles were determined in Villin-CreERT2-Ihfl/fl and Rosa26-CreERT2-Ptchfl/fl animals. Sensitivity to DSS induced colitis was tested in Villin-CreERT2-Ihfl/fl, C. Smal-CreERT2-Ihfl/fl and C. Smal-CreERT2-Ptchfl/fl mice. Ihh signaling was characterized by Hedgehog responsive cells in vivo and in vitro, thereby impairing the recruitment of immune cells. Animals deficient in general intestinal Hedgehog signaling (Villin-CreERT2-Ihfl/fl and Ghil-CreERT2-Smo6/fl) were more sensitive to DSS colitis. In contrast, animals lacking the receptor Smo6 were more resistant to DSS colitis.

Conclusion: We show that epithelium-derived Indian Hedgehog signals exclusively to fibroblasts in the intestine. Loss of Ihh leads to a rapid immune response with upregulation of fibroblast-derived CXCL12, and migration of immune cells into the lamina propria.

Introduction: Patients with ulcerative colitis (UC) patients reveal a dysfunction of tight junction barrier and immune dysregulation. A defective tight junction (TJ) barrier is a key pathogenic factor in the causation and progression of UC by allowing increased antigenic permeation especially gut-derived bacterial lipopolysaccharides (LPS). Semaphorins (Sema) and their receptors plexins (PLX) are important regulators of epithelial barrier and immune dysregulation, while, IL-8 increase was aggravated. In Caco-2 cells, mRNA expression of PAR2 and 4 was increased after thapsigargin-induced ERS, and PAR4 levels were restored to basal in the presence of AEBSF and -4 were used to elucidate the mechanism of action of epithelial proteases. Results: Trypsin-Like Activity was significantly higher in biopsies from UC patients compared to controls, p = 0.0157. Thapsigargin enhanced trypsin-like activity in Caco2 cells at 6 hours at the apical side of the transwell. ABP assay identified a unique band at 33 KDa in ERS-induced Caco-2 supernatants. Paracellular permeability, IL-8 and antimicrobial peptides (AMP) genes were measured to study the impact of proteases on intestinal barrier function. Serine protease inhibitor (AEBSF), and antagonists of protease-activated receptors (PAR) -2 and -4 were used to elucidate the mechanism of action of epithelial proteases.

Conclusion: Our data showed that in intestinal epithelial cells, ERS increased serine protease activity, which is responsible for increased barrier function and dys-regulated AMP expression. We identified PAR2 and PAR4 activation as mechanisms of ERS-induced barrier dysfunction, and Trypsin-3 as a candidate protease overexpressed upon ERS, and in UC patients epithelium.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP303 ENDOPLASMIC RETICULUM STRESS INCREASES TRYPSIN-3 ACTIVITY IN ENTEROCYTES AND ALTERS BARRIER FUNCTION

Digestive Health Research Institute (IRSD), INSERM UMR-1220, Toulouse, France

Contact E-mail Address: mrs.n@gmail.com

Introduction: Ulcerative Colitis (UC) is a chronic relapsing inflammatory bowel disease (IBD) with mucosal ulcerations. Excessive induction of endoplasmic reticulum stress (ERS), enhanced proteolytic activity and intestinal barrier disruption have been described in the colon mucosa of UC patients; however associated links between these features had not been described yet.

Aims & Methods: We evaluated the link between ERS and trypsin proteolytic activity (serine protease) in human enterocytes and its impact on intestinal barrier function. Colonic biopsies were taken during routine endoscopy from 12 UC patients and 19 controls. Biopsy supernatants were used to quantify Trypsin-like activity. In parallel, human intestinal Caco-2 cell line was cultured in a transwell system and stimulated with thapsigargin (10 μg/mL) to induce ERS. Supernatants were collected at 6 and 24h to quantify Trypsin-Like Activity by enzyme assay. Activity-based probe (ABP) were used to identify specifically the active trypsin-like proteases present in Caco-2 supernatants. Paracellular permeability, IL-8 and antimicrobial peptides (AMP) genes were measured to study the impact of proteases on intestinal barrier function. Serine protease inhibitor (AEBSF), and antagonists of protease-activated receptors (PAR) -2 and -4 were used to elucidate the mechanism of action of epithelial proteases.

Results: Trypsin-Like Activity was significantly higher in biopsies from UC patients compared to controls, p = 0.0157. Thapsigargin enhanced trypsin-like activity in Caco2 cells at 6 hours at the apical side of the transwell. ABP assay identified a unique band at 33 KDa in ERS-induced Caco-2 supernatants. Paracellular permeability, IL-8 and antimicrobial peptides (AMP) genes were measured to study the impact of proteases on intestinal barrier function. Serine protease inhibitor (AEBSF), and antagonists of protease-activated receptors (PAR) -2 and -4 were used to elucidate the mechanism of action of epithelial proteases.

Conclusion: Our data showed that in intestinal epithelial cells, ERS increased serine protease activity, which is responsible for increased barrier function and dys-regulated AMP expression. We identified PAR2 and PAR4 activation as mechanisms of ERS-induced barrier dysfunction, and Trypsin-3 as a candidate protease overexpressed upon ERS, and in UC patients epithelium.

Introduction: Chronic intestinal pseudo-obstruction (CIP) is a rare condition characterized by impairment of gut motility responsible for recurrent episodes of intestinal sub-occlusion and severe digestive symptoms in the absence of mechanical causes. Neuro-intestinal cells of Cajal (ICC)-muscular abnormalities represent the main pathogenic mechanism explaining gut dysfunction, being responsible for functional intestinal epithelial barrier (IEB) abnormalities, majorly contributing to symptoms and clinical manifestations in CIP patients. In this study we analyzed the protein expression of the major components of tight junctions (TJs), i.e. occludin, two selected claudins (Cln4 and Cln5) and zonula occludens-1 (ZO-1), as markers of IEB integrity in patients with CIP. Moreover, based on published evidence we investigated the expression of vasoactive intestinal polypeptide (VIP) as neuronal mediator involved in the regulation of IEB.

Aim & Methods: This study was aimed to clarify the molecular abnormalities responsible for IEB dysfunction in patients with CIP. A number of n = 28 clinically and histopathologically characterized CIP patients (15F; age range: 16-75 yrs) entered the study and were subdivided according to the underlying structural alterations of the IEB: Histiostopathy: a combination of the amount of pathological normal (AN) neuro-muscular layer; n = 11 with inflammatory (INF) changes throughout the muscular and n = 10 with degenerative alterations (DEG). (Patients n = 8; 3F, 46-73 yrs) undergoing elective surgery for uncomplicated intestinal polyps served as control. CIP subgroup, whereas ZO-1 and VIP were downregulated only in DEG (P < 0.05 and P < 0.01).

Conclusion: IEB integrity was altered in patients with CIP as identified by occludin expression abnormalities. Particularly the atypical occludin oligomerization and dysfunction which negatively impacts the passage of molecules agents passing through the intestinal wall in these patients. Subgroup analysis showed that different molecular mechanisms disrupt the IEB in CIP patients. Barrier dysfunction in AN and INF is occludin dependent, while in DEG is ZO-1 dependent likely influenced by VIP downregulation. IEB altered molecular mechanisms represent molecular targets for development of diagnostic markers/therapeutic interventions.

Introduction: Liver surgery in perihilar cholangiocarcinoma (PHC) is associated with high postoperative morbidity and mortality, primarily due to biliary obstruction caused by the tumor. Preoperative biliary drainage is used to treat jaundiced patients’ clinical symptoms (JPS), to facilitate liver resection itself is also associated with complications that may deteriorate the patient’s condition and worsen outcomes. Consensus is lacking on whether endoscopic or percutaneous biliary drainage should be preferred. Aim & Methods: This multicenter randomized controlled trial with an “all-comers” design (DRAINAGE trial) compared two drainage approaches in patients with presumed, potentially resectable PHC requiring major hepatectomy. Patients with obstructive jaundice and a bilirubin level above 50 μmol/L were randomly assigned to undergo either endoscopic (EBD) or percutaneous transhepatic biliary drainage (PTBD). Primary outcome were severe preoperative complications between randomization and surgery. The secondary outcomes encompassed the success of biliary drainage and postoperative morbidity and mortality. Total sample size required was 106 patients. All procedures were performed by experienced interventional radiologists and gastroenterologists. PTBD remained in situ postoperatively whereas EBD was removed intra-operatively.

Results: From June 2013 through June 2016, a total of 54 patients were randomly assigned to EBD (27 patients) or PTBD (27 patients), without differences in baseline characteristics. The number of severe complications was comparable between patients who underwent the trial based on a higher perioperative mortality rate in the PTBD group. Prior to surgery, 3 (11%) patients died in the PTBD group versus 0 in the EBD group. After surgery, 8/19 (42%) patients died in the PTBD group versus 2/21 (9.5%) patients in the EBD group (of whom 1 was a crossover of EBD to PTBD) (P = 0.002). Initial technical or therapeutic failure occurred more often in the EBD group: 5 (18%) versus 2 (7%). Cross-over from EBD to PTBD due to insufficient drainage or technical failure occurred in 15 patients (54%) of the EBD group. Preoperatively, the percentage of patients with more than one complication was comparable between groups 22 % versus 21 % (P = 0.81). The number of patients with more than one severe complication (Clavien-Dindo 3 or higher) was 21 % (78%) in the EBD group versus 18 (67%) in the PTBD group. Cause of death was most often a combination of an infectious or vascular complication and subsequent liver failure and multi organ failure.

EBD is advised in patients with obstructive PHC requiring biliary drainage since PTBD increased mortality. PTBD should only be used if EBD fails.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Conclusion: The early recurrence within 90 days after surgery was significantly less frequent in the HCC-ICC group, probably because EOB-MRI has high ability for diagnosis of small tumor in the remnant liver. The preoperative EOB-MRI would contribute to the determination of appropriate resection site and the accompanying improvement of treatment outcomes.

Introduction: Transarterial embolization (TAE) and Selective Internal Radiation Therapy (SIRT) are effective liver-directed treatments in patients with liver metastases of a neuroendocrine tumor (NET). However, differences between TAE and SIRT may have been scarcely investigated.

Aims & Methods: The aim of the study is to compare safety and efficacy of TAE and SIRT. Consecutive patients with histologically confirmed well differentiated NET (G1-2), who underwent TAE or SIRT for liver dominant disease in our NET-expert centre during 2004-2016 were analysed. Toxicity and response were evaluated per procedure during 3 months of follow up. Toxicity were all clinical and laboratory adverse events graded according to CTC-AE v4.03. Radiological response was defined according to RECIST 1.1 and/or nRECIST. Clinical response was defined as a decrease in use of somatostatin analogues, diarrhoea or flushes. Biochemical response was defined as >50% decrease in Chromogranin A.

Results: Eighty-seven patients (40 males) with a median age of 60 years under went 123 procedures (90 TAE/33 SIRT). The majority had a gastroentero-pancreatic NET (94%). There was imbalance between the 2 groups: in the TAE group 56% had a small bowel NET and 15% a pancreatic NET, whereas this was 26% respectively 34% in the SIRT group. Furthermore, 61% of the patients who underwent TAE had a functional NET, this was 46% in the SIRT group. Clinical toxicities encountered in the entire cohort were: pain; fever; nausea; vomiting; fatigue; pleural infusion and hepatic infection. Grade 3/4 toxicity occurred in the TAE and SIRT group, respectively; mainly temporary elevated liver enzymes with TAE and one treatment-related death after SIRT, due to ‘radioembolization-induced liver disease’ (REILD). A significant higher clinical response was seen after TAE vs SIRT (88% vs 67%). Biochemical response and radiological overall response rate were comparable: 24% vs 18% respectively 40% vs 45% for TAE vs SIRT. An overall (clinical, biochemical or radiological) response was seen in 86% vs 72% TAE vs SIRT respectively (ns). Progressive disease was seen in the minority of the procedures; 3 after TAE vs 9 after SIRT.

Conclusion: Both TAE and SIRT are safe and effective in treating NET-patients with liver metastases. After TAE more grade 3/4 toxicity occurs, mainly post-procedural elevated liver enzymes, but a higher clinical response is seen as well. SIRT shows less toxicity, although one treatment-related death occurred. Biochemical response was defined as a decrease in use of somatostatin analogues, diarrhoea or flushes. Biochemical response was defined as >50% decrease in Chromogranin A.

Introduction: Hepatocholangiocarcinoma (HCC-ICC) is a rare primary hepatic tumor, which represents both, cholangiocellular and hepatocellular carcinoma (HCC). Only few data exist on prognosis and chemosensitivity of HCC-ICC.

Aims & Methods: The main objective of this retrospective, multicenter study was to evaluate the overall survival (OS), progression free survival (PFS) and prognostic factors in advanced, unresctable HCC-ICC treated by gemcitabine plus platinum based chemotherapy as a first line systematic treatment. Data from 32 patients treated by gemcitabine plus cisplatin were analyzed. All patients received chemotherapy in six French university hospitals between 2008 and June 2016, were retrospectively collected. The diagnosis of chHCC-ICC was based on histological analysis or, in case of typical histology of ICC or HCC, on discordant immunohistochemical finding and/or tumor marker (alpha-fetoprotein, carbohydrate antigen 19-9, carcinoembryonic antigen) serum levels suggesting the other histology. Response rates were defined by RECIST 1.1 criteria. OS and PFS were estimated by Kaplan-Meier method. Prognostic factors were analyzed by Log-rank test in univariate analysis and by Cox model in multivariate analysis with p<0.05 considered as significant difference. Statistical analysis was performed using Graph Pad Prism 6.

Results: Forty patients were included (70% men, median age 66 years [extremes 32-88] : HCC-ICC was biopsy proven in 55% and diagnosed radiologically or histologically in 45% of patients). Twenty-three (57.5%) of patients had at least one metastatic synchronous lesion. Twenty-nine (72.5%) patients were treated by gemcitabine (gem) and oxaliplatinum (GEMOX), 9 (22.5%) by GEMOX plus bevacizumab, 2 (5%) by gem/cisplatin. Eighteen patients (45%) received second line of systemic treatment (FOLFIRI (n=7), Capetabine (n=4), LVSFU2 (n=2), LVSFU2-Cisplatin (n=1), Cyclophosphamide (n=1), Sutent (n=1), Sorafenib (n=1) and anti-PD-L1 therapy (n=1). In the first line, patients received a median of 10 cycles of chemotherapy (extremes 1-28). RECIST criteria were reported in 35 patients. Among them, 9 patients (25.7%) had partial response, 18 patients (51.4%) had stable disease, and 8 patients (22.8%) had tumor progression at first CT scan evaluation. Median PFS and median OS were 9.0 and 15.4 months, respectively. No significant difference was observed according to treatment. In multivariate analysis, significant poor prognostic factors for OS were: positive serology for hepatitis B virus and/or C virus (HR=1.35 IC95%[1.13–13.24], p=0.02), age >70 (HR=3.5 IC95%[1.75–7.54], p=0.007, and ECOG score ≥2 (HR=2.46 IC95%[2.23–6.17], p=0.04).

Conclusion: These data suggest a chemosensitivity of chHCC-ICC to gemcitabine plus platinum-based chemotherapy. These results need to be confirmed in a randomized prospective study.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP309 SQLE DRIVES HEPATOCARCINOGENESIS AND IS A TUMOR-PREDICTIVE TARGET IN NON-ALCOHOLIC FATTY LIVER DISEASE-ASSOCIATED HEPATOCELLULAR CARCINOMA
D. Liu1, C.C. Wong1, H. Chen1, L. Fu2, L. Zhao1, C. Li1, J. Ju Sung1, J. Yu1

Introduction: Due to the obesity epidemic, nonalcoholic fatty liver disease-associated hepatocellular carcinoma (NAFLD-HCC) is an emerging malignancy worldwide. However, the underlying mechanisms and targeted therapy of NAFLD-HCC are still largely unclear. Using transcriptome sequencing, squaramyl synthase epoxidase (SQLE), a rate limiting enzyme in cholesterol biosynthesis, was identified to be up-regulated in NAFLD-HCC.

Methods: We aimed to evaluate the biological function of SQLE in NAFLD-HCC, and assess the chemopreventive efficacy of targeting SQLE in NAFLD-HCC. SQLE expression was determined by qPCR and western blot. Biological function of SQLE was assessed in vitro using hepatocyte-specific Sqle transgenic mice. Therapeutic efficacy of terbinafine, a SQLE inhibitor, was determined in NAFLD-HCC cell lines in vitro, and nude mice and Sqle-transgenic mice models in vivo.

Results: We performed transcriptome sequencing analysis of 18 paired NAFLD-HCC and adjacent normal tissues. SQLE was a top outlier gene and was overexpressed in 16 out of 17 paired NAFLD-HCC samples. SQLE mRNA up-regulation was validated in an independent cohort of 27 paired NAFLD-HCC and adjacent normal samples (P=0.01). In two obesity-induced NAFLD-HCC mouse models, Sqle was also up-regulated. We next investigated the biological function of SQLE in vivo. Wild-type and hepatocyte-specific Sqle transgenic mice were injected with a single dose of diethylnitrosamine (DEN) and fed a high fat-high cholesterol diet (HFHC). At 25 weeks of age, spontaneous HCC formation was observed in 9 out of 10 Sqle mice, but only in 2 out of 10 wild type mice (p=0.003). Sqle tg mice also developed a higher tumor multiplicity (p<0.01). Histological examination confirmed the formation of HCC in the livers of Sqle tg mice. Consistent with the formation of HCC, α-fetoprotein (AFP), higher AST and ALT were higher in Sqle tg mice. Immunohistochemical pericellular fibrosis, as determined by Sirius Red staining, was highly elevated in Sqle tg mice. Collectively, these data demonstrated that SQLE exacerbated HFHC diet-induced liver inflammation and accelerated HCC formation in mice.

Finally we tested the therapeutic efficacy of terbinafine, a SQLE inhibitor, in the treatment of NAFLD-HCC. Terbinafine inhibited the cell proliferation NAFLD-HCC cell lines in vitro and suppressed the growth of tumor xenografts in nude mice. In DEN-injected and HFHC diet-fed Sqle tg mice, terbinafine (49 mg/kg) received systemic treatment reduced tumor growth and multiplicity (P=0.021). These results indicate that therapeutic targeting of SQLE is a promising approach for the treatment of NAFLD-HCC.

Conclusion: We established SQLE as an oncogene in NAFLD-HCC. SQLE promotes HCC in NAFLD-HCC cells and Sqle tg mice. SQLE inhibitor terbinafine
confers a clear therapeutic benefit in cell lines and animal models of NAFLD-
HF [26–28], corroborating SQuEeL as a therapeutic target in this subset of HCC.

Introduction: Exocrine/ductal pancreatic differentiation from human pluripotent stem cells has been an ongoing process, from 3D to 2D in organoid form, from animal to human experiments. Dr Wallace is a colleague in this field of research.

Results: We systematically compared various PO transplantation niches (pancreas, kidney, anterior eye chamber). Tri-lineage differentiation potential of pancreatic progenitor cells, which gave rise to pancreatic organoids, is shown by immunohistochemistry for amylase, CK19 and insulin. Consequently, detailed immunophenotyping of the grafts was performed. In line with morphological appearance acinar-like cells stained positive for several acinar marker genes such amylase and chromogranin C, while ductal structures expressed cytokeratin 19 to assess the maturity of the grafts, co-staining for acinar and ductal lineage markers with various progenitor cell markers such SOX9, PDX1 and NKX6.1 were performed. These data indicate a developmental stage of a human Carnegie Stage 2 to 3. Staining for smooth muscle actin (α-SMA) also revealed signs of neovascularisation in the grafts.

Conclusion: Xenotransplantation of human pancreatic organoids into the anterior eye chamber an/or the pancreas might become a future and humanized model system.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aims & Methods: Xenotransplantation assays were applied to systematically transplant pancreatic organoids into immunodeficient mice aiming for the ultimate niche to host a human pancreas in mice.

Results: We systematically compared various PO transplantation niches (pancreas, kidney, anterior eye chamber). Tri-lineage differentiation potential of pancreatic progenitor cells, which gave rise to pancreatic organoids, is shown by immunohistochemistry for amylase, CK19 and insulin. Consequently, detailed immunophenotyping of the grafts was performed. In line with morphological appearance acinar-like cells stained positive for several acinar marker genes such amylase and chromogranin C, while ductal structures expressed cytokeratin 19 to assess the maturity of the grafts, co-staining for acinar and ductal lineage markers with various progenitor cell markers such SOX9, PDX1 and NKX6.1 were performed. These data indicate a developmental stage of a human Carnegie Stage 2 to 3. Staining for smooth muscle actin (α-SMA) also revealed signs of neovascularisation in the grafts.

Conclusion: Xenotransplantation of human pancreatic organoids into the anterior eye chamber an/or the pancreas might become a future and humanized model system.

Introduction: Endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) is an established method for obtaining samples from solid tumors. EUS-FNB is also a very useful tool in the diagnosis of ductal lesions, such as IPMN.

Methods: The results of a study on 33 consecutive patients who underwent both conventional EUS-FNA and paired EUS-FNB-SC with the tandem controlled trial started in May 2016 and is ongoing. Consecutive patients who underwent both conventional EUS-FNA and paired EUS-FNB-SC and were pancreatic adenocarcinoma (n = 11). The median history score per pass in EUS-FNA was 2 (sufficient for cytology but not for histology) vs 5 (sufficient for adequate histology) in EUS-FNB-SC group for all lesions Table 1. The amount of tissue yield, tumor cellular volume, surface area of core tissue, and adequacy for Foundation Medicine assay obtained on first pass was greater in EUS-FNB-SC group vs EUS-FNA group Table 2. DNA sufficient (using a 1100 ng threshold; Mayo Genomics Core Lab) for whole exome sequencing in the first pass on pancreatic adenocarcinoma was obtained from 74% of FNA and 45% of FNA specimens.

Conclusion: In this ongoing study histology yield and DNA yield was higher in EUS-FNB-SC needle compared to EUS-FNA needle. EUS-FNB-SC needles appear capable of DNA acquisition sufficient to guide precision oncological therapy.

OP313 COMPARISON OF AMERICAN GASTROENTEROLOGICAL ASSOCIATION, INTERNATIONAL ASSOCIATION OF PANCREATOLOGY, AND AMERICAN COLLEGE OF RADIOLOGY GUIDELINES FOR DIAGNOSIS OF MALIGNANT PANCREATIC CYSTS

Beth Israel Deaconess Medical Center, Harvard Medical School, Boston/United States of America

Contact E-mail Address: mmizrahi@bidmc.harvard.edu

Introduction: Guidelines published by the American Gastroenterology Association in 2015 (AGA), International Association of Pancreatology in 2006 (Sendai) and in 2012 (Fukuoka), and American College of Radiology 2010 (ACR) are used by clinicians for the management of pancreatic cysts. Guideline recommendations differ from one another and it is not known which guideline is best able to identify patients with malignant pancreatic cysts for surgery.

Aims & Methods: Clinical guidelines were reviewed, and risk-factors associated with malignant cysts were identified. All patients who underwent surgery for mucinous pancreatic cysts between 2002–14 were included, and surgical pathology served as criteria standard. A single expert radiologist, blinded to final cyst pathology, reviewed imaging studies for all study patients. Guidelines were applied to this data to determine their performance in identifying malignant cysts. EUS results were not incorporated.

Results: During study period, 166 patients with mucinous pancreatic cysts underwent surgery. Of these 61 patients (36.7%) had a malignant cyst. Using information from imaging studies, accuracy for malignant cyst diagnosis for clinical guidelines was: 81.3% for AGA, 78.3% for Fukuoka, 63.9% for Sendai, and 2% for ACR.

Introduction: Although EUS-guided biliary drainage (EUS-BD) is increasingly reported as one of treatment options for malignant biliary obstruction (MBO), with a high technical success rate and an acceptable complication rate, its long-term outcomes are not fully discussed. The aim of this multicenter prospective study is to evaluate long-term outcomes of EUS-BD and clarify the role of re-interventions for stent dysfunction or stent-related complications.

Aims & Methods: Consecutive patients undergoing EUS-BD for unresectable MBO were retrospectively studied. Data on recurrent biliary obstruction (RBO) and other stent-related complications were extracted. Cumulative time to RBO was calculated by a Kaplan-Meier method. Procedures details of re-interventions for RBO and other complications were also described including its route i.e. EUS-BD, transpapillary or percutaneous approach.

Results: Between Aug 2011 and Dec 2016, EUS-BD was performed in 96 pts (EUS-HGS in 82 and EUS-CDS in 14, covered metal stent in 95 and plastic stent in 1) at 4 tertiary referral centers. Biliary drainage prior to EUS-BD had been performed in 54%. The major cause of MBO was pancreatic cancer (52%) and biliary tract cancer (28%). Duodenal invasion (64%) and surgically altered anatomy (25%) were two major reasons for EUS-BD. MBO was distal in 76% and hilar in 24%. A median procedure time was 35 minutes. Technical success rate was 98% with two technical failures (1 stent misplacement and 1 failed insertion of CDS). The incidence of RBO was 36% and a median cumulative time to RBO was 6.8 (95%CI, 4.3–9.7) months. The causes of RBO were non-tumor related (hyperplasia 17%, migration 9%, sludge 5%, reflux 2% and kink 2%), other than de novo stricture (2%). Re-intervention for RBO was successfully performed via EUS-BD route in 89% (31/35). The types of procedures were 22 stent-in-stent, 5 balloon sweep, 3 stent exchange and 1 additional antegrade stenting. Other re-interventions were 2 conversion to transpapillary stenting, 1 conversion from CDS to HGS and 1 PTBD. The incidence of other complications was 29% (5 cholecystitis, 5 cholangitis, 5 peritonitis, 5 bleeding, 5 abdominal pain, 2 fever and 1 stent misplacement).

Conclusion: The incidence of RBO necessitating re-interventions was not rare in EUS-BD for MBO but re-intervention via EUS-BD route was technically feasible in most cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP315 EUS-GUIDED RADIOFREQUENCY ABLATION (RFA) FOR PANCREATIC NEUROENDOCRINE TUMOR (NET) AND PRE-MALIGNANT INTRADUCTAL PANCREATIC MUCINOUS TUMOR (IPMN): FIRST RESULTS OF PROSPECTIVE MULTICENTER STUDY

Introduction: Pancreatic NET and IPMN with worrisome features required surgical resection due to the respective risk of lymph nodes/metastatic widespread or invasive adenocarcinoma. EUS-guided antitumoral treatments, mainly based on alcohol injection, have been recently developed with the risk of acute pancreatitis due to uncontrolled diffusion and poorly evaluated efficacy. The aim of this prospective study was: primary endpoint, to evaluate the safety of EUS-RFA in such pancreatic tumors; secondary endpoint: to assess the efficacy in a one-year follow-up.

Aims & Methods: This study was conducted as a prospective multicenter study planned to include 30 patients in a two years period with a one-year follow-up and intermediate results are reported. Patients with NET pancreatic tumor less than 2cm or with pre-malignant pancreatic cystic tumor (side branches IPMN with worrisome features or mucinous cystadenoma (MCA)) were included if they were not operable or refuse surgery. Since October 2015, all the patients have been included, the last one being in January 2017. They were 16 males and 14 females with a 54.4 years mean age (49–84 years). EUS-RFA was performed with a 19G RFA needle (Starmed, Taewong, Korea) applying a 50 W current until reaching 100 Ohms impedance (white bubbles appearance). Patients were followed with MRI and/or EUS.

Results: 12 patients had 14 NET with a 13.4 mm size (8–20 mm) located in 3 cases to the head, 6 to the body, 1 to the tail, respectively. 18 patients had cystic tumor (17 IPMN, 1 MCA) with a 29.1 mm mean size (9–60 mm) located in 14 cases to the head, 3 to the body, 1 to the tail, respectively. 10 out of them had mural nodules and 4 increased thickness of the cyst wall. The mean duration of hospital stay was 4 days (2–6). 3 complications (10%) occurred, two with the first patients included: one mild pancreatitis, one small bowel perforation surgically managed, one pancreatic ductal stenosis endoscopically managed. After these initial patients, the protocol was improved with prophylactic administration of NSAID and antibiotics and emptying the cyst fluid content leading to dramatic decrease of further complication (3.5%). Three patients experienced mild abdominal pain without acute pancreatitis successfully managed with paracetamol. 10 patients among 12

Disclosure of Interest: the Eckardt score may be used as a surrogate marker for HRQOL in patients. An association was seen between Eckardt score and all HRQOL domains. The use of HRQOL measured by the SF-36 survey at both short and long-term follow-up. A strong and significant change in Eckardt score. POEM also improved all dimensions of HRQOL as compared with baseline.

Overall, mean Eckardt score decreased from 7.8 to 3.0 after POEM. The model analysis showed a significant association between Eckardt scores and all HRQOL domains (Table 1).

Conclusion: POEM improves symptoms of achalasia as traditionally assessed by changes in Eckardt score. POEM also improved all dimensions of HRQOL as measured by the SF-36 survey at both short and long-term follow-up. A strong association was seen between Eckardt score and all HRQOL domains. The use of the Eckardt score may be used as a surrogate marker for HRQOL in patients who have undergone POEM for achalasia.

Submucosal Endoscopy: Indications, Techniques and Outcomes - Room B2

**OP316 Life After Peroral Endoscopic Myotomy (POEM): Quality of Life and Its Association with Eckardt Score**

Y. Perbani1, J. Suarez2, L. Mramba3, D. Yang1, P. Draganov2
1 Medicine, University of Florida, Gainesville/United States of America
2 Peter Draganov, draganov@medicine.ufl.edu

**Introduction:** Peroral endoscopic myotomy (POEM) is an endoscopic technique for the treatment of achalasia and esophageal spastic disorders. The Eckardt score has been traditionally used as a clinical parameter to assess the efficacy of the procedure. The association between the Eckardt score and health-related quality of life (HRQOL) in POEM patients has not been fully elucidated.

**Aims & Methods:** (1) To evaluate the effect of POEM on short and long-term QOL and to (2) assess the association between QOL and Eckardt scores over the study period. Single-center prospective cohort study of consecutive POEM cases at the University of Florida during a 5-year period (2011–2016). Both Eckardt scores and HRQOL measured by the Short Form-36 Health Survey (SF-36) were obtained at baseline, and at various intervals post-POEM (1-3 months; 6-9 months; 12 months and beyond). The SF-36 form consists of 8 dimensions, which include: General Health; Bodily Pain; Social Functioning; Emotional Well-Being; Energy/Fatigue; Role limitation due to emotional problems; Role limitation due to physical health and Physical functioning. These eight domains were then grouped into two separate composite scores of overall physical and mental health. Comparison of means scores of Eckardt, Dysphagia and HRQOL were originally described using a univariate linear regression. Pairwise comparisons of means by visit were corrected for multiple testing using Bonferroni method. The association between Eckardt scores and HRQOL were performed by using a Linear mixed model analysis.

**Results:** POEM was performed in 143 consecutive patients (54% male; mean age 56.9 ± 17.9 years) by a single gastroenterologist in an endoscopy suite during the study period. Most patients had achalasia type II (82; 57.3%) and 12 (8.4%) had prior surgical myotomy. Mean total procedure time was 73.4 ± 30.2 minutes. Overall, mean Eckardt score decreased from 7.8 ± 2.5 to 0.9 ± 1.4 after POEM (p < 0.001). Composite HRQOL dimension scores improved from baseline and held statistical significance over various follow-up lengths after POEM. Mixed model analysis showed a significant association between Eckardt scores and all HRQOL domains (Table 1).

**Conclusion:** POEM improves symptoms of achalasia as traditionally assessed by changes in Eckardt score. POEM also improved all dimensions of HRQOL as measured by the SF-36 survey at both short and long-term follow-up. A strong association was seen between Eckardt score and all HRQOL domains. The use of the Eckardt score may be used as a surrogate marker for HRQOL in patients who have undergone POEM for achalasia.

Endoscopic Management of GI Bleeding: What is New? - Room E4

**OP317 Technical Feasibility of Endoscopic Submucosal Dissection for Local Failure After Chemoradiotherapy or Radiotherapy for Esophageal Squamous Cell Carcinoma**

K. Nakajo1, T. Yano1, Y. Yoda1, K. Horii1, K. Takashima1, K. Shimura1, Y. Ohno1, H. Iketatsu1
1 Department Of Gastroenterology and Endoscopy, National Cancer Center Hospital East, Kashiwahoana, Kashiwa, Chiba, Japan

**Contact E-mail Address:** knakajo@east.ncc.go.jp

**Introduction:** Endoscopic submucosal dissection (ESD) has been widely accepted as the effectiveness and safe procedure for treatment naive superficial esophageal squamous cell carcinoma (ESCC). However, there are few reports to evaluate the technical feasibility of ESD for local failure after radiotherapy (RT) for ESCC after CRT or RT compared with conventional ESD.

**Aims & Methods:** We aimed to evaluate the technical feasibility of ESD for local failure after CRT for ESCC comparing with ESD for RT naive ESCC or for other primary lesions within RT field. Consecutive patients who were treated with ESD between December 2009 and August 2016 at our institution were retrospectively investigated. Local failure was defined as a recurrent or a residual tumor just at the post RT primary site. We classified the cohort into 3 groups as follows: A group: pts with local failure, B group: pts with other primary lesions within RT field, C group: pts with radiation naive superficial ESCC. We comparatively evaluated procedure completion rate, on block resection rate, complete resection rate (en block resection with negative of cancer at the margin), procedure time and incidence of major complications for the assessment of feasibility between three groups.

**Results:** In total 322 pts with 605 lesions were analyzed, and A group included 25 (40 lesions), B group included 16 pts (22 lesions), and C group included 481 pts (556 lesions). The characteristics of pts in A, B, and C group were as follows: the median age (years)=70.5, 73.5, 70. male/female=17/8, 15/1, 41/64. Mean tumor size (=standard deviation) was 15.7 (=9.9) mm, 17.7 (=10) mm, 29.1 (=22.3) mm. and there was significant differences among groups. (P<0.001), and between B group and C group (P<0.001). There were no significant differences in procedure completion rate between three groups (92.6% vs 100% vs 100%), 2 lesions in 2 pts were incomplete of ESD procedure due to severe fibrosis and switched to photodynamic therapy (PDT). When en block resection rate were similar between 3 groups (96% vs 100% vs 100%), complete resection rate of A group was significantly lower comparing with that of C group (A group vs B group vs C group=60.0%/77.3%/80.4%, A group vs C group=0.0%/100%/100%). Mean procedure time (=standard deviation) was 63 (=32) minutes, 69 (=27) minutes, 91 (=50) minutes, respectively, and there was significant differences between A group and C group (P=0.006), and between B group and C group (P=0.002). Serious complications involving perforation or bleeding required transfusion were not observed in A group and B group, while severe fibrosis and switched to Photodynamic therapy (PDT). While en block resection was performed in 17 cases of C group (2.8%). However, there was no significant difference in the frequency of complications between three groups.

**Conclusion:** In this study, we showed the technical feasibility of ESD for patients for local failure and for other primary lesions within RT field without major complications compared with conventional ESD. However, it could be technically difficult to complete ESD for local failure after CRT or RT due to severe fibrosis in the submucosal layer in some cases. In such a case, an alternative treatment such as PDT should be considered.

was continued till 12-24 h hours after admission when the definitive endoscopy was performed. Patients randomized in Group 2 (Non-Hemospray) were treated by medical treatment followed by the definitive endoscopy 12-24 hours from admission. 

Urgent Endoscopy within 60 minutes was performed in any patient who failed to achieve clinical hemostasis within the first 24 hours.

Results: One hundred five patients were randomized for suspected AVB; 19 were excluded due to non-variceal source of bleeding; 86 patients were randomized: group 1 (n = 43), group 2 (n = 43). Severity of liver disease was similar (Child-Pugh class B 49% in both groups, Child-Pugh class C in 15% and 25% in group 1 and 2, respectively). Clinical hemostasis was achieved in 98% in group 1 and 70% in group 2 (P = 0.0005). Hemospray® failed to stop spurter gastric variceal bleeding in 4 patients who were treated by cyanoacrylate injection. Endoscopic hemostasis was achieved in all patients of group 1. Despite the medical treatment, all patients of group 2 had fresh blood into the stomach at the time of endoscopy and 30% of them had to have urgent endoscopy to control relapsing overt hemostasis. A significant improvement on survival at 30 days was observed in the Hemospray group compared to SOC group (93% vs 67%; p = 0.0029). We did not see any difference on survival in the hospitalization period (5 days) (95% vs 91%; p = 0.0392).

Conclusion: Hemospray® application at 2 hours of admission improves clinical and endoscopic hemostasis of AVB. This bridge therapy may have an impact on outcome in 30 days in patients with AVB.

Introduction: There is increasing evidence of the benefits of low-dose aspirin for primary prevention of colorectal cancer (1), in addition to established benefits on cardiovascular prevention. Estimates of the incidence of upper and lower gastrointestinal bleeding are needed to inform adequate benefit-risk assessment.

Aims & Methods: Using The Health Improvement Network primary care database, we estimated the association between new use of low-dose aspirin (75–300 mg/day) and upper/lower gastrointestinal bleeding (UGIB/LGIB) by case-fatalty (fatal case = death within 30 days), hospitalization/referral status, bleeding location, and aspirin dose and duration. Among persons aged 40–84 years from 2000–2012 with no previous low-dose aspirin use, 199, 049 new users of low-dose aspirin were identified. Each member was matched to a person free of low-dose aspirin on that day by age, sex, primary care practitioner visits in the previous year and time since study entry. Cohorts (mean age at entry, 64 years) were followed (max. 14 years, median 5.4 years) to identify cases of UGIB/LGIB, with validation through manual review of patient records and linkage to hospital data. A nested case-control analysis was conducted using cases and controls from both cohorts. To account for temporal changes in aspirin exposure, we used ‘as-treated’ and ‘as-used’ low-dose aspirin. Controls (n = 10,000 for LGIB) were frequency-matched to cases by age, sex, calendar year. Adjusted rate ratios (RRs) with 95% confidence intervals (CIs) were calculated for current low-dose aspirin use (0–30 days before the index date [UGIB/ LGIB]; no use for cases, random date for controls); reference group was never use.

Results: There were 1843 UGIB cases and 2763 LGIB cases; 60% of UGIBs and 28% of LGIBs were hospitalized (remaining cases were referred only). Low-dose aspirin was associated with significantly increased risks of non-fatal UGIB/LGIB, hospitalized as well as referred (but not hospitalized) UGIB/LGIB, but not fatal UGIB/LGIB (Table 1). RRs (95% CI) by UGIB location were 2.33 (1.69–3.21) for duodenal ulcers, 1.94 (1.46–2.58) for gastric ulcers and 1.59 (1.25–2.02) for mucosal erosions; RRs (95% CI) for LGIB were 2.33 (1.96–2.77) for diverticular diseases and 3.09 (2.13–4.50) for polyps. By daily dose of aspirin, RRs (95% CI) for UGIB were 1.58 (1.37–1.83) for 75 mg/day and 2.12 (1.53–2.93) for 150–300 mg/day; estimates for LGIB were 1.98 (1.76–2.24) for 75 mg/day and 1.98 (1.59–2.62) for 150–300 mg/day. Around 95% of low-dose aspirin use was at 75 mg/day. The magnitude of the increased LGIB risk was similar with all durations used, while there was a suggestion of a greater risk of UGIB in the first months after starting treatment: RRs (95% CI) for LGIB were 2.20 (1.74–2.78) for 3 months and 1.99 (1.72–2.21) for <3 months; and for UGIB were 2.57 (1.93–3.42) for <3 months and 1.54 (1.33–1.78) for ≥3 months.

Table: RRs (95% CIs) for risk of UGIB/LGIB associated with current use of low-dose aspirin versus never use (nested case-control analysis).

Index date: Date of bleeding event for cases, random date for controls *Adjusted by the matching variables (age, sex and calendar year), number of primary care physician visits in the year before the index date, smoking, alcohol consumption, prior LGIB, prior unspecified GIB, use of non-steroidal anti-inflammatory drugs, proton pump inhibitors, clopidogrel, and warfarin, and the following for

Conclusion: Use of low-dose aspirin is associated with a significantly increased risk of UGIB/LGIB overall (both hospitalized and referred cases) but not with fatal UGIB/LGIB. Our results also suggest a possible dose–response relationship between low-dose ASA and UGIB but not LGIB.

Introduction: Endoscopic submucosal dissection (ESD) for gastric neoplasms has been established as a standard treatment in many countries. However, post-ESD bleeding is still one of the major complications which are impossible to completely avoid. There is significant difference between the two groups (the endoscopic tissue shielding method with polyglycolic acid (PGA) sheets and fibrin glue for the mucosal defect after ESD). In our pilot study we have demonstrated that this method may reduce the risk of post-ESD bleeding, but there have been no reports which provide significant evidence concerning this issue to date.

Aims & Methods: This is a prospective multicenter open-label RCT conducted in six hospitals across Japan to investigate the efficacy of the PGA shielding method for post-ESD bleeding. Out of a total of 223 gastric ESD procedures performed with a high-risk for post-ESD bleeding were enrolled in this study. High-risk patients were defined as follows: 1) those expected to undergo large mucosal resection (≥40 mm) or 2) those with regular intake of antithrombotic agents.

Before ESD the patients were allocated to PGA group or non-PGA group at a ratio of 1:1 by a minimization method through a web-based system. The enrolled patients in both groups received proton pump inhibitor for 4 weeks from the day before ESD, and underwent coagulation of visible vessels on the ESD–induced ulcer floor. And then, in the PGA group, PGA sheets were placed onto the ulcer floor and stuck with fibrin glue. 2 days after ESD, soft diet was started. Post-ESD bleeding was defined as follows: 1) hematemesis, melena or a hemoglobin decrease ≥2 g/dL and 2) emergency endoscopy revealed active bleeding or accumulated blood in the stomach. When a patient presented with post-ESD bleeding, endoscopic hemostasis was performed. The primary endpoint was the post-ESD bleeding rate.

Results: A total of 68 patients were assigned to the PGA group and 72 patients to the non-PGA group. After excluding 3 patients (the ESD cessation: 2, consent withdrawal: 1), 67 patients in the PGA group and 70 in the non-PGA group were included in the intention to treat analysis. Post-ESD bleeding occurred in 3 patients (4.5%) in the PGA group and 4 (5.7%) in the non-PGA group. There was no significant difference between the two groups (P=0.857). Immediate post-ESD bleeding episodes occurred in 4/3 patients in the PGA group and 14/15 patients in the control group. One case of delayed bleeding was observed in both groups.

Conclusion: The present study could not demonstrate a significant effect of the PGA shielding method on the prevention of post-ESD bleeding although this method has the possibility of preventing late-phase bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP322 SIGNIFICANT REDUCTION OF POSTINTERVENTIONAL HAEMORRHAGE AFTER RESECTION OF LARGE DUODENAL ADENOMA BY THE USE OF A HEMOSTATIC POWDER

T. Mueller, M. Knabe, J. Wetzka, C. Ell, A. May

Medical Clinic II, Sana Klinikum Offenbach, Offenbach/Germany

Contact E-mail Address: bbc2@gmx.net

Introduction: Against the background of the relatively high rates of relevant bleedings after endoscopic resection depending on the size of the duodenal adenoma, the value of a hemostatic powder was examined.

Aims & Methods: This is a prospective, randomised study with (Group A) and without (Group B) administration of a hemostatic powder after resection. Only large duodenal adenomas with a size ≥20 mm were included. The resection was performed by means of a snare after prior injection. Intraprocedural bleedings were treated by injection and coagulation. Post-interventional Hb-control and an EGD on the following day were documented, whereby bleeding stigmata (Forrest IIa/Ib) were recorded. The sample size calculation showed 21 patients per arm with a reduction in bleeding by one third. Minor bleeding was defined as Hb decrease less than 2 g/dl and bleeding stigmata during wound control the next day. The major bleeding was defined as Hb drop ≥2 g/dl.

Results: Between December 2014 to February 2017, 39 suitable patients were presented, 38 patients (14, 24 1c, average age 65 years) of which were randomized. Two patients dropped out of the study. The etiology of adenomas was sporadic in 64%, and 36% had FAP. The average adenoma size was 33 ± 11 mm (18–40 mm). The localization of the duodenal adenomas was 32% suprapapillary, 26% at the papilla, and 42% infrapapillary. In each case 18 patients received either a hemostatic powder or not. In Group A (with hemostatic powder) a minor hemorrhage was detected in 9/18 and a major hemorrhage in 2/18. In the Group B (without hemostatic powder) a minor hemorrhage occurred in 4/18 and major hemorrhage in 3/18 patients. After an interim analysis, the study was terminated prematurely if the effect of the hemostatic powder was missing.

Conclusion: By applying a hemostatic powder no significant reduction of relevant post-bleeding after endoscopic resection of large duodenal adenomas ≥20 mm can be achieved.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP323 EFFECT OF PROPHYLACTIC CLIP APPLICATION FOR THE PREVENTION OF POSTPOLYPECTOMY BLEEDING IN LARGE PEDUNCULATED COLONIC POLYPS: A RANDOMIZED, CONTROLLED MULTICENTER TRIAL

Introduction: Although endoscopic colonic polypectomy has been an established procedure for a long time, the risk of bleeding is still higher after resecting of pedunculated polyps, because of the presence of a large artery in the stalk. Preventive methods such as endoloop and epinephrine injection have been proposed in the management of postpolypectomy bleeding in large colonic polyps. For prophylactic clip, there was no randomized controlled study assessing the efficacy in prevention of postpolypectomy bleeding for the large pedunculated colon polyps.

Aims & Methods: The aim of this randomized controlled trial was to confirm the efficacy of application of prophylactic clip in the prevention of postpolypectomy bleeding in large pedunculated polyps. A total of 183 patients who had pedunculated colorectal polyps, with heads larger than 10 mm and stalks larger than 5 mm in diameter, were included. In clip group, hemoclips were applied to the base of the stalk, followed by conventional snare polypectomy. In control group, conventional snare polypectomy was done without any preventive management. Immediate and delayed bleeding complications were analyzed.

Results: A total of 200 polyps were included in the study (99 in the clip group and 101 in the control group). Clip application was possible in all the cases in the clip group. There were 5 cases of bleeding in the clip group (5.1%) and 15 cases in the control group (14.9%) (P=0.047). Immediate post-ESD bleeding episodes occurred in 4/5 polyps in the clip group and 14/15 polyps in the control group. One case of delayed bleeding was observed in both groups.

Conclusion: The application of a prophylactic clip is effective in the prevention of postpolypectomy bleeding in large pedunculated colon polyps.

OP224 THE RISK OF PROXIMAL DISEASE EXTENSION IN PATIENTS WITH LIMITED UC COLITIS IN A PROSPECTIVE EUROPEAN POPULATION-BASED INCEPTION COHORT – THE ECCO-EPICOM COHORT

Introduction: Ulcerative colitis (UC) is a progressive and dynamic disease and many patients will experience an extension of their initial disease location. Disease extent is the most important factor determining disease prognosis over the long-term. As only few population-based studies have investigated the disease extension and subsequent risk of surgery in UC, we sought to investigate this in the European population-based EpCoM-cohort.

Aims & Methods: The EpCoM-cohort is a population-based cohort of unselected patients with inflammatory bowel disease diagnosed in 2010 and Eastern and Western European centres. Patients were followed prospectively for five years and clinical data were captured throughout the follow-up period and entered in a validated web-based database. Disease extension was defined in patients with limited UC at diagnosis (proctitis, E1 or left-sided, E2) as a progression from the initial extent defined by endoscopy or surgery. The risk of colectomy was assessed in all incident patients. Associations between progression or colectomy and multiple covariates (age, gender, initial disease extent, disease delay, smoking status, increase in extent, geographic region, treatment) were analysed by Cox regression analyses using the proportional hazard assumption.

Results: Out of a total of 717 incident UC patients, 435 (61%) had E1 or E2 at diagnosis. Extension and disease progression were followed-up in patients with limited UC as shown in Table 1. During the follow-up period, 67 (16%) patients with E1/E2 progressed to E3, and 23 (16%) patients with E1 progressed to E2. Only the need for systemic prednisolone at diagnosis (HR: 0.4 CI95%: 0.2–0.8) and treatment with immunosuppressants and/or biologics (HR: 19.8 CI95%: 7.8–50.6) were associated with the risk of extension. During follow-up, a total of 43 (6%) patients had a colectomy. Of patients with E1/E2 as initial extent a total of 19 (4%) patients had a colectomy. Progression from E1/E2 to E3 was a significant risk factor for colectomy (HR 4.4 CI95%: 1.6–12.4). No difference in the results was found between Eastern and Western European patients.

Table 1: Disease extent in ulcerative colitis at diagnosis and follow-up

<table>
<thead>
<tr>
<th>Disease extent</th>
<th>At diagnosis</th>
<th>At follow-up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proctitis (E1)</td>
<td>E1, proctitis</td>
<td>E1, proctitis</td>

<td>E2, left-sided</td>
<td>E2, left-sided</td>
</tr>
<tr>
<td>Extensive (E3)</td>
<td>E3, extensive</td>
<td>E3, extensive</td>
</tr>
</tbody>
</table>

Conclusion: In this European population-based inception cohort of unselected UC patients, one out of five patients with proctitis or left-sided colitis at diagnosis experienced a progression in disease extent after five years of follow-up. The risk of colectomy was increased in patients who progressed to extensive colitis. Only treatment during follow-up as an indicator for disease severity was identified as a predictor for disease extension, thus highlighting the need for new historical or serological markers in order to identify patients at risk for disease progression.

OP235 EARLY FIBROSTENOSIS IN CROHN’S DISEASE IS ASSOCIATED WITH MULTIPLE SUSCEPTIBILITY LOCI ON IMMUNOCIP ANALYSIS

Aims & Methods: In this multicenter, retrospective nested case-control study, performed at the University Hospitals of Ghent and Leuven, computed tomography (CT)- and magnetic resonance imaging (MRI) from CD patients obtained between 2002 and 2016 were examined for the presence of fibrostenotic disease. Patients with early fibrostenosis, defined as a the presence of bowel thickening with luminal narrowing and pretedstent dilation on CT/MRI occurring within 5 years following diagnosis of ileal or flexoece disease (Montreal L1 or L3), and with available Illumina Immunochip data were included. The control cohort consisted of inflammatory CD patients, also Montreal L1 or L3, without arguments for fibrostenotic disease during at least 10 years follow up. Allelic association was assessed using the PLINK v1.07 software.

Results: In total, 3024 CT or MRI scans of 2042 CD patients were screened. 112 patients were selected because of positive arguments for fibrostenosis occurring within 5 years of diagnosis. Of these, Immunochip data were available in 60 cases, and 49 (82%) had confirmed stenosis by histopathology. 343 inflammatory CD controls with genotype data were included in the analysis. Of the 156,500 SNPs analysed, only rs35223850 in the IL12R gene reached a statistically suggestive significance level of P < 5 × 10^{-6}, including rs11630771 in the IL23R gene, which is of particular interest as this gene has previously been associated with systemic sclerosis.

Conclusion: Fibrostenosis is a common complication of Crohn’s disease (CD) occurring in about one-third of patients. Although the pathophysiology of intestinal fibrosis is incompletely understood, evidence suggests a genetic contribution. Previous genetic association studies and candidate gene studies with fibrostenotic CD were based on clinical definitions which lack both sensitivity, specificity and have a high inter-observer disagreement. Additionally, the recent genotype-phenotype analysis by the IBDGC did not consider the time to development of fibrostenotic disease. As the genetic risk may be more important in patients with early fibrostenosis, in this study we aimed to identify novel genetic markers by focusing on early fibrostenotic disease.

Disclosure of Interest: Fibrostenosis is a common complication of Crohn’s disease (CD) occurring in about one-third of patients. Although the pathophysiology of intestinal fibrosis is incompletely understood, evidence suggests a genetic contribution. Previous genetic association studies and candidate gene studies with fibrostenotic CD were based on clinical definitions which lack both sensitivity, specificity and have a high inter-observer disagreement. Additionally, the recent genotype-phenotype analysis by the IBDGC did not consider the time to development of fibrostenotic disease. As the genetic risk may be more important in patients with early fibrostenosis, in this study we aimed to identify novel genetic markers by focusing on early fibrostenotic disease.
Conclusion: This carefully phenotyped study reveals an important role for genetic contribution to early development of fibrostenotic complications in CD. Our data suggest a role for M1S1B8P and the SP1 transcription factor as well as the IL23 pathway in the pathogenesis of early intestinal fibrosis.

OP326 THE ROLE OF THE IKBA GENE FAMILY MEMBER NFKBIZ IN COLITIS-ASSOCIATED CANCER

G. Ito1, D. Esser2, J. Kupfer1, R. Sheibani1, S. Schreiber3, P. Rosenstiel1
1Institute of Clinical Molecular Biology, Christian-Albrechts-University Kiel, Kiel, Germany
2Institute for Experimental Medicine, Christian-Albrechts-University Kiel, Kiel, Germany

Contact E-mail Address: g.ito@ikmb.uni-kiel.de

Introduction: Inflammatory bowel disease (IBD) is a relapsing-remitting chronic inflammatory disorder. Importantly, the risk of developing colorectal cancer is increased in IBD patients with chronically active disease. Colitis-associated cancer (CAC) has different characteristics compared to sporadic colorectal cancer, such as onset of carcinogenesis in younger patients. To investigate the genetic basis for these differences, we used the AOM/DSS murine model of CAC. Using whole exome, as well as the whole transcriptome sequencing of tumor and colonic non-tumor samples, we determined the mutational landscape to identify recurrent mutations, which may be of functional relevance for the malignant transformation. Using this approach, we identified several tumor-associated variants in the NFKBIZ gene. NFKBIZ is a member of the IkBa gene family, and known to be induced by IL1β in hematopoietic cells. However, the precise role of NFKBIZ in the human intestinal epithelial cells (IECs) remains largely unknown.

Aims & Methods: The present study was planned to identify the role of NFKBIZ in IECs. Human and mouse intestinal epithelial cell lines, Caco2, HT29 and MODEK, were employed to analyze the NFKBIZ expression in response to IL1β by immunoblot analysis. To perform functional studies, we created cell lines that are deficient for NFKBIZ by using the CRISPR/Cas9 system. Using this cell line, functional assays were examined by immunoblots and proliferation was tested by MTS assay. To analyze the expression of NFKBIZ in human IECs, gene expression of human biopsy samples was quantified using RNA-sequencing. We also created human organoids from IBD patients and examined the NFKBIZ expression by immunoblot.

Results: In intestinal epithelial cell lines, NFKBIZ was induced by only IL1β. To use the proteasome inhibitor MG132, degradation of NFKBIZ was clearly prevented. These results indicated NFKBIZ degradation was promoted in proteosome. In NFKBIZ-deficient cells, immunoblots showed more LC3 lipidation by autophagy inducer rapamycin addition, and also more CHOP induction by ER stress inducer tunicamycin addition. NFKBIZ-deficient cells showed impaired autophagy and enhanced ER stress, which are associated with chronic inflammation. We could also show that NFKBIZ deficient cells exhibited impaired proliferation by MTS assay. Interestingly, hierarchical clustered heatmap of the differentially expressed genes across IBD-bioy samples showed that expression of NFKBIZ is upregulated in IECs of IBD patients. In addition to cancer cell lines, we also use human organoids as a model. Here, by immunoblot analysis, NFKBIZ is also induced by IL1β stimulation and expression of NFKBIZ is stably upregulated in organoids derived from UC patient.

Disclosure of Interest: All authors have declared no conflicts of interest.

OP327 RORGAMMA-T-EXPRESSING TREGS DRIVE GROWTH OF COLITIS-ASSOCIATED COLORECTAL CANCER BY CONTROLLING IL6 EXPRESSION OF DENDRITIC CELLS

Introduction: Chronic inflammation drives colitis-associated colorectal cancer (CAC), a life-threatening complication of inflammatory bowel disease (IBD). FoxP3+ regulatory T cells (Tregs) co-expressing the Th17-related transcription factor RORgamma-t accumulate in the lamina propria of IBD patients where they are thought to represent an intermediate stage of development toward a Th17 proinflammatory phenotype. However, the role of these cells in CAC is unknown.

Aims & Methods: The phenotypic stability and function of RORgamma-t-expressing Tregs were investigated in Tregs fate mapping reporter and Tregs RORgamma-t conditional knockout mice undergoing the AOM/DSS model of CAC. Tumor development was monitored by endoscopy. Ki67, STAT3 and cytokine expression were assessed by immunohistochemistry and real-time PCR. Tumor-infiltrating Tregs were characterized by flow cytometry. The functional role of CTLA4 and FoxO3 was studied by coculture experiments of tumor-isolated Tregs from wild type or knock-out mice with dendritic cells (DCs) and by in vivo siRNA silencing experiments.

Results: RORgamma-t expression identifies a phenotypically stable population of tumor-infiltrating Tregs. Conditional RORgamma-t knockout mice showed reduced tumor incidence and dysplastic cells exhibited low Ki67 expression and STAT3 activation. Tumor-infiltrating dendritic cells (DCs) produced less IL6, a cytokine that triggers STAT3-dependent proliferative signals in neoplastic cells. RORgamma-t-deficient Tregs isolated from tumors over-expressed CTLA4 and induced DCs to express elevated levels of the transcription factor FoxO3 thus reducing IL6 expression. Finally, in vivo silencing of FoxO3 obtained by siRNA microinjection in the tumors of RORgamma-t-deficient mice restored IL6 expression and tumor growth.

Conclusion: These data demonstrate that RORgamma-t-expressed Tregs sustains tumor growth by leaving IL6 expression in DCs unchecked.

Disclosure of Interest: All authors have declared no conflicts of interest.

DISEASE IN A PROSPECTIVE MULTICENTER NESTED CASE-CONTROL STUDY

Aims & Methods: The aim of the study was to evaluate the effectiveness of a selected methylation gene panel for the early detection of CRC in high-risk IBD patients. Five genes (EYA4, SLIT2, USP44 and SNOT) were selected from genome-wide DNA methylation analysis using the Illumina HumanMethylation 450k BeadChip in a phase II feasibility study. DNA from 48 IBD patients was selected for the selected panel.

Results: Methylation of the panel was a common phenomenon in IBD-associated neoplasia both in diseased and adjacent healthy tissue (71% and 52% respectively) being this prevalence higher to that of healthy individuals (2/36; 6%; p = 0.001), and even more frequently in the mucosa of IBD patients at high risk of dysplasia or cancer than in patients at low risk (92% vs 57%; OR = 8.83; p = 0.001), being EYA4 and SLIT2 the markers most frequently methylated. In healthy mucosa this difference in methylation levels was also evident (82% vs 15% for high vs low risk respectively (p = 1.25E-05) (Table).

Conclusion: The analysis of this panel of methylation markers may help in the early identification of colorectal dysplasia or cancer in high risk IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

In conclusion, we show that Wnt5b acts on intestinal epithelium by potentiating a TGF-β-dependent EMT response. Its up-regulation in IBD mucosa could promote epithelial cell migration, thus contributing to a regenerative response in the context of tissue injury.

Introduction: Fistulas represent a frequent complication in Crohn’s disease (CD) patients and surgical resection is often required. Despite some progress in understanding and improving the treatment of inflammatory bowel disease (IBD), more effective medical treatments are required, especially for CD patients with fistula formation. Previously, we demonstrated that epithelial-to-mesenchymal transition (EMT) plays a critical role for fistula development in CD patients. Preceding upregulation of TGF-β1, 6-integrin, and necroptosis along fistula tracts in CD patients seems to orchestrate a number of events contributing to fistula development by inducing EMT. Due to a lack of a reliable in vivo model, new drug developments are complicated. Here, we describe a new xenograft (XGR) mouse model of intestinal fistula resembling the human condition.

Aims & Methods: 12–18 weeks (w) old human fetal small intestine was transplanted subcutaneously onto the backs of SCID mice. After 12–16w, ~15% of the mature xenografts spontaneously developed enterocutaneous fistulas. Using systemic LPS treatment followed by mild skin irritation adjacent to the transplant, we established a reproducible model system, resulting in enterocutaneous fistulas within 2–4w. Samples were analysed by immunohistochemistry staining (IHC) for EMT-, immune cell- and necroptosis markers, as well as RNA sequencing.

Results: Histopathological analysis of the fistulating XGR samples revealed a characteristic loss of villous structures and flattening of the intestinal epithelial cells lining the fistula tract, resembling transitional cells described in human CD fistula samples. IHC stainings for various EMT markers (e.g. SLUG, β6-integrin) showed similar expression pattern as in samples from fistulas of CD patients. The expression of the mesenchymal marker alpha-smooth muscle actin confirmed the hypothesis that EMT plays a critical role for the fistula development in the XGR samples, as well. Inflammation in the XGR was apparent up- and downstream to the fistulous tracts. Most of this inflammatory response consisted of CD45 cells, but only very few murine DCs+ cells. Further necroptosis staining revealed large numbers of human CD3+ cells. Collagen staining showed that these inflammatory regions were associated with extensive fibrosis suggesting extracellular matrix remodeling. We also detected strong staining for necroptosis markers (RIP Kana4 and MLKL) in the fistulated XGRs compared to unfistulated control samples. RNA sequencing of inflated LPS-treated XGRs revealed a significant upregulation of genes related to IBD, necroptosis, ripoptosome and NF-κB signaling.

Conclusion: Our data demonstrate that the in vivo model recapitulates, both morphologically and mechanistically, the human disease. Necroptosis might be involved in fistula development, similar to human CD fistulas.
OP334 THE ROLE OF pH-SENSING RECEPTOR TDAG8 (GPR65) IN INTESTINAL INFLAMMATION
I. Tycmbarevich1, J. Cosin Roger1, S.M. Richards2, K. Baebler1, M. R. Spaling1, G. Russo1, K. Attrot1, I. Frey-Wagner1, C.A. Wagner1, B. Misselwitz1, K. Seussen1, G. Rogler1, C. De Valliere1

2Novartis Institutes for Biomedical Research, Basel, Switzerland

Introduction: The two major forms of inflammatory bowel diseases (IBD), Crohn’s disease (CD) and ulcerative colitis (UC), typically result in decrease of extracellular pH of the affected mucosa. Genome-wide association studies (GWAS) identified over 240 non-overlapping single-nucleotide polymorphisms (SNPs) associated with IBD. G-protein-coupled receptor 65 (GPR65) or T-cell death associated gene 8 (TDAG8) has been reported to be a genetic risk factor for IBD in recent GWAS. TDAG8 belongs to a family of proton-sensing GPCRs, including TDAG8, ovarian cancer G-protein coupled receptor 3 (OGR1) and GPR4. However, the role of TDAG8 is not fully understood.

Aims & Methods: In this study we investigate the role of TDAG8 in a murine IBD model. Chronic colitis was induced in WT and TDag8-/- (KO) mice with 4 cycles of 2% DSS in drinking water for 7 days followed by 10 days of regular drinking water. Colon specimens were obtained and RT-qPCR and immunohistochemistry (IHC) were performed. Quiescent peritoneal macrophages (MΦs) from WT and TDag8-/- mice were isolated, cells were treated for 24 h with pH 6.8 serum free medium to activate TDAG8, using pH 7.6 as negative controls. RNA was isolated for RNA sequencing.

Results: In the chronic colitis model, no significant differences in the typical inflammatory markers were observed between WT and KO groups. However, mRNA expression of IFNγ, TNF, IL6, INOS was increased in the KO group, but not significantly different from WT. For example, IL17α, Gata3, Foxp3 and RORc. IHC staining revealed that DSS-treated TDag8-/- mice showed increased immunoreactivity of MΦ marker F4/80 compared to WT and water controls. Protein staining of T cell marker CD3 showed no difference between WT and TDag8-/- mice. Interestingly, mRNA and protein expression of OGR1 were downregulated in TDag8-/- colon tissue. To further examine the role of TDAG8 in MΦs, we performed RNA-sequencing upon a 24 h pH shift from pH 7.6 to pH 6.8. Pathways in mouse MΦs, mediated by TDAG8, were positively enriched for regulation of lymphocyte and leukocyte activation, apoptosis and M1 regulation.

Conversely, pathways in TDAG8-deficient MΦs were upregulated for cytokine production involved in inflammatory response and M2 regulation. Moreover, expression of OGR1 was significantly downregulated in TDAG8-/- MΦs. Conclusion: No significant differences for colitis autoantigens were observed in chronic DSS colitis in WT and TDag8-/- mice, suggesting that TDAG8-dependent anti-inflammatory responses are not able to down-regulate inflammation in this IBD model. Although lack of TDAG8 did not affect outcomes in the murine chronic colitis model, TDAG8 was able to reduce the inflammatory response of macrophages. TDAG8 also upregulates expression of the pro-inflammatory pH receptor OGR1, potentially providing a feedback loop for pH dependent immune activation.

OP335 PRO-INFLAMMATORY HUMAN CD11C+ MACROPHAGES, BUT NOT THEIR TOLERIC CD11CDIM OR CD11C- COUNTERPARTS, ARE EXPANDED IN THE INFILATED MUCOSA FROM PATIENTS WITH INFLAMMATORY BOWEL DISEASE
D. Bernardo1, I. Mora-Gutierrez1, A. C. Marin1, A. Montalban-Arques1, S. Fernandez-Tome1, A. Diaz-Guerr1, R. Caminero-Fernandez2, S. Casabona2, P. Miranda2, F. Casals2, M. Caldas A Alvarez2, M. Jimenez3, F. De La Morena4, C. Santander4, M. Chaparro1, J. P. Gisbert1

Contact E-mail Address: d.bernardo.ordiz@gmail.com

Introduction: Inflammatory bowel disease (IBD), including Crohn’s disease (CD) and ulcerative colitis (UC), is a chronic inflammation of the human gastrointestinal (GI) tract. Macrophages (MΦs), the most abundant GI-monomonuclear phagocytes, are critical at shaping immune responses since they typically maintain the mechanisms of immune tolerance in health, although they can also exacerbate immune responses during inflammation. However, despite their relevance modulating GI-immune responses, there is not much information about their properties in the human GI-tract.

Aims & Methods: Our aim was to characterize human GI-MΦ subsets, phenotype and function both in health and in IBD patients. To that end, human intestinal biopsies were obtained from healthy controls and IBD patients (including UC and CD, both active and quiescent). Tissue was disaggregated and the lamina propria mononuclear cells cultured by flow cytometry. Human intestinal biopsies were cultured overnight to obtain GI-secretomes which were used to assess the mucosa capacity to recruit circulating CD14+ monocytes (enriched from the blood from healthy controls) on transwell culture assays.

Results: Human intestinal MΦ (identified within singlet viable cells as CD45+/HLA-DR+/CD14+) were further divided into CD11chigh, CD11dim and CD11c- counterparts. While the CD11chigh subset resembled the phenotype of circulating phagocyte (Dextran+) and pro-inflammatory CD14+ monoocytes (CX3CR1, SIRPα, CCR2, CD64), the CD11dim subset displayed an intermediate phenotype towards the CD11c- MΦ subset, which was not phagocytic (Dextran-), had higher expression of HLA-DR and CD64 and lower expression of CX3CR1, SIRPα, CCR2 and CD40. CD11c-MΦ displayed a higher production of IL-1β both in resting conditions and after LPS stimulation, compared with the CD11c- subset, which produced larger amounts of IL-10 and was hyporesponsive to LPS stimulation. In health, CD11c-MΦ were the predominant subset in the distal GI-compartments (distal and proximal colon) while CD11c- MΦ were in a higher proportion in the terminal ileum and became predominant in the duodenum. Total MΦ numbers were increased in the inflamed colon from IBD patients (both UC and CD), although not on the non-inflamed tissue from the same patients or from quiescent patients, due to specifically higher numbers of the CD11chigh subset. Finally, colon secretomes from healthy controls recruited circulating CD14+ monocytes, while such capacity was further increased on those from inflamed IBD patients (both UC and CD) but not on quiescent patients.

Conclusion: MΦ subsets are likely to represent transition stages from newly arrived pro-inflammatory monocytes (CD11chigh) to transient (CD11dim) and resident (CD11c-) MΦ as reflected by the mucosal capacity to recruit circulating CD14+ monocytes. This indeed further confirmed increased on active IBD patients where the CD11c+ macrophages are expanded.

Introduction: Lynch syndrome (LS) is associated with an increased risk of hereditary tumours. Regular surveillance (1–2 yearly intervals) has proven mismatch repair gene mutation carriers (mean age: 46 years, range 21–70 years) were randomized between conventional white-light colonoscopy and colonoscopy using chromoendoscopy in the colon proximal from the splenic flexure. After 2 years, both groups underwent colonoscopy using chromoendoscopy. The number of neoplastic lesions at baseline and at follow-up colonoscopy was recorded.

Results: The number of patients with neoplasia in the entire colon was not significantly different between chromoendoscopy and white-light colonoscopy (36/118 (0 CRC) versus 33/123 (2 CRC), p = 0.04). Chromoendoscopy took significantly more procedure time than conventional colonoscopy (p < 0.01), due to a significant difference in median withdrawal time (18 versus 12 minutes, p < 0.01). At follow-up colonoscopy after 2 years, no difference was found with respect to the number of patients with neoplastic lesions in the entire colon between the groups (35/118 (4 CRC) versus 32/123 (2 CRC), p = 0.26). The number of proximal adenomas found was also not significantly different (36 versus 47, p = 0.22).

Conclusion: Chromoendoscopy increases the detection of adenomas in LS, but does not significantly reduce the adenoma detection rate at follow-up endoscopy.

Contact E-mail Address: helmut.neumann@unimedizin-mainz.de

Introduction: The ASGE PIVI statement is proposing a negative predictive value (NPV) >90% for a new technology to leave distal diminutive colorectal polyps in place without resection. To our knowledge no prior prospective study has yet evaluated the feasibility of the most recently introduced Blue Light Imaging (BLI) system for real-time endoscopic prediction of polyp histology for the specific endpoint of leaving hyperplastic polyps in place.

Aims & Methods: Main study objective was the prospective assessment of real-time prediction of colorectal polyps by using BLI. Therefore, 177 consecutive patients undergoing screening or surveillance colonoscopy were included. Colorectal polyps were evaluated in real-time by using high-definition endoscopy and the BLI technology without optical magnification. The endoscopist described each polyp according to size, shape and surface characteristics (pit and vascular pattern, color, depression) and histology was predicted with a level of confidence (high or low).

Results: High-confidence prediction of histology was performed in 92% of polyps. Sensitivity of BLI for prediction of adenomatous lesions was 98.7%, with a specificity and accuracy of 97.4% and 98.2%, respectively. The positive and negative predictive values were calculated with 97.9% and 98.4%, respectively.

Conclusion: The most recently introduced BLI technology is accurate enough to leave distal colorectal polyps in place without resection. This approach has therefore the potential to reduce costs and risks associated with the redundant removal of diminutive colorectal polyps.

Introduction: Endocytoscopy (EC) enables in vivo observation of nuclei at about 500-fold magnification during gastrointestinal endoscopy.[1] We have reported the usefulness of EC for colorectal cancer detection, but clinical practice it seemed that there is a need for an easy-to-use diagnostic aid system for trainees with little experience. To address this task, we have developed a computer-aided diagnosis system for EC imaging (EC-CAD) that provides fully-automated classification of colorectal lesions (2, 3). And we have recently reported its diagnostic ability for invasive colorectal cancer.[4] Whether it is a lesion at risk of lymph node metastasis is important in considering the indication of surgical operation. Therefore, it is very important to distinguish lesions that may have lymph node metastasis such as invasive cancers from other lesions. In this task, it is thought that the EC-CAD can be a very useful diagnostic tool.

Aims & Methods: The aim of the present study was to evaluate diagnostic ability to distinguish between adenoma and invasive colorectal cancer. EC-CAD analyses EC images based on the information from nuclei and texture analysis. All 296 features (eight features from nuclei, 288 from texture analysis) are used as the data for evaluating EC images and EC-CAD automatically presents the pathological diagnosis. We used a support vector machine (SVM) to produce these many features. EC-CAD requires machine learning for construction of diagnostic algorithm. We used 8761 EC images for machine learning in the process of construction of the model. And we selected randomly 200 EC images, which were different from images used for machine learning, from data base of EC images for test data. We evaluated the diagnostic ability of EC-CAD for distinguishing invasive cancers from adenomas.

Results: The time taken for EC-CAD to diagnose the test image was only 0.3 seconds on average. The diagnostic ability of EC-CAD to distinguish invasive cancers from adenomas, the sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value (NPV) were 80.0%, 98.8%, 90.1%, 98.2% and 85.3%, respectively. In addition to the predicted pathological diagnosis, EC-CAD simultaneously present the probability of diagnosis calculated by SVM. When the diagnosis probability was 90% or more, the sensitivity, specificity, accuracy, PPV, NPV were 90.9%, 100%, 95.9%, 100% and 93.1%, respectively.

Conclusion: This study indicates the usefulness of EC-CAD system for EC imaging (EC-CAD) as a very useful diagnostic tool.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
SLs are important premalignant lesions, but its clinical and biological features and risk of malignant progression are not fully understood.

**Aims & Methods:** To establish accurate colonicoscopic diagnosis and treatment of SLs, we aimed to clarify the associations between morphological, pathological and molecular characteristics in SLs. A total of 401 premalignant and malignant colorectal lesions were categorized into 4 subtypes based on their structural diversity. Microsurface structures were assessed by magnifying colonoscopy according to Kudo’s pit pattern classification system. Type II pit pattern was subclassified into classical Type-II, Type II-Open (Type II-O) and Type II-Long (Type II-L). Biopsy specimens were obtained from all lesions for genomic DNA extraction, after which lesions were treated by endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD). BRAF/KRAS mutations and methylation of CpG islands were determined by using the five markers analyzed by pyrosequencing. CpG island methylator phenotype (CIMP) status was also evaluated by HpaII restriction digestion system. Type II-O was tightly associated with sessile serrated adenoma/polyps (SSA/Ps) with BRAF mutation and CIMP-high. Majority of lesions with simple Type II or Type II-L were hyperplastic polyps (HPs), while mixtures of Type II or Type II-L plus III/IV were characteristic to traditional serrated adenomas (TSA)s (sensitivity: 69%; specificity: 95%). Type II-positive TSA frequently exhibited BRAF mutation and CIMP-low, while Type II-L-positive TSA were tightly associated with KRAS mutation and CIMP-low. Analysis in lesions containing both premalignant and cancer components suggested that Type II-L-positive TSA may develop to KRAS mutated/CIMP-low cancers, while Type II-O-positive SSA/Ps exhibited CIMP-high.

**Conclusion:** Our results suggest that Type II subtypes may reflect distinct molecular subclasses in the serrated neoplasia pathway, and that they could be useful hallmarks to identify SLs at a high risk to develop CRC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**OP340 CLASSIFICATION OF CELL NUCLEI MORPHOLOGY OF EC FINDINGS IN COLORECTAL ENDOSCOPY**

Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama/Japan

**Contact Email Address:** kensichi.suzuki19860617@gmail.com

**Introduction:** Endoscopy (EC) is a next-generation endoscopy that enables diagnostic imaging at 450 × magnification. To date, excellent results have been achieved using EC classifications for qualitative diagnosis and assessment of depth of invasion of colorectal lesions (neoplasia/non-neoplasia accuracy: 96.5%; accuracy for carcinomas with massive submucosal invasion (SM-m): 96.3%).

**Aims & Methods:** In the EC classifications, lesions diagnosed as EC3a vary extensively from SM-m to SM-m, including some lesions that are unsuitable for endoscopic treatment. In order to improve the accuracy of assessing the depth of invasion based on the EC classification, we investigated the presence or absence of certain endoscopic factors in EC3a findings that could be indicators of SM-m. Lesions that were observed by EC between May 2005 and January 2015, we retrospectively examined 668 lesions diagnosed as EC2 or EC3, according to the EC classification. The presence or absence of 8 factors (1. branch-like glandular lumens, 2. wide and irregular glandular lumens, 3. unclear glandular lumens (ULs), 4. high degree of nuclear enlargement (HNE), 5. multilayered nuclei (MNs), 6. marked dilation of vescles, 7. marked wriggling vessels, and 8. fine granular structures) that are indicators of SM-m were examined by EC. In addition, we compared the diagnostic ability of EC for SM-m with that of other modalities (narrow-band imaging (JNET classification) and pit pattern (Kudo pit pattern classification)).

**Results:** The multivariate analysis indicated that unclear glandular lumens (ULs), high degree of nuclear enlargement (HNE), and multilayered nuclei (MNs) were the best useful factors for the diagnosis of SM-m or worse. The sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and positive likelihood ratio for the diagnostic accuracy of the EC3a subclassification were 88.9%, 91.3%, 75.0%, 96.6%, 90.8%, and 10.2, respectively (P < .001). The sensitivity, negative predictive value, and accuracy of EC were significantly higher than those of narrow-band imaging and pit pattern.

**Conclusion:** From the EC findings, the presence of ULs, HNE, and MNs are important factors for SM-m or worse outcomes. Furthermore, the EC3a subclassification taking these findings into consideration could be effective for the diagnosis of SM-m or worse.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

4Kyiv City Clinical Endocrinology Center, Kyiv/Ukraine

Contact E-mail Address: nazarikolbyiko@gmail.com

Introduction: We have previously shown that in rats with monosodium glutamate induced obesity supplementation of alive probiotics mixture with omega-3 leads to more pronounced reduction for steatosis degree (0.73 ± 0.21 vs 0.93 ± 0.22, p = 0.199) which accompanied with significant decreasing of triglycerides (9.8 ± 3.23 vs 8.7 ± 2.34, p < 0.05) in liver as compared to probiotic alone. Despite of animal data, randomized placebo-controlled trials (RCT) in NAFLD are still lacking in humans.

Aims & Methods: In respect to our experimental data we studied, in double-blind situation, the effects of co-administration of probiotic with omega-3 vs. placebo in type 2 diabetes patient with NAFLD detected on ultrasoundography (US). A total of 48 patients met the criteria for inclusion. They were randomly assigned to receive “Symbiter Omega” combination of probiotic biomass supplemented with fish and wheat germ oil (250 mg of each, concentration of omega-3 fatty acids 1-5%) or placebo for 8-weeks administered as a sachet formulation in double-blind treatment. The primary main outcomes were the change in fatty liver index (FLI) and liver stiffness (LS) measured by Shear Wave Elastography (SWE). FLI and LS were assessed in the placebo group (82.86 ± 2.45 to 81.09 ± 2.84; p = 0.156). In respect to our other endpoint the changes of LS measured by SWE in both interventional groups were insignificant, but more pronounced decrease was observed for interventional group as compared to placebo. Analysis of covariance (ANCOVA) showed that co-administration of probiotic with omega-3 lead to significant slight body weight loss, reduction of waist circumference, level of serum gamma-glutamyl transpeptidase (GGT), triglycerides (TG) and total cholesterol (TC). Markers of chronic systemic inflammatory state after intervention were lower only in Symbiter Omega group (IL-1β – 39.32 ± 35.66 vs 3.13 ± 3.05 (p = 0.029) as compared to week 8; TNF-α – 49.66 ± 3.51 vs 42.31 ± 3.05 (p < 0.001); IL-8 – 29.21 ± 1.83 vs 26.11 ± 1.58 (p = 0.029); IL-6 – 16.7 ± 3.06 vs 10.51 ± 2.03 (p = 0.003) and INF-γ – 178.45 ± 13.4 vs 153.32 ± 12.45 (p = 0.016) respectively.

Conclusion: In this RCT, we confirmed animal data previously reported by us, that co-administration of probiotic with omega-3 can reduce liver fat, improve serum lipids, metabolic profile and reduce chronic systemic inflammatory state. Therefore, modulation of the gut microbiota with probiotic and different nutrients, serum lipids, metabolic profile and reduce chronic systemic inflammatory state. The indication for PPI therapy in cirrhotic patients should therefore be carefully evaluated.

OP345 SYMPTOM ASSOCIATION PROBABILITY DETERMINES THE OUTCOME OF BACLOFEN THERAPY IN REFRACTORY GASTROESOPHAGEAL REFLUX DISEASE

Targid, Katholieke Universiteit Leuven, Leuven/Belgium

Contact E-mail Address: ans.pauwels@med.kuleuven.be

Introduction: A significant proportion of patients with gastro-oesophageal reflux disease (GORD) remains symptomatic while on proton pump inhibitor (PPI) therapy. PPIs significantly reduce the proportion of acid reflux, however they have no effect on non-acid reflux which can provoke symptoms in GORD patients. Baclofen, a γ-aminobutyric acid agonist, is able to decrease both acid and non-acid reflux. To date, studies with baclofen focused on mechanistic aspects in patients with proven ongoing weakly acid reflux, but the symptomatic outcome of patients with refractory GORD symptoms has not received much attention.

Aims & Methods: The aim of this study was to assess the efficacy of baclofen to add-on therapy in GORD patients who failed to respond to PPI therapy, in a randomized, parallel, double-blind, placebo-controlled study. Patients with an incomplete control of typical GORD symptoms (heartburn/regurgitation) in spite of PPI therapy were randomized into add-on baclofen 10 mg or placebo t.i.d. for 4 weeks to b.i.d. PPIs. Prior to the study and at the end of the treatment, patients underwent a 24 h impedance-pH monitoring. All patients were asked to fill out the ReQuest diaries starting 2 weeks prior to inclusion and continued during the week of treatment. All the data of the diaries were averaged per week. Reflux parameters post-treatment were compared to baseline using Wilcoxon signed rank test and were compared between baclofen and placebo using Mann-Whitney test. The differences in different ReQuest domains were compared using mixed models.

Results: 60 patients were included (age 47.5y (range 19–73), 41f/19m), with 31 patients into the baclofen arm and 29 into the placebo arm. One patient decided not to start with the medication and 5 patients did not complete the study due to side effects (headache, nausea, drowsiness); all 5 of them were taking baclofen. When dividing patients into symptom association probability (SAP) – (n = 29) and SAP+ (n = 25) at baseline, we found a significant time by condition interaction for general wellbeing (p = 0.001), with a significant difference in SAP+ patients between placebo and baclofen (p = 0.0434, after correction).

Disclosure of Interest: All authors have declared no conflicts of interest.
show general wellbeing benefit from treatment with baclofen. Women appear to be more sensitive to a placebo effect.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Per-Oral Endoscopic Myotomy (POEM) represents a less invasive alternative, as compared with conventional laparoscopic Heller's myotomy (LHM), for achalasia patients. It cannot be excluded, however, that the lack of fundoplication in the POEM procedure may result in a higher incidence of reflux disease, as compared with LHM.

Aims & Methods: Aim of our meta-analysis was to systematically assess the incidence of reflux disease after POEM and LHM, when taking into consideration symptoms, endoscopic and pH-monitoring findings. This systematic review was carried out in accordance with the guidelines of the preferred reported items for systematic review and meta-analyses. Literature search with PubMed, EMBASE, SCOPUS, Google Scholar and the Cochrane Central Register of Controlled Trials was performed to identify full articles on the incidence of gastro-esophageal reflux symptoms, endoscopic- and pH-monitoring-findings following POEM and LHM (with fundoplication). Heterogeneity among studies was assessed by using the I² statistic, and explored by means of sensitivity, sub-group and meta-regression analyses.

Results: From a total of 296 and 1379 records, 19 and 28 prospective studies, including 1542 and 2581 subjects who underwent POEM and LHM, respectively, were included. Pooled rate of post-procedure symptoms was 19.5% (95% CI: 18.5–20.5%) after POEM, and 8.4% (95% CI: 5.3–13.4%, I²: 80%) after LHM, respectively. Pooled rate estimate of abnormal acid exposure at 18.5–43.3%, I²: 93%) after POEM, and 7.6% (95% CI: 4.1; 13.7%, I²: 62.5%) after LHM. At meta-regression, heterogeneity was partly explained by POEM procedure may result in a higher incidence of reflux disease, as compared with LHM.

Discussion: Incidence of reflux-disease appears to be significantly more frequent after POEM than after LHM with fundoplication. pH-monitoring and appropriate treatment after POEM should be considered in order to prevent long-term reflux-related complications.

OP347 ESSENTIAL ROLE OF INTERLEUKIN-33-INDUCED INNATE LYMPHOCYTE CELLS IN DEVELOPMENT OF EOSINOPHILIC ESOPHAGITIS IN MICE

Gastroenterology And Hepatology, Shimane University School of Medicine, Izumo/Japan

Contact E-mail Address: n-oshima@med.shimane-u.ac.jp

Introduction: Eosinophilic esophagitis (EoE) is a chronic inflammatory disorder of the oesophagus characterized by mucosal infiltration of eosinophils. Although enhanced mucosal T helper type 2 (Th2) cell cytokine response is associated with the pathogenesis of EoE, the details are not fully understood. Interleukin (IL)-33 is a member of the IL-1 cytokine family that is constitutively expressed in epithelial cells. epithelial-derived IL-33 induces innate lymphoid cell 2 (ILC2) activities in various organs, which subsequently activates Th2 cytokines and leads to development of eosinophil-related allergic diseases. However, little is known regarding the roles of IL-33 and ILC2 activity induced by it in the pathogenesis of EoE. In the present study, several experimental protocols were designed to clarify these issues.

Aims & Methods: Using intraperitoneal sensitization with ovalbumin (OVA) followed by intranasal challenge with OVA in 8-week-old BALB/c mice, an EoE model was established. The presence of eosinophil infiltration-related esophagitis was confirmed by histological findings, while esophageal expressions of IL-33, IL-5, and IL-13 were examined by real-time PCR. Furthermore, production of IL-13 by cultured epithelial cells (HetA1) was examined by flow cytometry (FACS). To further investigate the effect of IL-33 on the pathogenesis of EoE, we established another model using 8-week-old BALB/c mice with intra-peritoneal injection of recombinant IL-33 (control, PBS injection). IL-33-induced esophageal infiltration of eosinophils (Siglec F+ and CD11b+) and ILC2 cells (Lineage−, CD25+ and CD127+) was detected by FACS. In addition, the expression of IL-33 in the background of Th2- and allergy-related cytokines in eosophagitis issues were investigated in this model using a PCR array system.

Results: In the OVA-induced EoE model, expressions of the IL-33, IL-5, and IL-13 genes in esophageal tissues were increased. In association with those cytokine levels, esophageal mucosa showed marked infiltration by eosinophils. Production of IL-33 by esophageal epithelial cells (HetA1) was clearly confirmed by FACS. In the IL-33-injected model, we found esophageal mucosa thickening following infiltration of eosinophils as well as the presence of other various inflammatory cells. Also, PCR array analysis demonstrated that injection of IL-33 significantly induced expressions of a variety of Th2- and allergy-related cytokines in the esophagus as compared to control mice. Moreover, FACS results clearly showed esophageal infiltration by CD25+ and CD127+ ILC2 cells, which was associated with the expression profiles of Th2- and allergy-related cytokines.

Conclusion: IL-33-induced ILC2 cell activity leads to infiltration of esophageal mucosa by eosinophils via production of Th2- and allergy-related cytokines, which may play an important role in EoE development.

OP348 GASTRO-EOSPHAGEAL REFUX AFTER PERORAL ESOPHAGEAL MYOTOMY: A SYSTEMATIC REVIEW WITH META-ANALYSIS

Gastroenterology And Hepatology, St. George's University Hospitals, London/United Kingdom

Contact E-mail Address: alex.straumann@hin.ch

Introduction: Eosinophilic Oesophagitis (EoE) is a rapidly emerging, chronic-inflammatory disease of the oesophagus. Until now, no approved drug therapy is available, although swallowed topical corticosteroids have indicated efficacy in the treatment of EoE.

Aims & Methods: To evaluate in a pivotal Phase 3 trial efficacy and safety of a novel budesonide orodispersible tablet formulation specifically designed for EoE for the induction of clinico-histological remission in adult patients with active EoE. Eighty-eight patients were randomised to receive 6-weeks double-blind (DB) treatment with either 1 mg budesonide orodispersible tablets (BUL 1mg) twice daily (BID) (n = 59) or placebo BID (n = 29). Non-responder could receive further 6-week open-label induction (OLI) treatment with BUL 1 mg BID. Primary endpoint: Rate of clinico-histological remission. Secondary endpoints: Rate of histological remission, change in peak eos/mm² hpf, rate of clinical remission, and resolution of dysmotility and oesophageal mucosal inflammation. The rate of clinical remission defined by EEsAI-PRO ≤ 20, rate of endoscopic normalisation. Secondary end-point (OLI): Rate of clinico-histological remission after 12 weeks of treatment with BUL 1 mg BID.

Results: The additional 6-week course of BUL 1 mg BID was highly effective and safe in bringing active EoE rapidly in clinical and histological remission, as well as in normalising endoscopic alterations. A prolongation up to 12 weeks brought additional 27% of patients into clinico-pathological remission.

Introduction: Swallowed topical corticosteroids are highly efficacious in inducing clinical and histological remission in patients with active eosinophilic oesophagitis (EoE) and also in maintaining such remission. However, it has not yet been evaluated if a long-lasting remission can be achieved, and whether maintenance treatment can be stopped once patients have achieved such a remission.

Aims & Methods: Since 2007, adult and adolescent EoE patients included into a large cohort at the Swiss EoE Clinics were treated long-term with swallowed topical corticosteroids. Clinical, endoscopic and histological disease activity was assessed at annual visits. In patients that achieved clinical (no EoE-related symptoms), endoscopic (absence of white exudates, furrows, and edema) and histological remission (peak eosinophilic count <5/hpf) for at least 6 months (defined as deep remission), treatment was stopped. All patients treated at the Swiss EoE Clinics according to this concept were analysed retrospectively.

Results: Thirty-three of the 370 patients (8.9%) who were treated with swallowed topical corticosteroids achieved deep remission. Mean age of remitters at disease onset was 35.7 years (±17.4) and median diagnostic delay was 5.4 years (IQR 1.9–15.1). Median time to deep remission was 26.0 weeks (IQR 4.3–77.0), 72.5 weeks (IQR 58.6–106.1) and 61.4 weeks (IQR 14.3–101.3), respectively. Median remission was achieved after a median of 82.9 weeks (IQR 64.4–172.3). The proportion of female patients was higher in the group of patients that achieved remission when compared to those that did not (53.3% vs 46.7%, p < 0.01). No other differences with regards to the age at disease onset, diagnostic delay, family history of EoE, concomitant atopic diseases and serum IgE levels between remitters and non-remitters were observed.

Conclusion: The results of our study show the long-term efficacy of swallowed topical corticosteroids in EoE. These results indicate that swallowed topical corticosteroids must be considered as a treatment option for EoE patients who do not respond to PPI therapy. Further studies are needed to determine the long-term safety and efficacy of this treatment option. However, these results suggest that swallowed topical corticosteroids could be a viable treatment option for patients with EoE who do not respond to PPI therapy.

Disclosure: All authors have declared no conflicts of interest.

OP350 PYRAMID REGISTRY: LONG-TERM SAFETY OF ADALIMUMAB BY AGE IN PATIENTS WITH CROHN’S DISEASE

Introduction: The global post-marketing observational registry PYRAMID assessed the long-term safety and effectiveness of adalimumab (ADA) as used in routine clinical practice in patients with moderately to severely active Crohn’s disease (CD).

Aims & Methods: Patients were enrolled in the registry if they were newly prescribed ADA or currently receiving ADA according to the local product label; patients were followed for up to 6 years. This analysis assessed the long-term safety of ADA by age subgroups (<40, 40–59, ≥60 years) at registry enrollment (baseline). Registry treatment-emergent (TE) adverse events (AEs), defined as any event with onset on/after first dose of ADA in the registry up to 70 days after last ADA injection are reported as events per 100 patient-years (PY).

Results: A total of 5025 patients in the registry received at least one dose of ADA and were included in the analysis; at baseline, 2981 patients (59.3%) were aged <40 years (female, 57.1%; median age, 29.9 years; median CD duration, 6.9 years), 1717 patients (34.2%) were aged 40–59 years (female, 57.8%; median age, 47.7 years; median CD duration, 13.0 years) and 327 patients (6.5%) were aged ≥60 years (female, 52.9%; median age, 64.0 years; median CD duration, 13.5 years). Of those aged ≥60 years at baseline, 23/327 (7.0%) were ≥75 years old. Cumulative registry ADA exposure by baseline age groups was 9681.1 PY (IQR 3458.2–21385.1). A total of 417 TEAEs were reported in the subgroup of patients aged ≥60 years at baseline; however, during the follow-up in the registry, 3 patients classified in the 40–59 years at baseline age group were diagnosed with lymphoma when they were ≥60 years of age. No patients in the ≥60 years group reported active/latent tuberculosis.

Conclusion: Long-term treatment with ADA was well tolerated in patients with moderately to severely active CD, irrespective of patient age. The rate of exposure to thiopurines in patients ≥60 years was generally higher in older (≥60 years) compared to younger patients (<60 years); however, no new safety signals were identified in this age group.

Introduction: A recent post hoc analysis of four adalimumab (ADA) clinical trials in patients with inflammatory bowel disease (IBD) demonstrated a lower risk of acute arterial events in patients with IBD than in those without. The aim of this study was to assess the impact of thiopurines and anti-TNFs on risk of acute arterial events in patients with IBD. Patients

Aim and Method: The study aimed to assess the impact of thiopurines and anti-TNFs on risk of acute arterial events in patients with IBD. Patients were included in the analysis who had a diagnosis of IBD and a history of at least 1 dose of ADA in the registry and were followed up until 31 December 2014. Occurrence of acute arterial events, cardiovascular risk factors (hypertension, diabetes, obesity, dyslipidemia, coronary artery disease) and previous arterial surgical procedures, and hospitalisations related to ADA was assessed. Acute arterial events included ischemic heart disease, cerebrovascular disease, and peripheral arterial disease excluding acute mesenteric ischemia. Risks of acute arterial events were compared between thiopurines and anti-TNFs exposed and unexposed patients with marginal structural Cox proportional hazard models adjusting for baseline and time-variant demographics, medications, and comorbidities, including IBD disease activity.

Results: A total of 178,360 IBD patients were included (54% females, mean age at cohort entry 46.3 years, 50.7% Crohn’s disease). Among them, 22.8%, 13.5% and 5.7% were exposed to thiopurine monotherapy, anti-TNF monotherapy and combination therapy during follow-up, respectively. Overall, 4376 incident acute arterial events occurred (incident rates: 5.6 per 1000 person-years), patients exposed to combination therapy (HR 95%: 0.44–0.85), anti-TNF + thiopurine therapy (HR 95%: 0.46–0.85), and thiopurine monotherapy (HR 95%: 0.46–0.85) compared to exposed patients, but the difference was only statistically significant for patients exposed to combination therapy (hazard ratio [HR] 0.91; confidence interval 95% [0.82–1.02], HR95%: 0.89 [0.77–1.04], HR95%: 0.82 [0.68–0.99], respectively). Similar findings were found for ischemic heart disease, cerebrovascular disease and peripheral arterial disease. The magnitude of risk reduction was highest in patients with Crohn’s disease exposed to combination therapy (HR 95%: 0.61 [0.44–0.85]).

Conclusion: Exposure to combination therapy with thiopurines and anti-TNFs is associated with decreased risk of acute arterial events in patients with IBD, particularly in men with Crohn’s disease. Prevention of acute arterial events should be considered in the benefit-risk balance assessment of thiopurines and anti-TNFs as first-line therapy in IBD.

Only events occurring within 28 days after the last dose are included in this table for calculation of proportion and IR.

Opportunist infection, malignancy (excl. NSMC), NSMC, MACE and GI perforation endpoints for Cohorts 1, 2 and 3 are based on adjudicated data; Adjudicated data do not include data from the P2 Study (A3921063; NCT00787202).

The proportion of patients who had premature study discontinuation in Cohort 3 (P2P3 LTE tofacitinib) was not evaluated because the UC programme was designed to allow patients who discontinued from the maintenance study (A3921096; NCT01485574) due to treatment failure to enter the LTE Study (A3921139; NCT01470612) for additional open-label treatment;

*Dose of death was aortic dissection.*

*Causes of death were: one case of aortic dissection (also reported in Cohort 1) and one case of pulmonary embolism, both occurring within 28 days of the last tofacitinib dose. A total of four deaths were recorded in Cohort 3, of which two deaths (one case of hepatic angiosarcoma and one case of acute myeloid leukaemia) occurred more than 28 days following the last dose of tofacitinib;*  

**Aims & Methods:** We performed a multicenter retrospective study in The Netherlands. Women diagnosed with IBD prior to their pregnancy giving birth from January 1999 through April 2015 were identified in 20 participating hospitals and were invited per letter to participate. After consent, information regarding disease characteristics, medication use, life style factors during pregnancy (smoking, folic acid intake), birth outcomes (gestational age, birth weight, major congenital abnormalities) and long-term health outcomes of children

**Introduction:** Long-term health outcomes of children born to mothers with Inflammatory Bowel Disease (IBD) are relatively unexplored. The aim of this study was to describe the long-term health of children born to mothers with IBD and to assess whether medication use affects outcome.

**Aims & Methods:** We performed a multicenter retrospective study in The Netherlands. Women diagnosed with IBD prior to their pregnancy giving birth from January 1999 through April 2015 were identified in 20 participating hospitals and were invited per letter to participate. After consent, information regarding disease characteristics, medication use, life style factors during pregnancy (smoking, folic acid intake), birth outcomes (gestational age, birth weight, major congenital abnormalities) and long-term health outcomes of children...
Our aim was to determine the safety of giving HZV while on anti-TNF medications. ECCO suggests administering HZV 3 weeks prior to starting the therapy.

The risk of herpes zoster (HZ) is elevated in patients with Inflammatory Bowel Disease (IBD). The number of children treated for one or more infections was the highest in 5-year-old children (n = 240, 38%) and year 2 (n = 138, 36%) than mothers with CD (n = 87, 55%) in year 5 (p = 0.0001). IBD type and infection rates were significantly over time to 104 (26%) children in year 5 (p = 0.002). However, birth outcomes were similar for both groups. Exposure to anti-TNF and/or thiotepa was not associated with adverse birth outcomes, however, after adjusting for disease activity, systemic steroids use was associated with preterm birth (OR 2.67, 95%CI 1.59–4.47). A total of 143 adverse health outcomes were reported in 132 children; 111 (11%) children were admitted to hospital for a severe infection of which, 74 (69%) occurred in the first year of life; 16 (2%) had growth failure and 16 (2%) children were diagnosed with a chronic disease before the age of 5 years. Seven children (1%) were treated for an adverse reaction to vaccination.

Information from the GPs was retrieved for 668 (67%) children showing a median number of antibiotic-treated infections per year of 0.3 (IQR 0.00-0.60). The number of children treated for one or more infections were the highest in year 1 (n = 240, 38%) and year 2 (n = 218, 38%). This infection rate decreased significantly over time to 104 (26%) children in year 5 (p = 0.0001). IBD type and IBD treatment did not influence long-term adverse health outcomes, adverse reaction to vaccination or infection rates.

Conclusion: In our long-term follow-up study, we found no evidence that IBD type or medical treatment for IBD during pregnancy affects long-term health outcomes of children. On behalf of the Initiative on Crohn and Colitis (ICC).

Inflammatory Bowel Disease (IBD) is a disease that affects the digestive system. There are two main types of IBD: Crohn’s disease and ulcerative colitis. People with IBD may experience symptoms such as abdominal pain, diarrhea, and fatigue. IBD is a chronic disease, which means it goes on for a long time and cannot be cured. However, it can be managed. There is no single test that can diagnose IBD. A combination of tests may be done to evaluate whether symptoms are caused by IBD.

In this study, we found that the risk of developing IBD is higher in people with a family history of IBD. Children of parents with IBD are at a higher risk of developing IBD than children of parents without IBD.

In the United States, the incidence of IBD is increasing. The exact cause of IBD is not known, but it is believed that a combination of genetic, environmental, and lifestyle factors play a role. Smoking and obesity are known risk factors for IBD. The risk of developing IBD is higher in people who smoke and have a higher body mass index (BMI).

The management of IBD includes medications, lifestyle changes, and surgery. Medications used to treat IBD include steroids, immunosuppressants, and biologics. Lifestyle changes, such as avoiding smoking and maintaining a healthy weight, can help manage symptoms. Surgery may be necessary if the disease is severe or if other treatments are not effective.

Conclusions: The main findings of this study are that IBD is a chronic disease that affects the digestive system. People with IBD may experience symptoms such as abdominal pain, diarrhea, and fatigue. IBD is caused by a combination of genetic, environmental, and lifestyle factors. The management of IBD includes medications, lifestyle changes, and surgery.

OP357 RELA/NF-kB CONTROLLED ONCO-IMMUNO CROSSTALK IN PANCREATIC CANCER – ROLE OF CCL20 AND CX3CL1 IN APOPTOSIS RESISTANCE

C. Geismann, F. Grohmann, S. Schreiber, A. Arlt
Department Of Medicine, University Hospital of Schleswig-Holstein, Campus Kiel, Kiel/Germany

Contact E-mail Address: cgeismann@email.uni-kiel.de

Introduction: Pancreatic ductal adenocarcinoma (PDAC) exhibits one of the worst survival rates of all cancers. While the majority of cancer, death rate show declining trends, PDAC register rising rates. For the majority of patients a “curative” intended resection is not feasible and the response rates to present chemo- and radiotherapeutic approaches remain highly unsatisfactory. One hallmark of PDAC is a profound desmoplastic stroma reaction. One component of this tumor microenvironment is a dysregulated immune response essentially contributing to therapy resistance of PDAC. We and others have shown that inflammation and tumorigenesis are functionally connected and controlled by the NF-κB pathway, mediating apoptosis resistance in PDAC. Aims & Methods: In the present study, a panel of human pancreatic carcinoma cell lines and cell lines isolated from PDAC mouse models were analysed for the role of RelA target genes in the resistance against chemotherapeutic drug or TRAIL induced apoptosis and the composition of the tumourmicroenvironment. Results: PDAC cell lines were treated with gemcitabine, etoposide or TRAIL and in dependency of the apoptosis capacity as described apoptotic resistant or sensitive. Resistant cells already exhibited a high basal RelA/NF-kB activity which was further strongly induced by TRAIL and in a lower extend but prolonged extent by the chemotherapeutic drugs. Inhibition of NF-κB by pharmacological, siRNA or Crispr/CAS9 approaches sensitized the resistant PDAC cells. Gel shift analysis revealed that the p65/RelA subunit is critical component of the NF-κB complex controlling a genomewide approach. In parallel we established the chemokines CCL20 and CX3CL1 as central (Top 5 upregulated) RelA/NF-kB target genes in resistant PDAC. Using Chip, lucifase and gel shift assays we were able to describe the RelA responsive element in the promoters of the genes. Realtime PCR, Western Blot and ELISA confirmed RelA dependent upregulation of CCL20 and CX3CL1 after TRAIL treatment. Surprisingly targeting CCL20 and/or CX3CL1 by siRNA, blocking antibodies or by downregulation of the CCL20 receptor CCR6 or the CX3CL1 receptor CX3CR1 had no effect on PDAC cell death or cancer cell migration. However, both chemokines were complementary in vitro, ex vivo and in vivo models we were able to show that these chemokines secreted by resistant PDAC cells act in a paracrine fashion, leading to an increased recruitment of inflammatory cells. Furthermore these PDAC cells were able to stimulate inflammatory cells (i.e. monocytes) which confer apoptotic protection of PDAC cells against TRAIL induced apoptosis. Conclusion: In conclusion we were able to establish a RelA controlled chemokine pathway in apoptosis resistant PDAC cells which does not confer direct apoptotic protection or migration of the tumor cells but instead leads to the recruitment and immune cell differentiation which in turn mediate apoptosis resistance of PDAC cells. Disclosure of Interest: All authors have declared no conflicts of interest.

ENDOLUMINAL AND TRANSLUMINAL INTERVENTIONS IN THE UPPER GI TRACT - ROOM E2

OP358 ENDOLUMINAL AND INTRACAVITAL VACUUM COMBINED WITH STENT-OVER-SPONGE (SOS) FOR TREATMENT OF FOREGUT PERFORATIONS AND LEAKS

P.V. Valli1, K. Mertens1, A. Kroeger1, P.M. Schneider2, C. Gutschow2,

Introduction: Iatrogenic and emergent perforations or anastomotic leakage of the upper GI tract can result in devastating manifestations or abdominal infections. Abscess drainage and defect repair, commonly achieved by surgical procedures in the past, are the crucial steps to control infection and life threatening sepsis. Endoluminal vacuum therapy for foregut wall defects has evolved as a promising endoscopic treatment option in addition to classical closure techniques using clips or stents. To improve suction and to maintain swallowed function, we combined endosponge (ES) treatment with fully covered self-expandable metallic stent (SIMS). Aims & Methods: ES therapy using the Endo-SPONGE or Eso-SPONGE (B. Braun Medical, Melsungen, Germany) was used in 18 consecutive patients suffering from foregut wall defects between 2012 and 2016 at our institution. Upon diagnosis, post-surgical leakage, iatrogenic or emetic perforation or chronic fistula dimensions were evaluated by oral and intravenous contrast-enhanced computed tomography (CT) and endoscopy. Depending on the defect type, ES was placed intraluminal or intracavitral and if feasible, combined with SEMS placement (SOST, stent-over-sponge). Results: Indications for ES were anastomotic leakage after surgery (n = 12, 66.7%), esophageal perforation (n = 4, 22.2%) and chronic foregut fistula (n = 2, 11.1%). The overall success rate with achievement of lesion closure was 83% (15/18). Ten patients were primarily treated with luminal ES placement (55.6%), whereas in 8 (44.4%) patients, ES were preferably inserted into the abdomen. In 12 (66.7%) patients, ES treatment was combined with SEMS over-stenting (Stent-Over-Sponge, SOS). The median number of utilized ES per case was 3.5 (range 1–17). ES remained in situ for a median time of 5 days (range 2–18). No adverse events directly connected to the ES/SEMS placement and their removal were recorded. Two patients developed developed esophageal stenosis after ES closure and were successfully treated by endoscopic dilatation. Conclusion: ES treatment is a successful method to treat infected foregut wall defects of any kind. ES plus SEMS over-stenting seems even more powerful than ES alone in cases of large infected cavities. ES or SOS treatment should always be evaluated in patients with upper GI leakage before performing a surgical repair. Disclosure of Interest: All authors have declared no conflicts of interest.

OP359 INTRADUCTAL BILIARY OR PANCREATIC ABLATION DURING ENDOSCOPIC AMPLULLECTOMY MAY REDUCE THE LONG-TERM RECURRENCE RATE

E. Perez-Cuadrado-Rohles1, H. Piessevaux2, T. Moresol1, R. Yeung1, T. Asoushali1, A. Joure-Mounir2, M. Komuta2, F.H. Deprez2, J. Mertens1, A. Kroeger1, P.M. Schneider2, C. Gutschow2

Introduction: The feasibility and outcome of endoscopic resection in ampullary tumors with intraductal growth remains unclear. Aims & Methods: All consecutive patients from 2000 to 2016 who underwent an endoscopic snare amputectomy with a 6-month minimum follow-up were included. Factors related to recurrence were collected and analyzed. Intraductal ablation by wire guided radiofrequency or wire-guided 6, 8 or 10 mm balloon catheters in cases of intraductal growth was evaluated in terms of safety and effectiveness. Results: Seventy-three patients (58 ± 14 ± 4, 49.3% men, 34.2% FAP) presented with an indication for endoscopic ampullectomy. Median tumor size was 20 mm (range: 8–80 mm) and 79.5% of patients were symptomatic at diagnosis. EUS detected intraductal infra- (n = 13) or supra-centricm (n = 3) ingrowth in 21.9% of cases (8 biliary and pancreatic, 3 pancreatic, 5 biliary). Ablation was performed by RFA in 2 patients and 6-10French cystostome in 14, followed by pancreatic and biliary stent drainage. There were no recurrences observed in these patients. In the full group, en-bloc resection was achieved in 34 lesions (46.6%, 28 R0-status) in a median of 1 (1–5) session. High-grade dysplasia was observed in 27 cases (37%) and adenocarcinoma in 6 (8.2%). Twelve patients experienced recurrence (16.4%) and 3 differentiations (median follow-up: 33 months). Familial adenomatous polyposis was not associated with recurrence (20% vs. 14.6%, p = 0.553). By multivariate logistic regression analysis, ≥2 endoscopic sessions was the only factor associated with recurrence (OR:7.60 [95% CI:1.869–30.896], p = 0.005). Complications (19.2%) were bleeding (n = 6), pancreatitis (n = 3), perforation (n = 3) and biliopancreatic stenosis (n = 2). There were no differences in the complication rate in patients with/without intraductal ablation (18.2%). Conclusion: Intraductal biliary and pancreatic ablation is feasible, safe and may reduce the recurrence rate in ampullary tumors with intraductal growth. Disclosure of Interest: All authors have declared no conflicts of interest.

OP360 EFFECT OF SUBMUCOSAL INJECTION IN ENDOSCOPIC PALPITECTOMY OF AMPULLARY TUMOR: A PROPENSITY ANALYSIS

1Department Of Internal Medicine, Armed Forces Capital Hospital, Gyonggi-Do/ Korea, Republic of
2Department Of Internal Medicine And Liver Research Institute, Seoul National University College Of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: kwasay@gmail.com

Introduction: The role of submucosal injection before the endoscopic palpitectomy (EP) is controversial. This study was aimed to investigate the effect of submucosal injection before EP on the recurrence and survival of ampullary tumors. Aims & Methods: Between March 2006 and March 2014, all patients who received initial curative EP at Seoul National University Hospital were retrospectively recruited. The early recurrence rate (within 3 months which presumed due to incomplete resection), recurrence-free survival and post-procedural adverse events were compared between the submucosal injection (SI) group and non-injection (NI) group. Outcomes were also assessed after matching according to propensity score to reduce the effects of selection bias and potential confounders.
Results: In total 122 patients were included; 26 in the SI group and 96 in the NI group. There were more frequent complications in SI group than NI group (9.6% vs. 8.3%, P = 0.010). The recurrence-free survival was not significantly different between the two groups (P = 0.145). After propensity score matching, total 26 pair patients were selected in both group. In this cohort, early recurrence was not occurred in any patient. Meanwhile, 7 (26.9%) patients in SI group had tumor recurrence (P = 0.010). The recurrent free survival of NI group was significantly longer than SI group (P = 0.024). In multivariable analysis, factors significantly related with recurrence-free survival was pathologic grade (P = 0.004) and sub-mucosal injection (P = 0.012). Before the propensity score matching, post-procedural adverse events were significantly more common in SI group than NI group (pancreatitis, 26.9% vs. 10.4%, P = 0.031; bleeding, 19.2% vs. 5.2%, P = 0.021; perforation, 7.7% vs. 0%, P = 0.004) however, the difference was decreased and not statistically significant in propensity score matched cohort.

Conclusion: Submucosal injection before the EP of ampullary tumor was related with more frequent early recurrence and shorter recurrence-free survival. Moreover, it was not reduced the rate of post-procedural adverse events. Submucosal injection should not be suggested before the EP.

Introduction: Several techniques have been developed for EUS-guided gastroenterostomy (EUS-GE) for the management of gastric outlet obstruction (GOO), including the direct (DGE) and balloon-assisted (BAGE) methods. A standardized approach to EUS-GE, however, is lacking and there are currently no data ascertaining the optimal technique.

Aims & Methods: We aimed to compare DGE with BAGE in terms of technical success and clinical outcomes. This is a multicenter, retrospective study involving 5 US and 1 European tertiary institutions. Consecutive patients who underwent EUS-GE with either the DGE or BAGE technique for malignant or benign GOO were included between 1/2014 and 10/2016. The primary outcome was technical success. Secondary outcomes included clinical success (ability to tolerate a full fluid diet), procedure time, and rate of adverse events with severity graded per the ASGE lexicon.

Results: In total 122 patients were included; 26 in the SI group and 96 in the NI group. Mean procedure time was significantly shorter in BAGE (31.2 min vs. 33.3 min, p = 0.057) between endoscopy and MIS cohorts (risk ratio 0.19; 95% CI, 0.04–0.71, p = 0.004). While there was no significant difference in late-term treatment success (96.2% vs. 84.0%, p = 0.19), endoscopy was associated with higher early (97.1 vs. 53.1%, p = 0.001) and mid-term (100 vs. 81.3%, p = 0.01) treatment success. Treatment failure was significantly higher for MIS (18.8% vs. 0, p = 0.001). There was no significant difference in mortality (2.9 vs. 6.3%, p = 0.61), adverse events (41 vs. 53.5%, p = 0.33), re-interventions and post-procedure length of stay (LOS). Introduction: Background: Pancreatic walled-off necrosis (WON) is a common and potentially fatal complication of acute pancreatitis. EUS-guided drainage is the primary treatment option for WON. However, data comparing the cost-effectiveness between different endoscopic drainage techniques is limited. The objective of this study was to evaluate the cost-effectiveness of lumen-apposing metal stents (LAMS) for WON compared to plastic stents (PS).

Methods: In this study, we conducted a cost-effectiveness analysis comparing LAMS to PS for WON. We collected data from a randomized clinical trial performed at a large academic medical center. We performed a propensity score-matched comparison of clinical outcomes, procedure characteristics, and cost. Our primary cost measure was the total clinical costs associated with WON, including hospitalization, intensive care unit (ICU) care, and endoscopy. Our primary clinical endpoints were symptom resolution and clinical success, which was defined as the resolution of WON and absence of complications.

Results: In total 122 patients were included; 26 in the SI group and 96 in the NI group. Mean procedure time was significantly shorter in BAGE (31.2 min vs. 33.3 min, p = 0.057) between endoscopy and MIS cohorts (risk ratio 0.19; 95% CI, 0.04–0.71, p = 0.004). While there was no significant difference in late-term treatment success (96.2% vs. 84.0%, p = 0.19), endoscopy was associated with higher early (97.1 vs. 53.1%, p = 0.001) and mid-term (100 vs. 81.3%, p = 0.01) treatment success. Treatment failure was significantly higher for MIS (18.8% vs. 0, p = 0.001). There was no significant difference in mortality (2.9 vs. 6.3%, p = 0.61), adverse events (41 vs. 53.5%, p = 0.33), re-interventions and post-procedure length of stay (LOS).

Introduction: Necrotizing pancreatitis is a highly morbid disease with poor clinical outcomes. The treatment strategy has evolved over time from open necrosectomy to other minimally invasive techniques.

Aims & Methods: We aimed to compare the clinical outcomes between minimally invasive surgery (MIS) and endoscopy. Consecutive patients with necrotizing pancreatitis. Consecutive patients with necrotizing pancreatitis were randomized to MIS or endoscopic interventions. MIS involved laparoscopic cystogastrostomy with internal debridement or video-assisted retroperitoneal debridement. Endoscopic interventions were tailored to the size and extent of the necrotic collection. Initial session involved drainage by single-gate, multi-gate or dual (endoscopic and percutaneous drainage) modality techniques followed by necrosectomy if required. Patients who underwent only percutaneous drainage and did not require surgical or endoscopic interventions were excluded. The primary end point was to compare the composite of major complications (new onset multi-organ failure, new onset multiple systemic complications, perforation of visceral organ, duodenal/peripancreatic stricture, bleeding on death). Secondary outcome measures were to compare early (≥25% decrease in size of necrotic collection with systemic inflammatory response syndrome [SIRS] resolution at 72 hours), mid (≥50% decrease in necrotic collection with symptom relief at 30 days) and late-term (complete resolution of necrotic collection with symptom relief at 6 months) treatment success (intention-to-treat), treatment failure (open necrosectomy or cross-over to the alternate treatment arm), adverse events, re-interventions and post-procedure length of stay (LOS).

Results: 66 patients were randomized to endoscopic (n = 34) or MIS (n = 32). The primary outcome occurred in 5.9% of endoscopic and 34.4% of MIS cohorts (risk ratio 0.17; 95% CI, 0.04–0.71, p = 0.004). While there was no significant difference in late-term treatment success (96.2% vs. 84.0%, p = 0.19), endoscopy was associated with higher early (97.1 vs. 53.1%, p = 0.001) and mid-term (100 vs. 81.3%, p = 0.01) treatment success. Treatment failure was significantly higher for MIS (18.8% vs. 0, p = 0.001). There was no significant difference in mortality (2.9 vs. 6.3%, p = 0.61), adverse events (41 vs. 53.5%, p = 0.33), re-interventions and post-procedure length of stay (LOS).

probabilities obtained from a systematic review of the literature. The unit of effectiveness is defined as successful endoscopic drainage without need for PD or surgery. The total cost of successful and unsuccessful endoscopic drainage are computed. Time horizon is set at 6 months. Costs in 2016 US$ are based on inpatient institutional costs from patients who underwent WOD drainage with LAMS or PS from 2014 to 2016. Physician fees are obtained from the American Medical Association. A third party payer perspective is adopted. Univariate sensitivity analyses are performed.

Results: For all in-patients, LAMS was more efficacious than PS with 92.3% and 84.0% of the patients achieving successful endoscopic drainage of WOD, respectively (incremental effectiveness: 8.25%, table 1). LAMS, however, was more costly with an average cost per patient of US$ 20,029 compared to US$ 15,941 with PS (incremental cost US$ 4089, table 1). The incremental cost effectiveness ratio favored LAMS at a cost US$ 49,214 per additional patient successfully treated. The cost of procedure for LAMS insertion was fixed at US$5237 in the model (based on the institutional cost). The sensitivity analysis showed that if the cost of procedure for LAMS insertion decreased below US$2647, then the cost per successful drainage associated to LAMS choice becomes better than PS. Additional sensitivity analysis performed by varying the main probabilities by ±20% and main costs by ±50% showed that these results are robust.

Conclusion: LAMS improves the effectiveness of endoscopic management of in-patients with WOD when compared to PS at an incremental increase in cost of US$ 49, 214 per additional patient successfully treated. The assessment of additional variations in health state probabilities and costs are needed to confirm the generalizability of these findings.

Aim of current study was to evaluate the role of multiplex PCR using specific primers against IS6110, MPB64 and Protein b for the diagnosis of GITB and compare it with histopathology. In this prospective study conducted from July 2015 to November 2016, adult cases of clinically suspected GITB and compare it with histopathology. In this prospective study conducted from July 2015 to November 2016, adult cases of clinically suspected GITB were recruited. All patients underwent mantoux test, contrast enhanced computed tomography of abdomen, esophagogastroduodenoscopy or colonoscopy as indicated. Multiple biopsies for tissue diagnosis were taken from lesions by a single observer. All specimens were subjected to Ziehl Neelsen staining for detection of acid fast bacilli. Tissue obtained were analysed by H&E and by two independent pathologists. Multiplex PCR on tissue specimens using specific primers against IS6110, MPB64 and Protein b was also performed. The performance of the assay was assessed using a composite gold standard for diagnosis of tuberculosis, which comprised a combination of clinical characteristics, microbiology smear showing acid fast bacilli, histopathology showing caseous necrosis with granulomatous inflammation and response to antitubercular therapy.

Results: A total of 35 cases of clinically suspected GITB were recruited. A final diagnosis of tuberculosis was made in 32 cases (duodenal n = 4, ileocolic n = 28) and rest 23 acted as control group. The mean age, haemoglobin and erythrocyte sedimentation rate of patients with tuberculosis were 36.41 ± 14.6 years, 10.2 ± 2.4 g/dl, 37.8 ± 15.3 mm/hr respectively. The most common endoscopic findings were ulcerations (75%), nodularity (46.8%), distorted ileocecal valve (28%) and strictures (21.8%). The most common radiological findings were mural wall thickening (65.6%), mesenteric lymphadenopathy (56%) and strictures (40%). The sensitivity, specificity, positive predictive value and negative predictive value of histopathology (H&E) for diagnosis of GITB was 28.12%, 100%, 100% and 48.89% respectively (Table 1). The sensitivity, specificity, positive predictive value and negative predictive value of multiplex PCR for diagnosis of GITB was 86.33%, 100%, 100% and 86.2% respectively (Table 1). Four patients who underwent surgical procedure for subacute intestinal obstruction while on treatment; rest twenty eight patients completed nine months of antitubercular therapy and improved.

Conclusion: Multiplex PCR using specific primers against IS6110, MPB64 and Protein b has a higher sensitivity compared to conventional techniques for diagnosis of GITB

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: To figure out whether the use of fecal sample mixture collected at consecutive five days could more accurately represent gut microbial community, 1-day and 5-day fecal samples were collected from 8 healthy adults and analyzed by 16S rRNA sequence.

Results: Our results indicated that both 1-day fecal samples and 5-day samples exhibited relatively high repetitiveness. The relative abundance of majority of bacterial taxa did not change between 1-day fecal samples and 5-day fecal samples. However, the alpha diversity of 5-day fecal samples was higher than that of 1-day fecal samples.

Conclusion: When the aims of studies are to analyze the relative abundance of specific OTUs among subjects, fecal samples collected at one day could be used. When microbial diversity is one of essential factors to be analyzed, the use of 5-day fecal samples may be more recommended.

Disclosure of Interest: All authors have declared no conflicts of interest.

*The unit of effectiveness is defined as successful endoscopic drainage of PP without need for percutaneous drainage or surgery. **Undominated: Since none of the strategies is both less costly and more effective from the other, there is no strategy with a “dominated” status.

OP366 - THE IN-HOSPITAL MORTALITY RATE FOR CLOSTRIDIUM DIFFICILE INFECTION HAS DECREASED OVER THE PAST DECADE IN THE UNITED STATES: A NATIONWIDE ANALYSIS

P.T. Kroener1, P. Irapinyo2, M.S. Abougergi2, C.C. Thompson2
1 Mt. Sinai St. Luke’s/West, New York/United States of America
2 Division Of Gastroenterology, Hepatology And Endoscopy, Brigham and Women’s Hospital, Boston/United States of America/MA

Introduction: Over the past decade, the rates of Clostridium difficile infection (CDI) and associated mortality were reported to have increased. This period saw significant epidemiological changes in terms of emergence of more virulent strains, development of improved diagnostic methods and new therapies. Though some studies have evaluated the burden of CDI at a national level, these are now relatively old and display limited number of outcomes. Therefore, the aim of this study was to explore the recent incidence, morbidity, mortality, and resource utilization of patients with CDI throughout the past decade using a national database.

Aims & Methods: Retrospective cohort study using the National Inpatient Sample from 2004 to 2013, which is the largest publicly available inpatient database in the US. All patients with an ICD-9CM code for a principal diagnosis code of C. difficile infection were included in the study. There were no exclusion criteria. The primary outcome was inpatient mortality. Secondary outcomes were inpatient morbidity, measured by colectomy rates; resource utilization, measured by colonoscopy rates and length of hospital stay (LOS), and total hospitalization charges (adjusted for inflation). Odds ratios and means were adjusted for age, sex, race, median income in the patient’s zip code, Charlson Comorbidity Index, hospital region, rural location, size and teaching status using multivariate logistic regression.

Results: A total of 3,325,872 patients with CDI were identified, of which 1,021,454 met the inclusion criteria and were included. Mean age was 68 years and 65% of patients were female. Total cases increased from 60,137 in 2004 to 111,285 in 2013. Figure 1 shows the mortality trend in the U.S. throughout the past decade. Although the mortality rate peaked at 4.1% in 2005, the overall mortality in the cohort decreased 44% during the past decade, from 3.6% to 2%. Of the patients with CDI, 16,313 (1.6%) underwent colonoscopy throughout the study period, while 4440 patients (0.4%) underwent colectomy. The use of colonoscopy, colectomy rates, and LOS decreased, while total hospitalization charges increased in throughout the study period. Table 1 shows all adjusted odds ratios, means and change magnitude for the variables.

Conclusion: Despite having peaked in the latter half of the past decade, Clostridium difficile infection mortality rates saw a significant decrease within the past 5 years in the United States. This may reflect the impact of improved diagnostic novel therapies and increased situational awareness. Similarly, colectomy procedures in patients with CDI declined during the study period. Regarding resource utilization, colonoscopy and hospital length of stay also decreased in the past decade. However, total hospitalization charges have increased significantly, in part reflecting the increasing costs of the new measures. OP367 - SINGLE-INFUSION FECAL MICROBIOTA TRANSPLANTATION IS NOT EFFECTIVE IN TREATING SEVERE CLOSTRIDIUM DIFFICILE INFECTION

Introduction: Fecal microbiota transplantation (FMT) is an effective therapeutic option against recurrent Clostridium difficile infection (rCDI). A growing body of evidence shows that a single fecal infusion achieves low cure rates after multiple fecal infusions.2-3 This finding is particularly remarkable when dealing with severe CDI, which has been identified as a predictor of failure after single fecal infusion.4-5 However, the efficacy outcomes of single and multiple fecal infusions for the treatment of severe CDI have been compared only in few studies to date.2

Aims & Methods: We evaluated a prospective cohort of patients who received FMT by colonoscopy for severe rCDI from June 2013 to January 2017. All subjects provided their written informed consent. This study was approved by our local ethics committee. rCDI and severe CDI were defined according to the ESCMID guidelines.4 In particular, severe CDI was defined as an episode of CDI with one or more specific signs and symptoms of severe complications, or a complicated course of disease, with significant systemic toxin effects and shock, and consequent need for Intensive Care Unit admission or colectomy.2 We defined treatment failure as post-procedural persistence of diarrhea, or diarrhea recurrence after an early improvement within 8 weeks after fecal infusion. Clinical cure was defined as disappearance of diarrhea. Multiple fecal infusions were administered when a single fecal infusion failed to treat CDI. Selection of donors, preparation of fresh and frozen feces, and FMT procedure, were carried out as previously described.2 All patients were carefully followed up until 8 weeks after FMT, by weekly clinical examinations.

Results: In the study period, 33 subjects with severe rCDI received FMT. They were mostly females (N = 20) and 74 year-old on average (range = 60-93). The mean number of previous recurrences was 3 (range = 1–5). Thirty subjects (91%) were inpatients. Pseudomembranous colitis was identified at endoscopic evaluation in 22 subjects (67%). A single fecal infusion was able to cure 9 of 33 patients (27%). Among nonresponders to single fecal infusions, 3 critically ill subjects were too unstable to repeat the procedure; 2 of them died for overwhelming CDI, and the other one died for other reasons not related to CDI. All remaining 21 subjects received repeated fecal infusions (mean = 3; range = 2–5), and 19 of them (90%) were successfully treated. In this series of patients, we performed a total of 68 infusions of feces, using feces from unrelated donors in 47 cases (69%), and frozen feces in 27 procedures (40%). Overall, FMT (including single and multiple infusions) was able to cure 28 of 33 patients with severe CDI (85%).

Conclusion: Our findings remark that single fecal infusions is not effective in patients with severe CDI and should be no longer considered as a reliable treatment option for this clinical picture. As severe CDI is a life-threatening disease, dedicated protocols, including multiple-infusion FMT, are necessary to offer patients an effective therapeutic option to cure this condition.

Introduction: Irritable Bowel Syndrome (IBS) is a gastrointestinal disorder charac-
terized by abdominal pain and altered bowel movements. Literature on PCR, no significant differences in the placebo group compared to baseline were observed, and neither between treatment and placebo. The GRS-QoL total score signifi-
cantly decreased for both the treatment and the placebo group 2 weeks after FMT (p < 0.01, and -0.57 ± 0.63, p < 0.05, respectively). Again, no differences between the two intervention groups were observed. The IBS-QoL total score was significantly increased for both, but not in the placebo group at 8 weeks (10.6 ± 6.3, p < 0.01). Similar results were observed in three out of eight SF-36 subscores, especially in the general health subscore. This score was significantly increased in the treatment compared to the placebo group 8 weeks after FMT (11.8 ± 3.6 compared to 7.7 ± 4.4, p < 0.01). No significant differences were noticed in the HADS scores, however, in the treatment group, the depression subscores showed a trend towards reduction 8 weeks after FMT compared to baseline (−1.4 ± 0.9, p = 0.08). This trend did not occur in the placebo group.

Conclusion: These data showed that there is a beneficial effect of FMT on symp-
tom scores and quality of life in IBS patients. This effect is also observed in the placebo group, although to a lesser extent, indicating that placebo-controlled studies are essential in IBS patients. The bowel cleansing and the processing of the faecal material might have contributed to the placebo effect. Further analysis on individual basis, separation into non-responders and respon-
ders as well as correlation with additional outcomes such as microbiota composi-
tion will provide more insight.

Conclusion: The durability of surgical and pneumatic dilatation therapy for achalasia appears to be similar over up to 9 years. There was no mortality associated with surgery but 1.87% of subjects died within 30 days of dilatation. Older age and increased co-morbidity predicted mortality in subjects.

Introduction: High-resolution manometry (HRM) allowed us to plot all the pressure changes consecutively from the pharynx through esophago-gastric junction. Chicago classification criteria classifies achalasia into three types as follows, type I (classic achalasia), mean integrated relaxation pressure (IRP) > upper limit of normal (a common finding in all achalasia subtypes), 100% failed peristalsis; type II, no normal peristalsis, pan-esophageal pressurization with ≥20% of swallow; and type III, no normal peristalsis, preserved fragments of distal peristalsis or premature (spastic) contractions with ≥20% of swallows. Pathophysiology of muscularis externa in classic achalasia has been characterized previously, however, correlation between findings of HRM and histopathology is still unknown among achalasia subtypes. We aimed to correlate the results of HRM and histology of muscularis externa in achalasia subtypes.

Aims & Methods: Peroral esophageal muscle biopsy (POEM-b) was performed during peroral endoscopic myotomy, and the specimens of muscularis externa obtained in the lower esophagus were used for histopathological analysis. Immunohistochemical staining for c-kit and nNOS was performed to assess the number of interstitial cells of Cajal (ICC)s and oxidoreductase that synthesize nitric oxide (NO; one of non-adrenergic, non-cholinergic neurotransmitters). Hemosytoxin Eosin and Azan-Mallory staining were used to assess fibrosis and atrophy. Full-layer normal slices from esophagectomies of patients with esophageal carcinoma were used as controls.

Results: Slides from 31 achalasia patients (Male: Female 14: 17, mean age 53.3 ± 16.2 years, type I: 19, type II: 8, type III: 4) were compared with 5 controls (Male 5, mean age 73.0 ± 5.4 years). The number of ICCs in type I and II was significantly lower than that of control, types I: 3.9 ± 1.5 cells/high power field [HPF] (p = 0.002), type II: 4.0 ± 2.1 cells/HPF (p = 0.01), control: 9.4 ± 2.8 cells/HPF. In type III achalasia, the number of ICCs were preserved: 8.2 ± 2.7 cells/HPF (p = 0.62). The number of nNOS-positive cells in type I achalasia: 3.3 ± 2.1 cells/HPF (p = 0.01) was significantly lower than that of control: 6.1 ± 1.3 cells/HPF. The number of nNOS-positive cells in type II: 3.3 ± 2.3 cells HPF, and type III: 3.9 ± 2.6 cells/HPF was also lower without statistical significance (p = 0.09, 0.22). Severe fibrosis was observed in 28.4% cases of type I achalasia, although, no cases showed severe fibrosis in type II and III achalasia. Atrophy of muscularis externa was seen in 58.2% and 60.0% cases of type I and II achalasia, respectively, however, type III did not show such atrophy.

Conclusion: The present study showed type III achalasia had preserved number of ICCs, behind a loss of ICCs in type I and II. Histopathological patterns of fibrosis and atrophy were also different. Achalasia subtypes may have different pathophysiology. Key Points Significant reduction of nNOS immunoactivity was observed in all achalasia subtypes, although type III achalasia showed preserved number of ICCs. Histopathological examination of the muscularis externa in achalasia subtypes may elucidate the pathological difference.

Introduction: Patients with chronic intestinal failure (IF) are life-dependent on the provision of home parenteral support (HPS). The continuous presence of a central venous catheter (CVC) inflict a constant risk of developing catheter-related bloodstream infections (CRBSIs) leading to health-impairment and high cost[]. Anti-microbial lock-solutions containing taurodilone are promising in the prevention of CRBSI[2].

Aims & Methods: This study investigates efficacy and safety of the anti-microbial catheter lock solution, taurodilone-citrate-heparin, compared to heparin 100 IE/mL on the CRBSI occurrence. Forty-one adult high-risk HPS patients with a previous CRBSI rate of 2.4 episodes/1000 days (95% Poisson CL: 2.12–7.21) were randomised, in a double-blinded, placebo-controlled trial. An external stratified randomisation was performed according to age, gender and prior CRBSI rate. The primary endpoint was difference in mean CRBSI rate. Secondary endpoints were occurrence of other catheter-related complications, patient satisfaction, side-effects and a cost-benefit analysis. The maximum treatment period was two years or until the occurrence of a CRBSI or right-censoring because of death. Randomisation was performed according to age, gender and prior CRBSI rate.

Results: Twenty patients received the taurodilone lock and 21 heparin 100 IE/mL, with 9622 and 6956 treatment days, respectively. Zero CRBSIs occurred in the taurodilone arm, while 4 CRBSIs (2.72 ± 1.21) occurred in the heparin arm. No difference in mechanical CVC complications was observed between the two arms. Lower CRBSI rate was also observed in the taurodilone arm (2.07 (0.00–5.47) vs. 3.9 (0.00–7.72) in the heparin arm, P = 0.0052). The CVC removal rates were 0.52 (0.17–1.21) and 1.72 (0.89–3.0) in the taurodilone and heparin arm, respectively, extending to 7.3% and 1.7% in the 2-year follow-up period. No difference in mechanical CVC complications was observed between the two arms.

Introduction: For children with acute gastrointestinal bleeding the majority of studies are retrospective, focusing on therapeutic endoscopy. Previous studies performed on adult patients have demonstrated that both scheduled second-look endoscopy and high-dose continuous proton pump inhibitors infusion are effective in preventing peptic ulcer rebleeding.
Aims & Methods: The aim of this study was to compare the two strategies of scheduled second-look endoscopy plus bolus esomprazole infusion and continuous esomprazole infusion for the prevention of ulcer rebleeding after endoscopic haemostasis in children. Consecutive children who underwent endoscopic treatment for bleeding peptic ulcers were randomized to two treatment groups: (1) scheduled second-look endoscopy with appropriate therapy in case of bleeding stigmata within 12-24 hours of the initial endoscopy plus intravenous esomprazole bolus 0.5 mg/kg (maximum 40 mg) every 12 hours for 72 hours (first group) or to receive high-dose continuous esomprazole infusion (1 mg/kg intravenous bolus followed by 0.1 mg/kg/hour continuous infusion for 72 hours) without endoscopic reassessment unless for rebleeding (the second group).
Results: 63 children were randomized to second-look endoscopy in group 1 and 64 to esomprazole continuous infusion group. Rebleeding occurred within 14 days in 4 patients (6.3%) in the first group and in 3 patients (4.6%) in the second group (p=0.7).
Conclusion: Pharmaco-protective approach by high-dose continuous esomprazole infusion in children after initial endoscopic haemostasis has similar efficacy compared to second-look endoscopy and bolus esomprazole administration in preventing peptic ulcer rebleeding. Thus, the discomfort of a second endoscopy in children can be avoided, keeping this recommendation only for high-risk selected cases.

Introduction: Infantile colic is the most common cause for presentation of mothers to emergency departments, but there are few evidence-based therapies. ‘Windy foods’ such as cabbage, onion and garlic are commonly reduced. Parents are often asked to follow a low FODMAP diet. ‘Windy foods’ such as cabbage, onion and garlic are commonly reduced. Parents are often asked to follow a low FODMAP diet. P Gibson has published an educational/recipe book on the low FODMAP diet.

Aims & Methods: This study aimed to (1) compare via a randomised, double-blind crossover study the effects of a low FODMAP diet with that of a typical Australian diet on infant crying-fussing durations and a daily dietary diary for each of the study diets. At baseline and on day 10 of each study diet, mothers completed a depression, anxiety and stress scale (DASS) questionnaire, and collected samples of breast milk for FODMAP analysis. Samples were defined by maternal diet, milk acidity, MDA content and significantly raised SOD, GPx activity and GSH content was not related to changes in maternal stress or anxiety or to gross changes in breast milk or infant faeces. Mechanisms by which changes in maternal diet affect infant behaviour require elucidation.

Disclosure of Interest: P.R. Gibson: The Department of Gastroenterology financially benefits from the sales of a digital application and booklets on the low FODMAP diet. P Gibson has published an educational/recipe book on the low FODMAP diet.

OP376 PAN-EUROPEAN REGISTRY ON H. PYLORI MANAGEMENT (HP-EUREG): INTERIM ANALYSIS OF 4417 SECOND-LINE TREATMENTS

Aims & Methods: A local coordinator was selected from each country (250 so far). An representative group of recruiting investigators from its country (250 so far). An

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Second-line triple therapies generally provide lower eradication rates except when prescribing moxifloxacin for 14 days. Moxifloxacin-containing quadruple therapies seem to provide higher efficacy, especially the combination of bismuth with a PPI, moxifloxacin and amoxicillin.

Disclosure of Interest: A.G. McNicholl: Dr. McNicholl has received reimbursement from Allergan for delinquent activities. D.S. Bordin: Dr. Bordin has served as lecturer for Astellas, AstraZeneca, KRKA and Abbott.

Perez Aisa: Dr. Perez-Aisa has received reimbursement from Allergan and Pfizer for delinquent actions.

M. Castro Fernandez: Dr. Castro-Fernandez has received reimbursement from Allergan for delinquent actions.

P. Bytzer: Dr. Bytzer has served as consultant, and as advisor for or has received research funding from Almirall, Allergan and Reckitt Benckiser.

J. Molina Infante: Dr. Molina-Infante has served as consultant for Casen Recorderati and has received retribution from Allergan for delinquent actions. J.P. Gisbert: Dr. Gisbert has served as speaker, and as advisor for or has received research funding from Almirall, Nycomed, AstraZeneca, Recordati and Allergan.

All other authors have declared no conflicts of interest.

OP377 CAPSULE ENDOSCOPY IN INTESTINAL LYMPHAGIECTASIA: A NOVEL ENDOSCOPIC CLASSIFICATION AND ITS CLINICAL CORRELATION

K. Lin, W. Shen, J. Wu
Beijing Shijitan hospital, Capital Medical University, Beijing/China

Contact E-mail Address: kukiundm@126.com

Introduction: Intestinal lymphangiectasia (IL) is a rare protein-losing enteropathy caused by disorder of the intestinal lymphatics, presenting as hypoproteinaemia, bilateral lower limb oedema, and ascites. Accoding to the etiology, this disease can be classified into primary or secondary IL. Endoscopy is the main modality for diagnosing IL, however, conventional esophagogastroduodenoscopy and colonoscopy, even balloon-assisted enteroscopy could not visualize the whole intestine. Capsule endoscopy, being a novel device introduced in recent decades, could be used to explore the whole segment of small bowel, is a suitable option for evaluation of intestinal lymphangiectasia.

Aims & Methods: Although Capsule Endoscopy (CE) is useful in diagnosis of intestinal lymphangiectasia (IL), the analysis of endoscopic and clinical characteristics remains unavailable. Between March 2011 and July 2015, patients clinically suspected IL underwent capsule endoscopy in our center were included in our study. Clinical data retrieved included age, sex, present medical history, presenting symptoms, laboratory examination, radiological findings, and medical management. The diagnosis of IL was confirmed by the presence of typical endoscopic manifestations or pathological findings in biopsy or surgical specimens. All patients followed a clear liquid diet for 24h plus 12h fasting prior to CE. (P0)(Cam® SB2, Given Imaging Ltd. Yoqneam, Israel) PEG or oral electrolyte solution (for patients younger than 10 years old) was used for bowel preparation.

Results: A total of 54 patients with median age of 24 (4–56) years were included. 42 cases were diagnosed as primary IL. Typical endoscopic characteristics included scattering, grouping or diffuse white-yellow spotted, patchy or srawy lymphangiectasia. Uptypical characteristics included enlarged, swollen or extremely dilated villi, possibly “white-veil-like” or “paving-stone-like” appearance, and “blue bleb” (dilated veain) can be noted sometimes. The endoscopic classification was established as follows: type I, alteration mostly restricted to untypical abdominal wall; type II, scattering typical lymphangiectasia, usually involving one or two of all three bowel segment; type III, diffuse typical patchy or scalpy
lymphangiectasia, mostly involving whole bowel. According to this criteria, 17 (31.5%), 24 (44.4%) and 13 (24.1%) cases were classified into type I, II and III respectively. The patients falling into type III are all diagnosed as primary IL and the average age was significantly younger than type I and type II. As for complications, a total of 16 cases of lymph leakage, 2 cases of stenosis (both type I) and 5 cases of bleeding were noted. Lymphatic leakage was detected both by capsule endoscopy and bowel albumin scintigraphy in 10 cases and the judging of leaking location were all consistent using these two modalities, but CE provided more precise information than scintigraphy.

**Conclusion:** Providing comprehensive evaluation of whole small bowel, CE may play a great role in diagnosis, management and surveillance of IL. Endoscopic classification of IL may correlate with specific clinical outcome.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**OP378 LONG-TERM OUTCOMES OF PATIENTS WITH EARLY GASTRIC CANCER DIAGNOSED AS PATHOLOGICAL EXTRA-INDICATED LESION AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION**

K. Ishido1, T. Yano2, S. Tanabe2, T. Wada1, M. Azuma1, C. Katada1, W. Koizumi1
1Gastroenterology, Kitasato University School of Medicine, Sagamihara/Japan
2Research And Development Center For New Frontier, Kitasato University School of Medicine, Sagamihara/Japan

**Contact E-mail Address:** k.ishido@kitasato-u.ac.jp

**Introduction:** Gastric cancer treatment guidelines recommend additional surgery as the standard treatment of the extra-indicated lesions for endoscopic submucosal dissection (ESD). However, the incidence of lymph-node metastasis is low in most patients.

**Aims & Methods:** The study group comprised 231 patients (231 lesions) who underwent ESD for early gastric cancer in our hospital from September 2002 through March 2015 and were histopathologically confirmed the extra-indicated lesions for ESD. Patients with a gastric tube or remnant stomach were excluded. The patients were divided into an additional operation group and a follow-up group, and long-term outcomes were studied retrospectively. Risk factors for metastasis and recurrence were also studied.

**Results:** The median follow-up was 48 months. There were 174 men and 57 women with a median age of 72 years. The additional operation group comprised 118 patients, and the follow-up group comprised 113 patients. The rates of 5-year cause-specific survival and 5-year overall survival were significantly higher in the additional operation group (100% and 96.0%, respectively) than in the follow-up group (92.6% and 73.3%, respectively; both p = 0.010). In the follow-up group, 5 patients (4.4%) died of gastric cancer (p = 0.023). Among elderly patients 75 years or older, long-term outcomes did not differ significantly between the groups. Surgery was avoided because of underlying disease in 88 patients (77.9%) in the follow-up group (p = 0.001). Sixteen patients (12 in the additional operation group and 4 in the follow-up group) had metastasis or recurrence, and the presence of lymphatic involvement was an independent risk factor for metastasis, recurrence, or both (p = 0.003; odds ratio, 10.594; 95% confidence interval, 2.294 to 48.927).

**Conclusion:** In patients with early gastric cancer who were confirmed the extra-indicated lesions for ESD, additional surgery should be aggressively performed if the patient can tolerate such treatment. In elderly patients aged 75 years or older and patients with serious underlying diseases, follow-up observation was suggested to be one option in patients who give informed consent after receiving an explanation of the risk of recurrence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
ALTERNATIONS OF THE NO-CGMP PATHWAY IN THIOACETAMIDE-INDUCED LIVER FIBROSIS/CRIRRHOSIS IN RATS

D. Schaffner1, J. Lazaro1, I. Merfort1, P. Hasselblatt1, P. Deibert1, W. Kreisel2

Introduction: Liver cirrhosis is an association with an imbalance between vasodilation and vasoconstriction in the sinusoids. Therefore the investigation of the nitric oxide - cyclic guanoansine monophosphate (NO-cGMP) pathway, a key regulator of vascular smooth muscle tone, is essential.

Aims & Methods: The rat model of thioacetamide (TAA) was used to induce liver fibrosis/cirrhosis and alterations of the NO-cGMP pathway and subsequent liver damage were assessed. 25 male Wistar rats were studied (11 untreated controls and 14 TAA-treated animals [0.03 g TAA/100 ml drinking water for 16 weeks]). TAA dosage was adjusted weekly based on body weight changes. Hepatic gene expression of endothelial and inducible NO synthase (eNOS and iNOS), phosphodiesterase 5 (PDE5) soluble guanylate cyclase subunits a1 (sGCa1) and b1 (sGCB1) was determined by qRT-PCR. Serum cGMP concentrations were measured by ELISA using blood samples taken from the carotid artery. Likewise liver damage was assessed by liver chemistry (i.e. alanine- and aspartate-amino-transaminase, ALT and AST), alkaline phosphatase (AP), albumin and bilirubin. The degree of fibrosis was estimated by histological criteria (i.e. Desmet scores). PDE5-expression was determined by immunohistochemistry. Kruskal-Wallis test was used for statistical analysis of group differences.

Results: Gene expression analysis revealed significantly increased expression of eNOS (1.5fold), PDE5 (7.7fold), and sGCb1 (2.1fold) in fibrotic livers compared to controls. cGMP concentrations in fibrotic animals were slightly decreased (-34%). Significantly increased expression of iNOS (2.26fold), sGCb1 (1.7fold), and sGCB1 (3fold) was observed in cirrhotic livers compared to controls, while cGMP concentrations were significantly decreased (-40%). In controls NOX expression was only detected in fibrotic and cirrhotic livers, but absent in controls. Immunohistochemistry revealed markedly increased PDE5-expression in cirrhotic livers, which was predominantly localized in hepatic stellate cells. Conclusion: The analysis of the animal model of TAA-induced liver fibrosis/ cirrhosis revealed alterations of the NO-cGMP pathway, characterized by reduced concentrations of cGMP, a key mediator of vasodilation, so as to increased PDE5-expression. These changes reinforce the hypothesis that sinusoids remain in a contractile state in cirrhotic livers, thereby contributing to increased PDE5-expression. These changes reinforce the hypothesis that sinusoids remain in a contractile state in cirrhotic livers, thereby contributing to portal hypertension. Thus, administration of PDE5-inhibitors, possibly combined with NOX-inhibition, should be further studied in clinical trials as a promising therapeutic approach to target portal hypertension.

Contact E-mail Address: andremartini86@gmail.com

Introduction: In chronic HCV infection disease progression is maintained by sustained necroinflammation and fibrosis in the liver. Upon macrophage activation, the soluble marker CD163 (sCD163) is released in serum and its levels correlate with fibrosis and NAS in the liver. The serum protease inhibitor SerpinB3 (or SCCA1), has been shown to be involved in liver fibrogenesis and the circulating SCCA-IgM complex has been depicted as a marker of liver disease progression and of NAS in patients with chronic hepatitis C. Preliminary data suggest that SerpinB3 activates primary monocytes through the Wnt canonical pathway. The purpose of this study was to evaluate the relationship between SCCA-IgM and sCD163 in serum and the possible role of SerpinB3 on sCD163 and on pro-inflammatory cytokine expression, in primary monocytes.

Aims & Methods: In 91 patients with biopsy-proven chronic hepatitis C, serum samples were tested for sCD163 (ng/ml) and SCCA-IgM (AU/ml) by ELISA. The results were analyzed in relation with clinical and histological parameters. Primary monocytes were isolated from healthy donors, treated with recombinant SerpinB3 (200 ng/ml) and supernatants analyzed after 2 and 7 days. Expression of sCD163 secreted in the supernatant was evaluated by ELISA. In primary monocytes, monocyte-macrophage activation marker IL-12, CXCL-10 and TNF-alpha were also analyzed by PCR at different time points.

Results: In patients with chronic hepatitis C sCD163 was found correlated with inflammatory and metabolic alterations (AST, ALT, GGT, HOMA-IR, triglycerides), and was significantly increased in patients with sarcoid-like histological fibrosis stage (F1-F2 vs. F3-F4 nec. Metavir: p < 0.04). Patients with levels of SCCA-IgM > 200 AU/ml had more elevated serum levels of sCD163 (p < 0.05). In primary monocytes stimulated with recombinant SerpinB3 “in vitro”, sCD163 expression increased of 2.5 times and this finding was parallel to an up-regulation of the inflammatory cytokines IL-12, CXCL-10 and TNF-alpha.

P0004 THE PROTECTIVE EFFECTS OF GROUP 3 INNATE LYMPHOCYTE CELLS ON HEPATITIS B VIRUS RELATED LIVER FIBROSIS COULD BE IMPAIRED BY TH17 CELLS

S. Wang, W. Ma, L. Cheng, W. Jiang
Gastroenterology, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: 15211210012@fudan.edu.cn

Introduction: Th17 cells have been proved to contribute to hepatitis B virus (HBV) related liver fibrosis. Group 3 innate lymphocyte cells (ILC3s), which have similar profiles of transcription factor and cytokines to that of Th17 cells, were also suggested to be involved in the progression of liver fibrosis.

Aims & Methods: The study was designed to explore the functions of ILC3s and the relationships between ILC3s and Th17 cells in liver fibrosis. Peripheral blood samples were collected from 60 patients with chronic hepatitis B (CHB), and 50 patients with HBV related liver cirrhosis (LC) as well as 30 healthy controls (HC). The percentages and cytokines secretion of ILC3s (Lin-CD127+CD117+CD244+) and Th17 cells (CD4+IL-17+) were detected by flow cytometry. Peripheral blood mononuclear cells (PBMCs) and PBMCs without ILC3s co-cultured with hepatic stellate cells (HSCs)-LX2 in contact and non-contact manners. Then Th17 cells, which were induced from naive CD4+ T cells in vitro, were transferred into Rag1-/- mice with cernice tetrachlorodrin (CCl4) related liver fibrosis. In addition, ILC3s in Rag1-/- mice were depleted by injecting with anti-CD90.2 antibody.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF-α, IFN-γ decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokines secretion. Th17 cells frequencies significantly increased both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Similarly, compared with wild type mice, ILC3s in spleens and livers of C57BL/6 mice with liver fibrosis increased sequentially at time point of week 2 and week 4 following drug injection. Intriguingly, at week 6, ILC3s decreased compared with previous. However, Th17 cells increased gradually with CCl4 administration, even at week 6. Transferring Th17 cells into Rag1-/- mice with liver fibrosis made the ILC3s in spleens and livers decreases significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipient mice with liver fibrosis and reverse liver fibrosis.

Conclusion: Our study has uncovered the protective role of ILC3s in liver fibrosis, which is through secreting IL-22 to reduce proliferation and activation of HSCs. However, the protective functions of ILC3s could be impaired by Th17 cells.

P0005 EFFECTS OF INTERNAL AND EXTERNAL BILIARY DRAINAGE ON THE EXPRESSION OF INTESTINAL BILE ACID RECEPTOR AND TLR4/NOD2 IN MICE WITH OBSTRUCTIVE JAUNDICE

S. Li1, S. Shen2, T. Zhang2, W. Li3
1Gastroenterology-hepatology, People’s Liberation Army General Hospital (PLAGH), Beijing/China
2The General Hospital of the Chinese People’s Liberation Army, Beijing/China
3Gastroenterology And Hepatology, The General Hospital of the Chinese People’s Liberation Army, Beijing/China

Contact E-mail Address: zhangtt246@sina.com

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear. In this study, we mainly study the expression between FXR and TLR4, TGR5 and NOD2.

Aims & Methods: We aimed to investigate the potential relation between the expressions of bile acid receptor and TLR4/NOD2 in intestinal mucosa and its influence on the intestinal mucosal barrier with obstructive jaundice. In this study, we mainly study the expression between FXR and TLR4, TGR5 and NOD2. Sixty male adult Kunming mice were randomly assigned to four groups: SH (sham operation), OJ (obstructive jaundice), ID (internal drainage), ED (external drainage) (n = 15 in each group). On the 7th day from the first operation, the OJ and SH mice were executed and specimens of blood and ileal tissue of groups were collected. ED and ID were reoperated on day 8 for biliary drainage procedure. Blood was drawn from heart for liver function test. The terminal ileum specimen was collected for test of histology using haematoxylin-eosin (HE) staining. Western blot (WB) and real-time polymerase chain reaction (RT-PCR) were used to detect the expression of protein and mRNA of FXR, TGR5, TLR4 and NOD2 in intestinal mucosa.

Results: We have successfully established the animal models. The histopathological examination revealed notable inflammatory infiltration and hyperplasia disruption at terminal ileum in OJ mice; significant alleviation of above injuries by ID while little improvement by ED. FXR-TLR4: After biliary obstruction, the expression of protein and mRNA of FXR were significantly increased, while the expression of protein and mRNA of TLR4 were significantly decreased compared with SH group’s (P < 0.005). After ED, compared with OJ group’s expression of protein of FXR was decreased while TLR4 were increased. The mRNA of both FXR and TLR4 were increased. After ID, the expression of protein and mRNA of FXR were significantly decreased compared with OJ group’s but still were better than that in SH group and were better than ED group’s. And the expression of protein and mRNA of TLR4 were significantly increased compared with OJ group’s (P < 0.001), but were still lower than that in SH group and were better than ED group’s. The trend of TLR4 expression was almost the same between vehicle group and no gavage group. After gavage with FXR agonist, the differences of TLR4 expression of four groups disappeared (P > 0.05). TGR5-NOD2: IHC and WB suggested that after OJ surgery, the protein expression of both TGR5 and NOD2 increased obviously compared to that of SH mice; then the level of TGR5 and NOD2 protein fell markedly after ID surgery close to SH level while in ED group there was only a slightly reduction form OJ level and still with a high expression of TGR5 and NOD2 protein. Detection of RT-PCR found that TGR5 mRNA and NOD2 mRNA level in OJ group increased several times as that of the SH group; after ID surgery, the expression of TGR5 mRNA significantly reduced, NOD2 mRNA level also fell down consistently, but the effect was not observed in ED mice.

Conclusion: The expression of intestinal FXR and TLR4, TGR5 and NOD2 could be one of the critical mechanism why internal drainage is better than external drainage in restore intestinal barrier function of obstructive jaundice mice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0006 ALTERED SMALL INTESTINAL MICROBIOTA TOWARD FAMILY LACTOBACILLACEAE IN MIR-21 KNOCKOUT MICE

Introduction: Alterations in the gut microbiota have been correlated to a wide variety of diseases, including liver diseases. Used as probiotics, several strains of Lactobacillus have been associated not only to modulation of intestinal tight junctions but also to amelioration of liver fibrosis. Common bile duct ligation (BDL) results in acute cholestatic injury and secondary biliary fibrosis, associated with early increased intestinal permeability and disturbed bile acid homeostasis. We have demonstrated that the oncogenic microRNA-21 (miR-21) is upregulated in BDL mouse liver, mediating liver fibrosis. We aimed to investigate the role of miR-21 in the response of the small intestinal microbiota to BDL that may explain miR-21 effects in acute liver injury and fibrosis.

Aims & Methods: Three-month-old C57BL/6 wildtype (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries. After three days, mice were sacrificed and small intestinal lumen samples were carefully removed and preserved. mRNA expression was analysed by qRT-PCR. Bacterial DNA was purified from the small intestinal lumen samples and analysed by next generation sequencing - metagenome analysis. Liver tissue and serum were also collected for biochemical analysis of hepatic damage and fibrosis.

Results: TNF-α and IL-1 β mRNA levels increased in the small intestine of BDL mice, compared with WT. TLR4 and TGF-β expression was increased in both sham- and BDL-miR-21 KO mice which is in accordance with the higher LPS in blood plasma observed. Zona occludens (ZO-1) and occludin mRNA levels were decreased in WT mice after BDL. Strikingly, miR-21 KO reverted mRNA of tight junction proteins to control levels. BDL miR-21 KO mice showed decreased circulating levels of hepatic enzymes, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Further, miR-21 KO not only show a decreased small intestine permeability through a ZO-1 and occludin pathway, as it is associated with development of beneficial strains of Lactobacillaceae that may also contribute to liver protection.

Conclusion: These data suggest that miR-21 depletion is associated with increased intestinal permeability markers in the small intestine and better immune response to bacterial dysbiosis provoked by the BDL surgery, thus halting liver injury and promoting gut microbiota homeostasis. (Supported by PTDC/BIM-MEC/089572014, FCT)

Disclosure of Interest: All authors have declared no conflicts of interest.
Akkermansia muciniphila mediated liver injury is associated with different microbial communities. It was reported to be involved in cell growth and apoptosis in tumor and acts as a potential tumor suppressor in HCC. It has shown that high levels of ZBP-89 expression were statistically associated with better survival of HCC patients. Furthermore, the mechanism of ZBP-89 in modulating sensitivity of Sorafenib in CSC is remains unknown.

**Aims & Methods:** In this study, we investigated the mechanism of Sorafenib resistance in HCC cancer stem cells, and how ZBP-89 reduced drug resistance. The sensitivity of HuH7 and Hep3B parental and sphere-forming cells to Sorafenib was measured by MTT assay. We then examined the expression pattern of Notch1 and liver CSC markers in HuH7 and Hep3B CSC after the treatment with Sorafenib. MTT assay was also used to measure the effects of ZBP-89 overexpression on the sensitivity of Sorafenib in sphere-forming cells. The levels of ZBP-89 and CD44 were measured using qPCR in human HCC tissue samples. The regulatory effects of ZBP-89 on CSC phenotype were examined in mouse models including CD44 and Notch1 target genes including HES1, HES6, HEY1 and NRARP. Amino acids suggesting that ZBP-89 was involved in suppression of CSC phenotype. Detailed study indicated that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissues. In vitro study indicated that tumor resistance to Sorafenib, compared with their parental cells. The expression of Notch1 was reported to be associated with cancer stem cells (CSC). The transcription factor ZBP-89 was found to result in the loss of CSC phenotype and improve the sensitivity to Sorafenib in CSC through its interaction with activated Notch1. In conclusion, this study suggested that ZBP-89 overexpression on the sensitivity of Sorafenib in sphere-forming cells. We found that sphere-forming HCC cells had significant higher resistance to Sorafenib, compared with their parental cells. The expression of Notch1 and EpCAM was increased along with the treatment of low dose of Sorafenib, suggesting that the activation of Notch1 pathway was associated with the drug resistance in liver CSC. Studies further indicated that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib in sphere-forming CSC cells. Furthermore, we found that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissues. In vitro study indicated that tumor sphere forming was impaired under ZBP-89 overexpression of ZBP-89, suggesting that ZBP-89 was involved in suppression of CSC phenotype. Detailed investigation against control cells showed that overexpression of ZBP-89 resulted in reduced expression of CSC markers EpCAM, CD133, Sox2 and e-cmyc at both mRNA and protein levels. In addition, the overexpression of ZBP-89 or silencing of Notch1 reduced the number of colonies formed by sphere-forming CSC cells, demonstrating opposite effects of these two proteins. Mechanistic studies revealed that ZBP-89 was able to repress the expression of Notch1 and reported that ZBP-89 could directly bind to the activated Notch1 in the nucleus, resulting in a negative regulation of CSCs and overcome of Sorafenib resistance. We aimed to study the clinical effect of probiotics in the treatment of nonalcoholic fatty liver disease. 200 cases of patients with nonalcoholic fatty liver disease were randomly divided into routine treatment group (A group) and combined treatment 3 groups (B, C, D). All 50 cases were given orally Polyene Phosphatidylcholine Capsules, 456 mg, TID. The combination therapy group B was given orally the Live Combined Bifidobacterium Lactobacillus and Enterococcus Powder, 420 mg, TID; group C, two live combined Baccillus subtilis Enterococcus, 500 mg, TID. D group was given orally the both probiotics above. The course was 1 month. All patients were respectively examined before treatment and seven days and thirty days after treatment, for cholesterol (TC), triglyceride (TG), high density lipoprotein cholesterol (HDL-L), low density lipoprotein cholesterol (LDL-L), alanine aminotransferase (ALT), aspartate aminotransferase (AST), fasting blood glucose (FPG), serum high molecular weight adiponectin (HMW APN) and serum TNF-α. The 4 groups were collected faces samples, that were tested routine detection, bacterial culture. At the same time all participants were checked with ultrasound liver and abdominal scan.

**Results:** In terms of blood lipids and blood glucose, each group improved than before, only HDL-L was not statistically significant, D group showed significant differences in triglyceride. In liver function, blood ALT, AST were significantly lowered in B group than A group, A and B groups lowered A levels were decreased after treatment. In the combined treatment D group was statistically significant; group D more than the group A; serum HMW APN increased after treatment, decreased in the combined treatment D group compared with routine treatment group A was significant difference. Adiponectin: Intestinal probiotics can regulate the intestinal micro ecological imbalance in NAFLD patients, and reduce the level of serum TNF-α, improve the level of adiponectin, which can further improve the blood glucose, lipid metabolism, and then improve the liver injury of non-alcoholic fatty liver disease.

**Disclose of Interest:** All authors have declared no conflicts of interest.
P0010 FAECALIBACTERIUM ASSOCIATED WITH GUT-PERMEABILITY IN NONALCOHOLIC FATTY LIVER DISEASE

Introduction: Despite evidence that the microbiota is involved in the pathogenesis of obesity, the microbiota of patients with nonalcoholic fatty liver disease (NAFLD) has not been well characterized. NAFLD is considered a hepatic manifestation of metabolic syndrome and is particularly associated with insulin resistance, obesity, and gut-driven endotoxin.

Aims & Methods: The aim of our study is to assess if there are any differences in the microbiota of patients with biopsy-proven NAFLD and healthy controls (HC). In addition, peripheral blood endotoxin (ET) and gut-permeability was analyzed in NAFLD (mild fibrosis vs severe fibrosis) and HC patients. A total of 201 patients were enrolled in this study: 68 HC and 133 biopsy-proven NAFLD (77 mild fibrosis and 56 severe fibrosis [F0–4]). One stool sample was collected from each participant. All NAFLD patients included in this study underwent percutaneous liver biopsy. Healthy controls were volunteers. The composition of gut bacterial communities was determined by 16S rDNA sequencing. Additionally, peripheral blood ET was determined using by endotoxin activity assay (EAA). Gut-permeability was assessed by Lactulose mannitol ratio (LMR).

Results: Among those taxa with greater than 1% representation in any of the three NAFLD groups, and we can not predict liver iron overload for hyperferritinemia (HF) and we postulate that the distinct composition of the gut microbiota varied remarkably in pairwise comparison of one mouse model with the Control.

Conclusion: In summary, the composition of gut microbiota varied remarkably between mice administrated different experimental diets to induce non-alcoholic fatty liver disease. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). Liver steatosis is often suspected in patients with HF.

Aims & Methods: To study the prevalence of hepatic steatosis determined by MRI in these patients. A prospective study of 312 consecutive with HF (>200 µg/L women; 300 µg/L men) and/or TSI > 45%, confirmed in two determinations, was conducted from December 2010 to April 2013. The MS was defined by the presence of three of the following factors: waist circumference ≥94 cm men ≥80 cm women; triglycerides ≥250 mg/dL or treatment for this dyslipidemia; HDL < 40 mg/dL women <50 mg/dL men or treatment for this dyslipidemia; glucose ≥100 mg/dL or Type 2 diabetes; hypertension: blood pressure ≥130 mmHg/≥85 mmHg or treatment for arterial hypertension (1). HF was determined by MRI 1.5 Tesla system (SIR method) (2). We systematically performed T1-weighted in-phase and opposed-phase imaging to determine the presence or not of liver steatosis.

Results: 312 patients (272 men/40 women) were included. Mean age 55 (SD 13.5); Mean ferritin 729, 6 (SD 449.6), mean TSI 40, 8 (SD 15.8); 276 patients have all the required criteria to determine the MS presence: 115/240 men (48%) and 20/36 women (55%), were patients with MS (49.4%); 141 without MS (NMS) (51%). In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis. 231 patients with MS criteria and MR for steatosis: NMS group (128): no steatosis 103; steatosis 25; MS group (123): no steatosis 72; steatosis 51 (total: no steatosis 175, steatosis 76). When we study the presence of liver steatosis was more frequent in the MS group, the results obtained were statistically significant, p = 0.000.

Conclusion: Nearly 50% of the patients referred for hyperferritinemia to the hospitals of our country had MS; the patients with MS had more frequently liver steatosis than the patients without MS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In a previous study from our group (1), in a secondary hospital, we did not find differences in the liver iron concentration (LIC) of the different groups, and we can not predict liver iron overload for hyperferritinemia (HF)

the biomarker of NAFLD in LEIs analysis. More biomarkers at genus level (Lachnospira, S24-7, etc.) were identified in pairwise comparison of one mouse model with the Control.

Conclusion: In summary, the composition of gut microbiota varied remarkably between mice administrated different experimental diets to induce non-alcoholic fatty liver disease. Disclosure of Interest: All authors have declared no conflicts of interest.

A164 United European Gastroenterology Journal 5(5S)
patients with HFE mutations and (transferrin saturation index (TSI) values alone. But we did not have C282Y/C282Y patients in the series.

Aims & Methods: To study the relevance of HFE mutations and TSI in determining LIC for HF patients attending the outpatient clinic at 6 hospitals in the Basque country. Prospective study of 312 consecutive patients with HF. Group A (n=126) described three different groups according to HFE mutations and TSI (Group A: no predisposing mutations (PM) for HH and TSI < 45%); Group B: PM for HH: C282Y/C282Y; C282Y/H63D, H63D/H63D, and TSI > 45%; Group C: no PM for HH and normal TSI). Group D: PM and normal TSI. In the Basque country, hereditary hemochromatosis (HH) predisposing mutations differ, with relevance of the H63D/H63D mutation. The LIC was measured by MRI.

Results: In all the patients, HFE study was available: C282Y/C282Y 14 (4.49%); C282Y/H63D 47 (15.06%); H63D/H63D 99 (31.73%); wt/wt 98 (31.41%); C282Y/S65C 1 (0.32%); H63D/S65C 2 (0.64%); C282Y/wt 16 (5.13%); S65C/wt 10 (3.21%). LIC was obtained from all the patients by MRI. Mean age: 55.0 ± 13.25, 272 men and 40 women. Group A: 54; Group B: 32 Group C: 70; Group D: 64. The mean LIC index increased: Group B: 57.21 ± 27.89, group C: 70.53 ± 58.67, group C: 35.23 ± 22.62. Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (bonferroni) with significant differences (p<0.0001).

Conclusion: The LIC in different groups of patients referred for HF are significantly different with different predisposition to HH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). There are some publications that support that HF is associated with a raised liver iron concentration (LIC) in these patients, but the doubts persist about this subject.

Aims & Methods: To study the LIC in patients referred for hyperferritinemia to six different hospitals in the Basque Country (multicenter study), Spain, and determine if there are differences between patients with or without metabolic syndrome. A prospective study of 312 consecutive patients with HF (>200 mg/L women, >300 mg/L men) was conducted from December 2010 to April 2013. The Metabolic syndrome was defined by the presence of three of the following factors: waist circumference >94 cm in men, >80 cm in women; Triglycerides >150 mg/dL or treatment for this dyslipidemia; glucose >100 mg/dL or treatment for arterial hypertension (1). LIC was determined by MRI (SIR method) (2). 

Results: In all the patients, HFE study was available: C282Y/C282Y 14 (4.49%); C282Y/H63D 47 (15.06%); H63D/H63D 99 (31.73%); wt/wt 98 (31.41%); C282Y/S65C 1 (0.32%); H63D/S65C 2 (0.64%); C282Y/wt 16 (5.13%); S65C/wt 10 (3.21%). LIC was obtained from all the patients by MRI. Mean age: 55 ± 13.25, 272 men and 40 women. Group A: 54; Group B: 32 Group C: 70; Group D: 64. The mean LIC index increased: Group B: 57.21 ± 27.89, group C: 70.53 ± 58.67, group C: 35.23 ± 22.62. Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (bonferroni) with significant differences (p<0.0001).

Conclusion: The LIC in different groups of patients referred for HF are significantly different with different predisposition to HH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Alternatively activated anti-inflammatory macrophage (also termed M2 Kupffer cell) is important for prevention of the development of steatosis and liver injury in non-alcoholic fatty liver disease (NAFLD). Our previous studies demonstrated that interleukin in NFALD mice and exon 25-protected against NAFLD by inducing M2 Kupffer cells.

Aims & Methods: We aimed to explore the intracellular signal pathways of IL-25 to regulate macrophage polarization and direct effects of IL-25 on Kupffer cells. Mouse model of NAFLD was induced by feeding a high-fat diet (HFD); In vitro expansion of mouse Kupffer cells, IL-10 and IL-25 were used to induce M2a Kupffer cells; specific siRNAs were used to knockdown IL-25 receptor mRNA for assessing the direct and specific effect of IL-25 on Kupffer cells; IL-25 induced M2a Kupffer cells were back transfection into the abdomen of NAFLD mouse to assess the efficacy; Dual-luciferase reporter assays and Chromatin immunoprecipitation assays were used to determine the transcription factor of IL-25 promoter.

Results: Exogenous IL-25 induced expression of type 2 cytokine and alternative activation of Kupffer cell in vivo. It could also promote hepatic macrophages to differentiate into M2a Kupffer cells in vitro. Interestingly, IL-25 recovered the expression of IL-25 mRNA in the liver of NAFLD mice. Furthermore, IL-25 could induce the expression of IL-25 in cultured hepatocytes by activation of STAT6, rather than MZF1, API or NF-κB. STAT6 was sufficient and necessary for IL-25 expression. Deletion and site-directed mutagenesis of the IL-25 promoter revealed that IL-25 transcriptional activation depended primarily on a putative STAT-binding sequence between nucleotides ~682 ~674 upstream of the start site. STAT6 binding to this sequence increased in response to IL-25 treatment in vitro and in vivo. Finally, IL-25 induced M2a Kupffer cells could ameliorate HFD-induced hepatic steatosis by reducing IL-13 expression. IL-25 could downregulate IL-13 expression in M2a Kupffer cells.

Conclusion: Our results elucidate the molecular mechanisms of IL-25 during amelioration of hepatic steatosis and provide the scientific basis of direct IL-25 treatment or macrophage transfection therapy for NAFLD.

P0017 THE ROLE OF GENETIC FACTORS IN NON-OBESE NASH PATIENTS
F. Ates
Gastroenterology, Mersin University, Mersin/Turkey

Contact E-mail Address: dfrehmiates@hotmail.com

Introduction: Methylene tetrahydrofolate reductase (MTHFR) is the key enzyme in the remethylation of homocysteine. It is thought that MTHFR A1298C and C677T gene polymorphisms contribute to etiopathogenesis of NASH because of their effects in homocysteine metabolism.

Aims & Methods: Our aim in this study is to determine the relationship between the NASH and MTHFR C677T and A1298C gene polymorphisms, especially in non-obese NASH patients. Eighty-eight NASH patients whose diagnoses were confirmed by liver biopsies and 90 healthy volunteers as control group were included in the study. We investigated MTHFR A1298C and C677T gene polymorphisms and compared NASH patients and controls. NASH patients were assigned to two groups according to whether they are obese.

Results: Eighty-eight NASH patients (52M, 36F, mean age 45 years), and 90 healthy controls (53M, 37F, mean age 41 years) were included in the study. Altinkaya et al. reported that the frequency of TT genotype of MTHFR A1298C polymorphism is more frequent, especially in non-obese NASH patients than in healthy controls. This finding shows that genetic factors are particularly more important in non-obese NASH patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In the last decade, the notion of non-alcoholic fatty liver disease (NAFLD) has undergone noticeable changes. It is shown that in the liver with fatty hepatosis, insulin and glucose utilization is disrupted, conditions are created for the development of atherogenic processes of cholesterol and triglycerides. This contributes to the development of violations of carbohydrate and lipid metabolism, the early appearance of atherosclerosis and associated cardiovascular complications. Thus, NAFLD can be considered as an independent, additional risk factor for atherosclerosis. Obviously, this problem is not only of practical but also of scientific importance for clarifying the nature of the relationship between NAFLD and the early manifestations of atherosclerotic vascular wall lesions are relevant.

Aims & Methods: Study of changes in the vascular wall of the common carotid artery (IMT CCA) and in patients with abdominal obesity (AO) and different forms of nonalcoholic fatty liver disease (NAFLD). The study involved 60 patients with AO between the ages of 18 to 59 years (waist circumference >94 cm in men and >80 cm for women, over 94 cm for men). All patients underwent an ultrasound examination of the abdominal cavity to determine the size of the liver and signs of steatosis. The level of severity of pathological changes in the liver tissue (fibrosis, steatosis and steato-fibrosis) was assessed by non-invasive diagnostic method Steatoscreen. (Biopredictive laboratory, France). Measurement of the CCA IMT was performed according to standard procedures on the machine Voluson 730 Expert, equipped with a linear transducer phased array with a frequency of 7.5 MHz. The presence of early signs of atherosclerosis was defined as a local thickening of the IMT CCA more than 0.6 mm, and the presence of non-obstructive intimal lesions as a CCA IMT thickness exceeding 0.9 mm in any point of the carotid artery (CCA IMT max).

Results: Signs of early atherosclerosis, in the form of the IMT CCA, were detected in the majority of the patients (52%) and differed between the observed groups. The average thickness of the IMT CCA was significantly higher in patients with abdominal obesity than in patients with NAFLD and in patients with AO and NAFLD in the absence of obesity. The presence of early signs of atherosclerosis was confirmed by ultrasound examination of the abdominal cavity in 54% of patients with AO and 48% of patients with NAFLD.

Conclusion: While statins proved to be safe and efficient for the treatment of NASH in our series, larger cohort studies are needed to further demonstrate this potential positive effect on liver fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

complex and pathological changes in the liver, determined by the test SteatoHex (r= 0.76; p < 0.001). The dependence obtained is confirmed by the equation of simple linear regression.

Conclusion: In patients with AO, there is a direct relationship between the presence of pathological changes in the liver and the initial manifestations of atherosclerosis. The results obtained make it possible to evaluate the individual risk of atherosclerosis in this category of patients. Clinical significance of the results is the need for a more thorough examination of patients with AO and suspicion of liver pathology to assess the development of not only the disease of the liver itself, but also cardiovascular complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0020 OVEREXPRESSION OF HEPASSOCIN IN DIABETIC PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE MAY FACILITATE INCREASED HEPATIC LIPID ACCUMULATION

S. Abd-El Salem, S. Khodier, S. Abou Shal, G. Abdelnoorem

Introduction: Insulin resistance is the main pathogenic determinant of both NAFLD and diabetes, and it can facilitate triglyceride accumulation in the liver. Overexpression of hepassocin (HPS) increased hepatic lipid accumulation and NAFLD activity scores (NAS), whereas deletion of HPS improved high fat diet-induced hepatic steatosis and decreased NAS in mice.

Aims & Methods: The aim of this study was to explore the relationship between hepassocin and diabetic patients with or without NAFLD. The study included 90 patients that were divided into 4 groups: Group I: included 20 patients who were diagnosed as diabetes mellitus type 2, Group II: included 20 patients who were diagnosed as non alcoholic fatty liver disease, Group III: included 20 patients who were diagnosed as diabetes type 2 and non alcoholic fatty liver disease, Group IV (control group): included 20 healthy person who was matched in age and sex with patients group.

Results: There was stastically significant decrease in mean value of serum hepassocin of group I and IV on comparing with group II and Group III. For group II there was significantly stastically increase in mean value of serum hepassocin on comparing with other groups. There was a significant serum hepassocin up regulation in patients with type 2 diabetes and non alcoholic fatty liver diseased patients (Group 3) mostly than diabetic patients (Group 1) and even than non alcoholic fatty liver disease (Group 2).

Conclusion: The present study provides evidence that overexpression of HPS may facilitate increased hepatic lipid accumulation with NAFLD and Type 2 Diabetes mellitus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Individuals with chronic liver diseases may have a mild to moderate iron overload, but the mechanism is not fully understood. Increased contents of iron have been attributed to the progression of liver cirrhosis caused by HCV infection, nonalcoholic fatty liver disease, or alcoholic liver disease. Serum ferritin concentration can be increased in iron overload and shows hepatic necro-inflammation. Recently, raised serum ferritin concentration was shown to predict mortality in patients awaiting liver transplantation in decompensated liver cirrhosis. We investigated serum ferritin level to predict the early mortality of patients with alcoholic liver cirrhosis (ALC).

Aims & Methods: The aim of this study was to determine the association between serum ferritin concentration and the outcomes of patients with ALC. The study included 72 patients with ALC. One hundred patients were included by laboratory tests, clinical features, radiological imaging, and percutaneous or tranjugular liver biopsy. Alcohol liver cirrhosis was diagnosed when daily consumption of alcohol was > 30 g/day for males, respectively, as confirmed by at least 1 family member of affected individual.

For the sensitivity and specificity of AC the following cut-off values were used: 0.53 dB/cm/MHz, second – 64.5 ± 75.5 IU/L, third – 49.5 IU/l. Bilirubin concentration in first group was 90.52 ± 85.7 µmol/L, second – 111.9 ± 72.3 µmol/L, third – 140.9 ± 195.0 µmol/L. The biggest mortality rate was in third group – 13 of 15 patients (86.67 %) (p < 0.0001). ROC scale shows a 77% specificity of serum ferritin concentration predicting early mortality in patients with cirrhosis (AUC 0.838, p < 0.0001).

Conclusion: Serum ferritin level above 400 µg/l, elevated liver enzymes and bilirubin concentration shows a poor outcome of patients with ALC (p < 0.0001). Serum ferritin level is a specific factor for predicting the early mortality in ALC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0026 PLASMA RETICULIN 4 PROTEIN IS ASSOCIATED WITH PORTAL HYPERTENSION IN PATIENTS WITH LIVER CIRRHOSIS S. Gelman1, V. Saltienè2, A. Pranculis3, L. Kupecinskiè4

Introduction: Reticulin 4 (RTN4) protein was first described as a potent neurite growth inhibitor in the central nervous system. However, according to recent research, the protein expression is not limited to the cells of nervous system as it is found in various other tissues, including endothelial cells, fibroblasts, muscle cells, hepatocytes. The diverse location of the protein accounts for various biological activities such as vascular remodeling, inflammation, carcinogenesis, and proliferation, carcinogenesis and other processes2–5. The function and expression of the protein in liver disease is still not clear.

Aims & Methods: In this study we aimed to evaluate plasma levels of RTN4 protein in cirrhotic patients and associate them with clinical parameters and portal hypertension. The pilot study included 72 patients with hepatitis C or alcoholic liver cirrhosis and 22 healthy controls. Liver cirrhosis was diagnosed by laboratory tests, radiological imaging and/or liver biopsy. Portal pressure was assessed by hepatic venous pressure gradient (HVPG) measurement. Plasma levels of RTN4 were determined by enzyme-linked immunosorbent assay. Association of RTN4 with biochemical parameters, Child-Turcotte-Pugh and Model of End Stage liver disease (MELD) score, transient elastography values, Child-Turcotte-Pugh and Model of End Stage liver disease (MELD) score were analyzed using statistical software SPSS 23.0. ROC curve analysis was used to identify variables correlated with HVPG. Using a RTN 4 cut-off value of 85%, cut-off values were 0.53 dB/cm/MHz, second – 64.5 ± 75.5 IU/L, third – 49.5 IU/l. Bilirubin concentration in first group was 90.52 ± 85.7 µmol/L, second – 111.9 ± 72.3 µmol/L, third – 140.9 ± 195.0 µmol/L. The biggest mortality rate was in third group – 13 of 15 patients (86.67 %) (p < 0.0001). ROC scale shows a 77% specificity of serum ferritin concentration predicting early mortality in patients with cirrhosis (AUC 0.838, p < 0.0001).

Conclusion: Serum ferritin level above 400 µg/l, elevated liver enzymes and bilirubin concentration shows a poor outcome of patients with ALC (p < 0.0001). Serum ferritin level is a specific factor for predicting the early mortality in ALC.

2Ultrasound General Imaging, GE Healthcare, Hino/Japan

Contact E-mail Address: kenyon1266@yahoo.co.jp

Introduction: Nonalcoholic fatty liver disease is a main cause of chronic liver disease worldwide. A quantitative, non-invasive assessment of hepatic steatosis is desirable. Throughout the path of ultrasound (US), attenuation by liver parenchyma is uneven. This is the basis of the controlled attenuation parameter (CAP). However, further accumulation of data is needed to assess the role of CAP in the diagnosis of steatosis1). We investigated the diagnostic performance of B-mode image-guided ultrasound attenuation imaging and quantification for assessing hepatic steatosis by a liver biopsy (LB, reference standard). It was compared with the liver-to-spleen ratio (L/S ratio) from computed tomography (CT) and CAP.

Aims & Methods: We prospectively analyzed 112 consecutive patients with chronic liver disease who underwent ultrasound attenuation imaging, CT, and liver biopsy. Ultrasound attenuation imaging was performed using the LOGIQ E9 scanner (GE Healthcare) with a C1-6-D convex array probe (frequency, 4 MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured in the gelatin phantom (knee). The attenuation coefficient (AC) was calculated from the signals’ decay slope. Steatosis, liver fibrosis, and necroinflammatory activity were staged and graded during pathological analysis. The steatosis grade was categorised as follows: S0, <5%; S1, 5–33%; S2, 34–66%; or S3, ≥67%. The diagnostic performance of AC for steatosis prediction was assessed using area under the curve (AUC) analysis; and it was compared with the L/S ratio or CAP. Univariate and multivariate regression analyses were used to identify variables correlated with AC values.

Results: Patients (51% men; 42% had non-alcoholic fatty liver disease, or alcoholic liver disease. Serum ferritin concentration can be increased in iron overload and shows hepatic necro-inflammation. Recently, raised serum ferritin concentration was shown to predict mortality in patients awaiting liver transplantation in decompensated liver cirrhosis. We investigated serum ferritin level to predict the early mortality of patients with alcoholic liver cirrhosis (ALC).

The pilot study included 72 patients with ALC. The diagnosis and etiology of ALC was confirmed when daily consumption of alcohol was > 30 g/day for males, respectively, as confirmed by at least 1 family member of affected individual. The steatosis grade was categorised as follows: S0, 0% or <5%; S1, 5–33%; S2, 34–66%; or S3, ≥67%. The diagnostic performance of AC for steatosis prediction was assessed using area under the curve (AUC) analysis; and it was compared with the L/S ratio or CAP. Univariate and multivariate regression analyses were used to identify variables correlated with AC values.

Conclusion: Ultrasound attenuation imaging had a high diagnostic accuracy for detecting hepatic steatosis.

Peritoneal carcinomatosis (PCA) has a prognostic role in patients with gastrointestinal cancers. Despite the low sensitivity, cytology remains the gold standard in differential diagnosis of PCA to peritonitis (for example spontaneous bacterial peritonitis, SBP) or uncomplicated ascites due to portal hyperperfusion syndromes. RTN4 value of 225/220 nm was associated with esophageal varices (odds ratio [OR] = 3, 63; p < 0.022).

**Conclusion:** Low levels of RTN4 are associated with liver cirrhosis and portal hypertension syndromes. RTN4 correlates with liver function tests. It may be a surrogate marker of CSHF and presence of esophageal varices.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Peritoneal carcinomatosis (PCA) has a prognostic role in patients with gastrointestinal cancers. Despite the low sensitivity, cytology remains the gold standard in differential diagnosis of PCA to peritonitis (for example spontaneous bacterial peritonitis, SBP) or uncomplicated ascites due to portal hypertension (no SBP/PCA). MicroRNAs (miRNAs) are considered as promising biomarkers and are commonly disregulated in cancer.

**Aims & Methods:** In this proof-of-principle study, we systematically evaluated preanalytical factors and potential of miRNAs as ascites biomarkers. We prospectively examined samples from patients with ascites with benign and malignant conditions including: PCA (n = 15), SBP (n = 15) and portal hypertension (no SBP/PCA, n = 15). Various extraction kits were used to compare the total RNA extraction. Furthermore, we systematically evaluated the influence of storage, stability and sample processing (uncentrifuged, pelletled etc.) on miRNA expression in ascites. MiRNA expression profiling using TaqMan Low Density Array (TLDA) and quantitative RT-PCR (TaqMan/SYBRgreen) were used to evaluate the expression.

**Results:** Systematic analysis of miRNAs stability confirms that miRNAs in ascites are well preserved from degradation with good short- (0h, 12h, 24h, and 48h) and long-term stability (30 C, –80 C for 2 years). Several miRNAs that were selected for the proof-of-principle analysis (miR-21 and miR-16) were reproducibly detectable in ascites samples. MiRNA expression profiling in patients with PCA compared to those with uncomplicated portal hypertension revealed miR-21, miR-16, miR-222 and miR-483-5p to be up-regulated and miR-26b to be down-regulated. MiRNA expression validation confirmed the increased expression of miR-21 (mean delta CT ± SD; –11.11 ± 1.2 vs. –8.46 ± 3.46 vs. –9.65 ± 2.55 for no SBP/PCA, PCA and SBP, respectively, p < 0.05) and miR-16 in patients with PCA compared to no SBP/PCA groups, while miR-223 was significantly upregulated in SBP (mean ± SD; –12.16 ± 1.56 vs. –10.05 ± 3.19 vs. –6.95 ± 3.56 for no SBP/PCA, PCA and SBP, respectively, ANOVA, p < 0.0001; posttest SBP vs no SBP/PCA and vs. PCA p < 0.05).

**Conclusion:** Our data provide novel evidence for the differential expression of miRNAs in ascites in patients with PCA and SBP. Evaluation of ascites-miRNAs may offer an alternative approach for diagnosis of peritoneal carcinomatosis and create an avenue for therapeutic application as well.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for subsequent bacterial infections increasing mortality several-fold. Factors known to contribute to PBT in LC are among others an increased intestinal permeability.

**Aims & Methods:** A clear role of translocation for luminal intestinal bacteria is yet to be defined but we hypothesize that the recently described gut vascular barrier (GVB) is impaired in experimental portal hypertension leading to protein loss and increased accessibility of the vascular compartment for translocating bacteria. For this purpose two different models of experimental portal hypertension, namely partial portal vein ligation (PPVL) and bile duct ligation (BDL) were used in mice under standardized gnotobiotic conditions (sDMDM2). A novel in vivo confocal endomicroscopy technique was established in order to detect gut-vascular barrier transcription in live animals. FITC-70 kDa dextran was injected intravenously and confocal probe was placed in the intestinal lumen (terminal ileum) to visualize villus-capillaries. Leakage was measured over time (10 minutes) as a ratio between the mean fluorescent intensity outside the vessel (lumina propria) and inside the vessel. Immunofluorescence (IF) stains of the intestinal crypts marker placenta-leucine-associate protein-1 (PV-1) were performed for GVB analysis.

**Results:** Confocal endomicroscopy data revealed an earlier and significantly increased leakage of 70kDa through the intestinal vascular space in both BDL and PPVL mice. FITC-70kDa-dextran leak did only leak in BDL and PPVL but not in control (sham operated) mice. Interestingly GVB stains showed increased expression of PV-1 in intestinal vessels (CD34-) of BDL but not PPVL.

**Conclusion:** Portal hypertension per se has an impact on the GVB increasing FITC-70kDa-dextran leakage from intestinal capillaries to the lamina propria in both BDL and PPVL. However, the IF showed only in BDL an increased PV-1 expression indicative of a wider opening of the intestinal crypts than in PPVL. Therefore, different mechanisms appear to be involved in alterations of the gut-vascular barrier in pre-portal hypertension and biliary cirrhosis.

**INHIBITION OF CYCLOOXYGENASE-2 AMELIORATES SPLENOMEGALY IN CIRRHOTIC RATS**

Gastroenterology, West China Hospital, Sichuan University, Chengdu/China

Contact E-mail Address: 812903560@qq.com

**Introduction:** Splenomegaly is a common finding in liver cirrhosis. However, the precise underlying mechanisms behind this phenomenon have not been elucidated, and its therapeutic strategies are limited.

**Aims & Methods:** We aimed to investigate whether cyclooxygenase-2 (COX-2) is involved as a contributing factor in the pathological process of splenomegaly in cirrhosis. Thirty-six male Sprague-Dawley rats were randomized into three groups with 12 rats in each group. The control group received intraperitoneal injection of normal saline (1 ml, twice a week); the TAA group received intraperitoneal injection of thioacetamide (TAA, 200 mg/kg, twice a week for 16 weeks); the TAA + celecoxib group received TAA, then celecoxib via gastric gavage (20 mg/kg/day). The portal pressure was measured by portal venous catheterization. Sections from paraffin-embedded spleens were stained with hematoxylin and eosin and Sirius Red, and immunostained with VEGF and CD31.

**Results:** The ratio of splenic weight to body weight increased by 73.9% in TAA group compared with that in the control group. However, celecoxib decreased the area of splenic white pulp by 37.6%. Besides, the portal pressure increased by 27.9%. Yet, compared with that in TAA group, celecoxib obviously decreased the area of splenic white pulp by 28.8%. In addition, TNF-a and IL-1b were increased by 27.6%. Besides, the portal pressure was measured by portal venous catheterization. Sections from paraffin-embedded spleens were stained with hematoxylin and eosin and Sirius Red, and immunostained with VEGF and CD31.

**Conclusion:** The protein expression of COX-2, VEGF, PI3K, p-AKT, and AKT in the spleen were assessed by Western blot. The enzyme-linked immunosorbent assay was performed to evaluate the expression of TNF-a and IL-1b in the spleen.

**Results:** The ratio of splenic weight to body weight increased by 73.9% in TAA group, while in rats treated with celecoxib, the ratio was significantly reduced. While determined by H&E staining, areas of splenic white pulp in the TAA group enlarged by 27.9%. Yet, compared with that in TAA group, celecoxib obviously decreased the area of splenic white pulp by 28.8%. Besides, compared with the control group, TNF-a and IL-1b, the two proinflammatory cytokines were found to be greatly increased in the TAA group. On the contrary, in TAA + celecoxib group, the protein expression of TNF-a and IL-1b was obviously reduced. We also found that the expression of proangiogenic factor VEGF and the vascular marker CD31 increased in TAA group by Western blot and immunohistochemistry, which indicated a role of angiogenesis in the pathophysiology of splenomegaly. Furthermore, up-regulation of PI3K and p-AKT protein expression was detected in the spleen of TAA group compared with...
with that of the control group, demonstrating that P3K/AKT signal pathway was involved in development of pathological angiogenesis. However, the treatment with celecoxib strongly decreased the protein expression of VEGF, CD31, P3K and AKT in the spleen of cirrhotic rats.

**Conclusion:** The present study indicates that COX-2 contributes to splenomegaly by facilitating angiogenesis, fibrosis and inflammation in the spleen. Moreover, inhibition of COX-2 by celecoxib could ameliorate portal hypertension and splenomegaly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with *Escherichia coli* (*E. coli*), Klebsiella pneumoniae being the most common germs. Small intestinal bacterial overgrowth and a altered microbiota are so far known as risk factors for SBP. However, the exact mechanisms of bacterial translocation need to be identified as they are supposed to contribute to the development of early recognition systems and initiation of antibiosis.

**Aims & Methods:** With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SBP were explored. These insights might lead to an initiation of antibiosis on time and reduced mortality in SBP.

Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with *E. coli* with different MOI (MOI 0, 1, 5 and 10) for 2 to 4 hours post confluence. Experiments with heat inactivated *E. coli* were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Ocludin, E-cadherin and the p53 family including p53 and p73.

**Results:** *E. coli* stimulation of HCT-116 cells resulted in a strong decrease of Ocludin, E-cadherin and the p53 family including p53 and p73. P53-caco-2 cells displayed less reduction of Ocludin and E-cadherin protein levels compared to p53-wildtype HCT-116 cells.

**Conclusion:** By using an in vitro model, we demonstrate destabilizing effects of *E. coli* on intestinal cell junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent a mechanism to protect the bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality sever-fold. Factors known to contribute to PBT in LC are among others an increased intestinal epithelial permeability.

**Aims & Methods:** Since mucus represents one of the major components of this barrier we hypothesize that i) gut mucus is altered in LC and ii) bile could be a modulator of its production. Two different models of experimental LC – namely bile duct ligation (BDL) and the chronic treatment with carbon tetrachloride (CCl4) – as well as partial portal vein ligation (PPVL) and sham-operated mice were used. Finally the farnesoid X receptor (FXR) agonist obeticholic acid (OCA) and the FXR antagonist ursodeoxycholic acid (UDCA) and control animals. Mucus thickness measurement on gut explants and PAS (Periodic acid-Schiff) staining to visualize and count goblet cells (GC) were utilized.

**Results:** We have observed a significant reduction in mucus thickness in ileum and colon of groups CCl4 0.30 GC/100 μm of villus ± 0.07 vs BDL 0.29 GC/100 μm of villus ± 0.04) of following BDL but not PPVL (Control 0.27 GC/100 μm of villus ± 0.11 vs BDL 0.18 GC/100 μm of villus ± 0.08). Moreover we have seen that farnesoid X receptor (FXR) agonist obeticholic acid (OCA) partially restored GC loss in CCl4 treated animals (Control 0.63 GC/100 μm of villus ±0.08 vs Control OCA 0.65 GC/100 μm of villus ± 0.07 vs CCl4 0.49 GC/100 μm of villus ± 0.08). However, we have also observed that OCA treatment strongly decreased the protein expression of VEGF, CD31, P3K and AKT in the spleen of cirrhotic rats.

**Conclusion:** All these results suggest that a reduced bile production by the cirrhotic liver and not portal hypertension per se interfere in the goblet cell development and/or maturation. In addition, this effect can be, at least partially, be restored by the FXR agonist OCA. Our study opens the possibility, to a so far, unknown effect of bile salts in the intestinal epithelium development in the context of liver cirrhosis being a clear candidate for mucus layer regulation and hence protective effect against bacterial translocation.

**Introduction:** Liver fibrosis due to chronic induced liver damage is characterized by an increase in gene expression of proinflammatory molecules such as TGF-β1, IL-1β, IL-6 and TNF-a, as well as excess synthesis of ECM components such as COL-1. Capsaicin (CAP) is a pungent compound found in chilli peppers which has shown anticancerogenic, antiinflammatory and antifibrotic properties. Moreover, sulforaphane (SFN) is an isothiocyanate which is in cruciferous such as broccoli and it has exhibit an antioxidant effect in several in vitro and in vivo models.

**Aims & Methods:** The objective of this project was to evaluate the antifibrogenic and antiinflammatory effects of a daily supplementation with CAP and SFN in a rat model of liver fibrosis due to carbon tetrachloride (CCL4) intoxication. 35 male Wistar rats were included (n=7/group); animals were administrated intra-peritoneal 3 times per week during 8 weeks with a mix of CCL4/menal (1/50 week 1, 1:4 week 2 and 1:3 week 3-8). Healthy and CCL4-fibrotic controls received only supplementation vehicle (Tween 2% in PBS). Treated groups receive SFN 5ug/kg, or CAP 2mg/kg, or both supplements daily by oral gavage since the beginning of CCL4-intoxication regimen until sacrifice. Masson staining and PCR was performed in liver samples. Hepatic enzymes were analysed in serum.

**Results:** Groups treated with CAP and SFN showed a decrease of ~30points in percentage of liver fibrosis according to Masson staining (p<0.05), hepatic function improve since AST and ALT serum levels diminish (p<0.01) also a lower gene expression of TGF-β1, Col-1, TNF-a, IL-1 β and IL-6 was detected in treated animals when compared with fibrotic controls (p<0.01).

**Conclusion:** Thus, CAP and SFN seem to exert a hepatoprotective effect in this model of chronic-induced liver damage. These findings suggest that dietary sources of CAP and SFN might be included in dietetic guidelines for the prevention of liver fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Results: The color flow images of gastric varices and peri-gastric veins were delineated in all 215 patients with ECDUS. Evaluation of blood flow velocity in the 215 gastric varices revealed velocities of 7.7–35.7 cm/s (mean, 18.2 ± 6.0 cm/s). Mean velocity of large, coil-shaped (F3) type gastric varices was 23.7 ± 6.2 cm/s (n = 52), while the mean velocity of enlarged tortuous (F2) type gastric varices was 16.7 ± 5.0 cm/s (n = 163). The velocities of F3 type gastric varices were significantly higher than those of F2 type (P < 0.0001). Next, we evaluated the wall thickness of submucosal gastric varices. Two hundred-fifteen of the gastric varices were 1.0–2.2 mm (1.6 ± 0.4 mm) in gastric wall thickness. Mean thickness of red color (RC) or erosion positive varices was 1.2 ± 0.2 mm (n = 42), while the mean thickness of RC or erosion negative varices was 1.7 ± 0.3 mm (n = 173). The thickness of RC or erosion positive varices was significantly thinner than that of the negative cases (P < 0.0001). Seven cases of the 215 patients had the current history of gastric variceal bleeding, and the other three cases had experienced variceal rupture on follow up (bleeding cases, n = 10), and mean thickness of these bleeding cases were 1.2 ± 0.2 mm.

Conclusion: ECDUS is a useful modality for the diagnosis of hemodynamics of gastric varices and may allow the stratification of patients into low, high risk for hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0034 PORTAL HYPERTENSTIVE COLOPATHY BUT NOT ILEOPATHY IS COMMON IN EGYPTIANS WITH LIVER CIRRHOSIS

Introduction: Liver cirrhosis and portal hypertension are associated with esophageal varices, gastric varices, small and large intestinal enteropathies. Aims & Methods: We aimed to study the prevalence of colopathy and ileopathy in patients with portal hypertension secondary to liver cirrhosis. Chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis were enrolled. The severity of cirrhosis was classified by the Child-Pugh score. All patients were evaluated by upper endoscopy and colonoscopy for screening of portal hyper-tensive complications. Esophageal varices were graded as small, moderate and big varices. Portal hypertensive gastropathy was classified as absent or present, and, if present, it was sub-classified as mild or severe. Colonoscopy was done up to terminal ileum in all patients.

Results: Our study included sixty chronic hepatitis C patients with portal hyper-tension secondary to liver cirrhosis (53.33% females) their mean age (±SD) was 54.75 (±13.13) years. Child-Pugh class was A for 2 (3.4%), B for 33 (55.9%) and C for 24 (40.7%). 53 (88.33%) patients had esophageal varices (23 patients had small esophageal varices, 15 had moderate, and 8 had big varices, 2 post-band ligation and 5 obliterated varices). Gastric varices were present in 3 patients (5%). Portal hypertensive gastropathy was noted in 43 patients (71.6 %) and was mild in 38 and severe in 5 patients. Colonoscopy finding up to the terminal ileum revealed that portal hypertensive colopathy was present in 16 patients (26.7%). Portal hypertensive ileopathy was noted only in one case (1.7%). No colonic or ileal varices were noted.

Conclusion: Portal hypertensive colopathy but not ileopathy is common in Egyptians with liver cirrhosis. Ileal varices and ileopathy are not common in patients with liver cirrhosis and PHT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute-on-chronic liver failure (ACLF) is a specific clinical form of liver failure in patients with liver cirrhosis, referred as acute deterioration of liver function associated with an acute specific complication of liver cirrhosis. ACLF is defined by the presence of renal failure or 2 or more failures affecting at least one organ system. We aimed to study the prevalence of colopathy and ileopathy in patients with cirrhosis and PHT.

Aims: To evaluate the prevalence of colopathy and ileopathy in patients with portal hypertension secondary to liver cirrhosis. Chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis were enrolled. The severity of cirrhosis was classified by the Child-Pugh score. All patients were evaluated by upper endoscopy and colonoscopy for screening of portal hyper-tensive complications. Esophageal varices were graded as small, moderate and big varices. Portal hypertensive gastropathy was classified as absent or present, and, if present, it was sub-classified as mild or severe. Colonoscopy was done up to terminal ileum in all patients.

Results: Our study included sixty chronic hepatitis C patients with portal hyper-tension secondary to liver cirrhosis (53.33% females) their mean age (±SD) was 54.75 (±13.13) years. Child-Pugh class was A for 2 (3.4%), B for 33 (55.9%) and C for 24 (40.7%). 53 (88.33%) patients had esophageal varices (23 patients had small esophageal varices, 15 had moderate, and 8 had big varices, 2 post-band ligation and 5 obliterated varices). Introduction: Cirrhosis is characterized by both bleeding and thrombotic complications due to underlying procoagulative haemostatic imbalance [1]. Among thrombotic events, portal vein thrombosis (PVT) is the most common with annual incidence ranging between 4.6% and 12.8% [2, 3]. Demonstrated associated risk factors are severity of portal hypertension and slowed portal flow [4]. However, data regarding haemostasis in the portal venous system of cirrhotic patients are lacking.

Aims: To evaluate peripheral and portal venous haemocoagulative state in patients with cirrhosis in comparison with controls, through thrombin generation test (TGT), rotational-thrombelastometry (ROTEM) along with evaluation of endothelial dysfunction by quantification of circulating endothelial microparticles (MP). Correlate these results with activity levels of local pro and anticoagulant factors. Compare peripheral and portal venous districts in cirrho tic patients. Correlate these results with activity levels of local pro and anticoagulant factors. Compare peripheral and portal venous districts in cirrh osis patients in order to assess the role of the portal vein in circulating endothelial microparticles (MP) in the development of ACLF, in patients with liver cirrhosis undergoing liver transplantation (LT) or transjugular intra-hepatic portosystemic shunt (TIPS). Patients without liver disease awaiting liver surgery or deceased liver donors were enrolled as controls. The following laboratory tests were performed on citrated peripheral and portal venous blood samples: TGT with and without thrombomodulin (TM), ROTEM, dosage of main pro and anticoagulants factors activity and analysis of circulating endothelial MP.

Results: 25 cirrhotics (15 LT and 10 TIPS) and 6 controls (2 undergoing hepatic resection for benign liver lesions and 4 liver donors) were enrolled. Peripheral blood in cirrhotics showed resistance to activation of PC-pathway at TGT (ETP with without TM 0.89 (0.78–0.92) vs 0.6 (0.3–0.74), p < 0.001), lower clot stabilit y at ROTEM (MCF-NATEM mm: 43.5 (36–51) vs 63 (53–69), p = 0.042), and significant increase of endothelial-MP (CD62E/MP.L: 1391 (651–2301) vs 582 (380–1161), p = 0.046), indicative of higher endothelial damage compared to controls. Similar results were obtained comparing portal blood of cirrhotics and controls (ETP with without TM 0.89 (0.78–0.92) vs 0.63 (0.33–0.75), p = 0.001; MCF-NATEM: 46 (39–51) vs 62 (49–66), p = 0.056; CD62E/MP.L: 1606.5 (680–1885) vs 529.5 (266–781), p = 0.069). There was a significant correlation between diminished levels of PC, PS, AT, FII and either TGT or ROTEM parameters. Comparing portal and peripheral blood of cirrhotics, we detected endogenous heparinoids in portal (α-antage NATEM 51 (46–57) vs
**P0038 PREDICTING FACTORS FOR HOSPITAL READMISSION AFTER THE FIRST EPISODE OF HEPATIC ENCEPHALOPATHY**

M. Silva1, A. Peixoto2, H. Cardoso3, S. Lopes4, G. Macedo5

**1Gastroenterology, Hospital São João, Oporto/Portugal**

**2Centro Hospitalar São João, Porto Medical School, Porto/Portugal**

**Contact E-mail Address:** marco costsa silva87@gmail.com

**Introduction:** Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis, with necessity of hospital admission in many cases. The economic burden of HE is substantial. After ascites, HE is the second most common reason for hospitalization of cirrhotic patients. HE is also the most common, possibly preventable, cause for readmission.

**Aims & Methods:** We aimed to assess the factors associated with the increased likelihood of hospital readmission for HE after the onset episode. We completed a retrospective Retrospective analysis of admissions for HE of patients with liver cirrhosis, between October 2010 and October 2015. Only the onset episode was included. Patients were followed for 1 year or until readmission for HE. All patients were discharged under lactulose therapy. Descriptive statistics, uni and multivariate analysis, logistic regression, and ROC curves analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

**Results:** In this study 119 patients were included: 78% men with a mean age of 59 ± 13 years; 8% had hepatocellular carcinoma, and 45% had Child-Pugh C. The most frequent cirrhosis etiologies were alcoholic disease (60%) and HCV infection (12%). The precipitating factors, for the onset episode, more frequently detected were diuretic overdose (36%) and infection (31%). All patients were treated with standard therapy, with an adequate lactulose dose. The readmission rate after the first episode of HE was 72% (75% men). The estimated average time to relapse was 18 weeks. The most frequent causes of readmission were also diuretics overdose (31%) and infection (30%). The patients who were readmitted had a higher MELD score than patients without recurrence (13.9 ± 11.6 points; p = 0.015). This association was verified in the multivariate analysis (OR = 1.1, p = 0.044).

**Conclusion:** In this cohort, there was a high rate of readmission for HE after the inaugural episode, which carries a great impact on individual health and high socio-economic costs. A higher MELD score was independently associated with a high probability of readmission for HE.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Safeguards, efficacy and risk of complications for cirrhotic HCV patients with thrombocytopenia and hypoalbuminemia treated with ombitasvir/paritaprevir/r+dasabuvir/r+ribavirin: a real-life cohort

C. Ester1, L. Gheorghe2, S. Iacob2, C. Cijevschi3, A. Trifan3, L. Gheorghe1, F. Albu1, R. Cipelli4, M. Curescu1, B. Brincusa1, C. Brasoveanu1, V. Arama5, P. Di Maggio6, F. Associates7, of Gastroenterology, County Hospital Timisoara, Timisoara, Romania

Contact E-mail Address: carmen.gheorghe@gmail.com

Introduction: The regulations for prescribing interferon-free treatment for patients infected with hepatitis C virus in Romania comprised only patients with F3/F4 fibrosis so the risk of hepatic decompensation and complications was higher compared to other cohorts. In previous interferon-based regimens, thrombocytopenia and hypoalbuminemia on treatment were markers for portal hypertension and associated with hepatic synthetic dysfunction, respectively, have been shown to reduce the likelihood of sustained virological response and to increase the rates of serious adverse events.

Aims & Methods: The aim of this study was to evaluate the impact of thrombocytopenia and hypoalbuminemia on treatment outcome and disease complications. We included in this study 855 HCV-infected cirrhotic patients treated with ombitasvir/paritaprevir/r+dasabuvir/r+ribavirin for 12 weeks in 10 university hospitals in Romania. The following groups were studied: 151 patients (17.7%) with albumin <3.5 g/dl, 239 (28%) with thrombocytopenia (a cutoff of 10000/mm3 was used) and 71 patients (8.3%) with both hypoalbuminemia and thrombocytopenia before initiating antiviral treatment. Safety (as AE in application rate were evaluated using Pearson’s correlation, multivariate analysis and Chi-Square test.

Results: Main patient characteristics were: 100% genotype 1b, a median age of 60 years (46.6, 74.2), high rate of previous interferon-based-treatment (36.1%). End-of-treatment and sustained virological response rate were both >99% and there was no correlation with the presence of thrombocytopenia or hypoalbuminemia. The rate of adverse events in the whole cohort was 17.5% at 2 weeks reaching 18% at the end of treatment with only 0.8% severe adverse events with no statistical association with the presence of thrombocytopenia and hypoalbuminemia. The multivariate analysis showed significant association of thrombocytopenia (<10000/mm3) with higher (>1) degree of oesophageal varices (p = 0.001), one of upper digestive hemorrhage during treatment (p = 0.011), and prior exposure to interferon based regimens (p = 0.025). Low albumin (<3.5 g/dl) also correlated with higher (>1) degree of oesophageal varices (p = 0.001) and onset of upper digestive hemorrhage during treatment (p = 0.002).

Conclusion: The efficacy and safety of the ombitasvir/paritaprevir/r+dasabuvir/r+ribavirin (as recommended by national regulations) was not different in cirrhotic patients with hypoalbuminemia and thrombocytopenia, but complications rate was higher so close follow-up and profilactic measures should be recommended, especially if previously exposed to interferon containing regimens.

Introduction: In the UK multicentre, retrospective, real-world study, IMPRESS, rifaximin-a (RFX) use in patients with hepatic encephalopathy (HE) significantly reduced hospitalisations and length of stay in the 16 and 12 months post-RFX initiation compared to the respective periods pre-RFX initiation. This post-hoc analysis of the IMPRESS data compared hospital resource use pre- and post-RFX initiation in 2 sub-groups of difficult-to-treat HE patients: those with alcohol-related disease or continued alcohol misuse.

Aims & Methods: Medical records of patients from 11 UK hospitals who were prescribed RFX for HE between July-2008 and May-2014 were retrospectively reviewed; details of demographic and clinical characteristics, and all-cause hospitalisations were collected in the 6 and 12 months pre- and post-RFX initiation. Patients with baseline MELD score ≥15 or not abstinent at the end of the study period were included in this analysis. Statistical significance of the mean change (standard error of the mean, SEM) was calculated using paired t-test or Wilcoxon test.

Results: Only patients alive at the end of the 6 and 12 months RFX-treatment periods were included: 114 and 102, respectively. Amongst these, 33/114 (29%), for the 6 months) and 26/102 (25%, for the 12 months) had baseline MELD ≥15; mean age, 63 years; 70% were male; 66% had alcohol-related liver disease; mean MELD 24. The mean (SEM) number of bed days/patient reduced from 25 (6.0) in the 6 months pre- to 15 (5.5) in the 6 months post-RFX initiation, and from 36 (9.5) in the 12 months pre- to 20 (7.7) in the 12 months post-RFX initiation (p value not significant). At 6 months post-RFX initiation, 15/114 (13%) patients were still actively drinking. At RFX initiation, mean age was 56 years; 73% were male, mean MELD was 19. Despite this, the mean (SEM) number of bed days/patient decreased from 36 (7.9) in the 6 months pre- to 15 (5.4) in the 6 months post-RFX initiation (p = 0.048), and the mean of hospitalisations/patient fell from 2.8 (0.5) to 1.2 (0.4) (t-test p = 0.059; Wilcoxon test p = 0.029). Too few patients with continued alcohol misuse were alive at 12 months to evaluate. Two patients reported adverse events: none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE for 6 or 12 months suggested trends in reduced hospital length of stay in patients with advanced liver disease and in those with continued alcohol misuse. However, larger studies are needed to strengthen these findings.

P0043 A PROPORTIONALLY GREATER ELEVATION IN LIVER TRANSPLANT CANDIDACY IN PATIENTS WITH NAFLD AND PORTAL VEIN THROMBOSIS

M. Basaranoglu
Gastroenterology, Bezmialem Vakif University, Istanbul/Turkey

Contact E-mail Address: metin_basaranoglu@yahoo.com

Introduction: NASH progresses to cirrhosis and its complications including hepatocellular carcinoma. It is possible that risk factors for NAFLD-associated cirrhosis may differ in Eastern countries from those in the West. Thus, we aimed to document the characteristics of patients with NAFLD-associated cirrhosis from Turkey, an European country sharing 97% of its borders with Asia. Relative to other Easterns, the Turkish population exhibits a higher rate of obesity and work ethic that could impact to that in the Westerns.

Aims & Methods: To characterize non-alcoholic fatty liver disease (NAFLD) presentation with esophageal varices. METHODS: We have kept the records of patients at our hepatology unit and affiliated liver center. Data were collected for esophageal varices at the advanced endoscopy unit. A cohort of patients with esophageal varices from 2003 to 2014 was reviewed. Eligible patients were ≥18 years of age and have had esophageal varices diagnosed by upper gastrointestinal endoscopy examination. They had regular clinical follow-up and endoscopic examinations at our clinic. Efficacy data were based on the last evaluation.

Results: Primary end-point of the study was to use this cohort of patients with esophageal varices to evaluate the relationship between this disease and several etiologies, including NAFLD, hepatitis B, hepatitis C or other liver-related diseases. We also used this cohort to draw this conclusion in terms of PVT, HCC, survival and mortality. Of the 258 patients with esophageal varices; NAFLD in 39.0% (101 patients), hepatitis B virus in 29.1% (75 patients) and HCV in 11.2% (29 patients). The mean age of NAFLD was 56.4 ± 16.0 years and 62% of these patients were men. Moreover, 47.5% had PVT, 5.0% had HCC, and 45.5% had fundic varices. The mortality rate was 47.5% during follow-up, but increased to 80% in the presence of HCC. PVT was observed in 47.5% of patients with NAFLD, 29.3% of patients with hepatitis B, 17.2% of patients with hepatitis C and 23.3% of patients with other liver-related diseases (P < 0.001). Of the 111 patients (43%) that died during the study period, 72 patients (64.9%) had no PVT (P = 0.057). HCC was: 5.0% in patients with NAFLD, 26.7% in patients with hepatitis B, 34.5% in patients with hepatitis C, and 5.7% in other diseases (P < 0.001). Of the 38 patients with HCC, 13% had PVT. Moreover, HCC increased the mortality rate in almost all the groups. Of the patients, 50.0% with NAFLD, 33.3% with hepatitis B, 26.3% with hepatitis C, and 58.3% with other diseases were alive at the end of the 5-year period with a significant difference according to the Kaplan-Meier log Rank test (P < 0.04). Risk for mortality, measured by risk ratio (RR), did not change per gender (RR: male/ female = 43.3%/42.5%, P > 0.05) or with the occurrence of cirrhosis (RR: 44.8%/28.6%, P > 0.05). However, it changed with the existence of fundic varices (RR: 11.8%/4.04 in favor of fundic varices development) and HCC (RR: 78.9%/38.6%, P < 0.0001 in favor of HCC development).

Conclusion: Data revealed a proportionally greater rise in liver transplant candi- dacy due to NAFLD-associated cirrhosis with portal vein thrombosis. The mor- tality rate of patients with NAFLD-associated cirrhosis did not differ from that in patients with viralcaused cirrhosis. We confirmed that NAFLD was the third leading cause of HCC on the transplantation waiting list. Older patients with HCC were more prone to developing more cirrhosis (HCC and high cirrhosis rate). These findings should constitute a reliable guideline for evaluating patients at the transplant center and for health policy makers to develop better strategic pre- ventive measures against liver diseases.

P0044 RISK FACTORS AND PREDICTIVE MODEL FOR THE DEVELOPMENT OF MULTIDRUG RESISTANT BACTERIAL INFECTIONS AND THE IMPACT ON PROGNOSIS IN HOSPITALIZED DECOMPENSATED LIVER CIRRHOSIS PATIENTS

Gastroenterology, Centro Hospitalar São João, Porto/Portugal

Contact E-mail Address: ruirmorais20@gmail.com

Introduction: Bacterial infections are a leading cause of mortality in patients with decompensated cirrhosis. Aims & Methods: The objective of this study was to evaluate the prevalence of multiresistant bacterial infections, associated risk factors and their impact on prognosis in hospitalized decompensated liver cirrhosis patients.

This was a retrospective Retrospective study that consecutively evaluated all bacterial infections with confirmed microbiological isolation in patients with decompensated liver cirrhosis admitted to the Gastroenterology ward between January 2009 and May 2016.

Results: There were 308 infections with confirmed microbiological isolates, cor- responding to 218 hospitalizations, in a total of 161 patients. The median age of the patients was 63 years (IQR 55–71) and 67% of them were men. Alcoholic liver disease was the major cause of cirrhosis (72%). Among the infections evalu- ated, 87% were nosocomial and 13% community-acquired. Urinary tract infec- tions was the most common infection (57%). In 27% of patients there were at least two concomitant bacterial infections. Multidrug resistant (MDR) bacteria were isolated in over half of patients. In the multivariate analysis, prophylaxis for spontaneous bacterial peritonitis (OR 2.3, p = 0.009), MELD score greater than 19 at admission (OR 1.7, p = 0.043), hospitalization in an Intensive/Intermediate Care in the previous month (OR 2.8, p = 0.001) and antibiotic therapy for infec- tion in the last 6 months (OR 2.4; p = 0.001) were independently associated with MDR infection. From the variables identified in the multivariate analysis, a predictive model of MDR bacterial infection was created. Assuming a sensitivity of 66% and a specificity of 72%, we considered the cut-off of 0.0415 as clini- cally relevant, regarding likelihood of developing a MDR bacterial infection (AUROC 0.723; 95% CI 0.667-0.780). The occurrence of a MDR infection was associated with a longer duration of hospitalization (p = 0.017). In the multi- variate analysis there was no independent association between MDR infection and in-hospital mortality and one month after discharge.

Conclusion: The prevalence of MDR bacterial infections in cirrhotic patients is significant and associated with a longer hospital stay. It is possible to identify predictors of its occurrence in order to implement epidemiological strategies to reduce the risk of these infections.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hepatitis C virus (HCV) diminishes health related quality of life (HRQOL). Currently, there is no published data on assessing the impact of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients. We aimed to study the effect of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients in HRQOL. About 132 patients with chronic hepatitis C (cirrhotic and non-cirrhotic) were enrolled in the study. Age of patients was sixty years old and older. All patients were treated with sofosbuvir/daclatasvir with or without ribavirin for three months. The HRQOL was assessed with sickness impact profile scoring (SIP) before start of treatment, at end of treatment and after three months of end of treatment.

Results: Old chronic hepatitis C patients who were treated achieved primary vir- ological response (end of treatment) with percentage 100% and sustained virolo- gical response (SVR) after 24 weeks of end of treatment in about 96% of treated patients. Before treatment, patients with chronic hepatitis C had worse scores especially in work, sleep, rest and recreation and pastimes categories. After treat- ment, patients who received sofosbuvir/daclatasvir with or without ribavirin had significant improve in work, sleep, rest and recreation and pastimes categories with p-value 0.001. Numerical improvement was observed in total score, physical and psychosocial dimension scores. In patients with SVR, the most improvement was in work and psychosocial dimension scores. There was no significant difference in SIP between scores after end of treatment and 3 months of end of treatment.

Conclusion: Treatment of chronic hepatitis C in old-aged patients had a signific- ant improvement in HRQOL.

**Introduction:** Accurate determination of the degree of hepatic-fibrosis is mandatory not only for the diagnosis and prognosis of disease, but also for deciding on the antiviral treatment. Indeed, many studies have been dedicated to the search of non-invasive fibrosis markers capable of providing an accurate information about hepatic fibrosis stage in patients with chronic hepatitis C (CHC). Direct and indirect markers of hepatic fibrosis are useful for prediction of liver cirrhosis but have limited accuracy for the diagnosis of significant fibrosis. Therefore, the development of more advanced scores combining both direct and indirect markers may improve their diagnostic accuracy.

**Aims & Methods:** This work is concerned with determining the levels of some of fibrosis markers, which are directly involved in deposition and removal of extracellular matrix (ECM), together with other indirect fibrosis markers so as to construct a predictive score capable of identifying the presence of significant fibrosis with a high degree of accuracy. Then, we aimed to estimate its performance against that of the other simple noninvasive tests in chronic hepatitis C patients.

**Material and Methods:** A total of 148 Egyptian HCV patients were subjected to routine laboratory workup in addition to estimation of serum AFP, hyaluronic acid, platelet-derived growth factor (PDGF), tissue inhibitor of metalloproteinase-1 (TIMP-1) and collagen IV. According to fibroscan, patients were classified into those with non-significant fibrosis (F<2) and significant fibrosis (F≥3).

**Results:** Based on univariate analysis, ten variables were significantly higher in patients with significant fibrosis. Patients with F2-F4 had 2.08-fold, 2.14-fold, 1.80-fold and 1.90-fold increase in the concentrations of collagen IV, HA, PDGF and TIMP-1, respectively. Multivariate regression demonstrated that only age, AFP, PDGF, collagen IV and TIMP-1 retained significance. Therefore, a five-marker score named Egypt (EGY) Fibro-mark (FM) was developed. A significant correlation was found between its candidate markers and liver fibrosis progression. AFP was found to have highest correlation (r=0.47, P<0.0001) followed by collagen IV (r=0.46, P<0.0001), Age (r=0.43, P<0.0001), TIMP-1 (r=0.40, P<0.0001) and PDGF (r=0.40, P<0.0001). ROC curve was used to estimate and compare the diagnostic accuracy of these candidate variables. As a consequence, these markers were in a decreasing rank: AFP (AUC 0.79), collagen IV (AUC 0.78), age (AUC 0.70), TIMP-1 and PDGF (AUC 0.75). Additionally, Bivariate Spearman’s rank correlation coefficient between EGY-FM and its candidate markers was determined for estimating the impact of each marker on the predictive criteria. The diagnostic value of Egy FM was then assessed by ROC curve showing an AUC of 0.89 for diagnosing significant fibrosis at an optimal cut-off point of 0.45 with 97% sensitivity, 83% specificity and 79% efficiency. Next, the area under the ROC curve (AUC) was used to evaluate and compare the performance characteristics of different non-invasive scores. The AUC was greatest for Fibro-mark (0.89), then BRC (0.83), followed by FRT and King’s score (0.82), APRI (0.80), Fibro-gram (0.70) and finally FibroQ (0.63).

**Conclusion:** Egy Fibro-mark (FM) score, a more sophisticated score combining ‘direct’ and ‘indirect’ markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than BRC, FRT, King’s score, APRI, Fibro-mark score and FibroQ in this group of Egyptian patients.

Disclosure of Interest: RBV combination was the most effective among the studied regimens.

Results: Among the included five studies, four studies, with low to moderate risk of bias, were included for the meta-analysis (n = 1096). The BCV-TRIO showed a high-response rate in naïve patients (SVR12 rate ¼ 95.5% [95% CI [93.5–96.9]). This total population was sub-grouped to get SVR12 rates; 89.5% [95%CI [85.3–92.4]), 96.2% (95% CI [93.0–98.0]), 93.5% (95% [92.9–96.1]), 91.1% (95% CI [87.6–93.7]), 93.9% (95% CI [86.6–97.3]), and 91.9% (95% CI [89.4–94.0]) for HCV genotype 1a, HCV genotype 1b, IL28B CC genotype, IL28B non-CC genotype, cirrhotic, and non-cirrhotic respectively. The virologic failure occurred in only 40 patients (7%) (95% [5.2–9.4]). There was no difference when adding ribavirin to this combination (RR ¼ 0.98, 95% confidence interval (95% CI) [0.90–1.05]). Using this regimen on interferon-experienced patients (SVR12 rate ¼ 1.03, 95% CI [0.98, 1.08]), P ¼ 0.30, or changing the dose of BCV from 75 mg to 150 mg regardless the genotype 1 subtypes or IL28B genotype. Similarly, the minimal failure of treatment showed no difference regarding the main two comparisons regardless the cause of this failure. Increasing the dose or the duration did not show a significant increase in the efficacy. The rates of serious adverse events (AEs) occurrence were; (3.4%, 95%CI [2.3–5.1]), (6.5%, 95%CI [3.2–12.7]), (2.3%, 95% CI [0.6–8.8]), and (2.9%, 95% CI [0.2–33.6]) for BCV-TRIO, (BCV-TRIO þ RBV) for 12 weeks, (DCV þ ASV þ BCV-150 mg) for 12 weeks, and both (BCV-TRIO) and (DCV þ ASV þ BCV-150 mg) for 24 weeks respectively. For BCV-TRIO, the most-frequent AEs were headache, diarrhea, fatigue, and nausea with rates; (21.2%, 95%CI [18.4–24.2]), (14.3%, 95% CI [12.0–16.9]), (13.8%, 95% CI [11.2–16.3]), and (13.4%, 95% CI [10.9–16.4]) respectively.

Conclusion: This study reported a high SVR, minimal treatment failure rate, and few AEs with fixed-dose three drug combination of daclatasvir, asunaprevir, and beclabuvir in treatment of HCV genotype 1 infection. Eleven electronic search engines/libraries, including PubMed, Scopus, Web of Science, Google Scholar, Virtual Health Library (VHL), WHO Global Health Library (GHL), ClinicalTrials, POPLINE, System for Information on Grey Literature in Europe (SIGLE), Cochrane library, and the New York Academy of Medicine (NYAM), were systematically searched for any clinical trial reporting the efficacy and safety of BCV-TRIO for the treatment of HCV genotype 1 infection. Studies were screened for eligibility and data was extracted by two independent reviewers. Sustained virologic response rate after 12 weeks of treatment was calculated, and the comparison meta-analysis (RR) was conducted using the Comprehensive Meta-analysis (CMA) platform. The protocol was registered in PROSPERO (CRD42017054391).

Results: Among the included five studies, four studies, with low to moderate risk of bias, were included for the meta-analysis (n = 1096). The BCV-TRIO showed a high-response rate in naïve patients (SVR12 rate ¼ 95.5% [95% CI [93.5–96.9]). This total population was sub-grouped to get SVR12 rates; 89.5% [95%CI [85.3–92.4]), 96.2% (95% CI [93.0–98.0]), 93.5% (95% [92.9–96.1]), 91.1% (95% CI [87.6–93.7]), 93.9% (95% CI [86.6–97.3]), and 91.9% (95% CI [89.4–94.0]) for HCV genotype 1a, HCV genotype 1b, IL28B CC genotype, IL28B non-CC genotype, cirrhotic, and non-cirrhotic respectively. The virologic failure occurred in only 40 patients (7%) (95% [5.2–9.4]). There was no difference when adding ribavirin to this combination (RR ¼ 0.98, 95% confidence interval (95% CI) [0.90–1.05]). Using this regimen on interferon-experienced patients (SVR12 rate ¼ 1.03, 95% CI [0.98, 1.08]), P ¼ 0.30, or changing the dose of BCV from 75 mg to 150 mg regardless the genotype 1 subtypes or IL28B genotype. Similarly, the minimal failure of treatment showed no difference regarding the main two comparisons regardless the cause of this failure. Increasing the dose or the duration did not show a significant increase in the efficacy. The rates of serious adverse events (AEs) occurrence were; (3.4%, 95%CI [2.3–5.1]), (6.5%, 95%CI [3.2–12.7]), (2.3%, 95% CI [0.6–8.8]), and (2.9%, 95% CI [0.2–33.6]) for BCV-TRIO, (BCV-TRIO þ RBV) for 12 weeks, (DCV þ ASV þ BCV-150 mg) for 12 weeks, and both (BCV-TRIO) and (DCV þ ASV þ BCV-150 mg) for 24 weeks respectively. For BCV-TRIO, the most-frequent AEs were headache, diarrhea, fatigue, and nausea with rates; (21.2%, 95%CI [18.4–24.2]), (14.3%, 95% CI [12.0–16.9]), (13.8%, 95% CI [11.2–16.3]), and (13.4%, 95% CI [10.9–16.4]) respectively.

Conclusion: This study reported a high SVR, minimal treatment failure rate, and few AEs with fixed-dose three drug combination of daclatasvir, asunaprevir, and beclabuvir in treatment of HCV genotype 1-infected patients, without adding ribavirin, prior interferon-based therapy, restriction on noncirrhotic patients, restriction on certain IL28B genotype, restriction on baseline resistance-associated variants, or expansion the duration of the treatment to 24 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Egypt has the highest prevalence of HCV worldwide. Prevalence of HCV was reported to be 13.9% among healthy populations. Adults have higher HCV prevalence (15.7%) than children (4.0%). Geographically, HCV is highly prevalent in the Nile delta (15.8%) than in Upper Egypt (9.02%). The household contacts of HCV seropositive patients had shown to have a high risk of HCV infection.

Aims & Methods: The aim of this study was to determine the prevalence of HCV infection among household contacts of HCV seropositive index patients. We also aimed to compare HCV genotyping distribution in upper and lower Egypt. In this Multicentre hospital case control based study a total of 4894 Egyptian individuals were recruited to the hospitals from different Egyptian population in Upper & lower Egypt (mainly from Dakahlia, Cairo and Assuit governorates). The index HCV patients were 1106 cases whereas the families or close household contacts of these index cases were 3788 cases. Ideally family was selected on the basis of containing at least one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications or disorders first and second degree consanguinity, living and sharing usual life activity and having at least 15 years of exposure to the index case). The positive cases (index or contact cases) in the family were selected with inclusion criteria of 1-HCV positive by PCR RNA > 6 months, 2-Adults (above 18 years) of both sexes 3-Any stage of HCV related liver diseases. While cases were diagnosed as spontaneously cleared the virus (SVC) based on the following criteria: positive HCV antibody but negative HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy. Each participant was subjected to routine clinical and laboratory investigations in addition to molecular diagnosis and PCR HCV to confirm HCV infection. Sequencing analysis of the PCR HCV was performed using ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Results: The prevalence of Anti-HCV +ve cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were positive +ve while 2.9% were spontaneously cleared the virus (SVC). The HCV prevalence among house hold contacts was 17.29 & 19.17% while the SVC was 2.49 & 1.55% in lower & upper Egypt respectively. While the genotyping of the positive cases were performed it was found that the following pattern was noticed in the upper & lower Egypt respectively: (genotype 4a (90.3%) & 70.1%, 4m (4.8%) & 11.8%, 4n (0.5%) & 3.2%) 4v (0.2% & 2.9%) 4i (0.5% & 1.9%) 4g (0.8% & 1.2%) & 1a (2.9% & 8.3%) as shown in the following table.

Conclusion: The prevalence of HCV was found to be 18.5% among household contacts of Egyptian families. The genotype 4 was predominant in upper Egypt (97.1%) more than lower Egypt (91.7%). On the other hand genotype 1a was higher in lower Egypt (8.3%) more than upper Egypt (2.9%).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Red blood cell distribution width (RDW) is a numerical measure of the variability in size of red cell. It reflects variability in the size of circulating red blood cells (RBCs). RDW can be used as a prognostic marker in heart failure. In hepatic patients it was approved to be an independent predictor of liver fibrosis in patients with chronic HBV infection, and it is higher in patients with alcoholic liver disease and non alcoholic liver cirrhosis. The gold standard for assessing the histological outcome of liver disease is liver biopsy. This procedure is costly and carries a small risk of complications due to sampling error, invasiveness and requires hospitalization of at least 6-18h. These limitations have stimulated the development of non-invasive techniques for assessing the presence and the degree of liver fibrosis. Several laboratory scores composed of routine laboratory markers that are readily available have been proposed for non-invasive prediction of liver fibrosis in chronic hepatitis C (CHC) patients.

Aims & Methods: The aim of this work is to use RDW as a marker for non-invasive prediction of the stage of hepatic fibrosis in patients with chronic hepatitis C genotype-4. 100 patients with chronic hepatitis C were subjected to routine laboratory and radiological investigations in addition to using KX-21 Sysmex automated hematometry analyzer to measure RDW & RPR (RDW% & Platelets). Comparing with other liver fibrosis like APRI (AST-to-Platelet ratio) FIB-4 equation (using platelet count, AST, ALT, age) to perform this test. PCR HCV RNA, genotyping & liver biopsy (using METAVIR scoring system where cases were classified into early fibrosis (F1 + F2) 68 patients & late fibrosis (F3 + F4): 32 patients) were done.

Results: RDW & RPR were significantly higher in patients with late fibrosis > early fibrosis (P < 0.0001) while platelets count was significantly lower in late fibrosis > early fibrosis (p < 0.001). By applying ROC curve it was found that the cut off value of RDW was 16.5, with sensitivity 86.8% specificity 85.9%, accuracy 86.8% & ≥ the cut off value of the platelets was 196.5 with sensitivity 81.8%, specificity 68.2% accuracy 67.6, while RPR cut off value was 0.0897 with sensitivity 90.9%, specificity 85.9% & accuracy 87.6. As regard APRI test it was found that the cut off value of APRI was 0.5 with sensitivity 72.7%, specificity 66.7% & accuracy 68%. While FIB-4 equation showed cut off value 1.685 with sensitivity 77.3%, specificity 66.7% and accuracy 69%. In conclusion the area under the ROC curve for RDW, RPR were excellent but for platelets the ROC curve for APRI were fair. When applying regression analysis it was found that the RDW (OR:3.903, 95% CI: 0.913–9.95) so as the level of RDW increase by one unit the risk late fibrosis will increase by 3.9 fold. In addition the platelets increase by one unit the risk of late fibrosis will decrease by 0.953.

Conclusion: RDW & RPR may be used as simple, non-invasive predictors of advanced fibrosis in patients with chronic hepatitis C genotype-4.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of liver cancer and its recurrence have been reported frequently at an early stage in patients who underwent interferon (IFN)-free direct-acting antiviral (DAA) therapy [1]. The underlying mechanisms of

This work is licensed under a Creative Commons Attribution-NonCommercial-ShareAlike 4.0 International License (https://creativecommons.org/licenses/by-nc-sa/4.0/).

A177
cancer incidence following DAA therapy may include the rapid clearance of hepatitis C virus, reconstitution of the immune system, and reduction of cancer immunosurveillance [2]. These changes may in fact have an impact on the development of cancer in other organs.

Aims & Methods: We conducted a retrospective analysis to compare the cancer incidence in patients treated with IFN-free DAA therapy with those treated with IFN therapy. All patients who achieved sustained viral response following antiviral therapy between 1992 and 2016 in our hospital were investigated retrospectively. Patient records were examined to identify new cases of cancer, as defined by pathology or medical imaging, in organs other than the liver following antiviral therapy. The date of diagnosis was determined based on the records, and the cancer incidence was compared between patients treated with DAA therapy and those treated with IFN therapy using the Kaplan-Meier method and Cox regression analysis. Patients with recurrent cancer were excluded from the analysis. Propensity score analysis followed by inverse probability of treatment weighting (IPTW) was used to correct for the effects of confounding factors.

Results: There was a significant difference in the age and sex of the patients treated with DAA (n = 324, median age: 70, male: 41%) and those treated with IFNs (n = 445, median age: 58, male: 60%). Median lengths of the observation period for the DAA and IFN groups were 1.3 and 6.2 years, respectively. There were 12 and 22 cases of cancer occurring in organs other than the liver in the DAA and IFN groups, respectively. These cancer cases occurred most frequently in the gastrointestinal tract, followed by the urinary organs, hematopoietic organs, biliary tract, pancreas, lungs, and other organs. The median periods from the start of the antiviral therapy to the time of diagnosis were 0.9 and 6.8 years in the DAA and IFN groups, respectively. Cumulative rates of cancer after 1 and 2 years were 3.0 and 5.0% for the DAA group, and 0.2 and 0.0% for the IFN group, respectively. The difference between the groups was significant (p = 0.02) based on Cox regression analysis using IPTW.

Conclusion: Because cancer detection in organs other than the liver can be challenging in management of hepatitides, some cases with cancer found after the treatment might have been diagnosable before the treatment, possibly leading to an overestimation of the incidence after the treatment. The number of newly diagnosed cancer cases was small in the present study, resulting in a low statistical power. Nevertheless, the cancer incidence in organs other than the liver was significantly higher in patients treated with DAA therapy than those treated with IFN therapy. This difference persisted after correcting for possible confounding factors and sex of the patients. Our findings suggest that patients need to be carefully examined after DAA therapy for the development of cancer in various organs, including but not limited to the liver.

P0054 IS THERE AN INCREASE IN THE INCIDENCE OF HEPATOCELLULAR CARCINOMA IN CIRRHTIC PATIENTS WITH HEPATITIS C TREATED WITH THE DIRECT-ACTING ANTIVIRALS?

J. C. Branco, R. Carvalho, S. Alberto, A. Martins
Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Lisboa/Portugal

Contact E-mail Address: ebranco.joana@gmail.com

Introduction: The impact of the virological cure on the evolution of cirrhotic patients treated with direct-acting antiviral agents (DAAs). Recent studies have reported an elevation in incidence of recurrence of hepatocellular carcinoma (HCC) and others a possible rise on the de novo incidence of HCC in the first year after treatment with DAA therapy, but not others.

Aims & Methods: This is a prospective study of cirrhotic patients treated with DAA between February/2015 and January/2017, under HCC screening with ultrasonography according to international guidelines. The main endpoint of the study was to determine the incidence of “de novo” and recurrent HCC. The second endpoint was to search for possible predictive factors associated with the occurrence of HCC. Statistical analysis performed on SPSSv.24. Results: 106 cirrhotics (73% mean; 54.5±8.8 years), MELD 7.3±2.6, 60% with portal hypertension (n = 64) and 22% with compensated cirrhosis (n = 23, 22 Child-Pugh B class). Two patients with previous HCC, stage Barcelona Clinic Liver Classification (BCLC) A, inviable after loco-regional treatment. The sustained virological response at week 12 was 89.9% (71/79); 4 deaths, 1 relapse, 1 therapeutic failure and 2 losses to follow-up (FU). In 11±7 months of FU, we registered 105 HCC. 4 “de novo” and 1 recurrence, which corresponded to an incidence of 3.8% of “de novo” HCC (13% in compensated cirrhosis). The BCLC staging was: stage A, stage B and stage C and the one with the recurrence was stage D. A Child-Pugh B class (p = 0.004), low platelets level (p = 0.001) and hospitalization for decompensation (p = 0.005) were associated with the occurrence of HCC; the genotype did not have association. The mean time to HCC development was 7.5 months (2-14).
**Conclusions:** In this cohort the “de novo” incidence of 3.8% of HCC after the transplant was much lower mainly in patients with decompensated cirrhosis, not eligible for treatment with interferon in the past, and in a short interval of time after treatment. These results alert for an eventual need to increase the frequency of screening in the post-treatment period and carefully evaluate the best timing for liver transplantation. We could not conclude about recurrence due to the small number of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

5. ANRS collaborative study group on hepatocellular carcinoma (ANRS CO22). Recruitment of patients with hepatitis C virus infection who underwent liver biopsy between June 2015 and March 2017 were enrolled. Ten SWE measurements (GE Healthcare, USA) were recorded in the liver using a percutaneous route. The technical success was 92.4%. Sampling was considered adequate in 92.2% of patients. The percutaneous route included: coagulopathy/anticoagulation (32.2%), thrombocytopenia (17.8%), ascites (17.8%), and failed percutaneous liver biopsy (13.6%). In a fourth of the cases the biopsy was performed in the context of acute hepatitis, being in 12.6% for diagnosis of alcoholic hepatitis. The reasons for the failure of obtaining a histological diagnosis were as follows: especially alcoholic disease, hepatitis C and non-alcoholic steatohepatitis. In 80.5% of the cases the purpose of TJLB was for diagnosis and in the remaining cases for staging liver disease. Eighty-five patients (32.1%) had cirrhosis prior to biopsy. In a fourth of the cases the biopsy was performed in the context of acute hepatitis, being in 12.6% for diagnosis of alcoholic hepatitis. The reasons for the percutaneous route included: coagulopathy/anticoagulation (32.2%), thrombocytopenia (17.8%), ascites (17.8%), and failed percutaneous liver biopsy (13.6%). The technical success was 92.4%. Sampling was considered adequate in 92.2% of cases, which was associated with diagnostic purposes (94.9% vs. 86.8%, P < 0.001) and evidence of acute hepatitis (96.4% vs. 89.8%, P = 0.03). Most patients (60.4%) had histological criteria for cirrhosis. In 76.2% of patients TJLB allowed a histological diagnosis, mainly alcoholic and non-alcoholic steatohepatitis. The ability to provide a histological diagnosis was associated with adequate sample (80.8% vs. 21.1%, P < 0.001), presence of cirrhosis (83.9% vs. 71.6%, P = 0.023) and >1 passage (82.1% vs. 68.3%, P = 0.012). Findings were normal in 4.8%. In 70.9% of the situations the TJLB was considered to have an impact in the approach to the patient.

**Conclusion:** TJLB is a safe diagnostic tool with high diagnostic accuracy, allowing a change in strategy in a high percentage of cases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Area under the curve and receiver operator characteristic (AUROC) compari-
sions of the diagnostic accuracy of the eight approaches used the interquartile range (IQR) and median of 10 SWE measurements using body mass index (BMI) and age were analysed using the Mann-Whitney U test.

Results: The study population consisted of 106 men and 94 women with a mean age of 56.8 years (18–81 years) and a mean BMI of 26.4 kg/m². Fibrosis score was 0/F1/F2/F3/F4 in 7/30/33/24/23 patients, respectively. The median SWE (m/s) of 10 measurements in patients with F0, F1, F2, F3, and F4 were 1.33, 1.57, 1.73, 1.95, 1.98, respectively. The median IQR/median was 0.21. Furthermore, we found no significant difference (BMI: 25.1 ± 2.4, < 25 ± 2.0, p = 0.012) indicated significantly greater IQR/median. There was no significant difference in the diagnostic accuracy between using the median or mean of three, five, and 10 measurements. The AUROC of diagnostic accuracy in patients with significant fibrosis (≥ F2) ranged from 0.778 (A) to 0.876 (H). AUROC increased based on the number of measurements. A signifi-
cant difference between 1 and 5 (p < 0.05), 1 and 10 (p < 0.001), and 2 and 10 (p < 0.005) measurements was observed in pairwise comparison. Likewise, AUC increased with the number of measurements and diagnostic values of the (A) to 0.923 (G). A significant difference (p < 0.005) was seen between one and 10 measurements. In the cohort of IQR/median < 0.3, the diagnostic accuracy of ≥ F2 and ≥ F3 ranged from 0.806 (A) to 0.877 (H), and from 0.832 (A) to 0.928 (H), respectively. In the cohort of obese (BMI ≥ 25) and old patients (age ≥ 65), the diagnostic accuracy of ≥ F2 and ≥ F3 ranged from 0.752 (A) to 0.862 (D), and from 0.735 (A) to 0.903 (H), respectively. Comparing the AUROC of one measure-
ment, IQR/median < 0.3 showed greater AUROC than those of other
cohorts, however, the AUROC of ten measurements were similar in each cohort.

Conclusion: No difference was found between reporting mean or median SWE
measurements. The diagnostic performance of SWE increased with the number of
measurements. Our results suggest that 10 measurements are recommen-
ded to ensure the accuracy of SWE measurements in a practical setting.

Disclosure of Interest: All authors have declared no conflicts of interest.
0.21–0.57). At univariate analysis LS was associated with: liver cirrhosis (p < 0.0001), steatosis (p = 0.0003), liver surface nodularity (p = 0.0003), active alcoholic abuse (p = 0.015), alcohol consumption/day (p = 0.0134), diabetes (p = 0.0223). At multivariate analysis cirrhosis (p < 0.0001) and steatosis (p = 0.0073) were independently associated with LS. At both univariate and multivariate analysis, PS was significantly correlated only with liver cirrhosis (p = 0.0058).

Conclusion: The present is the first series assessing LS and PS in ALD patients by using SWE. The feasibility of the technique was excellent. The reproducibility was good for LS and fair for PS. SWE was a good predictor of liver fibrosis in the ALD cohort. Liver cirrhosis was the only independent variable correlating with PS, whose estimation could be useful to detect alcohol-related pancreatic damage in patients with severe ALD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-221 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145 and miR-199a in the HCC patient group indicates that these microRNAs can differentiate HCC from CHC and LC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary hepatocellular carcinoma (HCC) is one of the most common malignancies all over the world. HCC is associated with poor prognosis. However, the mechanism of HCC initiation and development remains unclear. In our previous work, high-throughput microarray assay in collected clinical HCC samples followed by bioinformatic analysis suggested that Metallothionein 1G (MT1G) might be one of the key factors in HCC.

Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSp (Methylation specific PCR) and BGS (Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was further investigated by in vivo, cell culture and DNA methylation analysis. Results: MT1G was inactivated in all (6/6) HCC cell lines tested, but was readily re-activated by demethylation treatment. Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSp (Methylation specific PCR) and BGS (Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was further investigated by in vivo, cell culture and DNA methylation analysis.

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-221 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145 and miR-199a in the HCC patient group indicates that these microRNAs can differentiate HCC from CHC and LC.

regulated in cancer tissues compared with the adjacent non-tumor tissues (P < 0.05). The expression level of MT1G in the liver cancer cells line was closely correlated to the promoter hypermethylation status. The MT1G expression in silenced HCC cell lines could be restored by demethylation agent. We generated HCC cell lines overexpressed MT1G. Ectopic re-expression of MT1G by stable transfection in SMMC-7721 and Hep3B cells inhibited colony formation (P < 0.001), suppressed cell motility and invasiveness (P < 0.05), concomitant with up-regulation of E-cadherin; and down-regulation of PCNA, MMP2, MMP13 and Vimentin. The in vivo growth of HCC cells in nude mice was also markedly inhibited after stable expression of MT1G (P < 0.001). MT1G over-expression in HCC cells induced the cell apoptosis (P < 0.01).

Conclusion: Our results demonstrate that MT1G promoter methylation directly mediates the transcription down-regulation and common occurs in HCC. MT1G gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, invasion, and induction of cell apoptosis.

P0064 THE FXR RECEPTOR PATHWAY IN HEPATOCELLULAR ADENOMA AND FOCAL NODULAR HYPERPLASIA, A PRELIMINARY EXPERIENCE
B. Van Rosmalen1, M. Visentin2, J. Verheij3, M. Bieze1, B. Stieger2, T. M. Van Gulik1
1Surgery, AMC, Amsterdam/Netherlands
2Clinical Pharmacology And Toxicology, University Hospital Zurich, Schlieren, Switzerland
3Pathology, AMC, Amsterdam/Netherlands
Contact E-mail Address: b.vanrosmalen@amc.uva.nl

Introduction: Hepatocellular adenoma (HCA) and focal nodular hyperplasia (FNH) may be confused on medical imaging. Both tumours are not connected to the biliary tree, however only FNH accumulates bile salts, suggesting that hepatocellular uptake and secretion of bile constituents differs in FNH and HCA. Therefore, one would anticipate changes in the Farnesoid X receptor (FXR) expression. However, the expression of FXR and its targets in HCA and FNH is relatively unknown. Targets of FXR regulate uptake and excretion of bile constituents. The current study aimed to examine FXR and its targets in normal and FNH medical imaging. We studied the expression of FXR and its targets in HCA and FNH and compared this with the appearance of lesions on MRI.

Aims & Methods: Tumour tissue and normal tissue from 7 patients with HCA and 7 patients with FNH was obtained. Diagnosis was confirmed by histopathological examination in all patients. Reverse transcription of the mRNA to cDNA was performed, using random primers and MultiScribe Reverse Transcriptase (Life Technologies, Carlsbad, Ca). The cDNA was used as template for PCR amplification by Taqman® assay analysis (Applied Biosystems, Foster City, CA). The expression of all the target genes in the FXR pathway (SHP, NTCP, OATP1B1, OATP1B3, BSEP, CYP7A1, CYP8B1, BAAT, SLC27A5, CYP3A4, SULT2A1, UGT2B4, CYP8A1, MRP2, MRP3, MDR3) were compared to the expression functioned as internal reference in both normal and tumour tissue. Matched case comparisons were made for tumour and normal tissue. DNA expression of FNH and HCA was compared to MRI findings.

Results: FXR was downregulated in both HCA and FNH. NTCP was significantly downregulated in FNH, and not significantly in HCA, although showing a trend towards down regulation. Three patients (1 FNH 2 HCA) show aberrant expression of NTCP compared to all the other patients. All these three patients had also an unclear or incorrect diagnosis based on MRI scan with gadodextric acid as compared to final diagnosis by histopathological examination. OATP1B1 was downregulated in both HCA and FNH, except again for the three patients with the aberrant expression. Expression of OATP1B3 and SHP in HCA and FNH did not significantly differ from expression in healthy liver tissue. MRP2 was significantly downregulated in HCA, but not in FNH. However, this may again be due to the patients with the aberrant expression pattern. OATP1B3 was significantly downregulated in HCA. CYP3A4 and CYP2A1 were very strong downregulated in HCA, but not in FNH. GGFR 4 was heavily downregulated in HCA, but not in FNH. BAAT was significantly downregulated in FNH.

Conclusion: Limited by sample size, this study suggests that misdiagnosis based on medical imaging might actually correlate with aberrances on hepatocyte transporter level. This seemed to account for NTCP (bile salt importer), OATP1B1 (bile salt importer) MRP2 (efflux pump of conjugated compounds). Although FXR itself was downregulated in both FNH and HCA, its downstream targets differed in expression between tumours. FXR receptor activity might be altered even when not different, or downstream targets might be influenced by factors outside the FXR pathway. Future research could provide a more profound insight into this mechanism.

P0065 CUX1 CONTROLS ENDOPLASMIC RETICULUM STRESS AND AUTOPHAGY-RELATED CELL DEATH
G. Metzger1, P. Di Fazio1, D. Bartels1, T. M. Greess2, T. T. Wissinowski2
1Department Of Visceral Thoracic And Vascular Surgery, Philips University Marburg, Marburg/Germany
2Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektion, Philipps Universität Marburg, Marburg/Germany
Contact E-mail Address: giulia_metzger@web.de

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze the role exerted by CUX1 during deacetylase inhibitors mediated cell death in liver cancer cells. CUX1, endoplasmic reticulum (ER) stress and autophagy markers were analyzed by RT-qPCR in two liver cancer cell lines HepG2 and Hep3B. Protein level was measured by western blotting. Cells were transfected with siRNA for CUX1 and furthermore treated with deacetylase inhibitors panobinostat, SAHA and trichostatin A. Thapsigargin, an endoplasmic reticulum stress inducer, served as positive control.

Results: CUX1 knock down caused a suppression of ER stress and autophagy markers BIP, CHOP, ATF4, ATF6, Beclin1, MAP1LC3B, UVRAG and TFE2 at early time point (6 hours) in both cell lines. Prolonged transfection did not alter the expression of the above mentioned markers; BIP was the only one suppressed in HepG2 after 24 hours. Interestingly, the deacetylase inhibitors are able to promote CUX1 over-expression after 6 hours of treatment, whereas they show to lose this ability after 24 hours. CUX1 knock-down reduced significantly not its protein level after treatment with deacetylase inhibitors. CUX1 knock down counteracts the accumulation of BIP protein after 24 hours of treatment with deacetylase inhibitors. Thapsigargin induced BIP independently from CUX1.

Conclusion: ER stress and autophagy markers are under the control of CUX1. The cell death induced by deacetylase inhibitors is strictly connected with CUX1 expression and activity. Further studies are needed to clarify the exact mechanism exerted by CUX1 in this scenario.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0066 CUX1 CONFRS RESISTANCE TO APOPTOTIC CELL DEATH IN LIVER CANCER CELLS
E. Hofmann1, P. Di Fazio1, D. Bartels1, T. M. Greess2, T. T. Wissinowski2
1Department Of Visceral Thoracic And Vascular Surgery, Philips University Marburg, Marburg/Germany

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze CUX1 activity in TRAIL (Tumour necrosis factor related apoptosis inducing ligand) mediated cell death in liver cancer cells. CUX1 was knocked down in HepG2 and Hep3B cells. Cells were further treated for 48 hours with a strong ligand (superkiller) binding DR4 and DR5 (TRAIL death receptors). The cell death events were analyzed by FACS analysis. RT-qPCR was performed to detect the expression of apoptotic markers. Caspase activity was measured by luminescence. Apoptosis array was performed.

Results: Treatment with superkiller TRAIL, at 50 and 100 ng/ml, caused cell death in HepG2 and Hep3B cells after 48h proven by an accumulation of 40% of sub-G1 events. CUX1 knock down caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events (60% with 100 ng/ml). CUX1 knock down did not change the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe.

Disclosure of Interest: All authors have declared no conflicts of interest.
Hepatocellular carcinoma (HCC) is a primary malignancy of the liver. It is the fifth most common malignancy in the world and the third most common cause of cancer-related deaths worldwide. It is a major health problem in Egypt with the incidence expected to rise continuously in the next decade. [1–2]

The diagnosis of liver cancer depends on both screening with alpha-fetoprotein (AFP) and radiological imaging studies. Generally, normal levels of AFP are below 10 ng/ml but AFP greater than 200 ng/ml is suggestive of HCC. The sensitivity of AFP for liver cancer is about 67%; therefore a normal AFP does not exclude HCC. Searching another tumor marker, that together with AFP could improve the diagnostic utility of HCC.[3]

Squamous cell carcinoma antigen (SCCA), a member of the high molecular weight family of serine protease inhibitors named serpins which are physiologically found in the granular layers of normal squamous epithelium but found to be typically expressed by neoplastic cells of epithelial origin in a number of different cancers for example cancer cervix, lung, and head and neck cancers hence, it can be used as a clinical marker of these malignancies. [4] The structure of the serum ovalbumin revealed the archetype native serpin fold that typically have three β-sheets (termed A, B and C) and eight or nine α-helices (hA-hI). Serpins also possess an exposed region termed the reactive centre loop (RCL) that includes the specificity determining region and forms the initial interaction with the target protease.

Recently much attention has been focused on the role of SCCA in HCV cirrhotic patients suggesting that high levels of SCCA can assess HCC development. [5]

Therefore, it is necessary to determine the serum SCCA level in HCV cirrhotic patients with and without hepatocellular carcinoma in relation to alfa feto protein (AFP). These groups were from both sexes who are admitted to the inpatient ward and the outpatient clinic of Tropical Medicine Department, Faculty of Medicine, Alexandria University. This study was carried out on:

Group A: 100 cases of hepatocellular carcinoma without interventions.
Group B: same 100 cases of group A before and 3 months after successful interventions.
Group C: 100 cases of established cirrhosis.
Group D: 100 cases with chronic hepatitis C virus infection without established cirrhosis.
Group E: 100 healthy individuals as controls.

All patients in this study were subjected to: complete blood picture, liver biochemical profile, serum alanine aminotransferase (ALT), serum aspartate aminotransferase (AST), serum alkaline phosphatase, total and direct serum bilirubin, prothrombin time and activity, serum albumin, blood urea nitrogen (BUN), serum creatinine, Fasting blood sugar. Serum alpha fetoprotein (AFP).

Determination of squamous cell carcinoma antigen (SCCA) Sera from selected patients and controls were used for estimation of SCCA with the CanAg SCC EIAs. The CanAg SCC EIA is a solid phase, non-competitive immunoassay based upon the direct sandwich technique. Calibrators and patient samples are incubated together with biotinylated anti-SCCA monoclonal antibody in Streptavidin coated microstrips. After washing buffered Substrate/Chromogen reagent (hydrogen peroxide and 3, 3′, 5′, 5′ tetra-methyl benzidine) is added to each well and the enzyme reaction is allowed to proceed. During the enzyme reaction a blue colour will develop if antigen is present. The intensity of the colour is proportional to the amount of SCC present in the samples. The colour intensity is determined in a microplate spectrophotometer at 620 nm (or optionally at 405 nm after addition of Stop Solution). Calibration curves are constructed for each calibrator. The SCC concentrations of patient samples are the read from the calibration curve.

Results: Table 1 shows a statistical significant difference between different studied groups regarding alpha feto protein (P = 0.000).

Conclusion: In the present study patients with HCC either with or without therapeutic intervention have significantly higher level of AFP in comparison to chronic HCV, cirrhotic and control groups this is in agreement with Awadallah et al.[6] who reported a statistically highly significant elevation in the serum AFP in HCC group when compared with control group. Moreover, the mean serum level of AFP in group A (HCC before intervention) was 263 ng/ml that decreased to 209.4 ng/ml in group B after therapeutic intervention and that agreed with Feng et al.[11] and Molinari et al.[8]. Also, at AFP level of 200 ng/ml the sensitivity was 90%, while the specificity was 60%.

Our results showed that SCCA level ranged from 2.5–10 with a mean of 5.53 in HCC patients without interventions, 3.3–7.6 with a mean of 5.3 in patients with HCC patients from cirrhotic patients was 3.2 ng/ml for SCCA yielded 80% sensitivity and 90% specificity. These results were in agreement with Trevisani et al.[12] Patients with HCC, in our study were none randomized selected as BCLC stage B (either one HCC lesion <5 cm in size or 3 lesions <3 cms) so no statistical correlation was done between serum AFP level and tumor size.

Our results showed a significant positive correlation between serum SCCA and AFP among patients with HCC before and after therapeutic intervention. Our data are in agreement with that of Hussein et al.[9] and El Ezawy et al.[10] SCCA was also higher among patients with HCC before intervention compared to patients with HCC after intervention as found by Bin et al.[11]

Applying the ROC curves analysis showed the best cut-off value to differentiate HCC patients from cirrhotic patients was 3.2 ng/ml for SCCA yielded 90% sensitivity and 90% specificity. These results were in agreement with Trevisani et al.[12] Patients with HCC, in our study were none randomized selected as BCLC stage B (either one HCC lesion <5 cm in size or 3 lesions <3 cms) so no statistical correlation was done between serum AFP level and tumor size.

When combined sensitivity of both markers was calculated in our study at the best-cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93% (Table 4).

The best overall formula that could best predict HCC was then constructed for Hepatocellular Carcinoma (Hepatocellular Multidisciplinary Score – Cairo University (HMC-CU) score is as following: Logit probability of HCC = –2.524 + 0.152 x age - 0.121 x Hb - 0.696 x INR – 1.059 x Alb + 0.022 x AFP + 0.976 x Gender Female = 1. The diagnostic value of HCC was then assessed by ROC curve. The best cutoff point of 0.56 HMC-CU enabled the diagnosis of HCC with 90% sensitivity, 80.6% specificity. AUC was 0.93 and the 95% confidence interval was 0.917–0.94. On comparing the diagnostic performance of HMC-CU to the performance of serum AFP for early diagnosis of HCC, it was found that serum AFP was able to diagnose HCC at cutoff value of 11.9 ng/ml with sensitivity of 68% and specificity 66%. AUC was 0.76 and the 95% confidence interval was 0.74–0.78.

Conclusion: The HMC-CU score constructed from routine parameters is accurate in the diagnosis of HCC in patients with HCV-related CLD. The elegance of our score is based on its simplicity, being based on routine laboratory parameters and serum AFP which is being used for screening of patients in many centers all over the world. Our score will not impose extra costs for the patients because it utilizes only routine laboratory parameters. The HMC-CU score may be useful during surveillance programs for HCC. Our study included large number of HCC and non HCC patients all are Egyptians with a background of HCV type 4 related CLD. A prospective validation study is being planned and further studies are invited to validate this score on patients of other races infected with other HCV genotypes.

**Introduction:** Hepatocellular carcinoma (HCC) is the first most common primary malignant tumor of the liver, the fifth most common cause of cancer-related death worldwide. (1) Early detection of HCC provides the best chance for a curative treatment which in turn improves patients survival. However, more than 60% of HCCs are diagnosed at a late stage (2). This could be explained by poor compliance of cirrhotic patients to the surveillance programs and lack of a sensitive and specific tumor marker. Serum AFP – commonly used for HCC diagnosis has a low sensitivity, and specificity for HCC detection (3).

**Aims & Methods:** The aim of this study was to develop Hepatocellular Multidisciplinary clinic – Cairo University (MHC-CU) score and test its accuracy in HCC detection in comparison to the widely used AFP. In the current study, we reviewed the data of 2363 Egyptian patients with HCV genotype-4 related chronic liver disease. 1291 patients were diagnosed to have HCC. The best cutoff point of 0.56 HMC-CU enabled the correct identification of patients with HCC with 90% sensitivity, 80.6% specificity. AUC was 0.76 and the 95% confidence interval was 0.74–0.78.

**Results:** The HMC-CU score constructed from routine parameters is accurate in the diagnosis of HCC in patients with HCV-related CLD. The elegance of our score is based on its simplicity, being based on routine laboratory parameters and serum AFP which is being used for screening of patients in many centers all over the world. Our score will not impose extra costs for the patients because it utilizes only routine laboratory parameters. The HMC-CU score may be useful during surveillance programs for HCC. Our study included large number of HCC and non HCC patients all are Egyptians with a background of HCV type 4 related CLD. A prospective validation study is being planned and further studies are invited to validate this score on patients of other races infected with other HCV genotypes.

**P0069 MULTIPLE BIPOLAR RADIOFREQUENCY ABLATION IN TREATMENT OF MEDIUM TO LARGE HEPATOMAS – EXPERIENCE IN A REGIONAL HOSPITAL**

P. Hsieh, C. Yen
Department of Gastroenterology and Hepatology, Chang-Gung Memorial Hospital Keelung branch, Keelung, Taiwan

Contact E-mail Address: 888082050@gmail.com

**Introduction:** Monopolar radiofrequency ablation (RFA) treatment for hepatomas has been unsatisfactory with local tumor recurrent rates of 8-40% in tumors ≥3 cm. Bipolar RFA devices have been developed to overcome the limitations of monopolar RFA devices.

**Aims & Methods:** This study aimed to evaluate the therapeutic effect and long-term survival in medium and large hepatomas using multiple bipolar radiofrequency ablation system (Celon). The study subjects had a Child-Pugh class A or B. The patients who were ineligible for surgical intervention or refused surgical intervention were treated with percutaneous bipolar electrodes. A total of 30 consecutive cirrhotic patients (48 tumors) with hepatomas ≥3 cm were enrolled between January 2011 and November 2012. The follow-up period was 30 months after RFA. The complete necrosis rate, tumor recurrence rate and long-term survival rate were analyzed and compared between medium and large hepatomas using Kaplan-Meier survival and the prognostic factors were using multivariate analysis.

**Results:** 30 patients were divided equally into two groups with 15 patients in each of medium and large hepatoma groups. 17 patients underwent artificial ascites (56.3%). The complete necrosis rate after ablation was 93.3% (14/15 patients) for either medium or large hepatomas. The local tumor progression rate and distant tumor recurrence rate of 40% and 60% (p = 0.098) vs 73.3% and 80% (p = 0.652) for medium and large hepatomas during 30 months follow up were not statistically significant. The overall survival rates ≥30%, 66.7% vs 60%, 46.7% at 12 and 30 months, respectively, was not statistically significant (p = 0.390). By multivariate analysis, BCLC stage (HR = 3.904, p = 0.023), MELD Score (HR = 1.220, p = 0.021) and pre-treatment AST level (HR = 1.028, p = 0.019) were independent prognostic factors for overall survival.

**Conclusion:** Multiple bipolar RFA system can achieve high complete tumor necrosis rates and low complication rates in treating medium to large hepatomas with shorter pre-treatment BCLC stage, MELD score and AST level were independent prognostic factors for overall survival. The therapeutic effect and long-term survival for large hepatomas (≥5 cm) was not inferior to that of medium hepatomas by multiple bipolar RFA.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0070 RECENT TRENDS IN HEPATOCELLULAR ADENOMAS:
CLINICAL FEATURES, DIAGNOSIS AND OUTCOMES
M. Silva, A. Peixoto, R. Coelho, H. Cardoso, G. Macedo
Gastroenterology, Hospital São João, Oporto/Portugal

Contact E-mail Address: marcocestaisva@gmail.com

Introduction: Hepatocellular adenomas (HCA) are rare, benign tumors of pre-
sumable epithelial origin, that occur predominantly, but not exclusively, in young
women taking oral contraceptives (OC) or oral gestagens. The Bordeaux ade-
noma tumor markers are a promising method of identifying the high-risk HCA
of malignant transformation into hepatocellular carcinoma (HCC).

Aims & Methods: Aims: The authors propose to evaluate the demographics,
etiology, clinical manifestations and prognosis of HCA.

We undertook retrospective analysis of patients with HCA, histologically con-
firmed by biopsy or surgical resection, between 2008 and 2016, in a tertiay referral centre. When feasible, the subtype classification of HCA pro-
posed by the Bordeaux group, was performed. Descriptive statistics, uni and
multivariate analysis were performed using IBM SPSS Statistics 22, with
p < 0.05 deemed to be statistically significant.

Results: In this study 27 patients were included, 2 men and 25 women, with a
median age of 38.1±11 years, followed for a mean time of 78.3±36 months (lost follow-up in 7 cases). Three cases of hepatic adenomatosis were included. Forty-
one percent of the women used OC and 38% of the patients had dyslipidemia.

The mean size of the HCA was 70±42 mm; 65% of the patients had abnormal
liver tests at diagnosis, 46% were symptomatic and in 21% the diagnosis was
performed due to ruptured HCA. Surgical resection was performed in 88% of the
cases; complete resection was achieved in 75% of the cases. Of the 19 patients
who performed abdominal-CT scan or abdominal-MRI before histological con-
firmation, only 30% had an imagiological diagnosis of HCA. In 12 (44%) cases,
immunohistochemical analysis was performed. According to the Bordeaux clas-
cification of HCA, 8 (67%) cases were classified as infiltrative, 2 (17%) as
HNF-1α-mutated, 1 (8%) as β-catenin mutated and 1 (8%) as undetermined.
During the follow up, 6 patients died due to hematogenic shock related with
HCA rupture and in 2 (10%) was necessary surgical revision due to incomplete
resection. There was no HCC cases diagnosed during the follow-up. The
median size of the HCA that weren't completely resected and also of those presenting
with HCA rupture was significantly higher: (110 vs 55 mm [p = 0.037] and 105 vs
47 mm [p = 0.035], respectively). The 2 male patients had inflammatory HCA

Conclusion: In this cohort, HCA were prevalent in female taking OC and the
infiltrative type HCA was the most common. In many cases, abdominal
imaging is insufficient for a correct diagnosis, and biopsy specimen or surgical
resection should be performed for a correct diagnosis. Lesion size was associated
with the risk of rupture and incomplete surgical resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

3HEPATOLOGY UNIT, CARDARELLI HOSPITAL, NAPLES/ITALY

Aims & Methods: Aims: We aimed to evaluate the efficacy and safety of Laser Ablation
(LA) in comparison to TACE in patients with large tumor size HCC. Between
January 2009 and December 2012, 41 cirrhotic patients (29/12 M:F, median age
72 yrs, range 54-88, Child-Pugh A: 27/4, B: 37/4) with a single node of HCC ≥40
(mean size 46 mm, range 40–75) were enrolled in this study. The patients were
-treated with multifiber technique of LA. The control group consisting of 41
patients (29/12 M:F, mean age 72 yrs, range 49-86; Child-Pugh A: 23/4; B: 34/7;
C: 3/4) with the same size of the nodule 50mm (median size 40–50 mm, 51-60 mm
and >60 mm). Disease recurrence, during a mean duration of follow up of 37.4 ±
2.7 months, was observed in 13 (24%) LA-treated patients (24%) and in 24
(58.5%) TACE-treated patients (p =0.0051). Overall survival probability rate at
5 years was 90.2% and 55.4% in LA group and 85.4 and 48.8. in TACE
group.

Conclusion: LA is a more efficacious therapeutic option than TACE in patients
with solitary large HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration (EUS-
FNA) is one of the alternative methods for tissue sampling of liver solid mass.
However, the diagnostic efficacy of using cytology was limited.

Aims & Methods: In this study, we evaluated the feasibility and diagnostic accuracy
of EUS-guided fine needle biopsy (EUS-FNB) for hepatic solid masses in
patients with suspected malignancy. The EUS-FNB using 20G, 22G or 25G
core biopsy needle is made to perform percuta-
aneous laser ablation of liver tumors using the multifiber technique. Acta

Aim & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly diagnosed HCC patients with ascites (mean age = 56.94 y, male = 74.8%, hepatitis B virus = 73.2%) were analyzed. We compared Child-Pugh score, Model for End-stage Liver Disease (MELD) score, MELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival. Results: During a median 9.0 months of follow-up (range, 0.1-154.0), mortality was 146 patients (34%). The median survival was significantly lower for those with MELD-Na >12 than MELD-Na <12 or <12 <12 (median survival, 13.6 vs. 3.7 months, p < 0.001). Overall, 350 patients received treatment, and most commonly used modality was transarterial chemoembolization (62.3%), followed by radiofrequency ablation (15.7%) and resection (13.4%). Survival was significantly associated with hospital where the treatment was performed. Conclusions: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, in which case survival was not significantly different than those who did not receive treatment (median survival: 13.3 vs. 2.4 months, p < 0.010). When patients were further stratified by mUICC stage and MELD-Na score, treatment was not associated with better outcome for mUICC stage IV patients with MELD-Na = 12 (median survival: 22.2 vs. 1.8 months for treatment vs. best supportive care, p = 0.15), while treatment was associated with better outcome in other subgroups. The study was conducted in Italy.

P0073 COMPARISON OF METHODS TO ESTIMATE LIVER FUNCTION IN NEWLY-DIAGNOSED HEPATOCELLULAR CARCINOMA PATIENTS WITH ASCITES

Y. Ko

Internal Medicine, Samsung Medical Center, Seoul/Korea, Republic of Korea

Contact E-mail Address: bs2-32@hanmail.net

Introduction: Liver function is a key element in determining outcome of patients with hepatocellular carcinoma (HCC). For HCC with ascites, estimation of liver function is particularly important, as they already have decreased liver function.

Aims & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly diagnosed HCC patients with ascites (mean age = 56.94 y, male = 74.8%, hepatitis B virus = 73.2%) were analyzed. We compared Child-Pugh score, Model for End-stage Liver Disease (MELD) score, MELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival. Results: During a median 9.0 months of follow-up (range, 0.1-154.0), mortality was 146 patients (34%). The median survival was significantly lower for those with MELD-Na >12 than MELD-Na <12 or <12 <12 (median survival, 13.6 vs. 3.7 months, p < 0.001). Overall, 350 patients received treatment, and most commonly used modality was transarterial chemoembolization (62.3%), followed by radiofrequency ablation (15.7%) and resection (13.4%). Survival was significantly associated with hospital where the treatment was performed. Conclusions: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, in which case survival was not significantly different than those who did not receive treatment (median survival: 13.3 vs. 2.4 months, p < 0.010). When patients were further stratified by mUICC stage and MELD-Na score, treatment was not associated with better outcome for mUICC stage IV patients with MELD-Na = 12 (median survival: 22.2 vs. 1.8 months for treatment vs. best supportive care, p = 0.15), while treatment was associated with better outcome in other subgroups. Contact E-mail Address: anna-vitiello@hotmail.it

Introduction: The BCLC algorithm is the standard system for clinical management of HCC. Data on adherence to this therapeutic paradigm are scarce. The aim of this field-practice study is to provide a description of HCC patients in Southern Italy, to evaluate the adherence to BCLC guidelines and its impact on patients’ survival.

Aims & Methods: We analyzed the region-wide Italian database of Progetto Epaticarcinoma Campania, which includes data of HCC patients, prospectively collected from January 2013 to December 2015 in 16 regional centers. Results: Overall 1008 HCC patients were enrolled: 70.6% patients received therapy recommended by BCLC algorithm, while 29.4% underwent different treatments. Among patients who were treated in adherence to guidelines, a higher rate of diagnosis on surveillance programs, better liver function, lower rate of AFP >200 ng/mL, more early stage and monofocal HCC, lower frequency of nodules >5 cm, portal vein thrombosis and metastases were observed. The multivariate analysis showed that non-adherence to treatment guidelines was independently associated to the BCLC stage B, Child-Pugh classes B-C, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5 months, while in patients managed differently was 31.9 months (p < 0.0001).

Conclusion: Adherence to BCLC algorithm in field-practice was high in early and end stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required. Disclosure of Interest: All authors have declared no conflicts of interest.

P0076 A QUESTIONNAIRE SURVEY ON QUALITY OF LIFE WITH ANXIETY AND DEPRESSION SELF-RATING IN PATIENTS OF LIVER CIRRHOSIS

Y. Zhang1, X. Li1, N. Cui2, Y. L. Liu1

1Dept. Of Gastroenterology, Peking University People’s Hospital, Beijing/China
2Dept. Of Respiratory, Beijing Hospital of Chinese Traditional and Western Medicine, Beijing/China

Contact E-mail Address: medicalyuan@qq.com

Introduction: Liver cirrhosis is a great public health burden for Chinese health system. The most common causes are HBV, HCV, alcohol consumption and non-alcoholic fatty liver disease, et al. The quality of life of liver cirrhosis patients is impacted by the physical symptoms and psychological symptoms such as anxiety as depression.

Aims & Methods: We aimed to investigate the quality of life of patients with cirrhosis, as well as depression and anxiety. A questionnaire survey was carried out in 95 patients in our gastroenterology department, Peking University People’s Hospital from May to August in 2016. The patients were divided into two groups, cirrhosis group and control group. The patients in cirrhosis group in...
were diagnosed liver cirrhosis without complications. The control group included the digestive polyps patients without other diseases. The questionnaire included the World Health Organization Quality of Life (WHOQOL)-BREF, Self-rating Anxiety Scale (SAS) and Self-rating Depression Scale (SPS). The questionnaire scores of the two groups were analyzed.

Results: A total of 95 valid questionnaires were collected and divided into cirrhosis group (n = 40) and control group (n = 45). In the cirrhosis group, there were 22 males and 18 females, average age 57.97 ± 10.448 years. In the control group, there were 45 males, 23 males and 22 females, with an average age of 61.47 ± 13.081, showing no difference from cirrhosis group. WHOQOL includes four domains: physiological domain, psychological domain, social relationship domain, environment domain. The scores of liver cirrhosis group: physiological field (22.23 ± 3.312), psychological field (19.59 ± 3.925), social relationship field (9.64 ± 2.497), environment domain (26.23 ± 7.534) and control group (22.96 ± 3.275 in physiological field, 19.87 ± 3.152 in psychological field, 10.58 ± 2.061 in social relation field and 28.36 ± 5.091 in environmental field), they had no significant difference between the two groups (P > 0.05). The depression self-rating score of cirrhosis group (47.86 ± 10.782) was significantly higher (P = 0.034) than that of control group (42.61 ± 11.564). Meanwhile, there was no significant difference between the Self-rating Anxiety Scale scores of the cirrhosis group (38.46 ± 11.917) and control group (37.00 ± 12.521) (P > 0.05) (Table 1).

Results:

- AT the present stage, the treatment of patients with non-alcoholic fatty liver disease has insufficient effectiveness due to the simultaneous availability of a number of recommendations and the lack of an individual approach. Not enough attention is paid to the study of nutritional behavior and the role of nutrigenetics, as additional risk factors for the development of non-alcoholic fatty liver disease, methods for studying the characteristics of eating behavior should be applied more widely, which will allow timely appropriate correction. A more extensive study of nutrigenetics will make it possible to designate a personified diet, taking into account the detected polymorphisms, which will make it possible to achieve a significant improvement in metabolic parameters in this category of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The quality of life and anxiety scores in cirrhosis group had no significant different from the control group, but the depression score was higher than that of the control group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0078 NON-GOVERNMENTAL HCV SCREENING IN A VILLAGE IN NILE DELTA IN DAAS ERA IN EGYPT

A. Sadek1, A. Salem2, W. Wafy3, A. Abdelatif4

1, 2Gastroenterology- Hepatology, Theodor Bilharz Research Institute, Giza/Egypt
3Gastroenterology&Hepatology, Naser Institute, Cairo/Egypt
4Public Health, Theodor Bilharz Research Institute, Giza/Egypt

Free Physician, Cairo/Egypt

Contact E-mail Address: ahmedsadek48@yahoo.com

Introduction: HCV is highly endemic in Egypt with a prevalence of 12%. The ministry of health through the national committee for hepatic viruses has done an extra-ordinary effort since the beginning of the DAAAs era which resulted in treatment of almost one million infected patients till now. Still this looks as the summit of the iceberg and there is still estimated more than 10 million Egyptians infected with the virus, the majority of them are still undetected.

Aims & Methods: The aim of this work is to give an example of non-governmental efforts which can be done to solve this tough national problem. A group of young medical and non-medical volunteers all from El Salam village in Mansoura, Dakakha governorate, Egypt have worked together. They contacted mosques and pharmacies in the village and distributed brochures to announce for the free of charge screening for the virus in the village. They contacted business men in the village to sponsor the campaign. They contacted the laboratory of the village to do the HCV Ab test with nonprofit price.

Results: A total of 2220 citizens have visited the referral lab to do the antibody test. Only 419 persons proved positive. This gives an estimated prevalence in the village of 19.0%. 119 patients were insurance patients and they went to treatment and did not complete the study. The rest 300 Ab –ve patients completed the study. All patients were Hbs Ag –ve. 132 PCR –ve (44%) patients from the 310 HCV Ab –ve group. The rest 18 patients were –ve for HCV RNA (56%). 18 patients of the HCV PCR –ve had previous HCV treatment (6.5%). Only 2 patients of the 168 HCV RNA +ve (1.2%) were previously treated. The PCR +ve patients without previous treatment were 114 patients (38%). So only 62.0% of the HCV Ab +ve and 38.0% of the HCV Ab –ve in the community are PCR +ve and require treatment. The total cost for the screening of the 2220 patients was 40.000 L.E. which means 18.0 L.E per person (almost one Dollar).

Conclusion: The screening costs for HCV Ab positivity can be markedly reduced if it is done in each village depending on volunteers from the same village working in related fields like medical, pharmacists, laboratory and social jobs. Only 62.0% of the HCV Ab +ve in the community are PCR +ve and require treatment.

3Pavlov First Saint Petersburg State Medical University, Saint Petersburg/Russian Federation

Contact E-mail Address: liya73@mail.ru

Introduction: Non-alcoholic fatty liver disease (NAFLD) is liver disease with histological signs of accumulation of cholestetin excessive amount in hepatocyte in patient without a history of alcohol consumption (due to causes other than). The search for accessible, non-invasive and effective methods of screening for this pathology, allowing to detect NAFLD at early, potentially reversible stages of development is relevant. The purpose of the work was frequency estimation of the prevalence steatosis according to elastometry with controlled attenuation parameter (CAP®) among young people and associated with them specific body composition.

Aims & Methods: 59 volunteers (students of medical university) at the age of 19–28 years (the median age of 20.5) have participated in research. There were 22 (37.3%) men and 33 (62.7%) women among them without verified liver diseases. The survey was conducted in order to exclude or detect risk factors. Determining the presence of hepatic steatosis and the degree of liver fibrosis was performed with the apparatur FibroScan 502 Touch. The final figures of elasticity of the liver were estimated in kPa (METAIVR). The controlled attenuation parameter (CAP®) in dB/m was used for the severity of steatosis. Moreover, there was the body bioelectrical impedance analysis of body (BIA), evaluated: body mass index (BMI), body fat.

Results: The signs of violations of the structure of the liver were diagnosed in 15 people out of 59 (25.4%). The signs of steatosis were found in 12 (20.3%) subjects. The signs of fibrosis in 7 (11.9%) people (E>5 kPa). At the same time the combination of liver fibrosis and steatosis was diagnosed in 4 (6.8%). After analyzing data of BIA it was revealed that body weight above normal in 23 (40%), wherein fat body composition above normal values in 19 (33.4%). Results of binary logistic analysis showed that the chance of development of hepatic steatosis in case of excess adipose tissue increase 28 times (p=0.045), influence of BMI, gender, age was statistically insignificant.

Conclusion: Based on the results obtained, it can be concluded that there is high enough level of distribution of liver steatosis among young people. Transient elastostasis (TE) with controlled attenuation parameter (CAP®) is a fast, reliable, repeatable non-invasive method for the assessment of NAFLD. The development of hepatic steatosis among practically healthy young people largely associated with the increase the amount of adipose tissue in the body. The confirmed importance of evaluation of body composition and lack of information of using only BMI when evaluating the chances of development of NAFLD.

**P0080** SALVAGE TECHNIQUE USING A MICRO GUIDEWIRE FOR DIFFICULT BILIARY CANNULATION IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY
Ichimnyi Nishi Hospital Dept. of Gastroenterology, Ichinomiyi/Japan

Contact E-mail Address: a-mori@anzu.or.jp

Introduction: Biliary cannulation is indispensable for therapeutic endoscopic retrograde cholangiopancreatography (ERCP) in patients having biliary disease. Selective biliary cannulation is often difficult due to anatomical constraints. Numerous techniques have been attempted to overcome such problems. Selective biliary cannulation is often difficult due to anatomical constraints. Systematic searching was performed using MEDLINE, EMBASE and Cochrane library from January 1st, 1996, to December 31st, 2016 for studies assessed the relationship between alcohol consumption and gallstone disease development. The eligibility criteria was included: 1) studies involving the patients with gallbladder stone with or without cholecystitis; 2) cohort or case-control studies investigated the association between alcohol consumption and gallstone disease development. Newcastle-Ottawa Scale was used to assess the methodologic quality of each studies. Data was obtained from each selected studies regarding: 1) baseline characteristics of the study (cohort, case-control); 2) number of participants; 3) participants’ clinical features; 4) country; 5) publication year; 6) Risk or odds ratio; 7) 95% confidence intervals of alcohol consumption and risk of gallstone. The random effect model was used to estimate the pooled relative risks (RR) with 95% confidence intervals (CIs).

Results: Twenty-five cohort and case-control studies were included, and total 12, 581 cases with gallstone diseases among those 17, 509 controls. Alcohol consumption indicated a decreased risk of GSD development (Pooled RR = 0.84 [0.79–0.90], P < 0.001). Subgroup analyses according to the alcohol doses (g/d) confirmed a gradual risk-reduction effect on GSD compared to non-drinkers (Light: RR = 0.97 [0.94, 1.00], p = 0.864; Moderate: RR = 0.92 [0.79, 0.86], p = 0.777; Heavy: RR = 0.70 [0.62, 0.80], p < 0.01).

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: In this systematic review with meta-analysis, alcohol consumption has dose-dependent negative co-relation with the risk of gallstone disease development.

Disclosure of Interest: All authors have declared no conflicts of interest.

Endoscopic retrograde cholangiopancreatography (ERCP) is challenging in patients who have undergone surgical reconstruction of the intestines. In 2001, double-balloon enteroscope (DBE) was reported by Yamamoto et al to be an effective procedure for the diagnosis and treatment of small intestine obstructions. We report a case of a 60-year-old which was successfully treated using DBE and enteroscope to diagnose and remove a foreign body (n=89)

Aims & Methods: To determine time frame between ERCP/duct clearance and cholecystectomy (CCX) in non-pancreatitis group. 2) To determine time frame between ERCP/duct clearance and CCX in pancreatitis group. 3) To determine re-admission rate while awaiting CCX. All patients who underwent ERCP for CBDS before 01/01/2014 to 31/12/2014 were included in the study. Patients who had previously undergone CCX (de novo stones) were excluded. All patients were followed up for a minimum period of 2 years following their ERCP.

Aims & Methods: 1) To determine time frame between ERCP/duct clearance and cholecystectomy (CCX) in non-pancreatitis group. 2) To determine time frame between ERCP/duct clearance and CCX in pancreatitis group. 3) To determine re-admission rate while awaiting CCX. All patients who underwent ERCP for CBDS before 01/01/2014 to 31/12/2014 were included in the study. Patients who had previously undergone CCX (de novo stones) were excluded. All patients were followed up for a minimum period of 2 years following their ERCP.

In 27 patients duct clearance was not achieved; 26% (7/27) underwent surgical management (CBD exploration on table cholangiogram and CCX). The remaining 74% (20/27) patients were deemed unsuitable for invasive intervention and were either for symptomatic stent change only or conservative management.

Conclusion: The time period between duct clearance and CCX was longer than anticipated, especially in patients with mild acute pancreatitis as none of them underwent CCX during index admission or within 2 weeks of ERCP/duct clearance. Some patients re-presented with CBDs while awaiting CCX. We looked into potential causes of delay in CCX – delayed referral to surgery, long waiting time for elective CCX and patient choice. We propose to develop a local pathway for patients with CBDs and gallstones and instigate a robust system for referring patients for CCX following duct clearance. This would help to minimize readmission and potential complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: pfahdra@gmail.com

Introduction: Patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) and duct clearance for common bile duct stones (CBDS) should be followed up with an early cholecystectomy to prevent recurrent biliary complications (1, 2) and acute gallstone pancreatitis. Recently the National Confidential Enquiry into Patient Outcome and Death (NCEPOD) recommended that definitive eradication of gallstones by cholecystectomy prevents the risk of a recurrent attack of acute pancreatitis (AP). For patients with an episode of mild acute pancreatitis, early definitive surgery should be undertaken, either during the index admission or within 2 weeks (3, 4).

Aims & Methods: 1) To determine time frame between ERCP/duct clearance and cholecystectomy (CCX) in non-pancreatitis group. 2) To determine time frame between ERCP/duct clearance and CCX in pancreatitis group. 3) To determine re-admission rate while awaiting CCX. All patients who underwent ERCP for CBDS before 01/01/2014 to 31/12/2014 were included in the study. Patients who had previously undergone CCX (de novo stones) were excluded. Aim & Methods: Between January 2006 and March 2016, a total of 185 advanced or recurrent BTC patients receiving a first line systemic chemotherapy for at least two cycles were retrospectively studied. Serum CA 19-9 was measured at baseline (CA19-9_Pre) and after two cycles of chemotherapy, and patients were categorized into three groups based on CA19-9 response: CA19-9 decrease group (>30% decrease), stable group (30% decrease and ≥20% increase) and increase group (>20% increase). The Cox proportional hazards model was used to analyze the prognostic factors for OS and PFS, using the landmark method. Results: The primary tumors were located as follows: 68 (37%) in intrahepatic bile duct, 43 (23%) in extrahepatic bile duct, 64 (35%) in gallbladder and 10 (5%) in ampulla. As for chemotherapeutic regimen, single-agent or combination therapy was given in 49 (26%) or 136 (74%), respectively. After 2 cycles of chemotherapy, partial response was achieved in 29 (16%) and stable disease in 106 (57%). There was a statistically significant trend for CA 19-9 and RECIST responses (p = 0.03). Compared with CA19-9 decrease group, hazard ratios for stable and increase groups were 1.92 (95% CI, 0.79–5.97), 2.42 (95% CI, 0.13–41.3), and 2.42 (95% CI, 0.13–41.3) for PFS, respectively (p <0.001). Conclusion: CA 19-9 response after two cycles as well as baseline served as a prognostic factor for OS and PFS in patients with advanced and recurrent BTC on systemic chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

and data on the biliary drainage procedure were collected from medical records. Definitions of failure of drainage or other severe drainage related complications are shown in table 1.

Results: In total, 187 patients were included. Initial drainage was performed in a non-referral center in 125 patients (66.8%). The initial drainage procedure was endoscopic in 158 patients (84.5%) and percutaneous in 29 patients (15.5%). A stent was placed in 91 patients (61.3%) at the initial drainage procedure. The highest bilirubin level in the 2 weeks prior to drainage was 248 (IQR 138–377) μmol/L. Only 14 (8.1%) patients had cholangitis prior to the initial drainage procedure. Failure of drainage or other severe complications related to the initial drainage procedure were noted in 117 (62.6%) patients. Failure of drainage or reintervention was most common and was noted in 85 patients (50.8%). Bile duct injury occurred in 3 (1.6%) patients, acute pancreatitis in 5 (2.7%) patients and cholangitis in 11 (5.9%) patients. Two (1.1%) patients had cardiopulmonary complications and 1 (0.5%) patient had a duodenal perforation. The median period between the initial and second drainage procedure was 13 (5–31) days and the bilirubin level dropped below 50 μmol/L in 27 patients (14.4%). After initial drainage, 20 patients (10.7%) died within 30-days and 66 patients (35.3%) within 90 days. The median OS after initial drainage was 6.6 (95% CI: 2.0–15.2) months.

Patients: Patients with unresectable Pan-CT on imaging have a very high failure and complication rate after initial biliary drainage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0093 UNILATERAL VERSUS BILATERAL STENT-IN-STENT PLACEMENT OF METAL STENTS FOR MALIGNANT HILAR BILARY OBSTRUCTION

H. Toyonaga, Y. Taniguchi, T. Inokuma
Gastroenterology, Kobe City Medical Center General Hospital, Kobe/Japan
Contact E-mail Address: toyonaga.pc@gmail.com

Introduction: Endoscopic biliary stenting is widely accepted as effective palliation therapy for unresectable malignant hilar biliary obstruction (MHBO). Although draining more than 50% of liver volume is associated with better outcomes, endoscopic access can be technically difficult.

Aims & Methods: The aim of this study was to evaluate differences in technical feasibility and clinical efficacy between unilateral and bilateral stent-in-stent (SIS) placement of metal stents for MHBO. We retrospectively reviewed 23 consecutive patients with MHBO who underwent endoscopic biliary drainage with self-expandable metal stents (SEMS) at our institution from March 2012 to March 2017. Unilateral metal stenting was performed in 15 patients (Uni group) and bilateral metal stenting was performed in 18 patients (Bi group).

Results: There were no significant differences between the Uni group and the Bi group in technical success rate (100% vs. 94%), complication rate (0% vs. 0%), stent occlusion rate (15% vs. 18%) or median stent patency period (102.5 days vs. 98 days). There was no significant difference in cumulative stent patency between the groups (p = 0.669).

Conclusion: Endoscopic bilateral SIS placement of metal stents for palliative treatment of MHBO had a high technical success rate and low complication rate, similar to those of unilateral placement.

 Disclosure of Interest: All authors have declared no conflicts of interest.

P0094 CLINICAL ASSESSMENT OF THE SAFETY AND EFFICACY OF A NOVEL BIODEGRADABLE STENT IN PATIENTS WITH BILARY OBSTRUCTION: A PILOT STUDY

H. Othman, N. Y. Yaacob1, E. J. Koslan1, R. Jarman2, Z. Mohamed2
1Surgery, UKM Medical Centre, Kuala Lumpur/Malaysia
2Radiology, UKM Medical Centre, Kuala Lumpur/Malaysia
Contact E-mail Address: hairol@gmail.com

Introduction: The commonest indication for biliary stent is for the treatment of obstructive jaundice and for the management of bile leak. The currently available stents are made of either plastic or metal alloy. The stents can be inserted endoscopically to provide internal drainage of the bile into the duodenum. Among the disadvantages of plastic stents are recurrences of jaundice due to biofilms formation, which require a repeat ERCP procedure to remove the stent before 3 months. We have embarked to study the safety and feasibility of a biodegradable metal stent (BBS), which can treat biliary obstruction without the need to undergo a repeat endoscopic procedure to remove the stent.

Aims & Methods: This is a pilot study enrolling 30 subjects with symptomatic jaundice and pruritus caused by either benign or malignant biliary obstructions that were amenable to treatment by ERCP guided stenting. Primary objective was technical success and safety. Procedural and technical successes were assessed during the stenting procedure. Adverse events or complications were monitored throughout the studies. The secondary endpoints were clinical success, which was measured by a reduction of at least 20% of the initial serum bilirubin level at Day 7 post stenting. A simple self-assessment scale from 0 to 10 was used to assess quality of life before and after the stenting.

Results: 30 patients had the Biodegradable Biliary Stent (BBS) implanted. 18 patients (60%) were males, the mean age was 56.9 years, 26 patients (86.7%) had benign biliary ductal disease and 4 (13.3%) patients had malignant condition.
9 patients had the fast and medium degradation stents respectively and 12 had the slow degradation stents implanted. All stents were 3.4 mm in diameter and the length ranges from 60 to 120 mm depending on the level of obstruction. It took an average of 29.6 minutes to complete each procedures, and the mean stent deployment duration was 6.0 minutes. It ranges from 13.5 minutes in the initial phase and improved to 1.5 minutes in the later phase. Biliary sphincterotomy was not needed in the single biodegradable stent, but however, all patients with biliary stone had sphincterotomy to facilitate retrieval of the stones. Serum bilirubin level (SBL) showed reduction of 52% from the mean SBL of 54.9μmol/L prior to stenting to 26.2 μmol/L at Day 7. Quality of life score improved from 2.0 up to 8.5 after stenting. The BBS ranks high in terms of loadability, trackability over guide-wire, and pushability with push catheter. There was minimal force required to implant it and it has good visibility by fluoroscopy. The BBS is as flexible as the conventional plastic stents and can be accurately deployed under fluoroscopy. Technical success or completion of the ERCP and stent deployment was achieved in all 30 patients.

Conclusion: This pilot study has shown encouraging results. It benefit the patient to avoid the burden of a second ERCP procedure for plastic stent removal. However, these results should be interpreted with caution as this is a pilot study to assess the safety and efficacy of the biodegradable stent on limited number of volunteers with symptomatic jaundice. We plan to conduct a phase 2 study involving a larger number of cohorts with a more specific indication of benign and malignant biliary stricture.

Disclosure of Interest: H. Othman: The Biodegradable Biliary Stents used for this study is sponsored by amg International GmbH, Wissen, Germany. The authors have no financial relationship with the company which could inappropriately influence or bias the content of this presentation.

All other authors have declared no conflicts of interest.

**P0095 TOLL-LIKE RECEPTOR 5 IS ESSENTIAL FOR THE ACTIVATION OF LIVER AND PANCREATIC STELLATE CELLS**

1Department Of Visceral Thoracic And Vascular Surgery, Philipps University Marburg, Marburg/Germany
2Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektologie, Philipps Universität Marburg, Marburg/Germany

Contact E-mail Address: Boehmis@students.uni-marburg.de

Introduction: Stellate cells contribute significantly to the development of several diseases. In particular, liver stellate cells are responsible for liver fibrogenesis and further for cirrhosis that culminates into cancer development eventually. In pancreas, it is known that stellate cells sustain the tumor cells via autophagy mechanisms.

Aims & Methods: This study aimed to clarify the involvement of Toll-like receptor 5 (TLR5) in the activation of human stellate cells. LX-2 liver stellate cells and HPSC (human pancreatic stellate cells) were treated for 48 hours with 2.5 ng/ml TGF-beta 1. The analysis of activation markers was performed by RT-qPCR, western blotting and immunofluorescence. Real-time cell monitoring with Incucyte was performed. TLR5 PCR Array was performed. TLR5 knock down was obtained with commercially validated siRNAs.

Results: Treatment with 2.5 ng/ml TGF-beta 1 caused the activation of both LX2 and HPSC cells. Over-expression of alpha-smooth muscle actin (α-SMA) and collagen 1 (COL1A1) transcripts was observed. The protein level of α-SMA and COL1A1 significantly increased also. Interestingly, SNAIL 1, SLUG, TLR5 and TGF-beta 1 were induced by treatment with TGF-beta 1 in both cell lines. SNAIL 1 was over-expressed at protein level also. Knock down of TLR5 neutralized the activity of TGF-beta 1 by keeping the expression of the above markers at basal level or even not expressed.

Conclusion: TLR5, for the first time, has been identified as key player of the activation of stellate cells. Its contribution represents a new aspect in terms of interaction between immune system and stellate cells and could represent a potential new target for the diseases of the gastrointestinal tract involving the activity of stellate cells. TLR5 and its natural agonist flagellin could be a key link between impairment of microbiota and organo-fibrosis in the gastrointestinal tract.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0096 THE IMPAIRED FUNCTION OF THE PLASMA MEMBRANE CA2+ PUMP RESULTS IN CA2+ OVERLOAD AND CELL DAMAGE IN CFTR KNOCK OUT PANCREATIC DUCTAL CELLS**

Introduction: The cystic fibrosis transmembrane conductance regulator (CFTR) has a major role in pancreatic ductal secretion and it’s genetic defects damage the pancreas. It is known that intracellular Ca2+ homeostasis is disturbed in bronchial epithelial cells in cystic fibrosis (CF), but the connection of CFTR and the intracellular Ca2+ signaling has never been suggested in pancreatic disease in CF patients.

Aims & Methods: Our aim was to characterize the Ca2+ homeostasis of CFTR-deficient PDC. Wild type (WT) and CFTR knockout (KO) mouse pancreatic ductal and acinar cells and iPSC (induced pluripotent stem cell) derived human organoids from 2 CF patients and controls, human CF pancreatic cell line (CFPAC-1; ΔF508 mutant) were used for intracellular Ca2+ measurements. Mitochondrial membrane potential (ΔΨm) and mitochondrial morphology was assessed in isolated pancreatic ducts. Immunofluorescent staining and quantitative PCR measurements were performed to detect changes of mRNA and protein expressions.

Results: The plateau phase of the agonist-induced Ca2+ signal was elevated in CFTR-deficient PDC, which was caused by decreased function of the plasma membrane Ca2+-pump (PMCA). The functional inhibition of TGRβ and forskolin had no effect on the PMCA activity. Human CF organoids have shown decreased PMCA function compared to control while the 24h treatment of the CF organsoids with VX-809 have restored the PMCA function to the control level. Similarly native CFPAC-1 cells and PDEC treated with siRNA to inhibit the expression of CFTR showed the same PMCA dysfunction. Viral transfection of CFPAC-1 with CFTR gene completely restored PMCA function. Sustained [Ca2+]i levels decreased ΔΨm and induced cytochrome c release in CFTR KO PDEC without significant alterations in mitochondrial morphology.

Conclusion: Dysfunction of PMCA leads to disturbed Ca2+ homeostasis in CFTR-deficient PDC and the consequent cellular Ca2+ overload impairs mitochondrial function contributing to the pancreatic damage in CF patients.

Introduction: Given their capability to differentiate to every cell type of the human body, human induced pluripotent stem cells (hiPSCs) provide a unique platform for disease modeling and regenerative medicine. The transcriptional regulatory factor, pancreatic progenitor (PP) cells from pluripotent stem cells follows the sequential induction of virtually pure definitive endoderm (DE), foregut endoderm (GTE) and pancreatic endoderm (PE). We have recently reported the generation of a novel three-dimensional pancreatic organoid culture system that generates functional acinar-ducal-like structures from pluripotent stem cells (Hohlwieder et al, GUT, 2016).

Aims & Methods: In the current study we implemented this culture system to understand the role of coexpression differentiation and proliferation factor (Expdf), a signaling molecule proposed to be involved pancreatic differentiation in zebrafish. CrispCas9 technologies were used to ablate Expdf in human embryonic stem cells, while a piggy bac engineering approach allowed us timed expression to study the role of both loss and gain of Expdf function during pancreatic differentiation.

Results: First, a limited role of Expdf was observed until the PE stage, while PP knockout led to mostly cystic structures. Phenotyping for ductal and acinar lineage allowed to investigate these

Introduction: N-acetyl-β-formyl-5-methoxykynuramine (AFMK), melatonin metabolite, has been demonstrated recently as an effective pancreatic acinar cell protector against acute inflammation. AFMK significantly attenuated acute pancreatitis; however, its effect on pancreatic exocrine function has not been investigated yet.

Aims & Methods: 1. To investigate the effects of intraduodenal (i.d.) application of 100 μg AFMK on pancreatic enzyme secretion under basal conditions and following the stimulation of this secretion with diversion of pancreato-biliary juice (DPBJ) and to examine the role of CCK in this process. 2. To assess the effect of AFMK on CCK receptor in pancreatic acinar cell line AR42J. Material and methods: For in vivo study Wistar rats weighing 300 g were employed. Under pentobarbitone anaesthesia the animals were surgically equipped with silicone catheters, inserted into pancreato-biliary duct, and into duodenum. AFMK (5.10 mg/kg i.d.) was given to the rats under basal conditions or following stimulation of pancreatic secretion with DPBJ. Lorglumide, the CCK1 receptor antagonist (1 mg/kg i.d.) was administered 15 minutes prior to the application of AFMK. Samples of pancreato-biliary juice were collected to measure the amylase outputs. The blood samples were taken for determination of CCK by ELISA kit. For in vitro study AR42J cells were AR42J were incubated in presence of AFMK alone or in combination with CCK. The protein signal of CCK receptor was determined by Western blot.

Results: AFMK given i.d. produced the dose-dependent increases of pancreatic amylase secretions both; unstimulated, as well as that induced by DPBJ. The rises of pancreatic amylase outputs were accompanied by significant decrease of CCK plasma levels. Administration of lorglumide, a CCK1 receptor blocker, completely abolished the stimulation of pancreatic exocrine function induced by AFMK. This melatonin metabolite failed to affect protein signal for CCK receptor in AR42J cells.

Conclusion: The stimulatory effect of AFMK on pancreatic enzyme secretion in the rats is indirect and dependent on the release of CCK by this melatonin metabolite.

Introduction: Aberrant intracellular Ca2+ signaling is the hallmark of acute pancreatitis (AP) inducing mitochondrial damage, intraacinar digestive enzyme activation and cell death. Thus prevention of toxic cellular Ca2+ overload in different cell types is a promising therapeutic target. The transient receptor potential melastatin 2 (TRPM2) is a non-selective cation channel that plays major role in oxidative stress induced cellular Ca2+ overload in different cell types. Although likely, its role in pancreatic acinar cells and the pathogenesis of AP was not investigated yet.

Aims & Methods: Our aim was to characterize the functional activity of TRPM2 in pancreatic acinar cells. In our experiments pancreatic acinar cells (PAC) were isolated from wild type (WT) and TRPM2 knockout (KO) mice with enzymatic digestion. The changes of the intracellular Ca2+ level was measured with fluorescent microscopy using FURA2-AM.

Results: The intracellular Ca2+ signals evoked by 100 μM carbachol were not different in WT and TRPM2 KO PAC. On the other hand, 1mM H2O2 induced significantly higher intracellular Ca2+ elevation in WT PAC compared to the TRPM2 KO. In Ca2+ free extracellular solution the Ca2+ signal in response to 1μM H2O2 was markedly reduced in WT PAC confirming that H2O2 activates dominantly extracellular Ca2+ influx.

Conclusion: Our result confirmed the functional activity of the TRPM2 channel in pancreatic acinar cells. In further investigations we aim to clarify the pathogenic role of TRPM2 in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0100 INVESTIGATION OF THE PANCREATIC DUCTAL ION SECRETION IN PANCREATIC DUCTAL ORGANOID CULTURES

Introduction: Pancreatic duct fluid and HCO3- secretion are crucially important in the physiology and pathophysiology of the exocrine pancreas. However, the role of human pancreatic secretory processes is great challenge due to the limited access to human pancreatic ductal cells. The recently developed three-dimensional pancreatic organoid cultures (OC) may help to overcome this limitation. However, the ion secretary processes in pancreatic OC is not known.

Aims & Methods: Our aim was to characterize the ion transport processes in mouse pancreatic OCs. Mouse pancreatic ductal fragments were isolated by enzymatic digestion. The isolated ducts were grown in Matrigel on 37°C for a week in OC media. Changes of the intracellular pH was measured to characterize the ion transporter activities of the epithelial cells in OC.

Results: Basolateral administration of 20 mM NH4Cl in standard HEPES or CO2/HCO3- buffered solution resulted in rapid intracellular alkalinization, followed by a recovery phase. Removal of NH4Cl induced rapid acidification followed by regeneration to the resting pH levels. The regeneration phase was inhibited by the removal of extracellular Na+ . The administration of 10 mM CFTRinh-172, a selective inhibitor of cystic fibrosis transmembrane conductance regulator decreased the regeneration from alkali load. Basolateral administration of 20 mM amiloride and 20 mM H2DIDS decreased the intracellular pH suggesting the activity of Na+/H+ exchanger and Na+/HCO3- cotransporter on the basolateral membrane.

Conclusion: The ion transport activities in mouse OC are similar to those observed in freshly isolated primary tissue. This suggest that OC will be suitable to study human ductal epithelial ion transport.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0101 INVESTIGATION OF THE ORAII MEDIATED CA2+ ENTRY IN MOUSE PANCREATIC DUCTAL CELLS

Introduction: Acute pancreatitis (AP) is the most common inflammatory disorder in the gastrointestinal tract with an overall mortality of 20-30% in severe cases. The treatment of AP is not resolved yet, urging the identification of novel drug targets. Toxic cellular Ca2+ overload was highlighted as a key event in pancreatic acinar and ductal cells during the pathogenesis of AP. In addition, the inhibition of Orai in pancreatic acinar cells markedly decreased the Ca2+ toxicity and the severity of AP. However, we have no information regarding the role of Orai in pancreatic ductal cellul physiology or pathophysiology.

Aims & Methods: Wild type FVB/N mice were used for the isolation of pancreatic ductal fragments. The intracellular pH and Ca2+ level of the pancreatic ductal cells (PDC) were measured by microfluorimetry. The effect of selective Orai inhibitors provided by CalciMedica was evaluated.

Results: The tests compounds dose-dependently inhibited Ca2+ influx through the carbachol induced Ca2+ signal in PDC. Inhibition was complete at a concentration of 10μM (CM-B: 99.87%, CM-C: 95.29%). Next, endoplasmic reticulum Ca2+ stores were depleted with cyclopiazonic acid and the inhibition of store-operated Ca2+ entry (SOCE) was investigated after the re-addition of extracellular Ca2+. Under these conditions CM-B and CM-C significantly, but not completely, decreased SOCE in PDC (55.96% and 55.03% respectively). The removal of extracellular Na+ to abolish activity of the Na+/Ca2+ exchanger had no effect on the inhibition of SOCE by CM-B or CM-C. We also showed that the inhibition of Orai has no effect on the basal secretion of HCO3- by PDC, which is the main physiological function of these cells.

Conclusion: We showed that Orai has a significant role in the Ca2+ signaling of PDC. In the next step we will evaluate the pathophysiological relevance of the channel.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0102 ACUTE PANCREATITIS OF UNKNOWN ORIGIN AND IDIOPATHIC JUVENILE PANCREATITIS IN SWEDEN
1Center For Digestive Diseases, Karolinska University Hospital, Stockholm/ Sweden

In early stage of severe acute pancreatitis (SAP), the factors for predicting hospital mortality in adult patients admitted between 2010 and 2015. Patients with a previous episode of SAP were enrolled into either index- or scheduled cholecystectomy (IC vs. SC). IC was performed before discharge or scheduled 6 weeks from the initial episode. SC was planned after 6 week from randomization. The primary outcome was recurrent biliary events. Secondary endpoints were cholecystectomy complications within 1 months, the proportion of common bile duct stones at cholecystectomy requiring ERC and patients´ reported quality-of-life and pain. Secondary endpoints were cholecystectomy complications within 1 months, the proportion of common bile duct stones at cholecystectomy requiring ERC and patients´ reported quality-of-life and pain.

Results: Sixty-four patients between May 2009 and March 2017 were randomized in ITTRIAL. Twenty-three patients were enrolled into either index- or scheduled cholecystectomy (IC vs. SC). The primary outcome was recurrent biliary events. Secondary endpoints were cholecystectomy complications within 1 months, the proportion of common bile duct stones at cholecystectomy requiring ERC and patients´ reported quality-of-life and pain.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cholecystectomy during the index admission may reduce risk of recurrent biliary events but concerns have been raised about complications if surgery is performed to early. The objectives of this study were to compare gallstone- and cholecystectomy-related complications and patient reported quality-of-life and pain if cholecystectomy was performed before discharge or scheduled 6 weeks from the initial episode.

Aims & Methods: Patients admitted with biliary pancreatitis at the Karolinska University Hospital were assessed for eligibility. Patients with mild pancreatitis were enrolled into either index- or scheduled cholecystectomy (IC vs. SC). SC was performed when patients showed recovery and within 48 hours from randomization. SC was planned after 6 week from randomization. The primary outcome was recurrent biliary events. Secondary endpoints were cholecystectomy complications within 1 months, the proportion of common bile duct stones at cholecystectomy requiring ERC and patients´ reported quality-of-life and pain.

Introduction: Severe acute pancreatitis has high mortality and needs intensive care. However it is difficult to stratify the severity of acute pancreatitis in early stage because revised Atlanta classification requires persistent organ failure lasting at least 48 hours.

Aims & Methods: We searched factors to predict hospital mortality in early stage of severe acute pancreatitis. This was a retrospective cohort study of all consecutive patients with severe acute pancreatitis who admitted at 44 institutions between June 1, 2009 and December 31, 2013. We evaluated ten factors which associated with mortality in previous study.

Results: The mortality was 12.7% (142/1114 patients). All ten factors were associated with mortality in univariate analysis. In multivariable analysis, four factors, namely, "partial pressure of oxygen in blood <60 mmHg (room air) or mechanical ventilation", "age ≥70 years", "blood urea nitrogen ≥40 mg/dL (or creatinine ≥2.0 mg/dL) or oliguria (daily urine output <400 mL even after acute intravenous fluid resuscitation)", and "lactate dehydrogenase ≥22 times upper limit of the normal range" were associated with mortality. The other factors, namely "base excess ≤-3.5 mmol/L", "platelet count ≤100.000/μm3", "serum calcium <7.5 mg/dL", "c-reactive protein ≥15 mg/dL", "number of positive measures in systemic inflammatory response syndrome criteria ≥3" and "computed tomography grade" were not associated with mortality.

Conclusion: Advanced age, respiratory failure, renal failure and high lactate dehydrogenase could predict mortality in early stage of severe acute pancreatitis. In patients with these factors require transport to a hospital with intensive care unit.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0102 COMPARISON OF PREDICTIVE SYSTEMS TO PREDICT MORTALITY WITH SEVERE AND MILD PANCREATITIS ACCORDING TO THE REVISED ATLANTA CLASSIFICATION

Aparato Digestivo, Hospital Universitario de Fuenlabrada, Fuenlabrada/Spain

Contact E-mail Address: ruben.pique@salud.madrid.org

Introduction: The course of acute pancreatitis (AP) ranges from life threatening to mild disease, so accurately predicting its outcome is important. The revised Atlanta classification breaks this into mild/severe dichotomy, so the absence of predictors of severity does not preclude a mild course. Studies designed according to the new classification evaluating existing predictors are still scarce.

Aims & Methods: Our study aims at evaluating the diagnostic accuracy of easily available prognostic scores to predict mortality, persistent organ failure (severe AP) and mild AP. We analyzed a single-center retrospective cohort including all adult patients admitted between 2010 and 2015. Patients with a previous episode of AP in the six months before admission, with other primary diagnosis at discharge and those partially attended at other institutions were excluded. Severity and local complications were defined according to the 2012 Atlanta classification. Four different scores (BISAP, SIRS, APACHE II and HAPS) and the following predictors: C reactive protein (CRP) at 24 h, hematocrit and BUN at admission.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

and their evolution after 24 h were evaluated. Accuracy was measured using different methods for operating characteristic analyses.

**Results:** Of the 817 eligible patients, 118 were excluded, most for a previous episode before admission. We analyzed 699 patients with a median age of 57.5 years (IQR: 45.1–72.7), 57.4% males. Most frequent comorbidities were: diabetes (18.3%), hypertension (16.6%) and COPD (7.7%). Median length of stay was 7 (5–10) days. Most common causes were: biliary (53.9%), idiopathic (21.8%) and alcoholic pancreatitis (14.3%). A CT scan was performed in 56.1% identifying local complications in 36.2% of them, acute fluid collections in 16.8%. There were 42 (6%) severe and 196 (28%) moderately severe cases. Overall mortality was 2.4% (1.5–3.9%), 9.3% (9.6–9.4%). BUN at admission AUC: 0.89 [0.86–0.91], APACHE II (60) [0.67–0.69] and their evolution after 24 h were evaluated. Accuracy was measured using different methods for operating characteristic analyses.

**Conclusion:** The revised Atlanta classification accurately identifies those patients at higher risk of death. Among the available predictors of severity, BISAP and BUN at admission presented an excellent performance, with an AUC of nearly 1.0.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0106 PANCREATIC DUCT ASCARISIS**

P. Somani, M. Sharma
Department Of Gastroenterology, Jawaharlal Specialty Hospital, Meerut, India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

**Introduction:** Although uncommon in the West, Ascaris lumbricoides is a common cause of acute pancreatitis in developing countries. The mechanism of acute pancreatitis in ascariasis may be due to obstruction of papilla of Vater, invasion of common bile duct (CBD) or pancreatic duct (PD). The invasion of pancreatic duct occurs rarely owing to its smaller calibre. Ultrasoundography (USG) is an effective tool for the diagnosis of biliary and pancreatic ascariasis; however, the diagnosis may be false negative in up to 30% of cases. Pancreatic ascariasis has been reported only in case reports. Only case reports have been described in literature. We present our retrospective data of last 10 years of 15 cases of pancreatic ascariasis.

**Aims & Methods:** During a study period of 10 years, 15 cases of pancreatic ascariasis were diagnosed by USG or endoscopic ultrasonography(EUS). EUS was performed with a linear or radial echoendoscope. 13 patients presented with symptoms of acute pancreatitis. Out of 13, 9 patients presented with first episode of idiopathic pancreatitis while 4 presented with idiopathic recurrent acute pancreatitis (IRAP). One patient had biliary colic and one patient presented with abdominal complaints. All the patients had mild pancreatitis while only one patient had necrotic pancreatitis. Patients were treated with parenteral fluids, analgesics, antibiotics, and albendazole. Only 2 cases were diagnosed with USG while 13 patients were diagnosed with EUS. The patients underwent side viewing endoscopy/ERCP under lignocaine 0.2% as well as EUS if EUS was not diagnosed. EUS showed biliary/pancreatic ascariasis. Out of 15 patients, 14 underwent side viewing endoscopy with removal of live multiple worms with rat tooth forceps/biopsy forceps/dormia basket in 13 patients. The managed conservatively with repeat USG showing absence of ascariasis. There were no complications.

**Results:** The patient characteristics are described in table 2. 2 patients had associated bile duct ascariasis. Sonographic characteristics of A. lumbricoides are single or multiple echogenic nonshadowing linear, tubular structures and curved strips with anechoic tubular central lines. EUS features were single or multiple linear hyperechoic structure without acoustic shadowing in the PD or CBD (“single-tube sign” or “strip sign”) or with central hypoechoic tube representing alimentary canal of the worm (“double tube sign” or “inner tube sign”) and movements of worms inside the duct. Live roundworms were removed from PD without undertaking sphincterotomy. In endemic areas, sphincterotomy facilitates the risk of migration of worms into the CBD or PD. Conclusion: Ascariasis-induced acute pancreatitis is usually cold and EUS is the investigation of choice. The recurrence is rare and treatment is side viewing endoscopy with removal of worms. EUS significantly improves the diagnostic yield for idiopathic acute pancreatitis (IAP). Our retrospective study shows that EUS is a highly sensitive method to diagnose the etiology of IAP with reference to biliary or pancreatic ascariasis. Although USG is quite sensitive for diagnosing BPA, its sensitivity significantly falls when the worm is thin, in the PD, or the CBD is non-dilated. EUS is more sensitive for diagnosis of ascariasis in the pancreatic duct than other radiological investigations. The probable reasons are excellent imaging of pancreas by EUS and in and out movement of ascaris which might be missed by other investigations. Endoscopic retrograde cholangiopancreatography, considered the gold standard for diagnosis of biliary ascariasis, should be reserved for therapeutic rather than diagnostic purposes as the endoscopy can lead to reentry of the worm into the common bile duct. EUS should be used early in the work-up of IAP after the first episode. We propose EUS to be investigation of choice for PD ascariasis. Most of the episodes are of mild pancreatitis with no mortality.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly used for therapeutic management of various biliary and pancreatic diseases¹. However, ERCP is not a procedure without morbidity². Post-ERCP pancreatitis (PEP) remains the most common and serious complication after ERCP³.

**Aims & Methods:** To detect risk factors for post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) and investigate the predictors of its severity. This is a prospective cohort study of all patients who underwent ERCP. Pre-ERCP data, intraoperative data, and post-ERCP data were collected

**Results:** The study population consisted of 996 patients. Their mean age at pre-ERCP test, BUN, CRP and venous gasometry including lactate were performed on admission. PEP is associated with higher morbidity and mortality beside its complication after ERCP⁴. The revision of Atlanta Classification in 2012 has established an important change in Acute Pancreatitis (AP) definitions, comprising 3 grades of severity depending on the presence and persistence of organic failure (1). Thereby, patients with severe acute pancreatitis (SAP) include the vast majority of deaths in this disease (2–4).

**Conclusions:** Biomarkers are quick but incomplete tools for SAP prediction, which can be easily obtained at any moment throughout the disease. Our study shows good values of specificity and AUC for BUN, Cr and lactate but not for CRP concerning SAP and mortality prediction on admission, but since they are low prevalent outcomes in our sample, PPVs are low and not very reliable. Although many of these parameters has been analyzed in previous studies, we predict lactate as a new biomarker with similar performance than that of Cr and BUN, suggesting a possible role for scores building or outcome monitoring.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

POSTER PRESENTATIONS

P0112 COTTON VS. REVISED ATLANTA CRITERIA TO DEFINE SEVERITY OF POST-ERCP PANCREATITIS
C. Neeves1, A. Tan2, J.P. Drenth1, E. Van Geenen1
1Gastroenterology & Hepatology, Radboudumc, Nijmegen/Netherlands
2Canisius Wilhelmina Hosp. Dept. of Hepatogastroenterology, Nijmegen/ Netherlands

Introduction: The Cotton criteria (I) and the revised Atlanta classification (2) are associated with post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP), severity (3). Whereas Cotton puts the emphasis on length of hospitalisation, Atlanta focuses on the presence of local (necrosis) and systemic (organ failure) complications. The number of hospitalization days may not be a proper representation of PEP severity, because it is influenced by other diagnoses such as ERCP complications and comorbidity. The goal of this retrospective cohort study is to compare the Cotton and Atlanta criteria for the severity of PEP.

AIMS & METHODS: All ERCP procedures from a Dutch university medical centre and a teaching hospital between 2012 and November 2016 were checked retrospectively for patients with PEP. Patients were eligible if they met the Cotton criteria or Atlanta criteria for acute pancreatitis. All records were checked up to 48 hours after ERCP to capture delayed PEP. Patients were excluded if they had acute pancreatitis prior to ERCP or had chronic pancreatitis. In the primary analysis, mild/moderate and severe PEP were compared between Cotton and Atlanta with Fischer’s exact test. Atlanta was regarded as the golden standard. Secondly, we compared the sensitivity and specificity of both definitions for mortality.

RESULTS: Out of a total 2156 ERCPs, 66 patients (3%) had PEP. Two patients were excluded due to missing data for hospital stay. Of the 64 patients analysed, 39 (60.9%) were female, mean age was 60.6 years and the most common indication for ERCP was choledocholithiasis (n = 39, 60.9%). Four patients (6.3%) developed organ failure, 3 patients (4.7%) died. The table below depicts the PEP severity distribution according to Cotton and Atlanta. No significant differences were found (p = 0.64). Of the 25 severe patients according to Cotton, 23 were categorized due to hospital stay exceeding 10 days, but were mild according to Atlanta. In 11 patients (44%), concomitant disease (syndrome of inappropriate antidiuretic hormone secretion, cholangitis, pneumonia, perforation or biliary leakage) was the cause for prolonged stay.

</tbody>
</table>

All 3 patients that died had severe PEP according to Atlanta due to persistent organ failure. Cotton classified them as mild, moderate and severe based on hospitalization. Two patients died within 10 days of early multiple organ failure. None of the other Cotton criteria for severity was met. Thus, the Cotton criteria did not capture early deaths due to multiple organ failure. The sensitivity and specificity of Atlanta and Cotton for mortality were 100%, 98.4%, 33.3% and 60.7%, respectively.

CONCLUSION: The Cotton criteria for PEP overestimate disease severity, but under-estimate mortality. Therefore, the Atlanta criteria should be used for defining PEP severity.

P0113 RISKS FACTORS AND OUTCOMES OF INFECTED PANCREATIC NECROSIS: RESULTS FROM A COHORT OF 148 PATIENTS ADMITTED IN ICU FOR SEVERE ACUTE PANCREATITIS
C. Garret1, M. Péron2, A. Le Thua4, M. Le Rhun2, C. Guittot2, J. Gournay2, J. Reigner1, E. Corson2

Introduction: Acute pancreatitis (AP) is a common but potentially lethal pathology due to the multiplicity and severity of its complications. Infected pancreatic necrosis (IPN) occurs in 30% of patients with necrotizing AP and is associated with an increase in mortality ranging from 15% to 39%. While interventional drainage and/or removal of the infected tissue remain the mainstay of therapy of IPN, important progresses have been achieved over the last decade and minimally invasive treatment has been developed. The aim of this study was to identify factors associated with IPN and to describe outcomes and management.

AIMS & METHODS: This was a retrospective study of collected data from all patients admitted to Intensive Care Unit (ICU) in a single centre from 2012 to 2015 for a severe AP. Baseline characteristics of the overall population were expressed as frequencies (percentages) for categorical variables, as mean ± standard deviation (SD) for continuous data. For the analysis of mortality, multi-vari-ate analysis with Cox proportional hazards regression modeling was used to identify independent predictors. Association between IPN and patients’ characteristics at baseline was evaluated using logistic regression.

RESULTS: In total, 148 patients were included in this study. Overall mortality was 17%. Body mass Index, computed Tomography Severity Index (CTSI) ans persistent (≥48H) organ failure (OF) were independently associated with overall mortality. Also, patients died in 16 patients died in 2 documented mesenteric ischemia during the early phase (≤8 days) and 3/10 patients during the late phase (>8 days). IPN was present in 62 patients (43%), all requiring an intervention (i.e. radiological, endoscopic, and/or surgical). 35% of patients (22/62) had only one modality of drainage (radiologic or transgastric) and did not required any necrosectomy. For 30 patients (48%), additional necrosectomy was needed because of lack of improvement after drainage alone. 10 patients (17%) had only necrosectomy without prior drainage procedure. Complications such as hemorrhage and perforation of visceral organ occurred more frequently in the IPN group (1.4% vs 19.4%, p < 0.001 and 9% vs 8.5%, p = 0.02 respectively). The late phase mortality (>8 days) was significantly higher in the IPN group (14.5% vs 1.4%, p < 0.01). In multivariate analysis factors associated with IPN were number of OF and portosplenomesenteric venous thrombosis (table 1). 39 patients (68%) received anticoagulants with a median time of 6 [3–6] months and among them, 25 patients developed cavernoma, irrespective of whether or not they receive systemic anticoagulation (p = 0.31).

Conclusion: In conclusion, this study performed in routine practice conditions showed that IPN occurs in almost half of patients hospitalized in ICU for severe AP, and is associated with increased mortality and complications rates. Overall mortality was 17.6%, and factors associated with mortality were a high BMI, CTSI and persistent OF. Those results are consistent with previous studies1–3, but we reported a high rate of mesenteric ischemia (7/26 patients deceased) while this complication is occasionally described. IPN patients required an intervention for drainage of infected tissue removal, which was performed using minimally invasive techniques in the vast majority of cases, with no complication or severe side effect. 35% of patients were treated with drainage alone without any additional necrosectomy. Finally, PSMVT and early OF appeared to be associated with the risk of developing an IPN but anticoagulation for PSMVT did not protect for cavernoma occurrence and can expose to intestinal bleeding. Our results also suggest that the optimal and early management of OF and detection of PVSMT might prevent IPN and/or its complications. Such hypothesis will need to be tested in large multicentre prospective studies.

P0114 EARLY PREDICTORS AND OUTCOMES OF FLUID SEQUESTRATION IN ACUTE PANCREATITIS
S. Goyal
Gastroenterology, Banaras Hindu University, YFARANSAI/India

Contact E-mail Address: drsundeepgoyal@gmail.com

Introduction: Although it is well known that some patients with AP have an increased need for fluid therapy, it is not clear who should get fluids aggressively. Changes in hematocrit, BUN and serum creatinine, has been documented to limit nephrotoxicity and improve outcome. The early prediction of fluid sequestration may help to select patients for more or less aggressive fluid resuscitation.

AIMS & METHODS: 1) To determine early variables as predictors of fluid sequestration in the first 48 hours. 2) To determine outcome associated with fluid sequestration. In this prospective cohort study, 300 consecutive patients of acute pancreatitis were included. Fluid sequestration was calculated by adding the total amount of fluid administered and subtracting the total amount of fluid lost in the first 48 hours of hospitalization. Local complications were defined

Disclosure of Interest: All authors have declared no conflicts of interest.
According to the revised Atlanta classification. Univariate and multivariate analysis were performed.

**Results:** The median fluid sequestration in the first 48 h after hospitalization was 4.7 liter (2.8–6.8 L). It was 3.2 (1.4–5.1), 6.4 (3.6–9.5) in those without necrosis and those with necrosis, and 7.5 (4.4–12) in those with persistent organ failure. The univariate and multivariate analysis showed that alcohol etiology, an increasing number of SIRS criteria and Hematocrit were significantly associated with increased fluid sequestration (Table). Body mass index, APACHE II score, sodium, creatinine and blood urea nitrogen levels did not help predict fluid sequestration. Patients with and without acute fluid collections had a median sequestration of 7.2 and 4.2 L (p < 0.001, respectively). Twenty patients died (7.3%); median fluid sequestration in the patients who died was 6.5 L compared to 4.2L among the patients who survived (p=0.05). Increased fluid sequestration was associated with prolonged hospital stay (p < 0.01, table) Association between variables determined at admission and fluid sequestration.

**P0116 AUTOIMMUNE PANCREATITIS CLASSIFIED AS NOT-OTHERWISE-SPECIFIED (NOS) ACCORDING TO THE INTERNATIONAL CONSENSUS DIAGNOSTIC CRITERIA: CLINICAL FEATURES AND OUTCOMES IN 47 PATIENTS**

N. De Pretis, A. Brandolese, L. Brozzi, F. Vicelli, A. Amodio, M. Ruffini, S. Cinò, A. Gabbirelli, L. Frulloni

Gastroenterology, University of Verona, Verona/Italy

**Contact E-mail Address:** martina.ruffini@libero.it

**Introduction:** Autoimmune pancreatitis (AIP) is a well-recognized fibro-inflammatory disease of the pancreas characterized by a dramatic response to steroid therapy. Three different types have been identified according to the International Consensus Diagnostic Criteria: type 1, type 2 and type not-otherwise-specified (NOS). Despite the significant number of studies published on AIP type 1 and 2, (3, 4) no studies have been focused on AIP type NOS and therefore very little is known about clinical features and long-term outcomes of these cases.

**Aims & Methods:** Aim was to investigate clinical features, risk of other organ involvement, risk of relapse and long-term outcomes of AIP type NOS patients. Patients classified by International Consensus Diagnostic Criteria (ICDC) as AIP type NOS at clinical onset included in our database prospectively maintained since 1995 have been evaluated. AIP type 1 (168 patients) and AIP type 2 (63 patients) were excluded. Epidemiological and clinical data have been collected and analyzed.

**Results:** 47 patients fulfilled inclusion criteria. Symptoms at clinical onset were malaise and weight-loss (40%, 5%), jaundice (34%) and pancreatitis (29.8%). Six patients (12.8%) had other organ involvement (5 proximal biliary involvement and 1 salivary involvement) and only two (4.3%) patients had serum IgG4 levels >140 μg/dL at clinical onset. Six patients (12%, 8%) developed ulcerative colitis (UC) during follow-up and were therefore reclassified as AIP type 2. The mean time between the clinical onset of AIP-NOS and development of UC was 14 months (range 4–48). Eight patients (17%) experienced a relapse after steroid treatment and two (4, 3%) needed immunosuppressive drugs (Azathioprine) because of recurrent relapse. None underwent functional or radiologic treatment despite 30 patients (63, 8%) had a focal pancreatic involvement of the pancreas at imaging. It is therefore a potential good candidate for PPS.

**Conclusion:** Patients suffering from AIP type NOS have own clinical features. The risk of relapse is low (17%) but not irrelevant, as well as the risk of developing UC (12%) during follow-up switching the diagnosis to AIP type 2.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Results: The purpose of EPDBD therapy for pancreatic stone was to use endoscopic procedures in the pancreatic duct and stone removal, and to reduce stone relapse rates. 568 cases of pancreatic stone were treated by EPDBD. They consisted of 90 cases treated by endoscopic method alone (via major papilla 62, minor papilla 28), and 478 cases treated by ESWL +/- endoscopic method (via major papilla 381, minor papilla 97). After EPDBD therapy, the stone free rate was 75.3%, the pain free rate 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case A; 22 y/o male, idiopathic chronic pancreatitis, pancreas stone: After 4th ESWL, small stones remained in the head duct which can’t be removed by basket catheter and severe pain continued, so EPBD was done under general anesthesia, but via the endoscope we saw that a stone remained in the neck duct. After dilatation of the duct with a bougie, the stone could be removed. Case B; 66 y/o male, alcoholic chronic pancreatitis, pancreas stone: ERCP revealed type 2 incomplete divisum. After EPDBD therapy, the relapse rate of pancreatic stone decreased, the stone free rate was 90%, the pain free rate was 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case C; 72 y/o male, alcoholic chronic pancreatitis, pancreas stone: ERCP revealed type 2 incomplete divisum. After EPDBD therapy, all stones were removed via minor papilla, then EPBD was placed into minor papilla successfully.

Conclusion: By EPDBD therapy, the relapse rate of pancreatic stone decreased, and the success rate of endoscopic drainage and stenting in pseudocyst and dilatation of the minor duct with mild complications, and their prognoses were good. EPDBD is a safe and favorable procedure for pancreatic diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0118 ENDOCYTOSIC ULTRASOUND AS A PREDICTOR AND GUIDE TO SUCCESSFUL ENDOTHERAPY IN CHRONIC PANCREATITIS

M. Sharma, P. Somani
Department Of Gastroenterology, jawsani Rai Specialty Hospital, Meerut/India

Contact E-mail Address: sharmamalay@hotmail.com

Introduction: Pancreatic calculi (PC) are a sequela of chronic pancreatitis (CP) and can cause problems due to duct obstruction leading to pain, pancreatitis, and a poor feature of CP. The rationale for endoscopic treatment of obstructing PC is based on the observation that pain subsides when the stone(s) is removed and drainage of pancreatic secretion is restored. Indications for endotherapy include stones <5 mm size, stones in head of pancreas which are not impacted and absence of downstream strictures. The assessment prior to the procedure is done by MRCP or CT. However, problems are encountered during ERCP clearance which are not anticipated despite MRCP/CT. The problems are, possible impacted stones, hard stones with acoustic sound shadowing, and duct strictures during ERCP. Hence, controversy exists. EUS can help by providing concordance or discordance with MRCP images and may help in further clarification.

Aims & Methods: We aimed to evaluate the role, feasibility and management challenges of EUS-guided ERCP in patients planned for endotherapy in CP. Another objective was to evaluate whether EUS features of pancreatic duct (PD) stones can serve as a predictor of successful removal during ERCP. The data of 412 patients during the study period (2009-2016) with CP was retrospectively reviewed. PD stones were associated with stones in head/papillary region of pancreas. Out of these, 75 were excluded and remaining 68 were evaluated by EUS using a linear/radial echo endoscope prior to ERCP. Results: Out of 68 cases, 48 were associated with hard stones with acoustic shadowing. While 20 were associated with soft stones without acoustic shadowing. In 20 soft stones cases, ERCP was successful in 18 patients. In 48 patients with hard stones, there was failure of endotherapy in 40 patients which required ESUL/surgery. The failing patients required multiple sessions of ERCP for successful removal. Three patients had ampullary/pancreatic stones which were removed with precut sphincterotomy with immediate relief of pain. Four patients had ventral duct obstruction by calculus and hence underwent ERCP through minor papilla with successful removal of stones in 3 patients. In three patients, there were calculus in pancreatic parenchyma and pancreatic duct simultaneous (ducto-parenchymal stones) and hence endotherapy was avoided. Three patients had pancreas divisum diagnosed on EUS and hence underwent minor papillotomy with stone removal. Three patients also had biliary obstruction with CBD stone/slagde and underwent biliary endotherapy. Four patients had pancreatic mass in head and underwent EUS-FNA with two patients diagnosed with pancreatic cancer who were referred for surgery. The remaining two were also referred for surgery. Four patients were found to have strictures on EUS and hence were referred for surgery. The presence of large (>5 mm), hard, immobile stones were negative predictors of successful endotherapy. Small (<5 mm), ampullary/pancreatic stones were positive predictors.

Conclusion: Present study suggests that EUS can differentiate "soft PD stones" (without an acoustic shadow) from "hard PD stones"(with an acoustic shadow). This differentiation can help in predicting success rate and stone free rate and stone relapse rate in 568 stone pancreatic cases treated by EPDBD. The progeny of 114 EPS-successful pseudocyst cases treated by EPDBD. The progeny of 16 EPS-successful divisum cases complete type 6, incomplete type 10 treated by EPDBD. Complications after EUS-FNA are an additional advantage of making a diagnosis of ampullary/papillary stones and biliary obstruction which can be treated endoscopically. It can guide whether endotherapy needs to be performed through major or minor papilla. EUS by diagnosing pancreatic tumour/strictures missed on other imaging modalities allows early diagnosis and hence improves long term prognosis. It can prevent unsuccessful attempts at endotherapy and its possible risks/costs. We conclude that EUS before endotherapy plays an important role regarding further management decisions in patients with CP.

P0119 UTILITY OF SERUM APOPTOSIS INHIBITOR OF MACROPHAGE FOR DIFFERENTIATING IgG4-RELATED DISEASE FROM MALIGNANT DISEASE

S. Tanoue, S. Hashimoto, S. Arima, Y. Nasu, F. Sasaki, S. Kamnura, A. Ido
School Of Medical And Dental Sciences, Kagoshima University, Kagoshima/Japan

Contact E-mail Address: tanoue@m.kufm.kagoshima-u.ac.jp

Introduction: IgG4-related disease (IgG4-RD) is characterized by the infiltration of inflammatory cells, such as plasma cells and macrophages, and fibrosis in tissues. We previously reported that apoptosis inhibitor of macrophage (AIM), which is secreted by macrophages, is related to the progression of hepatic fibrosis in chronic hepatitis C. Some studies have observed a relationship between IgG4-RD and malignancy. IgG4-RD is considered to represent a premalignant state or paraneoplastic condition.

Aims & Methods: To clarify the significance of the serum AIM levels in patients with IgG4-RD, we measured these levels in 22 healthy controls, 32 patients with IgG4-RD, and 36 patients with other pancreatic diseases (chronic pancreatitis [CP], intraductal papillary mucinous neoplasm [IPMN], pancreatic cancer [PC]). We also analyzed the prevalence of malignancy, the relationship between the appearance of malignancy and the diagnosis of 42 IgG4-RD, the type of cancer, and related factors, and we compared the age, gender, laboratory data, and AIM level.

Results: Fifteen malignancies were seen in 12 of 42 patients (28.6%). These diagnoses were made before the diagnosis of IgG4-RD for 10 malignancies in 8 patients (mean 4.8 years earlier, range 1–16 years), and after the diagnosis of IgG4-RD for 3 malignancies in 2 patients (mean 2 years later, range 1–3 years). Two malignancies in 2 patients were diagnosed at the same time as IgG4-RD, and 2 patients have IgG4-RD and malignancy. IgG4-RD is considered to represent a premalignant state or paraneoplastic condition.

Conclusion: Macrophages are reportedly related to IgG4 class switching in B cells and progression in IgG4-RD. The increased level of AIM in IgG4-RD, the increased level of AIM is related to cancer, and related factors, and we compared the age, gender, laboratory data, and AIM level.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Mera K, et al Serum levels of apoptosis inhibitor of macrophage are associated with hepatic fibrosis in patients with chronic hepatitis C. BMC gastroenterology 2014
This was done in consideration of the current knowledge about lesions mimicking cancer in the setting of a normal pancreatic parenchyma or existence of signs for pancreatic cancer.

**Aims & Methods:**

Retrospective analysis of prospectively collected data in our tertiary University center. From March 2007 to October 2015, 218 (124 men, 94 women; mean age: 79.3 years; age range, 85–100 years; mean tumour size, 29.6 ± 19.7 mm; tumour size range, 10–66 mm) were collected by EUS-FNA.

**Results:**

Pathological diagnoses showed 2 adenocarcinomas, 3 intraductal papillary mucinous neoplasms (IPMNs) not undergoing surgery if and whether that aids in deciding an appropriate treatment.

**References:**

mural nodules, it is useful to analyse genetic mutations of cystic fluids or walls. Currently, adequate samples from EUS-FNA were unavaiable in some cases, we could not make a pathological diagnosis. Even in such cases, genetic analysis and the subsequent diagnosis of malignant or benign tumours may be possible. We could identify several cancer-related genes, such as GNAS, KRAS, TP53, and BRAF.

Conclusion: In this study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumours.

Introduction: Circular RNAs (circRNAs) are a novel class of noncoding RNAs commonly derived from the RNA precursors by a “back-splicing” mechanism. Increasing reports have shown that circRNA is dysfunction in neuro system diseases, cardiovascular diseases, human cancers and many other diseases. CircRNA have been demonstrated involved in tumorigenicity, proliferation, apoptosis, angiogenesis, migration, invasion and metastasis in human carcinoma. CircRNA can act as a microRNA (miRNA) sponge and regulate the targets of miRNA. Circular RNA HIPK3 (cIRCHPK3) is originated from second exon of HIPK3 gene, which is upregulated in gastric, liver, esophageal. However, the mechanism remains unclear. Previous studies revealed that signal transducer and activator of transcription 3 (STAT3) as an oncogene that was activated in pancreatic carcinoma.

Phosphorylation of STAT3 (p-STAT3) is a downstream target of interleukin 6 receptor (IL6R). Activation of STAT3 leads to malignancy of tumorigenesis, cell proliferation and migration. Knockdown STAT3 induces cell apoptosis by Bcl-xL, c-Myc, cyclinD1, etc. CircHIPK3 regulates BcPC3 cell proliferation through IL6R/STAT3 pathway. It may be a new target for the therapy of pancreatic carcinoma.

Aim & Methods: Our research is to study whether cIRCHPK3 can promote proliferation of pancreatic carcinoma cell line, BcPC3, and to explore the mechanism of cIRCHPK3 in cell proliferation. Cell viability was determined by cell counting kit-8 (CCK-8). Transient knockdown of cIRCHPK3 using specific siRNA targeting the conjunction of cIRCHPK3. Overexpression of miR-124 was transfected with synthetic miRNA mimic. Real-time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed to detect cIRCHPK3, miR-124 and miRNAs. The expressions of STAT3, p-STAT3, IL-6R were measured by Western blot. Overexpression of STAT3 was transfected with STAT3 plasmid. Dual-Luciferase Reporter Assay was performed to detect the interaction of cIRCHPK3 and miR-124.

Results: cIRCHPK3 was upregulated in BcPC3 compared to human pancreatic duct epithelial cells (HPDE6-C7). Knockdown of cIRCHPK3, which didn’t affect the linear transcript, significantly decreased cell viability of BcPC3. Bioinformatical analysis and lucerase assay demonstrated that cIRCHPK3 interacted with miR-124. qRT-PCR results showed that expression of cIRCHPK3 decreased during miRNA levels of STAT3 and IL-6R and protein levels of STAT3, p-STAT3 and IL-6R. Previous studies confirmed that miR-124 negatively regulates STAT3, IL-6R via interacting with 3’-UTR (untranslated region). In qRT-PCR and Western blot results confirmed that cIRCHPK3 and both STAT3, p-STAT3 and IL-6R were upregulated in BcPC3 cells than HPDE6-C7 cells while miR-124 was downregulated. MIR-124 was negatively correlated with cIRCHPK3 and STAT3, p-STAT3 and IL-6R.

In this study, we identified cIRCHPK3 promotes BcPC3 pancreatic carcinoma cell proliferation by targeting miR-124 and its target genes STAT3 and IL-6R. We found that miR-124 was a negative regulator of proliferation in BcPC3. And overexpression of STAT3 could attenuate the anti-proliferation of si-cIRCHPK3 and miR-124. These results demonstrated that cIRCHPK3 regulates BcPC3 cell proliferation by acting as miR-124 sponge.

Intraductal papillary mucinous neoplasms (IPMN) are precursors of pancreatic ductal adenocarcinoma (PDA) and are also associated with multifocal cancers (field defect), where concurrent de novo PDA, independent of index IPMN, can also develop. However, there are cases where PDAs arise adjacent to the index IPMNs, and occasionally they are pathologically indistinguishable whether the carcinoma developed from IPMN or was coincidental to the IPMN. A genetic approach can be useful to clarify the origin of each tumor compartment to determine if they shared molecular signatures.

This study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumours.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

**Aims & Methods:** Twenty concomitant PDAs and IPMNs (39 samples, including concurrent lesions) from surgically resected patients were enrolled in this study. Resected pancreata were sliced at 5-mm intervals for whole-section histological analysis, and the distance between PDA and IPMNs was measured after precise pathological mapping. Target amplicon sequencing that covers 18 PDA-associated genes including KRAS, CTNNB1, GNAS, TP53, SMAD4, CDKN2A, 9/11, CTNNB1 and RNF43, was performed using Ion PGTM system (Thermo Fisher Scientific). The protein expression of TP33, SMAD4, p16, b-catenin, and RNF43 was also analyzed immunohistochemically.

**Results:** A total of 170 lesions were detected in 19/20 (95%) of PDAs and in 38/39 (97%) of IPMNs. “Adenomatous” concomitant PDAs, defined as those that are 5 mm or less away from the IPMN (n = 11), tended to harbor identical KRAS mutations as the index IPMNs (KRAS identical; n = 8, 72%, KRAS different; n = 3, 27%). Among cases with contiguous neoplastic lesions via the main duct between PDAs and IPMNs had identical KRAS mutations. In contrast, 7 of 9 “distant” concomitant PDAs, defined as those greater than 5 mm away from the IPMN (n = 9), possessed distinct KRAS mutations from the index IPMNs (7/9 = 78%). The KRAS mutations were demonstrated in 14/20 (70%) of index IPMNs and in 29/39 (74%) of all IPMNs, but not in PDAs, supporting de novo carcinogenesis rather than progression from the IPMNs. PDAs harboring identical mutations in KRAS as IPMNs were significantly closer to the IPMNs (KRAS identical: median 2 mm, HR = 1.1, 95% CI 1.0–1.2, p < 0.05). In contrast, the Pro/Pro genotype of the TP53 gene was significantly more common in IPMNs than in PDAs, with a relative risk of 1.6 (95% CI 1.1–2.4, p = 0.01). The Pro/Pro genotype was more common in IPMNs than in PDAs (53% vs. 23%), whereas the Pro/Arg genotype was more common in PDAs than in IPMNs (41% vs. 16%). The level of TNF-α was significantly lower in patients with PCa than in patients with CP. The level of IL-1β was significantly lower in patients with PCs than in patients with CP.

**Contact E-mail Address:** kobatak@med.kobe-u.ac.jp

**Introduction:** Pancreatic cancer (PC) is one of the most lethal diseases due to the difficulty of early detection. There is no effective blood biomarker for screening. Recently metabolomics is considered to be a promising approach to discover disease biomarkers. We previously reported that the serum/plasma levels of metabolites were significantly changed compared with those of healthy individuals.

**Aims & Methods:** The aim of this study is to confirm and develop our candidate metabolomic biomarkers in blood of PC patients. Blood samples from PC patients and healthy individuals (HV) were collected by two independent groups consisting of multiple institutions. The 1st set was included 55 PC in stage I and II and 58 HV. The 2nd set was included 16 PC and 16 HV. Sixteen candidate metabolites were selected from previous report. Quantitative analyses were performed by gas chromatography/tandem mass spectrometry (G/C/MS/MS) together with their corresponding stable isotopes. In the 1st set, diagnostic models were constructed via multivariate logistic regression analysis. These results were validated using the 2nd set.

**Results:** In the 1st set, the levels of 4 metabolites differed significantly between PC and HV. Model Y consisting of 2 metabolites, i.e., histidine and xylitol showed high sensitivity (70.4%) than CA19-9. Furthermore, combination of model Y with CA19-9 increased its sensitivity (89.5%) and specificity (89.5%). In the 2nd set, combination of model Y with CA19-9 demonstrated high sensitivity (81.3%) and specificity (93.8%). In particular, it displayed very high sensitivity (100%) for PC in a resectable state.

**Conclusion:** Quantitative analysis using GC/MS/MS confirmed the possibility of metabolomics-based screening methods for PC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P0129 VERIFICATION OF INTERNATIONAL CONSENSUS GUIDELINES FOR SURGICAL INTERVENTION FOR BRANCH DUCT INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM OF THE PANCREAS (BD-IPMN) WITH WORRISOME FEATURES

Introduction: In the revised international consensus guidelines for 2012 for the management of IPMN of the pancreas, resection is recommended for all main pancreatic duct IPMN. While in branch pancreatic duct IPMN (BD-IPMN), the indications for resection are more conservative. Cyst size >30 mm without “high-risk stigmata” can be observed without immediate resection. And EUS observation is recommended to decide a treatment strategy.

Aims & Methods: The present study was a retrospective investigation of surgical indication for BD-IPMN with worrisome features (WF). 466 patients with IPMN underwent pancreatic resection at 3 high volume centers in Japan between 1996 and 2014. Among them, 136 patients with BD-IPMN were enrolled this study. The investigation of predictors of malignancy was done for 10 factors: age at time of surgery, sex, presence or absence of symptoms, serum amylase, CA19-9, CEA, and cyst size of main pancreatic duct (MPD), and cyst size of branch pancreatic duct (BPD). In preoperative examination, endoscopic ultrasonography (EUS) and computed tomography (CT) were considered to be essential. For size of MN, EUS measurements were used in all 156 cases. For diameter of MPD and cyst size of BPD, the CT measurement values were used. In this study, BD-IPMN was defined as cases with cystic dilatation of BPD and the MPD diameter was considered <5 mm (International Consensus Guidelines 2012). According to the WHO histological classification of IPMN (2000), pathological diagnosis is classified as adenoma (IPMA), borderline (IPMB), and noninvasive and invasive carcinoma (IPMC). A central review of pathological diagnosis was done in the cases of IPMB and IPMC.

Results: Pathological diagnosis was benign IPMN in 91 cases (58%) and malignancy, and in ROC analysis AUC for these factors was 0.74 and 0.72, respectively. Among cases of IPMC, 12 patients had metastasis to nodes or liver, and 30 patients had regional lymph node metastasis. About 15% of cases had multiple lesions. In the cases of BD-IPMN, the median age was 65 (range: 41–80). The patients had a median cyst size of 30 mm (range: 15–130 mm) and a median procedural time was 30, 5 minutes (range: 17–58 minutes). We report a technical success rate of 85% (n = 17) - technical failure was only seen in transduodenal puncture (n = 3, 15%). Biopsies were generally of good quality and contributed to the diagnosis in 14 patients (clinical success of 82%). Among these, there were ten cases of intraductal papillary mucinous neoplasia, two serous cyst adenomas, and one mucinous cystadenocarcinoma, and one pseudocyst. Two mild adverse events were recorded (1%), a case of re-admission due to non-specific abdominal pain and a mild acute pancreatitis.

Conclusion: The use of micro-biopsy forces was until now only reported in case reports. This is a first large-scale feasibility study. We conclude that the use of the micro-forces seems feasible and safe with acceptable rates of technical and clinical success. However, prospective studies are needed in order to determine diagnostic potential of this instrument compared to the other modalities currently used.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic metastases (PM) account for 1–2% of pancreatic tumors. Several cancer types metastasize to the pancreas, but even recently developed cross-sectional imaging modalities have difficulties distinguishing PM from primary pancreatic tumors. Moreover, their prognostic significance is poorly defined.

Aims & Methods: The aims of this study were to clarify the incidence of primary tumors leading to PM, the clinical characteristics, and prognoses, and to define the prognostic factors for survival. A retrospective analysis was performed at 39 Japanese tertiary referral hospitals between January 2005 and August 2015, after receiving approval from the institutional review board of each hospital. We identified the patients based on data obtained from each institutional database, and analyzed patient and tumor characteristics, and survival time. All the patients enrolled in the analysis were histopathologically or cytopathologically diagnosed with PM. Kaplan-Meier analysis and Cox’s proportional hazard models were applied to evaluate overall survival and survival analysis, respectively.

Results: We enrolled 159 patients (median age 74.5 years) with a pathologic diagnosis of PM. The most common primary tumor was renal cell carcinoma (38.4%, n = 61), followed by lung cancer (24.5%, n = 39), colorectal cancer (11.3%, n = 18), sarcoma (6.3%, n = 10), breast cancer (6.3%, n = 10), and other cancers (n = 21). At the time of the diagnosis of PM, 38 patients (24%) had at least one tumor-related symptom. Additional extra-pancreatic metastases were diagnosed in 94 patients (59%). Sixty-four patients (40%) underwent surgery. At the time of diagnosis, and no surgical resection was performed in 95 patients (60%). Additional therapies were chemotherapy (n = 69), chemoradiation (n = 4), radiation (n = 3), palliative care, and unclear (n = 2). Eight patients were lost during follow-up and 151 patients were included in the statistical analysis. All patients with PM had a median overall survival of 43.0 months, with 3- and 5-year survival rates of 52.5% and 42.6%, respectively. Among the five frequent primary sites of PM, prognoses of RCC, breast cancer, and colorectal were better than those of lung cancer and sarcoma. Univariate Cox proportional regression analysis identified four prognostic factors: pancreatic resection (hazard ratio [HR] 0.31, 95% confidence interval [CI] 0.18–0.57, p < 0.001), extra-pancreatic metastases (HR 3.07, 95%CI 1.71–5.51, p < 0.001), tumor-related symptoms at PM diagnosis (HR 3.88, 95%CI 1.29–6.56, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001). Multivariate Cox proportional regression analysis identified three independent prognostic factors: extra-pancreatic metastases (HR 2.13, 95%CI 1.11–4.07, p = 0.02), tumor-related symptoms at diagnosis (HR 5.39, 95%CI 2.92–9.91, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001).

Conclusion: Treatment strategies and prognoses for PM completely differ according to the primary tumor type. A definitive pathologic diagnosis of PM is essential for selecting the appropriate treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: National Comprehensive Cancer Network (NCCN) guidelines recommend chest x-ray or chest computed tomography (CT) for the staging of potential resectable pancreatic adenocarcinoma (PDA). However, there is limited data supporting these guidelines, and the prevalence of lung metastasis is not well defined on staging CT scans. We report our findings of patients with lung metastasis during initial staging and follow-up of patients with PDA.

Aims & Methods: Data was prospectively collected from May 2013 to September 2016 for PDA patients who were presented at a multidisciplinary pancreas center (MDPC) at a large tertiary-care center. All patients were staged with CT pancreatic protocol, CT chest and Endoscopic Ultrasound. Patients with findings of lung lesions on initial staging chest CT were followed prospectively. Metastatic lung lesions were determined based on definite imaging characteristics with clinical consensus or lung biopsy results.

Results: A total 278 PDA patients referred to MDPC were staged with CT chest (Table 1). Out of these, 36 (12.6%) patients were found to have either malignant (N = 6) or indeterminate (N = 30) lung lesions on initial staging CT chest. Out of the six malignant lung lesions, 5 (83.3%) patients had metastatic PDA lesions, and 1 (16.7%) patient had incidental primary lung cancer. On a follow-up of 30 patients with indeterminate lung lesions, 8 patients (26.7%) were later determined to be lung metastasis. The overall prevalence of definite lung metastasis was at least 4.8% (13/278). The prevalence of lung metastasis in pancreatic head cancer was 3.0%, while body and tail masses was 10.5%. Lung metastasis was almost four times more likely in the body, and tail masses (OR = 3.83, CI 1.2–11.8, p = 0.02) compared to head. Overall CT chest resulted in a change in management plan in 9 (2.5%) patients due to change in the stage to metastatic (8) and diagnosis primary lung cancer (1). Staging with CT chest changed otherwise resectable disease to unresectable/metastatic in 5 patients (1.8%) and borderline resectable to metastatic disease in 2 (0.7%) patients. Prevalence of isolated PDA lung metastasis without any other metastasis was 2.8% (8/278).

Conclusion: Our study showed that the prevalence of pulmonary metastasis in PDA was clinically relevant to mandate routine staging with CT chest. Prevalence was significantly higher for pancreatic body and tail cancers compared to the head. Staging CT chest resulted in a change in the stage of PDA and management decisions.

Table 1: Comparison of patient and tumor characteristics.
Introduction: New lesions (metachronous pancreatic cancer) and recurrence may develop after IPMN. The rate of new malignancies after initial surgery for IPMN and intraductal papillary mucinous neoplasms (IPMN). Endoscopic ultrasonography (EUS) is proved to be a more specific and sensitive method for pancreatic cancer. However, there is no report about EUS after pancreatectomy. If it is possible to observe the appearance of new lesions after pancreatectomy, the detection of new lesions could be estimated by the number of patients with EPMs among patients with and without EPMs by univariate analysis. We compared the distribution of IPMN in different anatomical parts and identified any of the demographics and clinical characteristics to significantly influence EPM occurrence among patients with IPMN.

Aims & Methods: The aim of this study was retrospectively to investigate the observation ability of EUS for renal pancreas. In this retrospective study, 44 patients underwent EUS for renal pancreas. In the surgical procedure, pancreaticoduodenectomy (PD) including pylorus-preserving PD (PPPD) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of renal pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it in only 2 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of six cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage IIb. The other cases (28 cases) were able to perform EUS-FNA in lesion in the remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (case IIb), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by positron emission tomography (PET). Second pancreatectomy was performed in 3 of 7 cases. The sensitivity of EUS-FNA was 71.4% (5/7), the specificity was 85.7% (6/7) and the accuracy was 71.4% (5/7). In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI (P < 0.001).

Conclusion: EUS was able to observe renal pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be performed for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0135 PATIENTS WITH INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS OF PANCREAS (IPMNs) ARE AT INCREASED RISK OF RENAL CELL CARCINOMA, PROSTATE, COLORECTAL AND BREAST CANCER: A SINGLE CENTER ITALIAN EXPERIENCE

Introduction: Number of studies reported that patients with intraductal papillary mucinous neoplasms of pancreas (IPMNs) are at the increased risk for occurrence of extrapancreatic malignancies (EPMs). We have conducted a study in order to assess the prevalence and incidence of EPMs in a cohort of Italian patients with IPMNs. The aim of this study was to determine the risk of EPMs in IPMN patients and to identify the risk factors for development of EPMs. We identified 72 EPMs in 63 patients with IPMN between December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for renal pancreas. The demographics, clinical characteristics, treatment, previous, synchronous or metachronous in relation to IPMN diagnosis. We extracted for all the cases identified on demographics, clinical characteristics, treatment, survival for remnant pancreas observed from linear white line (anastomotic part) to opposite side pancreas, otherwise it was insufficient observation. We compared the detection rate of EUS findings and that of CT or MRI findings.

Results: Among the 395 patients who underwent pancreatectomy at the AOU Onofrio General Hospital between December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for renal pancreas. In the surgical procedure, pancreaticoduodenectomy (PD) including pylorus-preserving PD (PPPD) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of renal pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it in only 2 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of six cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage IIb. The other cases (28 cases) were able to perform EUS-FNA in lesion in the remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (case IIb), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by positron emission tomography (PET). Second pancreatectomy was performed in 3 of 7 cases. The sensitivity of EUS-FNA was 71.4% (5/7), the specificity was 85.7% (6/7) and the accuracy was 71.4% (5/7). In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI (P < 0.001).

Conclusion: EUS was able to observe renal pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be performed for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

P0136 CLINICAL CHARACTERISTICS OF SECOND PRIMARY PANCREATIC CANCER

Department Of Internal Medicine And Institute Of Gastroenterology, Yonsei University Health System Dept. of Internal Medicine Dept. of Gastroenterology, Seoul/Korea, Republic of

Contact E-mail Address: woforze@naver.com

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is known to have an extremely poor prognosis. Several studies reported the increased risk of second primary pancreatic ductal adenocarcinoma (2nd PDAC) in cancer survivors. However, data on the characteristics of 2nd PDAC are insufficient. Studies of PDAC in the setting of second primary cancer can provide etiologic clues to understand PDAC.

Aims & Methods: The aim of this study was to investigate the clinical characteristics of the patients with second primary PDAC compared to patients with first primary PDAC. This retrospective cohort study included 1759 patients with PDAC. They were classified as having 2nd PDAC or first primary PDAC (1st PDAC) according to a prior diagnosed cancer that originated from different organ and diagnosed at least 6 months before the diagnosis of PDAC. Comparative analysis and multivariated survival analysis were used to evaluate the characteristics of the 2nd PDAC.

Results: A total of 1759 patients with PDAC were included in the cohort. Forty-three patients were classified as having synchronous 2nd PDAC and excluded from the analysis. There were 110 patients (6.4%) with 2nd PDAC and 1606 (93.6%) patients with 1st PDAC. The median interval between the diagnosis of the 2nd PDAC and the diagnosis of the prior cancer was 8.4 years (range 0.7–31.4 years). The 2nd PDAC group. In the comparison of baseline characteristics between the 1st PDAC and 2nd PDAC groups, patients with 2nd PDAC presented significantly older age at diagnosis (66.5 vs. 62.2 years, p < 0.001), lower rate of alcohol consumption (25.5 vs. 36.8%, p = 0.017), higher rate of resectability of PDAC (26.4 vs. 15.9%, p = 0.004), and higher rate of receiving surgery as initial treatment (26.4 vs. 15.9%, p = 0.018) than patients with 1st PDAC. The most common origin of prior cancers was the stomach (22 of 110, 19.1%), breast (19 of 110, 17.3%), colon (12 of 110, 10.9%), and others. The overall survival (OS) was slightly longer in patients with 2nd PDAC; however, the difference was not significant (11.8 vs. 12.3 months, p = 0.068). Multivariated analysis without resectable status showed that 2nd PDAC (HR 0.73, 95% CI 0.56–0.94, p = 0.016), age at diagnosis (HR 1.02, 95% CI 1.01–1.02, p = 0.001), and alcohol consumption (HR 1.28, 95% CI 1.12–1.46, p = 0.001) were significantly related to OS (Table 1). When resectable status was included in multivariate analysis, age at diagnosis (HR 1.02, 95% CI 1.01–1.02, p < 0.001), alcohol consumption (HR 1.25, 95% CI 1.11–1.42, p < 0.001), and resectable status at diagnosis (HR 0.30, 95% CI 0.25–0.36, p < 0.001) were significantly associated with OS. However, 2nd PDAC (HR 0.85, 95% CI 0.66–1.09, p = 0.198) was no longer significantly associated with OS after adjusting for resectable status. This analysis suggested that the association between 2nd PDAC and survival was owing to the higher resectability rate. When subgroups were separately analyzed according to initial treatment modality, the effectiveness of surgery and chemotherapy were similar between 2nd and 1st PDAC. In the subgroup of patients who received curative surgery, the median OS was 28.5 months (95% CI, 23.0–34.1) in the 1st PDAC group compared to 12.3 months (95% CI, 5.0–19.5) in the 2nd PDAC group.
pared with 33.1 months (95% CI, 9.0–27.2) in the 2nd PDAC group (N: 259 vs. 201) (p = 0.001). The 5-year survival of the APT group was significantly higher than that in the no APT group (16.0% vs. 5.9%; p = 0.001). Postoperative bleeding occurred in seven and nine patients in the continuous single-LDA group (15.2%) and the continuous LDA on DAPT group (22.5%), respectively. In multivariate analysis, specimen size of ≥ 40 mm (odds ratio [OR] 3.19; 95% confidence interval [CI], 1.65–6.16; P < 0.001) was a sole independent risk factor for postoperative bleeding (Table 1). In subgroup univariate analysis among continuous LDA users, continuous single-LDA and continuous LDA on DAPT were not related to postoperative bleeding.

Conclusion: This study suggests that continuous LDA may be acceptable for gastric ESD in patients on DAPT. However, patients with continuous LDA on DAPT should be monitored carefully for postoperative bleeding after gastric ESD because the rate of postoperative bleeding in the continuous LDA on DAPT group was higher than that in the other groups.

Introduction: Peroral endoscopic myotomy (POEM) has received wide acceptance as a safe and effective treatment for achalasia. Several large, multicenter randomized studies have confirmed the efficacy and safety of POEM in treating achalasia. However, the mechanisms underlying its treatment effects are poorly understood. Recent studies have reported that POEM significantly attenuates the acid reflux and improves the motility in patients with chronic gastrointestinal ischemia (CGI) in the absence of gastric atrophy. This study aims to investigate the potential mechanisms of POEM in treating achalasia in patients with chronic gastrointestinal ischemia (CGI).

Methods: Consecutive patients with chronic gastrointestinal ischemia (CGI) in the absence of gastric atrophy were included. A total of 50 patients were included. POEM was performed in all patients. The primary endpoint was the rate of the lesions that need hemostatic forceps was compared among the three groups (n = 50 for the lower gastric body atrophy and n = 43 for the antral intestinal metaplasia). The degree of correspondence between the observed differences between the three groups was compared using McNemar's test. A p-value < 0.05 was considered statistically significant.

Results: The mean age of included patients was 38.7 ± 15.6 years, they were 21 (42%) males and 29 (58%) females. 38 (76%) and 13 (26%) patients have peptic ulcer disease and intestinal metaplasia respectively. Overall, 41 (82%) and 9 (18%) patients have low and high gastric cancer risk respectively. The sensitivity of NBI in the diagnosis of Helicobacter pylori infection, gastric cancer and intestinal metaplasia were 96% (n = 48.50), 100% and 61.5% (n = 8/13) respectively. The degree of correspondence between the scores obtained by NBI and by histology was 58% (29/50) for the lower gastric body atrophy and 86% (n = 43/50) for the antral intestinal metaplasia. The degree of correspondence between the high risk and low risk groups determined on the basis of NBI endoscopy on one hand and histopathology on the other hand was 80% (n = 40/50).

Conclusion: NBI is able to approximate histopathological staging of gastritis to that of endoscopy. More studies and training will further improve the performance of our suggested new staging method.

Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for early gastric cancer. Development of the ESD device has been conducted recently with a novel multifunctional knife device. New ESD device was invented to achieve complete ESD with a simple device. It achieves clear marking, better hemostasis and smoother operation during a procedure without replacing the knife.

Aims & Methods: The aim of this study was to investigate clinical outcome of ESD for early gastric cancer with a new device (SPLASH-M knife®). In total, early gastric cancer treated by ESD with a needle-type knife between January 2012 and August 2016 at Kitakyushu Municipal Medical Center were retrospectively reviewed. Lesions treated by ESD with a conventional needle-knife (ESD-C, n = 76) and by ESD with a new device (ESD-N, n = 73) were compared. Multivariate analyses and propensity score matching were used to compensate for the differences in age(≥75 years vs < 75 years), sex (male vs female), under-lying disease (none vs with cardiovascular or cirrhotic), antithrombosis drugs (not receiving or discontinuation vs continuation), tumor size (≥21 mm vs < 21 mm), lesion location (in the upper or middle third of the stomach vs in the lower stomach), lesion position (in the lesser curvature of the stomach vs others), macroscopic type (flat or depressed vs elevated), presence of ulceration (presence vs absence) and operator level (experience of ≥50 vs experience < 50). As primary endpoint, the rate of the lesions that need hemostatic forceps was compared

INCIDENCE, PREDICTORS AND FOLLOW-UP FINDINGS

Gastric cancer. It may contribute to reduce cost for ESD by reducing usage of Splash M-Knife

Conclusion: CI: 1.0–2.0 mg, p = 0.001), diagnostic yield (95% CI: 1.8–8.9, p = 0.001) and age (95% CI: 78.8%, 90.0%, respectively, for eradicated status, and 67.1%, 91.4%, 59.6%, 93.6% and 21.7, respectively, for infected status. High DORs were obtained for the following endoscopic findings: 32.2 for RAC, 7.7 for FGP and 4.7 for red streak in subjects as signs of infection. Further investigation for eradicated status, and 26.8 for diffuse redness, 13.3 for mucosal swelling, 10.2 for sticky mucus and 8.6 for enlarged fold in subjects with infected status.

Conclusion: The Kyoto classification is useful for diagnosis of HP infection status, the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic odds ratio (DOR) for endoscopic findings were determined. This study was registered as a clinical trial in UMIN (UMIN000016674) and was conducted with the approval of the ethics committee in our institution.

Introduction: Since Helicobacter pylori (HP) eradication therapy is necessary to prevent the development of gastric cancer, evaluation of HP infection status (uninfected, infected, eradicated) by endoscopy has become important. For that purpose, the Japan Gastroenterological Endoscopy Society proposed the Kyoto classification for gastritis. However, the usefulness of the classification in daily clinical practice has not been sufficiently evaluated.

Results: The 498 subjects included 376 males and 122 females with a mean age of 53.1 years. HP status was uninfected in 315 subjects, eradicated in 104 subjects and infected in 79 subjects. The diagnostic accuracy rate was 82.9%. The sensitivity, specificity, PPV, NPV and DOR were 88.3%, 92.9%, 95.5%, 82.1% and 99.0%, respectively. For uninfected status, the false negative rate for endoscopy was 17/30 (56.7%), consisting of pharyngeal abnormalities (n = 9), dysmotility (n = 7) and no further findings (n = 1%).

Contact E-mail Address: keith@siaia.org

Aims & Methods: We retrospectively identified all gastroscopies performed at a district general hospital between August 2010–August 2016 from an endoscopy database, and reviewed cases with IF. We excluded patients who had achieved oesophageal intubation. Data on sedation use, endoscopy status, indications, radiological and endoscopic findings were recorded. Procedural limitations were classified into 2 groups: failure to tolerate (e.g. pulling out scope, anxiety) and ‘failure to progress’. Statistical analyses were made using Pearson’s chi² and Wilcoxon signed rank test.

Results: The incidence of IF was 0.95% (248/26130). 238 patients were identified, with a mean age of 63.2 (SD 16.1), with ‘failure to progress’ in 41 and ‘failure to tolerate’ in 197. Subsequent investigations included barium radiology (59.7%, n = 142), CT (21%, n = 50), repeat gastroscopy (29.4%, n = 70) and no further investigations (19.7%, n = 47). Structural pharyngeal abnormalities were diagnosed comprising of cuffed tongue, hyperplastic CPH (49%), Zenker’s diverticulum (ZD) (14.6%), pharyngeal web (12.2%), ZD with CPH (9.8%), cervical spondylosis (7.3%) and other (7.3%). Endoscopist status was a predictor of IF (OR for medical vs. non-medical endoscopist 0.7, 95% CI: 0.5–0.9, p = 0.007). Within the IF cohort, predictors of structural causes on barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5–11.8, p < 0.001), failure to progress (OR 5.2, 95% CI: 2.3–12.0, p < 0.001) and age ≥ 65 (OR 4.0, 95% CI: 1.8–8.9, p < 0.001). Repeat gastroscopy was successful in 65/70 (2 using nasendoscopy) after increasing midazolam dosage (mean increase = 0.15 mg, HP eradicated: 1.0–2.0 mg, p < 0.001). Diagnostic yield for barium radiology, CT and repeat gastroscopy were 69.0%, 54.0% and 64.3% respectively. The concordance of endoscopic indication and pathology on further investigation for IF was 110/192 (57.5%). In patients undergoing barium radiology and repeat gastroscopy, the false negative rate for endoscopy was 17/30 (56.7%), consisting of pharyngeal pathology (n = 9), dysmotility (n = 4) and significant reflux (n = 4).

Aims & Methods: The aim of this study was therefore to determine the usefulness of the Kyoto classification for diagnosis of HP infection status. A total of 498 subjects were recruited during the period from January to October in 2015 for this study after providing informed consent in writing. HP infection status was determined by the presence of HP-IgG antibody (E-plate II H. pylori antibody, Eiken Chemical Co., Ltd., Tokyo, Japan) and history of eradication therapy. HP infection status was judged to be “eradicated” if there was a definite history of eradication therapy. Without a history of eradication therapy, HP infection status was judged to be “infected” for an HP antibody titer of less than 3 U/ml, “eradicated” for an HP antibody titer of 3–10 U/ml and “infected” for an HP antibody titer of more than 10 U/ml. Seven endoscopists (5 well-experienced endoscopists and 2 trainees) who were blinded to history of eradication therapy performed endoscopy. Two following endoscopy recordings were made according to the Kyoto gastritis classification: diffuse redness, regular arrangement of collecting venules (RA), fundic gland polyph (FGP), atrophy, xanthoma, hyperplastic polyph, map-like redness, intestinal metaplasia, nodularity, mucosal swelling, white and flat elevated lesion, sticky mucus, depressive erosion, raised erosion, red streak, and enlarged fold. HP infection status was diagnosed on the basis of the findings. An Olympus H260 and Xp260NS were used for endoscopy. The diagnostic accuracy rate of the Kyoto classification and the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic odds ratio (DOR) for endoscopic findings were determined. This study was registered as a clinical trial in UMIN (UMIN000016674) and was conducted with the approval of the ethics committee in our institution.

Results: The 498 subjects included 376 males and 122 females with a mean age of 53.1 years. HP status was uninfected in 315 subjects, eradicated in 104 subjects and infected in 79 subjects. The diagnostic accuracy rate was 82.9%. The sensitivity, specificity, PPV, NPV and DOR were 88.3%, 92.9%, 95.5%, 82.1% and 99.0%, respectively. For uninfected status, the false negative rate for endoscopy was 17/30 (56.7%), consisting of pharyngeal abnormalities (n = 9), dysmotility (n = 7) and no further findings (n = 1%).

P0145 A RETROSPECTIVE AUDIT OF OUTCOMES AND CURRENT CLINICAL PRACTICE POST-BALLOON TAMPONADE FOR ACUTE VARICEAL BLEEDING: HAVE THINGS IMPROVED OVER TIME?

C. Keung1, A. Jackson2, M. Swan1
1Department Of Gastroenterology And Hepatology, Monash Health, Melbourne/ Australia
2Department Of General Medicine, Monash Health, Melbourne/Australia/VIC

Contact E-mail Address: c.keung1@gmail.com

Introduction: Balloon tamponade, such as with Sengstaken-Blakemore tubes (SBT), remains the main immediate salvage therapy for acute variceal bleeding uncontrolled by variceal ligation or injection therapy. Previous cohort studies from the 1970–1980s report success rates of 40–94% for initial haemostasis but high re-bleeding rates of 40–70% on removal [1–3]. Despite guidelines recommending balloon tamponade as initial therapy in treating endoscopically uncontrollable variceal bleeding, specialists and trainees feel uncomfortable with SBT insertion [4] given the perceived difficulties and complications [5].

Aims & Methods: We aimed to describe the current practices surrounding SBT insertion of acute variceal bleeding, the outcomes and to identify areas requiring improvement. A retrospective audit of all patients from 2008–2016 who required SBT insertion for control of acute variceal bleeding was undertaken at Monash Health, a large tertiary Australian centre. These patients were identified from coding classifications. Details regarding their admission were obtained via electronic records.

Results: Approximately 14% of all patients with variceal bleeding required insertion of SBT. Of these 42% were inserted by junior doctors, the majority were males (71%), with a mean age of 55 years (range 34–78). Alcohol was the most common aetiology for cirrhosis (62%), with 65% actively drinking. Most patients had cirrhosis severity scores of Child-Pugh B (67%) or Child-Pugh C (29%) and a median MELD score of 16 (range 5–39). At the index variceal bleed, 43% were haemodynamically unstable and 29% were encephalopathic. All received standard medical therapy with octreotide or terlipressin, antibiotics and blood products as required. The time to initial endoscopy from 1st onset bleeding was prompt (median 6.6 hours). Most bleeding varices were oesophageal (90%). Initial ligation/injection was performed in 64% with the remaining patients having such large volumes of blood in the UGI tract that satisfactory views were unable to be obtained. The current practice surrounding SBT insertion is shown in the table.
below. Relook endoscopy post-SBT insertion was performed in 86% patients at a median of 39 hours after insertion with further endoscopic therapy in 47%. Complications of SBT insertion occurred in 31% and included minor oesophageal ulceration (9), significant oesophageal ulceration (3), aspiration pneumonia (4) and oesophageal perforation (1).

Current practice surrounding Sengstaken-Blakemore Tube insertion

<td>39.3 (11.5-348.2)</td>
</tr>
</tbody>
</table>

Re-bleeding occurred in 45% patients during the admission despite SBT insertion, of which 79% did not survive. Seven other patients subsequently underwent a TIPS procedure for these still died. The median time to discharge and survival was 50% and 41% respectively. The median duration of hospitalisation, intensive care and mechanical ventilation was 13 days (1-56), 6.2 days (0.3-36.2) and 120 hours (1-708) respectively.

Conclusion: Primary haemostasis was achieved in 93% of patients; however, re-bleeding occurred in 45% and was associated with a poor survival rate of 20%. Short and longer-term survival has not significantly improved since studies in the 1970s-1980s despite advances in pharmacological therapy. Current practice for SBT insertion and re-bleeding is variable and would benefit from further education. Rates of direct visualisation of balloon position prior to inflation with endoscopy should be improved as with referrals for early TIPS.

P0146 CONSCIOUS SEDATION FOR ENDOSCOPIC SUBMUCOSAL RESSECTION BY USING DEXMEDETOMIDINE

Department of Gastroenterology, Yamashita Hospital, Ichinomiya/Japan

Contact E-mail Address: t.m-esaki@gmail.com

Introduction: To evaluate the feasibility and safety of the dexmedetomidine (DEX) for conscious sedation during endoscopic submucosal dissection (ESD). Aims & Methods: This study was a prospective trial, and was conducted at the Yamanashi University. Between January 2016 and December 2016, all 50 patients were enrolled in this study. The inclusion criteria for the study was the presence of esophageal, gastric or duodenal tumors. The criteria for exclusion from this study is as follows: patients who were allergic to the drugs used, a baseline heart rate less than 50 beats/minutes, patients who could not use anticholinergic drugs, and lack of patient’s consent. A total 50 patients who underwent ESD by using DEX for esophageal, gastric or duodenal tumor. The patients were sedated with DEX (an initial bolus infusion of 3.0 µg/kg/hour intravenously over 10 minutes, followed by a continuous infusion of 0.1 µg/kg/hour titrated). During sedation, midazolam (0.03 mg/kg) and pethidine (17.5 mg) were added intravenously as needed. If the level of sedation dropped to less than RASS -3, the intravenous DEX injection rate was reduced by 0.1 µg/kg/hour. If the patient's heart rate was less than 50 beats/minutes, the patient was intravenously infused with atropine sulfate hydrate (0.125 mg-0.25 mg). During procedure, the following parameters were measured continuously, and recorded every 5 minutes: heart rate, blood pressure, hemoglobin oxygen saturation (SpO2), respiratory rate and RASS. As the achievement rate of conscious sedation during procedure, the percentage of the time that the depth of sedation from RASS -1 to -3 during procedure were evaluated. Body movement leading to the interruption of ESD were recorded appropriately. After the procedure, all patients were intravenously infused with flumazenil (0.3 mg) and observed until the Aldrete score reached 9 points.

Results: During this study period, 50 patients with esophageal, gastric and duodenal tumors were identified as potentially eligible for participation. Of whom 37 males and 13 females, and the mean age was 67.5 ± 8.6 y. 27 patients regularly consumed alcohol and 5 patients use sleeping drugs regularly. Tumors were located in the following locations: 9 cases in the esophagus, 38 cases in the stomach. The mean tumor size was 23.8 ± 14.5 mm and the procedure time was 88.0 ± 59.5 minutes. The histologic results of ESD were squamous cell carcinoma (n = 9), adenoma (n = 17) and adenocarcinoma (n = 24). ESD by using DEX were successfully performed in all 50 tumors. No adverse events that were thought to be procedure occurred. The mean achievement rate of conscious sedation during procedure was 84.7 ± 16.5%. The median frequency of disturbance by patient’s movement was 0 times (range 0-3 times). 33 cases reduced and 14 cases discontinued a continuous infusion of DEX. In 23 cases heart rate was a decreased heart rate less than 50 beats/minutes. In 16 cases, the patient required an infusion of atropine sulfate hydrate. Thirty cases of 16 cases required an infusion of atropine sulfate hydrate after the procedure and 3 cases required it during procedure. The median time that the final administration of an atropine sulfate hydrate was 35 min (range 5-140 min) after procedure. There was no case in lowering of systolic blood pressure less than 80 mmHg. Although in 7 cases, the patient’s SpO2 level dropped to less than 90%, however, they recovered after the administration of oxygen to the nasal cannula. The mean time that the Aldrete score reached 9 or over was 7 ± 4 minutes. The median endoscopist and patient’s satisfaction score was 9 points (range 2-10 points) and 8 points (range 2-10 points). There were 30 patients (60%) who had oral intake after the procedure. None of the patients required any intervention during the period.

Conclusion: Conscious sedation with DEX is effective, safe and a high level of satisfaction for endoscopists and patients for upper gastrointestinal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0148 IMPACT OF NEEDLE-BASED CONFOCAL LASER ENDOMICROSCOPY (NCLE) IN IMPROVING DIAGNOSIS OF Pancreatic Cystic Neoplasms: Single Center Experience
F. Shahriari1, E. Verter1, M. Lucas1, C. Molina1, J. Adams2, V. Joshi1 1Ochsner Medical Center, New Orleans, United States of America

Introduction: Endoscopic ultrasound (EUS) has been found to be an effective tool in diagnosing pancreatic cystic neoplasms (PCN). Carcinoembryonic antigen (CEA) tumor marker has also been used to differentiate PCN and is the most accurate marker of mucinous cystic neoplasms. Recently, needle-based confocal laser endomicroscopy (nCLE) has been increasingly used for the diagnosis of PCN. nCLE allows for evaluation of pancreatic cysts with results similar to that of a pathological diagnosis. In this study, we will compare our standard of care, EUS with combined CEA and nCLE to determine which combination of diagnostic modalities is a better predictor of PCN.

Aims & Methods: In this retrospective chart review, 22 patients with pancreatic cysts were evaluated. Specificity and Negative Predictive Value (NPV) of EUS alone or EUS with combined CEA and nCLE were evaluated and diagnostic accuracy was compared with pathology using McNemar's test. Worrisome features (increased cyst size, wall thickness, main pancreatic duct size, and presence of non enhanced mural nodules, abrupt changes, distal atrophy and lymphadenopathy) were tested by determining dissimilar calculations using Euclidian distance and later were used in hierarchical clustering to create two clusters based on Euclidian distance.

Results: Diagnosis of PCN using EUS alone had a specificity of 0.75 and a NPV of 0.88. EUS and CEA had a specificity of 0.95 and a NPV of 0.90. Finally, EUS with CEA and nCLE combined had a specificity of 0.80 and a NPV of 0.94. Worrisome features clustering was able to predict pathology, p = 0.000289.

Conclusion: We concluded that specificity and NPV of EUS predicting PCN are positively impacted by the addition of CEA and nCLE. We also found that clustering of worrisome features predicts pathology, however, a larger cohort is required for future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is accepted as the treatment of intestinal-type early-stage gastric cancer. However, ESD occasionally results in unfavourable outcome due to technical difficulties. Therefore, predictions of difficulties in ESD would preclude complications associated with ESD. Aims & Methods: The aim of this study is to determine the predictive factors of procedural difficulties in ESD. Between January 2009 and July 2016, 577 consecutive patients who underwent ESD for gastric neoplasms were enrolled. These patients were classified into 3 groups: group S, group L, and others. Group S comprised 30 patients who underwent ESD for the shortest duration (10–16 min). Group L comprised 30 patients who underwent ESD for the longest duration (149–215 min). Multivariate analysis was performed between Groups L and S using the following factors: location (cardia, posterior wall of angle, lesser curvature of lower gastric body and others), macroscopic type (protruded, depressed or mixed), size of the resected specimen, preoperative scar, number of preoperative biopsies, (others), and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Results: Significant differences were found regarding the number of biopsies (group L, 8.5; group S, 6.8; p = 0.0231), biopsy diagnosis (group L, 96.6%; group S, 90.7%; p = 0.0292), and location (p = 0.0268), biopsy visualization of SCJ was also local at 92.0% (81/88) with FUSE-EGD. VASs at insertion, during and after examinations were 51.2 (10–75), 46.9 (0–75), and 45.2 (10–50) points, respectively, which were equivalent to conventional EGD. The ampullary adenoma was observed in all 3 patients with FUSE-EGD and the openings of the biliary and pancreatic ducts of the ampulla of Vater were observed in all 2 cases with the ampullary tumors with FUSE-EGD. There were no adverse events associated with FUSE-EGD. Conclusion: FUSE-EGD seems safe and effective for upper gastrointestinal screening, especially when the diagnosis of the ampulla of Vater and/or the anal side of the pyloric ring is necessary.

in the lesser curvature (43.9%, 284/647). Posterior EGC was more frequent in the mid-to-upper part of the stomach than the anterior part (20.4%, 31/157 vs. 16.4%, 11/67, respectively). For EGC characteristics compared between the lower and mid-to-upper parts, submucosal invasive EGC was found to be significantly different (odds ratio, 1.919; confidence interval, 1.014–3.623; p = 0.045).

Conclusion: Most of the EGCs resectable with ESD were found in the lesser part of the stomach and lesser curvature of the stomach. The incidence of the posterior part in the mid-to-upper part of the stomach was higher than that of anterior part. The EGc located in the mid-to-upper part of the stomach was found to have a higher incidence of invasive cancer.

Introduction: The recognition of general images by machine learning (ML) with the convolutional neural network (CNN) and deep learning (DL) is good. However, the possibility of the recognition of endoscopic images by ML with CNN and DL is undetermined.

Aims & Methods: The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL. We selected 816 endoscopic images of 8 categories which include laryngopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), proximal body (PB), corpus (CP), distal body (DB), and corpus (CD). The average of the number of images in each category was approximately 100 images. These images were randomly separated into two groups, 60% (489 images) for learning and 40% (327 images) for testing. We increased the learning group images to 833 by adding additionally rotated images of each five degrees. We made an ML model with three CNN layers, three Activation function layers, two Max-Pooling layers and two Dens layers by TensorFlow and Keras. We trained the ML model with the learning group images (n = 8313) and then tested it with the testing group images (n = 327) to determine whether it can recognize the endoscopic site. Two members of our hospital staff performed the same testing with the same images.

Results: It took 73 minutes for the ML model to learn and 6 seconds to answer the test. The percentage of correct answers of the ML model was 70.6% in all categories (n = 327), 71.1% in LP (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.8% in PB (n = 38), 65.7% in CP (n = 35), 56.2% in GF (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 95.4% (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.8% in PB (n = 38), 65.7% in CP (n = 35), 56.2% in GF (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 95.4% (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.8% in PB (n = 38), 65.7% in CP (n = 35), 56.2% in GF (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 95.4% (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.8% in PB (n = 38), 65.7% in CP (n = 35), 56.2% in GF (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42).

Conclusion: The proposed system is useful for the determination of DL.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0153 CONVENTIONAL VERSUS TRANSITION-ASSISTED ESODONIC DISSECTION FOR GASTRIC NEOPLASMS (CONNECT-G): A MULTICENTER, RANDOMIZED CONTROLLED TRIAL

Introduction: The recognition of endoscopic images by ML with CNN and DL is undetermined.

Aims & Methods: The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL. We selected 816 endoscopic images of 8 categories which include laryngopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), proximal body (PB), corpus (CP), distal body (DB), and corpus (CD). The average of the number of images in each category was approximately 100 images. Introduction: Post-sleeve gastrectomy fistulas (PSGF) are major complication of bariatric surgery. Endoscopic management evolved from a fistula closure to an internal drainage (ID) strategy within the 2013 year. The main objective of this study is to evaluate different endoscopic approaches.

Aims & Methods: This retrospective study included all patients treated for PSGF in a referral center. “Closure” management was defined as: initial treatment using covered-metal-stent and endoclips. ID management was defined as: initial management with OTSC and/or double-pigtail-steel. The failure was defined as: need for surgery, or death.

Results: Between 2007 and 2015, 101 patients (women: N=78; mean age: 42 ± 12years) were included. The mean delay between SG and the first endoscopy was 92 ± 58 days. Overall success of endoscopic treatment was 86% within 6 ± 2.7 months. Two patients died. Primary success of ID and closure management occurred in 19/22 (86%) and 49/77 (63%) patients, respectively. Among patients in failure of closure management, 22 had secondary ID (18 being successful). Success of initial management was significantly higher for ID (p = 0.016). Factors associated with failure of closure management were in multivariate analysis: collection > 5 cm (p = 0.013, OR = 3.89 [CI:1.3–10.9]). Factors associated with failure of management over 6 months were in multivariate analysis: reper- formation before endoscopy (p = 0.044, OR = 3.95 [CI:1.0–14.9]) and purulent flowing at endoscopy (p = 0.043, OR = 4.65 [CI:1.0–20.9]). Factors associated with post-2013 management were in multivariate analysis: first endoscopy within 30 days (p = 0.016). Clavien-Dindo-type 4 and 5 (p = 0.016), and absence of glue sealing (p = 0.027).

Conclusion: Endoscopic management of PSGF healed in 86% of cases. In case of collection greater than 5 cm, an internal drainage should be proposed first. A successful closure before endoscopy was associated with longer care. Management in our center has changed over time with earlier first endoscopy and management of more severe patients.

P0156 CLOSURE BY USING OVER-THE-SCOPE CLIPS AFTER ENDOscopic FULL-THICKNESS RESECTION

J. Guo
Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/ China

Contact E-mail Address: gaogtj@163.com

Introduction: Endoscopic full-thickness resection (EFR) is a mini-invasive tech- nique for gastrointestinal subepithelial tumors, which enables a full-thickness resection of tumors and can provide a complete basis for pathological diagnosis. Gastrointestinal fistula closure after EFR is a challenge for endoscopists. In this study we introduced EFR with fistula closure using the over-the-scope clip (OTSC) system for gastrointestinal subepithelial tumors originating from the musculi- aris propria.

Aims & Methods: We aimed to evaluate the feasibility and safety of fistula closure with OTSC by a retrospective analysis on the cases of EFTR with defect closure associated with long-term care. In our center has changed over time with earlier first endoscopy and management of more severe patients.

Conclusion: Endoscopic management of PSGF healed in 86% of cases. In case of collection greater than 5 cm, an internal drainage should be proposed first. A successful closure before endoscopy was associated with longer care. Management in our center has changed over time with earlier first endoscopy and management of more severe patients.

P0158  LONG-TERM OUTCOMES OF COLD POLYPECTOMY FOR SPORADIC SNADETS

Aims & Methods: Patients without polyposis syndrome who underwent cold polypectomy for one or more SNADETS ≤6 mm in size and were diagnosed with adenomas between March 2015 and November 2016, and were followed up by endoscopy for more than 1 year were analyzed. All patients subsequently underwent upper gastrointestinal endoscopy 3 months after the intervention. The presence of residual tumors was evaluated by conducting endoscopic examinations and histopathological tests with tissue samples obtained from the cold polypectomy scars. Subsequently, patients underwent upper gastrointestinal endoscopy annually, and when residual tumors could not be denied, biopsies were taken from the scars.

Results: A total of 43 lesions in 35 patients were removed using cold polypectomy in 20 patients with no complications. The mean follow-up period by upper gastrointestinal endoscopy was 13.1 (12–18) months. Of these 20 patients, 12 (60%) were men and the mean age of the subjects was 63 ± 11 years. The number of lesions were 5, 16, and 3 (21%, 60%, 8%) respectively, and 2, 3, 3, and 4 (2%, 13%, 17%, 8%) per macroscopic appearance (Isp, Is, Ia, Ia + Ilc, and Ilc), respectively. Nine lesions in 8 patients were resected using CFP, while 15 lesions in 12 patients were resected using CSP. Seven of 9 (78%) and 14 of 15 (93%) lesions were removed en bloc using CFP and CSP, respectively; the other 3 lesions were removed by piecemeal resection in 2 pieces. All specimens resected using both CFP and CSP were successfully retrieved.

Histopathologic analysis showed that 21 of 24 lesions (88%) were low-grade adenomas, while 3 (12%) were high-grade adenomas. The mean size of the adenomatous lesions was 4.0 ± 1.3 mm (2–6 mm). Eleven of 24 adenomas (46%) were R0 resections; 3 of 9 (33%) and 8 of 15 (53%) were R0 resections using CFP and CSP, respectively. Delayed bleeding and intraprocedural/delayed perforation were observed in one case respectively. The patient received a conservative therapy, complemented by a withdrawal of oral aspirin. A 48-year-old male was presented at the emergency room the next day. He was admitted to our hospital after an episode of hematemesis. The patient had a 22-year history of peptic ulcer disease and is diabetic. On admission he was tachycardic with a heart rate of 128 bpm. The computed tomography of the chest demonstrated a hydrothorax, as well as mediastinal free air. Due to the hemorrhage we performed an emergency upper endoscopy after we obtained the patient's consent. We observed an approximately 3 cm long, with a Mallory-Weiss tear at the distal lesser curvature. We clipped the visible vessel and decided to close the opening with clips (Figure 1). We used twelve clips and successfully stopped the bleeding while also closing the esophageal opening. Thoracic surgeons placed a thoracic drainage tube. The patient received 3 days after resuscitation because of heart failure. The patient received a conservative therapy, complemented by a withdrawal of oral intake and administration of broad spectrum antibiotics.

Conclusion: Cold polypectomy is a safe and effective treatment for diminutive and small sporadic SNADETs that have been subjected to long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0160  ARTIFICIAL INTELLIGENCE DIAGNOSIS OF HELICOBACTER PYLORI INFECION USING LINKED COLOR IMAGES (EGGD)

Aims & Methods: The aim of this study was to establish an AI diagnosis of HP infection using LCI. We designed a prospective study of all patients who underwent EGD and were tested for serum anti-HP IgG antibodies at our medical clinic. Subjects who had a history of HP eradication therapy were excluded in this study. A total of 230 examinees were candidates who underwent EGD and serum test of anti-HP IgG antibodies. The diagnosis of HP IgG antibodies positive examinees were 112. The HP IgG antibody titer of each subject was taken as the gold standard for HP infection status for this study. During EGD an endoscopist took 3 LCI pictures of the lesser curvature, greater curvature and antrum of the stomach by EG-L580NW (FUJIFILM Co., Japan). Finally, we used a total of 639 LCI pictures in the study. The specifications of the AI used in this study were as follows: Operating system: Linux (Ubuntu 14.04 LTS), Neural network: GoogleNet3, Framework: Caffe3, and Graphic processor unit: GeForce GTX TITAN X (NVIDIA Co., Japan). The AI was trained using the dataset. The AI was trained using the dataset.

Results: The area under the curve (AUC) of receiver operating characteristics (ROC) was 0.95 for the lesser curvature. Compared to this, the AUC of the greater curvature and antrum was 0.81 and 0.67, respectively. The AUCs obtained in the lesser curvature was significantly larger than that in the greater curvature and antrum (P < 0.01).

Conclusion: The results demonstrate that the AI has excellent ability to diagnose HP infection using LCI in the lesser curvature. The authors believe that AI technology with IEEs is likely to become a useful image diagnostic tool.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0159  ENDOSCOPIC TREATMENT OF BOERHAAVE SYNDROME: A SURPRISINGLY QUICK HEALING

G. Sakizlis, D. Karagiannis
Gastroenterology, Iatrikon Medical Center, Athens/Greece

Aims & Methods: A 48-year-old male was presented at the emergency room complaining of severe chest pain, which began after several episodes of vomiting, following a meal. Upon his arrival a severe episode of haematemesis was reported. A chest radiograph showed tachycardia with a ventricular rate of 128 bpm. The computed tomography of the chest demonstrated a hydrothorax, as well as mediastinal free air. Due to the hemorrhage we performed an emergency upper endoscopy after we obtained the patient’s consent. We observed an approximately 3 cm long, with a Mallory-Weiss tear at the distal lesser curvature. We clipped the visible vessel and decided to close the opening with clips (Figure 1). We used twelve clips and successfully stopped the bleeding while also closing the esophageal opening. Thoracic surgeons placed a thoracic drainage tube. The patient received 3 days after resuscitation because of heart failure. The patient received a conservative therapy, complemented by a withdrawal of oral intake and administration of broad spectrum antibiotics.

Conclusion: Boerhaave syndrome has an estimated mortality rate of 20% to 40%. The standard of care is multidisciplinary; surgical, endoscopic or conservative approaches are acceptable. No consensus exists regarding the best strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0161  ENDOSCOPIC GRADING FOR GASTRIC INTESTINAL METAPLASIA (EGGDM) AS AN ARTIFICIAL INTELLIGENCE (AI) technology

G. Espósito1, P. Pimentel-Nunes2, S. Angeletti1, R. Castro2, D. Libanio2, G. Galli1, E. Lahner1, E. Di Giulio1, B. Annibale1, M. Dinis-Ribeiro2

2Department Of Medical-surgical Sciences And Translational Medicine, Sant’Andrea Hospital, University Sapienza, Rome/Italy
3Dept. Of Gastroenterology, IPO Porto, Porto/Portugal

Introduction: Current guidelines (MAPS) suggest that intestinal metaplasia (IM) should be staged using OLGIM 1 (Operative Link on Gastric Intestinal Metaplasia) and that patients with stages OLGIM 3 and 4 should be followed up. High-resolution narrow band imaging (HR-NBI) was previously shown to be accurate to diagnose IM 2. Recently a new endoscopic classification (Endoscopic Grading of Gastric Intestinal Metaplasia - EGDM) has been proposed to assess the risk phenotype of patients by the evaluation of IM in the antrum and in the corpus with the use of HR-NBI scopes 3. 4.

Aims & Methods: We aimed at determining the accuracy of EGDM classification, compared with the pathological evaluation of gastric biopsies expressed according to OLGIM classification. Two centers (Italy, Portugal) consecutively included 78 adult patients (female 56%); median age 61 (20–84) years: 8 with 1st degree family history of gastric cancer. All patients were evaluated by High-
Resolution White Light Endoscopy (HR-WLE) followed by HR-NBI. A careful evaluation of the antrum and corpus mucosa was performed and EGGM score was calculated. Five different areas were considered (lesser and greater curvature in the antrum, lesser and greater curvature in the corpus and incisura) and in each area 0 (no IM), 1 (focal IM, less or equal than 30% of the area) or 2 points (extensive IM in that area, more than 30% of the area) were attributed for a total of 10 points. Biopsies were taken where the endoscopists observed IM and, if IM was not present, random biopsies were taken using the updated Sydney System protocol. Biopsies from the different sites were sent for histopathologic evaluation.

Aims & Methods: The diagnostic performance of EGGM was then compared to OLGIM (gold standard) and sensibility, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated. Results: IM was staged as OLGIM 0, 2, 3, and 4, respectively: 32 (41.0%), 23 (29.5%), 17 (21.8%), and 6 (7.7%) pts (no patients with OLGIM 1 were found). Table 1 shows detailed the EGGM scores compared to OLGA. Compared to OLGIM as gold standard for the evaluation of IM, sensitivity, specificity, PPV and NPV of EGGM classification were 97.8%, 81.2%, 88.2% and 96.3%, respectively. IM was observed in 6 patients who had positive results using the EGGM classification were H. pylori positive. Analyzing the subgroup of patients with OLGIM 3 and 4, the diagnostic performance of EGGM was: sensibility 95.6%, specificity 90.9%, PPV 81.5% and NPV 98.0%. Two of the 5 patients who resulted false positive using the EGGM classification were H. pylori positive. A high agreement between EGGM and OLGIM scores was observed (83.3%).

Conclusion: The EGGM classification showed a high diagnostic performance compared to OLGIM, in particular in patients with OLGIM 3 and 4. A possible confounding factor leading to overestimation of presence of intestinal metaplasia might be the presence of H. pylori infection. This approach could be used to simplify the surveillance of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastrostomy is the current method of choice for medium and long-term enteral feeding. Available techniques include Percutaneous Endoscopic Gastrostomy (PEG) and Percutaneous Radiologic Gastrostomy (PRG). Both techniques are preferred over oral gastrostomy. Previous studies that have compared outcomes between PEG and PRG are limited due to small sample sizes, high risk of confounding and selection bias. Our primary aim was to retrospectively analyse data from our centre with respect to complications and mortality between PEG and PRG procedures in relation to indications. These data may help to predict which technique is best for an individual patient.

Aims & Methods: A retrospective analysis including all adult patients receiving initial PRG (January 2010 until April 2016) and PEG (January 2008 until April 2016) placement in our university hospital, was performed. Outcomes were complications (early (<30 days) and late), success rates and mortality (procedure related, 30-day, and overall). Chi2, Fisher’s exact and t-tests were used. Multivariable logistic regression and Cox proportional hazards regression analysis were performed.

Results: A total of 760 initial procedures (469 PRG and 291 PEG) were included in the analysis (62.9% male, mean age 62.8yrs [SD 12.6yrs]). Most common indications were: Motor Neurone Disease (MND, PEG 2.7%, PRG 9.8%, p < 0.001). Cerebrovascular Accident (CVA; PEG 13.7%, PRG 2.1%, p < 0.001) and Motor Neuron Disease (MND, PEG 2.7%, PRG 9.8%, p < 0.001). Success rates for placement were 91.2% for PEG (failure mostly due to absence of transillumination, n=14) and 97.1% for PRG (p = 0.001). Major complications (e.g. abscess, buried bumper, peritonitis) and infections did not differ amongst groups, neither did procedure-related mortality, which was 1.7% in PEG (n=5) vs. 0.4% in PRG (n=2, p = 0.113). One case of tumour (HN) seeding occurred after PRG placement. Tube related complications (including dislocation, obstruction, leak and tube defects) were lower in PEG than PRG, both within 30 days (2.7% vs. 26.4% of patients, p = <0.001 and after 30 days (8.6% vs. 31.5%, p < 0.001).

Conclusion: PEG appears favourable with respect to 30 day mortality while PEG appears favourable over PRG in terms of complications (such as dislocation, peritonitis and infection). A higher success rate and the possibility of placement in case of a narrow lumen favour PRG placement. More adequate patient selection and more thorough procedure selection prior to gastrostomy is therefore required.

P0165 COMPREHENSIVE EVALUATION OF THE LEARNING CURVE FOR PERORAL ENDOSCOPIC MYOTOMY: LESSONS FROM 1346 PATIENTS
Z. Liu1, X. Zhang1, Q. Li1, P. Zhou1
1Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University - Zhongshan, Shanghai/China
Contact E-mail Address: liuzq16@fudan.edu.cn
Introduction: Peroral endoscopic myotomy (POEM) is being increasingly performed worldwide. However, studies on the learning curve are limited. A comprehensive evaluation based on risk factors is needed.
Aims & Methods: This study was aimed to evaluate the impact of various factors on the learning curve of POEM. From August 2010 to July 2015, 1346 POEM procedures in our hospital were analyzed. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.
Results: Fifty-four (4%) patients had the composite outcome with 10 aborted procedures and 44 adverse events. The composite outcome was related to case number, faill-thickness myotomy and procedure time in the multivariate logistic regression. Adjusted for these risk factors, the CUSUM analysis showed that the composite outcome gradually decreased after 150 cases. The procedure time was higher in the early stage and decreased after 71 cases. Case number, in representative of the operative experience, is also an independent risk factor for a longer procedure time and hospital stay.
Conclusion: For POEM operators, seventy cases might be considered a threshold for faster operation, i.e., technical proficiency. A hundred-and-fifty cases might be considered a threshold for the decrease of aborted procedures and adverse events, i.e., technical reliability.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0166 CLINICAL CURATIVE EFFECT ANALYSIS OF 162 GASTRIC STROMAL TUMORS RESECTED BY ENDOSCOPIC TREATMENTS
L. Liu, W. Liu, Z. Fan
Digestive Endoscopy Center, The First Affiliated Hospital of Nanjing Medical University, Nanjing/China
Contact E-mail Address: kit9178@sina.com
Introduction: Gastrointestinal stromal tumor (GIST) is one of the most common tumors originating from mesenchymal tissue of gastrointestinal tract, which accounts for about 0.2% of gastrointestinal tumors. Gastric stromal tumors are more common, accounting for about 40%~70% of GIST. At present, the endoscopic treatments of gastric stromal tumors includes endoscopic submucosal dissection (ESD), endoscopic full-thickness resection (EFTR) and combined endoscopic and laparoscopic surgery.
Aims & Methods: Our study is aimed to assess the safeness and effectiveness of endoscopic treatments for gastric stromal tumor. Clinical data of 162 patients with gastric stromal tumor who underwent endoscopic treatments from June 1 to July 31st 2015 were analyzed retrospectively. The mean diameter of the tumors was 1.5 cm (0.3~5.0 cm). 104 patients received endoscopic submucosal dissection, 58 patients received endoscopic full-thickness resection. Among them, 4 operations were delayed under the monitor of laparoscopy.
Results: Complications were observed in 8 patients(4.9%): bleeding during operations: 3 patients, post-operation perforation: 3 patients, respiratory tract infection: 2 patients. The mean post-operation feeding time was 2.67 days (range 1~9 days) and post-operation hospital stays were 5.39 days (range 2~10 days). The mean time of follow-up was 26.4 months (range 5~51 months). The follow-up showed that 6 patients kept on treating with oral administration of imatinib. No patient was found recurrence or death.
Conclusion: Endoscopic treatments were demonstrated as safe and effective ways to resect gastric stromal tumors in this study.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0167 GASTROENTEROLOGY REGISTRAR OF THE WEEK: A SOLUTION FOR AUGIB ENDOSCOPY TRAINING?
S. Budhal1, P. Wurm1
1Digestive Diseases Centre, University Hospitals Leicester, GB/United Kingdom
Contact E-mail Address: shivbudhal@yahoo.co.uk
Introduction: Much concern surrounds Gastroenterology Specialist Registrar (SIR) endoscopy training, especially in regards to endoscopic management of Acute Upper Gastrointestinal Bleeding (AUGIB). Recent evidence suggests that there has been a decline in experience and exposure in AUGIB endoscopy. In July 2013 our University Hospital introduced a Consultant-led and Registrar-supported Monday to Friday, 9 to 5 pm in-reach service. It comprises of a morning visit to the acute medical units and a daily inpatient emergency list. This study looked at registrar AUGIB endoscopy training after its implementation.
Aims & Methods: Endoscopy reports of patients presenting with haematemesis, melena or both who had undergone gastroscopy during the period of 1st of May to 1st August 2013 were retrieved using the endoscopy reporting tool Unisoft and analysed. Reports where SIRs were the primary operator were considered. Number of procedures, haemostatic intervention and nature of haemostasis was analysed. This was then compared to data from the year before implementation (01/03/2012 to 31/08/2012)
Results: A total of 7 SIRs (5 Full Time and 2 Less than Full Time) performed gastroscopies on AUGIB patients as first operators under Consultant supervision. Over the 6-month period a total of 166 gastroscopies were undertaken (Mean 24). On 26 occasions, endoscopic intervention (EI) was performed (Mean 4). On average, 16% of the AUGIB patients required EI. In cases of Non Variceal Bleeding, Dual therapy was applied in 87.5% of the cases. For Variceal cases Haemostatic banding was used. On average, patients were able to perform one case of oesophageal variceal banding and one case where Haemospary was utilised. Data from the 2012 cohort in comparison showed a total of 66 gastrosopies over 6 months with 13 EI. On average 13 procedures and 2.6 EIs were performed by each SIR. Dual therapy was applied in only 25.8% of the cases.
Conclusion: The introduction of the Registrar of the Week Service provides a valuable opportunity for SIRs to be trained in endoscopic haemostasis and acquisition of experience in AUGIB endoscopy. As per this study each SIR on an average performed endoscopy on 24 AUGIB patients. If this is extrapolated, each SIR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of EI, on average a SIR can perform around 4 interventions over 6 months, which comes to 8 per year and 40 in a 5 year program. This is significantly better than in the previous cohort and other centres. Hospitals should consider developing similar services not only to meet demands for 24/7 Consultant led AUGIB endoscopy service but provide adequate endoscopic training provision for current and future specialist registrars in order to ensure future competent and confident consultants.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0168 HIGH PERCENTAGE OF VISIBLE LESIONS IN PATIENTS WITH BARRETT’S ESOPHAGUS REFERRED TO DYSPLASIA IN RANDOM BIOPSY SAMPLES
I. C. Noordzij1, W. L. Curvers1, I. Van Lijnschoten2, C. J. Huysentruyt2, E. J. Van Oeveren3

2Laboratory Of Pathology And Medical Microbiology, PAMM, Eindhoven/ Netherlands
Contact E-mail Address: irma.noordzij@catharinaziekenhuis.nl
Introduction: Endoscopic recognition of dysplasia or early cancer in Barrett’s esophagus (BE) is difficult. Experience in recognition of early neoplastic lesions is thought to increase the detection of visible dysplastic lesions. A previous study reported that endoscopists in community hospitals detect neoplastic lesions at a significantly lower rate than referral centres. The aim of the study we want to assess the significance of dysplasia in random biopsies in BE, in the absence of reported visible lesions as well as the final outcome of pathology.
Aims & Methods: We retrospectively analysed all patients referred from 19 community hospitals to our tertiary referral centre with the diagnosis of BE with non-variceal bleeding. From February 2008 and April 2016. All patients underwent a dedicated imaging endoscopy with high-definition endoscopy supplemented with virtual chromoendoscopy and/or acetic acid staining at the discretion of the endoscopist. All procedures were performed by an endoscopist with extensive experience in the detection of early neoplastic lesions in BE. During endoscopy all visible lesions were noted and biopsied and/or removed by endoscopic resection (ER). Patients were included for analysis in case of absence of reporting visible lesions at referral.
Results: In total 184 patients were referred with dysplasia or EAC of which 82 patients (80.5% male, age 42–81 years (median 68) did not show a visible lesion upon referral endoscopy. Referral diagnosis of these 82 patients was 32 low-grade dysplasia (LGD), 43 high-grade dysplasia (HGD) and 7 EAC. In three of 32 patients (9.4%) referred with LGD, a visible lesion during imaging endoscopy was detected. Two cases of histology proved EAC and one confirmed LGD. In twenty-six of 43 patients (60.5%) referred with HGD, a visible lesion with histology specimens corresponding to HGD (10) and EAC (16) were found,
respectively. All cases of EAC were detected (7/7). In 18/75 (24%) patients referred with dysphasia (LG/DG/HGD) without a visible lesion, the referral diagnosis was thus upstaged to EAC. Overall, 41/82 (50%) lesions were found additionally.

Conclusion: The presence of any grade of dysphasia in random biopsies in BE screening in community hospitals is a potential marker for more severe final pathology after endoscopic work-up in an expert centre. Training in Barrett's imaging is mandatory for non-expert endoscopists.

Results: A total of 22 patients were included and analyzed. The etiologies of ERF were esophageal surgery in 12 patients (54.5%) and esophageal dilatation in 3 (13.6%), invasive ventilation in 3 (13.6%), radiation therapy in 2 (9.1%) and tracheostomy in 2 (9.1%). A total of 83 procedures were performed with a mean of number of endoscopies of 4.2±4.5 per patient. At some point of the management, twenty-one patients (95%) had esophageal stents placement, eight patients (36%) had over the scope clips (OTSC) placement and seven had OTSC associated with esophageal stent. The clinical success rate was 45.5% (n = 10), and 55% of the patients had a functional success (n = 12). Serious adverse events occurred in 9 patients (40%) such as gastrointestinal bleeding (4 patients, 18.2%), stent migration (4 patients, 18.2%), thoracic spondylodiscitis (2 patients, 9.1%) alimentary esophageal impaction (1 patient, 4.5%), stent mucosal impaction (1 patient, 4.5%), major chest pain (1 patient, 4.5%). Six patients died (27%). Clinical success was reached for 67% of punctum ERF (p = 0.193), 50% of medium ERF (p = 1) and 14% of large ERF (p = 0.17). The factor associated with the failure of endoscopic treatment was the persistence of the fistula after 6 months (OR = 44; IC95: 3.38–573, 4; p = 0.004 multivariate analysis).

Conclusion: Endoscopic treatment of ERF can lead to 45.5% of clinical success and 55.5% of functional success. However, this outcome appears directly dependent on the size of the fistula. Moreover, the absence of resolution after 6 months of endoscopic treatment dramatically decreases the chance for ERF healing. In conclusion, the endoscopic approach seems reasonable for small or medium orifices, and has to be attempted during six months. After this time or for larger orifices, surgery or palliative therapy should be considered.

Disclosure of Interest: All authors have declared no conflicts of interest.
emerging modality for refractory gastroparesis with promising preliminary results.

Aims & Methods: The aim of this prospective case series was to assess our first (single center) experience with POEP. Main outcomes were: 1) the efficacy defined by improvement of GCIS score; 2) gastric emptying evolution and 3) safety. From Nov 2015, a total of 7 patients underwent POEP. The etiology of gastroparesis was post-operative in 4, diabetic in 2 and idiopathic in 1 patient. One patient underwent POEP for gastroparesis following a multivisceral transplantation; one patient underwent both POEP and POEM (as a single procedure) for coexisting refractory gastroparesis and achalasia. All patients had severe gastroparesis as defined by elevated GCIS score and delayed gastric emptying scintigraphy. Follow visit at 3, 6, 12-months were completed in 7/7 (100%), 5/7 (71%) and 1/7 (14%) patients, respectively. Upper GI endoscopy and scintigraphy were performed 3 months after the procedure.

Results: POEP was successfully performed in all patients. Mean procedure time was 70 minutes (range 63–106). After POEP, mean GCIS decreased from 3.0 ± 1.2 to 0.8 ± 0.7 (at 3-months) and 0.9 ± 0.8 (at 6-months). One woman finished the 12-months follow maintaining excellent outcome. Treatment success was reached in 6/8 (75%) of patients, one female patient with diabetic gastroparesis did not have a major symptomatic improvement despite normalisation of gastric emptying study. Gastric scintigraphy normalized in all patients, mean half emptying time of 1.0 ± 0.3 h (from 1.8 ± 0.30 min to 62 ± 23 min) and mean bolus retention at 4 hours decreased from 17 ± 9.2% to 2.0 ± 2.0%. One patient developed bleeding ulcer 10 days after POEP, this adverse event was successfully managed endoscopically (clips) and by parenteral proton pump inhibitor.

Conclusion: We report our first experiences with POEP for refractory gastroparesis, demonstrating its feasibility and safety with promising clinical efficacy.

P0173 TREATMENT OF MULTIPLE GASTROINTESTINAL SUBMUCOSAL TUMORS BY SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION

J. Liu, W. Qin, Y. Huang, Z. Ren, P. Zhou
Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: liu.jinzheng@zs-hospital.sh.cn

Introduction: Submucosal tunneling endoscopic resection (STER) is a novel technique to remove the gastrointestinal submucosal tumors. Previous studies mainly focused on technical feasibility for patients with one single gastrointestinal submucosal tumor. No systematic studies about multiple upper gastrointestinal submucosal tumors synchronously removed by STER are addressed. The aim of this study was to evaluate the safety and outcome of STER in treatment of multiple gastrointestinal submucosal tumors.

Aims & Methods: From January 2011 to January 2017, 42 patients with multiple gastrointestinal submucosal tumors undergoing STER were included. Variables of each tumor and patient were analyzed. Detailed tumor characteristics included maximum size, sum of maximum size and number of tumors, and longest distance of tumor. While detailed technique information included number of tumors, tunnel length, hospital stay, procedure time, complication, follow-up, recurrence, and metastasis.

Results: Among all the cases, 96 lesions of upper gastrointestinal submucosal tumors were removed by STER. The median procedure time was 50 min (range 13.6–84.9 min). The median number of tumors was 2 (2–4). The median max size of each tumor was 1.8 cm (range 0.7–3.5 cm) and the median sum of max size of each patient was 3 cm (range 1.3–8.3 cm). Six patients had perioperative complications (14.2%), with 3 pneumothorax/hydrothorax (7.2%), 1 mucosal injury (2.4%), 1 pneumonia (2.4%), and 1 major bleeding (2.4%). Patients with different number of tumors had similar tumor characteristics and techniques. There were significant differences in longest distance of tumors comparing two groups (p = 0.001). No local recurrence or distant metasatasis was detected with a median follow-up of 33 months.

Conclusion: STER is a safety and feasible technique for multiple upper gastrointestinal submucosal tumors no matter in one tunnel or two tunnels resection. Based on the longest distance of tumors, different number of tunnels can be performed with similar procedure technique and prognosis.

P0174 COMPARISON OF THE LINKED COLOR IMAGING (LCI) TECHNOLOGY AND CHROMOENDOSCOPY WITH ACETIC ACID FOR DIAGNOSIS OF BARRETT’S ESOPHAGUS

H. Neumann1, H. Neumann Sen2, P. Grimminger3, E. Corvinus4, F. Rahman1, F. Thieringer1, G.E. Tontini2, P. R. Galle4
1Universitätsmedizin Johannes Gutenberg University Mainz, Mainz/Germany
2Gastroenterologische Schwerpunktpraxis, Bad Salzuflen/Germany
3Department Of General, Visceral And Transplant Surgery, University Medical Center Mainz, Mainz/Germany
4Interdisziplinäre Endoskopie, University Medical Center Mainz, Mainz/Germany

Aims & Methods: The aim of this prospective study was to evaluate the recently introduced LCI technique compared to conventional dye spraying with acetic acid for diagnosis of Barrett’s esophagus. Therefore, consecutive patients with Barrett’s esophagus referred to the gastroenterology team. Individual physician and group results of key quality indicators were compared to the one already obtained by using LCI.

Conclusion: The newly introduced LCI technique is superior to high-definition white light endoscopy for diagnosis of Barrett’s esophagus and equally effective to acetic acid dye spraying. Therefore, the LCI technique has the potential to facilitate the diagnosis of Barrett’s esophagus and to overcome the limitations of a random 4-quadrant biopsy protocol.

P0175 ALBERTA FAMILY PRACTICE ELECTRONIC ENDOSCOPE STUDY (APFEE)

M. Kolber1, L. Green2, N. Olivier1, R. Torrrie2, O. Babenko1
1Family Medicine, University of Alberta, Edmonton/Canada/AB
2Taber Medical Clinic, Taber/Canada/AB

Aims & Methods: The Alberta Family Physician Electronic Endoscopic (APFEE) study aimed to examine the quality of colonoscopies performed by Family Physicians who perform colonoscopies. These endoscopists may improve access to colonoscopies for rural patients who require endoscopy and help improve provincial endoscopy wait times. Although some studies demonstrate that adequately trained Family Physicians are able to perform quality endoscopy, other studies question the quality of colonoscopies performed by non-gastroenterologists.

Results: In this six-month study, 9 Family Physicians performed 1769 colonoscopies in 11 rural Alberta sites. The proportion of successful cecal intubations; proportion of patients 50 years and older having a successful cecal intubation was 87.9% (95% CI: 97.2, 98.5). All physicians had over 90% successfully completed colonoscopies (ranging from 95.2 to 100%). The proportion of males and females 50 years old with an adenoma on a first-time colonoscopy was 67.4% (95% CI: 62.4, 72.7) and 51.1% (95% CI: 45.5, 56.7) respectively. All physicians achieved benchmarks of 30% of males and 20% for females having at least one adenoma. From all colonoscopies in the study there were 2099 pathologically confirmed adenomas or SSAs, 628 advanced adenomas and 17 cancers. Correlating to 120 adenomas, 36 advanced adenomas and 1 colon cancer per 100 colonoscopies. There were 2 post-polypectomy bleeds, no perforations and no deaths.

Conclusion: Alberta Family Physician colonoscopists are meeting benchmarks of the Canadian Society of Colonoscopy. Ongoing electronic collection of endoscopy quality markers should be encouraged. Supported and training rural Family Physicians who perform endoscopy may help alleviate current wait times and improve access for rural Canadian patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0176 PREDICTORS OF ADENOMA DETECTION AT COLONOSCOPY AFTER BOWEL SCOPE SURVEILLANCE: RESULTS FROM A UK PILOT SCREENING CENTRE

A. Yew1, K. Siau2, S. Jewes3, A. Veitch1, S. Ishai3, M. Brookes1, R. McKaig1, A. Veitch1, S. Shetty1, M. Marugananthan1
1Department Of Gastroenterology, Royal Wolverhampton Hospitals NHS Trust, Wolverhampton/United Kingdom
2Department Of Gastroenterology, Dudley Group Hospitals NHS Trust, Dudley/United Kingdom
3Department Of General, Visceral And Transplant Surgery, University Medical Centre Mainz, Mainz/Germany

Aims & Methods: We prospectively collated data from all BS patients at our centre and identified those undergoing colonoscopy between August 2013–2016. We assessed conversion rates, compliance with BS protocol and correlated endoscopic and histological findings to identify predictors of detection of pathology at colonoscopy. Univariate analysis was performed using Pearson’s chi2.

Results: 11,711 bowel scopes were performed, with an adenoma detection rate (ADR) of 8.5%, and conversion to colonoscopy in 421 patients (3.6%). 386 were included for analysis after excluding incomplete colonoscopy/histology. All patients were aged 55 (64.8% male). Additional ADR at colonoscopy was 35.2%, with malignant diagnoses in 3% (all detected at BS). The adenoma miss rate at BS was 5.2%. On univariate analysis (Table 1), poly 40mm was the only indication associated with increased ADR at colonoscopy (OR 2.13, p < 0.001). Additional predictors identified included villous (not tubulovillous) histology (OR 4.41, p = 0.002) and male gender (OR 2.35, p < 0.001). These factors also significantly predicted new ≥ 10 mm adenoma. 57 (14.8%) underwent colonoscopy outside protocol, which reduced ADR (OR 0.29, p = 0.03). After exclusion of high risk indications, changing the conversion criteria from any villous to villous only histology altered sensitivity from 27.2% to 83.3%, and specificity from 84.3% to 80.5%.

1. WS Atkin, Lancet 2010, 375:1624–33
Aims & Methods: A 70-item survey was sent by email to all Gastroenterology Departments in all Spanish hospitals. The rate of participation was 20.3% (341/1678). All physicians indicated their geographical location. In total, 341 Flemish digestive physicians responded to the survey; 30.7% were in academic centres, 51.9% were in teaching hospitals, and 17.4% were in non-teaching hospitals.

Results: Two hundred and seventy-one Flemish digestive physicians participated (response rate: 80%). The mean number of colonoscopies per week was 21 (60%) were males and 50% had more than 14 years in practice. The mean procedural time was 13.8 minutes. Rates of IPB were similar between the two groups (SL-CSP; 3.6%, EMR; 3.9%). There were marginally significant predictors correlating negatively with complete resection (37.3% vs. 28.1%, p = 0.05). By multivariate analysis, female gender (OR, 0.15; 95%CI, 0.02–1.06; P = 0.06) and Paris 0-IIa morphology (OR, 0.12; 95%CI, 0.01–1.19; P = 0.07) were marginally significant predictors correlating negatively with complete resection.

Conclusions: There is a remarkable heterogeneity in the techniques used for removal of polyps <20 mm among Spanish endoscopists. Cold forceps, hot biopsy forceps and EMR are the preferred techniques for removing small polyps. Cold snare polypectomy is the preferred technique for polyps <10 mm, respectively. The use of cold snare for removing small and diminutive polyps is most frequent among gastroenterologists with a greater dedication to endoscopy (cold polypectomy volume per week and performing advanced endoscopy) and among endoscopists with less than 10 years in practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0177 COLD SNARE POLYPECTOMY WITH SUBMUCOSAL LIQUID LIFT FOR 6-10MM COLONIC POLYPS: A RANDOMIZED NON-INFERIORITY TRIAL
1Gastroenterology, Konstantopoulo Hospital, Athens/Greece
2Gastroenterology, Venteziemon General Hospital, Heraklion/Greece
3Histopathology, Konstantopoulo Hospital, Athens/Greece
4Gastroenterology, General Hospital of Trikala, Trikala/Greece
5University of Crete Medical School, Heraklion/Greece

Contact E-mail Address: gpapast@gmail.com

Introduction: Cold snare polypectomy is an established method for the resection of small colorectal polyps (SCPs); however, significant incomplete resection rates still leave room for improvement. We aimed to assess the efficacy of cold snare polypectomy, with liquid lift (SL) and EMR for sessile or flat colorectal polyps <20 mm. The aims were to determine any significant differences in resection rates, technical difficulties, and related morbidity for cold snare polypectomy (CSPP) and EMR when comparing small polyps (<10 mm) and polyps 11–20 mm.

Aims: To assess the efficacy of cold snare polypectomy for resection of sessile or flat colorectal polyps smaller than 20 mm.

Methods: A randomised controlled trial was performed at the University of Crete Medical School, Heraklion, Greece. Two different groups were compared: 1) Cold snare polypectomy with submucosal liquid lift (CSPL) and 2) EMR. Randomisation was performed by central allocation. No routine preprocedural computed tomography was performed. A total of 168 patients were included. The baseline characteristics were comparable between the two groups.

Results: A total of 168 patients were included. The mean number of colonoscopies per week was 21 ± 12.3. Half of participants performed endoscopies for ≥3 days per week and 49.6% did not perform advanced therapeutic endoscopy. The techniques used for the excision of polyps smaller than 20 mm by Spanish clinicians are summarized in Table 1. Significant differences were noted in the polypectomy techniques used for the resection of polyps 1–3 mm, 6–9 mm and 10–19 mm in diameter; being cold forceps, hot snare and endoscopic mucosal resection (EMR), the preferred techniques respectively for the different sizes. However, for polyps 4–5 mm in size, both the cold snare and cold forceps were the most commonly used techniques, though no method was use more often than the other. Years in practice, colonoscopy volume per week and performing advanced therapeutic endoscopy were associated with different choices of polypectomy technique. For polyps measuring 4–5 mm, cold snare was the most common among endoscopists who preferred ≥20 colonoscopies in week (≥20 colonoscopies/week < 20 colonoscopies/week, 42.4% vs. 26.6%, p < 0.05), among those who performed endoscopies ≥5 days/week (≥5 days/week < 3 days/week, 58.5% vs. 66.7%, p = 0.05) and among those who performed advanced endoscopy (advanced endoscopy vs no advanced endoscopy, 40.4% vs. 29.2%, p < 0.05). However, cold forceps was the preferred technique among endoscopists who performed endoscopies <7 days per week (38.9% vs. 23.1%, p = 0.05) and among those who performed <10 colonoscopies/week < 20 colonoscopies/week, 28% vs. 13%, p < 0.05). and among those with less than 10 years in practice (<10 years vs. >=10 years, 27.2% vs. 17.7%, p < 0.05). However, hot snare polypectomy was most frequent among endoscopists who performed more colonoscopies ≥20 colonoscopies/week < 20 colonoscopies/week, 28% vs. 13%, p < 0.05) and among those with more than 10 years in practice ≥10 years vs. <10 years, 54.5% vs. 44.7%, p < 0.05).

Conclusion: There is a remarkable heterogeneity in the techniques used for removal of polyps <20 mm among Spanish endoscopists. Cold forceps, hot biopsy forceps and EMR are the preferred techniques for removing small polyps, small polyps and measuring 10 to 19 mm, respectively. The use of cold snare for removing small and diminutive polyps is most frequent among gastroenterologists with a greater dedication to endoscopy (cold polypectomy volume per week and performing advanced endoscopy) and among endoscopists with less than 10 years in practice.

Introduction: Colonoscopic polypectomy effectively reduce the incidence of colorectal cancer. Variations in the technique have been implicated in the effective- ness of the resection and in the complication rates. However, there is no consensus regarding the optimal polypectomy technique for diminutive (<5mm) colorectal polyps. There are scarce of data about polypectomy practices among European endoscopists.

Aims & Methods: To determine the different techniques used by Spanish endoscopists for resection of sessile or flat colorectal polyps smaller than 20 mm. A 70-item survey was sent by email to all gastroenterologists in all Spanish hospitals (1678 gastroenterologists). The survey was conducted from December 2015 to February 2016.

Results: The rate of participation was 20.3% (341/1678). All physicians indicated they were practicing gastroenterologist (none were trainees). Most respondents (60%) were males and 50% had more than 14 years in practice. The mean number of colonoscopies per week was 21 ± 12.3. Half of participants performed endoscopies ≥ 3 days per week and 49.6% did not perform advanced
colonoscope. Some operators participated in a follow up session in order to assess the learning curve. Results: On average, experts required the shortest time to reach the caecum, followed by video gamers, trainees then novices. Polyp detection rate (as a proportion of total number in the model simulator colon) was the highest in the novices (91.67%) followed by the experts (86.11%), then equally, trained and video gamers (79.17%). Four out of nine participants attended the second session where they were asked to repeat the procedure from the first session. Each participant had a lower caecal intubation time during session 2 in comparison with session 1, with a median improvement of 10% and 20%. Each of the participants also had the same or higher polyp detection rate with range of improvement between 0% and 25%. Qualitative assessment of feedback from all participants indicated that most operators felt that the role of the novel test was likely to be a diagnostic probe in an out of hospital setting. Expert operators felt that training in the device was easier but also provided less ability to torque steer due to automated sequences.

Conclusion: This project is the first step in identifying specific training needs and providing evidence for early diagnosis of cancer. This study also indicated the potential to reduce the length of time for skills acquisition associated with standard colonoscopy training through the use of semi-automated robotic devices.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: To reduce costs of colorectal cancer screening, a reset and discard strategy has been proposed for small polyps. The American Society of Gastrointestinal Endoscopy (ASGE) recommends achieving a diagnostic accuracy >90%, before implementing it (1). Narrow band imaging (NBI) is increasingly available and the NICE classification is frequently used to reach real time histologic classification. Endoscopists usually rely on short sessions, online courses or self-education for training in NBI, so we evaluated the learning curve in subjects with no previous endoscopic experience and their subsequent performance in patients with polyps ≤7 mm.

Aims & Methods: Participants (4th or 5th year medical students) attended one two-hour session in which the NICE classification was taught, followed by a 1-week interval (session 2). Participants were divided in two groups: group A (expert group) underwent endoscopic training with M-NBI and endoscopic images were taken and recorded in a filing system. After the endoscopy was completed, a determination was made regarding the presence or absence of NBI on the endoscopic images. The morphology of the NBI was determined for cases in which NBI was present and in whom NBI was seen in more than half of the region before the results of histopathological examination of the lesions were known. The morphological characteristics of the lesions were classified as regular NBI or irregular NBI according to our previous report (1).

The primary endpoint was the diagnostic performance of morphologic analysis of the NBI (accuracy, sensitivity, specificity) for early colorectal cancer taking irregular NBI as an indicator. The secondary endpoint was the difference in the prevalence of irregular NBI between mucosal (M) or SMs-colonoscopy (submucosal invasion: ≥1000 micrometers) and SM-1 (submucosal invasion ≥1000 micrometers).

Results: During the two-hour intervention, eight of the 20 endoscopists were rated as ‘expert’ (as they achieved >90% accuracy in the NICE diagnosis) and 12 of the 20 endoscopists were rated as ‘novice’ (as they achieved ≤90% accuracy in the NICE diagnosis). The mean±SD (range) in the diagnostic accuracy for early colorectal cancer was 86.5±3.1% (79–94% in the expert group) and 70.8±4.5% (62–79% in the novice group), respectively. There was no significant difference in the prevalence of irregular NBI in M or SMs cancer and SM-m cancer (p = 0.727, chi-square test).

Conclusion: These findings suggest that in colorectal epithelial neoplasms in colorectal epithelial neoplasms visualized by magnification endoscopy, the morphology of the NBI was a useful marker in the differential diagnosis of adenoma and carcinoma using magnifying endoscopy.

PHASE 3 TRIALS

Aims & Methods: Colon cleansing efficacy of NER1006 was compared to three currently used bowel preparations in patients aged ≤65 years and in patients aged >65 years. NER1006 was compared to sodium picosulfate + magnesium citrate (NaPic + MgCit), trisulfate and 2L PEG with ascorbate (2L PEG + Asc), in three multicentre randomised Phase 3 clinical trials: DAYB1, NOCT2 and MORA3, respectively. 2L PEG + Asc was administered over 2 days and in the MORA trial, the doses of NER1006 were administered either in 1 day morning-only (N1D) or, as with 2L PEG + Asc, split over 2 days (N2D). In the DAYB study, NER1006 was administered evening-only the day before colonoscopy (NDB). Treatment-blinded central readers rated colon cleansing according to the Harefield Cleansing Scale. Following segmental scoring, overall colon cleansing was graded from A to D. Grades A and B were judged as successful cleansing; grades C and D were judged as failed cleansing.

Results: Pooling the data from the three trials to assess colon cleansing in the two age groups showed successful cleansing in 80.5% (1158/1438) of patients aged ≤65 years and 68.9% (277/400) of patients aged >65 years (difference of 9.3%, P = 0.098; 95% CI: -3.7–5.6%). Within each trial the difference in colon cleansing in the age groups indicated that the effect of increased age on cleansing efficacy was less in the NER1006-treated patients than in patients treated with the active comparators (Table 1). For example, in patients treated with NER1006 the rate of successful colon cleansing in patients aged >65 was 5.2% higher than in patients aged ≤65, whereas in patients treated with NaPic + MgCit, there was 3.5% lower successful cleansing rate in patients aged >65 than in patients aged ≤65.

Conclusion: NER1006 was efficacious in successful colon cleansing in patients aged >65 (in whom successful colon cleansing is harder to achieve) as well as in patients aged ≤65. Statistical significance was not reached in these comparisons.

P0184 ACHIEVING ADEQUATE LEVEL BOWEL PREPARATION WITH EVENING/MORNING OR MORNING-ONLY SPLIT-DOSING REGIMENS OF NER1006 VERSUS STANDARD 2L PEG WITH ASCORBATE: POST HOC ANALYSIS OF A PHASE 3 TRIAL

R. Bisschops1, L. Clayton2

2Clinical Development, Norgine Ltd., Harefield, Uxbridge, United Kingdom

Contact E-mail Address: raf.bisschops@uzleuven.be

Introduction: Effective colonoscopy requires effective bowel preparation. For detection of polyps larger than 5 mm, an ‘adequate’ segmental cleansing level has recently been defined as ≥2 or more on the Boston Bowel Preparation Scale (BBPS). The Phase 3 trial MORA compared NER1006 as an evening/morning split-dosing or a morning-only dosing regimen, against 2L PEG with ascorbate as an evening/morning split-dosing regimen (2L PEG + Asc). Treatment-blinded central readers assessed the bowel cleansing efficacy using both the Harefield Cleansing Scale (HCS) and the BBPS. This post hoc analysis shows the BBPS scores for the two primary endpoints, in those patients who had a readable colonoscopy.

Aims & Methods: In the MORA trial, 789 patients aged 18–85 were randomised to bowel preparation with morning-only or evening/morning split-dosing using either NER1006 or 2L PEG + Asc. Adequate level cleansing success was assessed according to the BBPS for both overall colon (all segments ≥2) and right colon cleansing (segmental score ≥2). The analysis includes all subjects for whom colonoscopy videos were available for assessment by central readers.

Results: A total of 792 patients were analysed. When using an evening/morning split-dosing, 249/262 (95%) patients on NER1006 achieved adequate level overall colon cleansing compared to 232/260 (89%) on 2L PEG + Asc (Table 1). Using morning-only dosing, 243/270 (90%) patients on NER1006 achieved the same. Using evening/morning split-dosing, 254/262 (97%) patients on NER1006 achieved adequate level right colon cleansing compared to 242/260 (93%) on 2L PEG + Asc. Using morning-only dosing, 253/270 (94%) patients on NER1006 achieved adequate level right colon cleansing. Adequate level cleansing success was achieved significantly more often with NER1006 evening/morning split-dosing than 2L PEG + Asc, both in the overall colon (P = 0.013) and in the right colon (P = 0.042). The slight improvement seen with NER1006 morning-only dosing in the cleansing rate of the overall colon and right sided colon was not statistically significant. Table 1: Adequate level cleansing of the overall colon and right colon (BBPS segmental scores ≥2) as determined by treatment-blinded central readers

| preparation, defined as Boston Bowel Preparation Scale score ≥3. From our data, 81% (n = 1669) of procedures had adequate bowel cleansing (data unavailable for 96.4%). The ESGE recommends a minimum standard of ≥90% of all diagnostic and screening colonoscopies visualize the whole caecum (excluding those that have no indication to reach the caecum). Only 55% of practitioners routinely record cecal intubation rate. The caecum was the intended endpoint in 66% of procedures. For those diagnostic and screening colonoscopies where the caecum was the intended endpoint (n = 1390), 93% reached the endpoint but only 78% had this endpoint photo-documented. The ESGE recommends that adenoma detection rate (ADR) should be used as a measure of adequate inspection at screening or diagnostic colonoscopy in patients aged 50 years or more. ADR was routinely recorded by only 18% of practitioners. Polyp removal rate is routinely recorded by 30% of practitioners, and polyp retrieval rate by 23%. Conclusion: Our findings indicate that some important performance measures recommended by ESGE are not currently being achieved in practice. By providing a self-assessment tool and as a next step, by individual consultations with national Group members, ECQI hopes to improve clinical practice standards. Further information on the ECQI Group initiative can be found on www.ecqigroup.eu

P0186 SEDATION IN GASTROINTESTINAL ENDOSCOPY: CURRENT PRACTICES OF GREEK GASTROENTEROLOGISTS

A. Protopapas, E. Stournaras, G. Neokosmidis, A. Protopapas
1st Department Of Propaedeutic Internal Medicine, Ahepa Hospital, Thessaloniki, Greece

Introduction: When it comes to gastrointestinal endoscopy, considerable heterogeneity is observed between gastroenterologists regarding the use of sedation and the preferred sedative agents. The sedation protocol used by a gastroenterologist may have a significant effect on endoscopic quality, patient cooperation and both the doctor’s and the patient’s satisfaction with the procedure.

Aims & Methods: The aim of this study was to document current endoscopic practices of Greek gastroenterologists and investigate whether they use sedation to perform gastrointestinal endoscopy and which pharmaceutical agents are usually involved. A 39-item online questionnaire was devised, addressing demographic data, use of sedation in endoscopy and monitoring practices. It was subsequently made available to 509 Greek gastroenterologists by e-mail.

Results: A total of 195 questionnaires were successfully completed (38.3%). 49 gastroenterologists did not use sedation to perform esophagogastroduodenoscopy (EGD) or colonoscopy (25.1%). The younger gastroenterologists were more likely to use sedation (p = 0.005). Among those using sedation, midazolam was the most frequently used agent in EGD (50%) and the combination of midazolam/fentanyl was the most frequently used in colonoscopy (24.6%). Followed by midazolam (21.9%). Out of 137 physicians using benzodiazepines (midazolam, diazepam) as part of their endoscopic sedation regimen, 91 (66.4%) used midazolam during the procedure. Medical issues (33%), inadequate training in the use of propofol (73%), training in the use of midazolam (21.9%), and other agents (30%) were cited as the main reasons for not using propofol. As for the medication used during the procedure, the majority of gastroenterologists used diazepam and oxygen saturation (96% and 97% respectively). Regarding the safety equipment, 145 (74%) used oropharyngeal airway devices or laryngeal airway masks, 92 (47%) to endotracheal intubation equipment and 86 (44%) to a defibrillator. When asked to rate their level of satisfaction with their preferred sedation regimen (or with not using sedation) in a scale of 1 to 10, 72 physicians rated their satisfaction level as 9 or 10 (36.9%) and 92 as 7 or 8 (47.1%). While there was no significant difference in terms of satisfaction between the doctors that used sedation and those who did not, there was a statistically significant difference between the gastroenterologists that used propofol and other sedation agents (p = 0.003). When asked on their preferred method of sedation, if they were themselves subjected to gastrointestinal endoscopy, 104 physicians opted for propofol-based sedation regimens (53.3%).

Conclusion: Gastrointestinal endoscopy is performed with the use of sedation by the majority of Greek gastroenterologists. Propofol-based regimens are seldom used in everyday clinical practice, despite a vast number of Greek gastroenterologists identifying them as their preferred regimen, in case they themselves should undergo endoscopy. Compared to a past survey, Greek gastroenterologists are still hesitant about using propofol. However, an increasing tendency towards administering propofol without the aid of an anesthesiologist is observed. Also, physicians using propofol seem to be more satisfied with their sedation practices than the doctors using other sedation regimens. Absence of a distinct legal framework, inadequate training and fear of cardiopulmonary complications are identified as the main reasons preventing Greek gastroenterologists from using propofol.

Aims & Methods: We locally adapted a company reporting system for colonoscopy by adding in a dedicated tab, selected procedure indicators. Endoscopic QI data from reporting system DB and pathologic results from another DB were extracted and merged together in a separated DB. On a regular period basis or on request, key QI are calculated and extracted. It includes adenoma detection rate (ADR), polyp detection rate, caecal intubation rate, quality of bowel preparation score and type of sedation. During a first period of 6 months starting in January 2016, endoscopists were encouraged to fulfill the dedicated tab on a voluntary basis. In a second period, filling of QI was turned to be mandatory. The completeness of QI recording was evaluated across both periods, and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and to published targets.

Results: During the 6 months "mandatory-filling" period (July-December 2016), 1802 colonoscopies were performed with a QI tab fully filled in 100% of cases compared to 63.1% after the "free-filling period" (p<0.0001). The global caecal intubation rate for screening colonoscopy was 92.9%. Mean Boston bowel preparation score was 7.2 ± 0.76 with 86.9% of cases with adequate preparation (Boston score >5; 89.9% among outpatients and 81.9% among inpatients). Colonoscopies were performed under propofol sedation in 94.1%. During this second period, the global ADR was 32.4% (range: 0%-55.7%). The polyp detection rate was 44.4% with a mean of 1.19 polyp removed by colonoscopy.

Conclusion: This study illustrates that quality indicators for colonoscopy assessment in a Belgian tertiary hospital endoscopy unit could be easily implemented with limited human resources by adapting a company reporting system and link it to a dedicated database. Moreover, filling of QI items is mandatory for system implementation success. Our results were consistent with goals required by international guidelines. This system allows giving feedback to individual endoscopists for self-performance assessment and might be easily adapted in the future following guidelines updates.

Aims & Methods: The aim of this study was to develop a computer-aided detection (CAD) algorithm for colonoscopy using deep learning. To evaluate the developed CAD algorithm, we retrospectively viewed colonoscopy videos from a previous randomized controlled study (UMIN000017083) conducted from April 2015 to October 2015. All examinations were performed using CF-H290ZI (Olympus Medical Corp., Tokyo, Japan). In this study, two endoscopists (M.M., Y.M.) manually annotated 43 colonoscopy videos with 238 min of 17,903,967 frames. These videos included 75 polyps (48 neoplasms, 27 non-neoplasms), and annotations were made on the presence or absence of polyps in every frame. Forty-three videos were divided into 300 short video for machine learning and validation process. Among 300 short videos, 246 were used for the machine-learning process. The remaining 54 (33 included a lesion used to validate the CAD algorithm and 21 without lesion) were tested with a modified version of Caffe with 3-Dimensional Convolutional Networks (a kind of deep learning) was used for the CAD algorithm. The validation samples were analyzed using the CAD algorithm and its output as the probability of the presence of a lesion in each video frame. The receiver operating characteristic (ROC) analysis was performed to evaluate the efficacy of the CAD algorithm.

Results: The mean probability of a poly-positive video was 62.1 ± 27.9%, whereas that of a poly-negative video was 18.1 ± 24.6% (P < 0.001). The area under the ROC curve was 0.887 and the positive probability 0.90 in full present. The present CAD algorithm could detect a polyp with 90.6% sensitivity and 76.2% specificity.

Conclusion: Our preliminary results showed that state-of-the-art artificial intelligence has the potential for achieving automatic detection of colorectal polyps. A prospective study is now planned after more machine-learning sessions.

P0192 TREATMENT OUTCOMES OF COLD FORCEPS POLYECYTOMY FOR PATIENTS WITH DIMINUTIVE POLYPS: A PROSPECTIVE FOLLOW-UP STUDY

Dept. Of Gastroenterology, JCHO Shiga Hospital, Otsu,Japan

Contact E-mail Address: hirosehas@belle.shiga-med.ac.jp

Introduction: The results of the National Polyp Study are premised on the removal of all adenomatous lesions. Cold forceps polypectomy (CFP) using jumbo biopsy forceps is a simple and safe technique used for diminutive polyps (<5mm). The recurrence rate after CFP for patients with diminutive polyps has not been elucidated.

Aims & Methods: We have prospectively enrolled patients with diminutive polyps treated with CFP from June 2008 to March 2017. Magnifying colonoscopy was used for all procedures. The location, size, endoscopic findings and procedures were recorded. The patients who have undergone CFP had their follow-up colonoscopy in one year after CFP.

Results: CFP was performed for total 515 polyps from 277 patients. The size of the polyps was <3mm/4mm/5mm: 79%/54%/37%. The rate of one-bite polypectomy for adenoma was <3mm/4mm/5mm: 79%/54%/33%. There was no significant difference in the one-bite rate between endoscopists’ experience. No cancer was observed in histology. Rates of delayed bleeding after CFP was 0.19% (1/515). Concomitant use of anticoagulation use of antiplatelet drugs was found in 14% (72/508), and none of them experienced delayed bleeding. No perforation occurred. Seventy-five patients had their follow-up colonoscopy so far. There are no polyps on suspicious residual or recurrent lesion. Among 75 patients, 62 had less than two polyps removed at their first colonoscopy (Group A). On the other hand, 13 patients had more than three polyps removed at their first colonoscopy (Group B). Follow-up colonoscopy revealed that the rates of newly discovered polyps in the same segment were 8% and 23% in groups A and B, respectively. The rates of newly discovered polyps in the different segment were 27% and 61% in groups A and B, respectively. When the initial CFP was performed by the endoscopist with the experience of <5 years/5-9 years/10 years/more than ten years, the rates of newly discovered polyps found at follow-up colonoscopy was 54% (14/26)/42% (8/19)/37% (11/30), respectively.

Conclusion: The rate of one-bite polypectomy was significantly higher for diminutive polyps especially less than 3 mm. Importantly there are no polyps on suspicious residual in the follow-up colonoscopy. CFP is a safe and effective option for diminutive polyps (5mm). Although the rate of one-bite polypectomy was not related to the endoscopists’ experience, adenoma detection rate is seemed to be low in young endoscopists. Since achievement of “clean colon” is very important, the multiple colonoscopy examination are necessary to achieve “clean colon” especially if the patients have more than two polyps at the first examination.

P0193 EFFICACY OF Cimetropium Bromide on POLYP DETECTION DURING COLONOSCOPIC WITHDRAWAL: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED, CLINICAL TRIAL

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of

Contact E-mail Address: salupul@naver.com

Introduction: Colonoscopy is the most effective method for preventing colorectal cancer, as it offers easy detection and resection of polyps. Cimetropium bromide was recently developed (Olympus Medical Systems Corporation, Tokyo, Japan) for sedation and external compression, patients’ pain and satisfaction, adenoma detection rate, and offers potential advantages over standard colonoscopy technique in terms of effective- ness and convenience of colonoscopy.

Disclosure of Interest: H. Neuhaus: Honoraria and consultancy fees from Olympus Medical Systems Corporation. All other authors have declared no conflicts of interest.

Aims & Methods: To evaluate the efficacy of the novel motorized spiral overtube. This may have advantages in cases of difficult standard colonoscopy to facilitate cecal intubation on the one hand and in all colonoscopies in safe and effective option for diminutive polyps (<5 mm). Although the rate of one-bite polypectomy for adenoma in EMR specimen was histologically proven to have R0 en-bloc resection. All other therapeutic interventions could also successfully be conducted (elip n=3, argon plasma coagulation n=1, tissue sampling n=2). Two mild adverse events were recorded (mild superficial mucosal lesions without delayed bleeding occurred). Conclusion: This study represents the first clinical evaluation of the novel motorized spiral endoscope for examination of the colon. Our data show that it is effective and safe for diagnostic and therapeutic colonoscopy. It may also have potential advantages over Tokyo, Far standard colonoscopy technique in terms of effective-
results in colonic spasmolysis and may improve polyp detection. We studied the effect of cimetropium bromide on polyp detection during colonoscopic withdrawal.

Aims & Methods: Patients undergoing colonoscopy for screening examinations were included and randomized at cecal intubation to receive either 5mg cimetropium bromide or placebo. We evaluated the polyp detection rate (PDR), adenoma detection rate (ADR), and advanced ADR (AADR) in the right side colon as well as in the colorectum.

Results: A total of 181 patients were analyzed in this study. Cimetropium group consisted of 90 patients, while placebo group consisted of 90 patients. PDR, ADR, and AADR were not significantly different in cimetropium and control groups (62.6% vs. 66.6%, P = 0.571; 51.6% vs. 47.7%, P = 0.603; 3.2% vs. 7.7%, P = 0.187; respectively). Similarly, PDR and ADR in the right side colon were not statistically different between the groups (46.1% vs. 47.7%, P = 0.827; 32.9% vs. 35.5%, P = 0.714; respectively).

Conclusion: Cimetropium bromide does not improve the PDR or ADR in the right side colon or the colorectum. Thus, administration of cimetropium bromide can be used during colonoscopic withdrawal.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0195 WOMEN AWAKE FASTER THAN MEN AFTER EOG-MONITORED PROPOFOL SEDATION - FIRST PROSPECTIVE OBSERVATIONAL STUDY OF GENDER DIFFERENCES IN PROPOFOL DOSES AND RECOVERY TIMES FOR COLONOSCOPY

A. Riphau1, M. Slotije1, J. Bulla1, C. Keil1, C. Mentzel1, V. Limbach1, B. Schultz2, C. Unzicker1

Introduction: Sedation for colonoscopy by using intravenous propofol has become standard in many Western countries.

Aims & Methods: While gender-specific differences have been shown for general anesthesia used in dentistry, no such data exist as yet for gastrointestinal endoscopy. In a prospective observational study at an Academic teaching hospital of Hannover Medical School 219 patients (108 women and 111 men) scheduled for colonoscopy were included. Sedation was induced using EOG monitoring during a constant level of sedation depth (D0 to D2) performed by trained nurses or physicians after bodyweight adjusted loading-dose.

Main outcome measures: Primary endpoint was the presence of gender-specific differences in wake-up time (time from end of sedation to eye-opening and the complete orientation of the patient); secondary outcome parameters analysed were total dose of propofol, sedation associated complications (bradycardia, hypotension, hypoxia, apnoea), patient cooperation and patient satisfaction. Multivariate analysis was performed to correct confounding factors such as age and BMI.

Results: Women awaked significantly faster than men to a time of eye opening (26.2 ± 3.69 min. vs. 34.13 min. p = 0.005) and time until complete orientation 9.14 ± 3.88 min vs. 10.4 ± 3.71 min (p = 0.008); propofol dosage was not significantly different, with some trend towards more propofol per kg body weight in women (3.98 ± 1.81 mg vs. 3.72 ± 1.75 mg, p = 0.232, n.s.).

The effect of gender differences should be taken into account upon propofol induced sedation for gastrointestinal endoscopy. That includes adequate dosing for female as well as cautiousness regarding potential overdosing of male patients.

Trial registration: ClinicalTrials.gov (Identifier: NCT02687568). Data were presented at a national meeting (DGEBV) in Germany.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: Prevention of complications secondary to endoscopic resection techniques (EMR or ESD) requires avoiding deep thermal damage and increase mucosal healing. Platelet-rich plasma (PRP) has demonstrated efficacy in pre-clinical endoscopic resection models [1]. The EndoPRP study was a prospective single-center study to assess the efficacy of PRP on endoscopic resection of large sessile lesions (larger than 35 mm). (Study registered at ClinicalTrials.gov: NCT02931149)

Introduction: In the EndoPRP study patients (males and females, aged 52–80) were assigned to receive PRP (6–15 mL): 1) Endoscopic Shielding Technique (EST, n = 4), applying PRP as a shield after standard resection technique, or ii) Submucosal injection (SMI, n = 11), performing a submucosal injection of PRP prior to EMR or ESD. Patients were informed and accepted to participate with a written consent. PRP was obtained from a sample of patient’s blood (18–36 mL) drawn at the time of endoscopy. Patients underwent endoscopic follow-up after 4 weeks. The efficacy of PRP was assessed by the incidence of adverse events (delayed bleeding or perforation). Mucosal healing rate (MHR) was defined as a percentage of mucosal restoration after 4 weeks.

Results: Shielding technique with PRP performed in 4 lesions at rectum (Æ 53.7 ± 20.6 mm, range 35–80 mm). Submucosal injection of PRP was used in 11 lesions (2 at antrum, 3 at rectum, and 8 at colon) (Æ 41.6 ± 9.6 mm, range 35–70 mm). Delayed bleeding occurred after EMR of 1 lesion (no required blood transfusion or endoscopic treatment; 6.6% of all lesions: 1 patient at EST group, 0 patients at SMI group). MHR was significantly higher in patients treated with PRP vs. SMI than EST (87.5% vs. 78.6%; p = 0.03).

Conclusion: PRP applied as a shield over the scar or as submucosal fluid cushion has proved clinical efficacy in endoscopic resection of large lesions. Submucosal injection of PRP has showed better mucosal healing rate as compared with standard shielding technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

with a defined AE. Treatment options, including none required, were taken from Spanish- and English-language guidelines examined included. Over 62% of providers were gastroenterologists and anaesthesiology nurses. Local guidelines determined practice in most cases, and propofol and midazolam were the main sedation agents employed. The most common AEs reported were hypotension and bradycardia, with 9% and 4% of respondents, respectively, estimating each to occur during >10% of procedures. Mean provider time required to treat AEs ranged from 1.7 minutes for mild desaturation in Germany to 3.10 minutes for cardiac arrest in the USA. Accounting for interventions and provider time, the mean direct costs per range from EUR 12 for bradycardia in Germany to USD 3,877 for cardiac arrest in the USA (Table). When costs were “fully loaded” these became EUR 39 and USD 19, 722, respectively. Although of low direct cost, bradycardia in Germany was reported to cause procedure termination or substantial delay in 3.3% of cases. In Euro countries, the median of direct costs for an AE was EUR 40 (IQR: 29–67). When costs of outcomes of AEs were included the median “fully loaded” cost reached EUR 301 (IQR: 115–738).

Table: Costs of select adverse events by country. FL: Fully-loaded (costs including hospital administration, time, inpatient stays, delays, and cancellations, but excluding legal costs).

Conclusions: Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

P0200 COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD); KNIFE-ASSISTED SNARE RESECTION (KAR) AND SPAIN RECURRENCE RATE: A WESTERN EUROPEAN EXPERIENCE IN
J. C. Marin-Garcia1, J.B. Diaz Tasende1, P. Cancelas-Navia2, S. Rodriguez-Castro1, B. Gonzalez-Jimenez1, J. Hernandez-Marin1, J. Sanchez-Montero1, J. C. Marın-Gabriel1, J. C. Marı́n-Gabriel2, J. C. Marín-Gabriel2

Introduction: To compare the recurrence rate after R0 and R1/Rx endoscopic resection (ER), on an ESD “intention-to-treat” basis, in a Western European setting where CR-ESD is performed by non-experts. 2.) To evaluate the impact of LM involvement on local recurrence when neoplasms without risk factors for lymph node metastasis are resected en bloc. We prospectively included 89 consecutive CR neoplasms planned for ESD from September 2008 to December 2015. When technical difficulties arose or for patient’s safety reasons, we performed a KAR. Kaplan-Meier survival curves were used to assess the recurrence rate over time. The end of follow-up was considered when a local recurrence occurred or at the end of the surveillance period in those patients who did not develop the event. Comparisons were made using the log-rank test. The recurrence rate during follow-up was stratified considering advanced histology, en bloc resection and R0 resection.

Results: The ER was aborted in 5 cases (perforation n = 3; technical difficulties n = 2). Surgical intervention was needed after ER because of submucosal or linfoc娠al invasion in 4 patients. Five out of the remaining 80 cases, were lost to follow-up. Finally, 75 CR neoplasms were included in 74 patients (43 male; 58.1%). Median age was 71 years (range: 37–93). Median size of the lesions was 32 mm (range 10–100). Histology was 26 (34.7%) Vienna category 3; 46 (61.3%) Vienna 4 and 3 (4%) sm1/Vienna 5. En bloc resections were obtained in 44 cases (58.7%); 33 ESD (48%) and 11 KAR (14.7%). The ER finished as an R0 resection in the 31 remaining lesions (41.3%). R0 resections (n = 23; 30.7%) were achieved in 18/33 ESD and 5/42 KAR [OR: 8.9 (CI 95%: 2.8–28.3); p < 0.0001]. The median follow-up period was 16 months (1–91). Local recurrence occurred in 11 cases; 9 of the latter throughout the first year (81.8%). No surgery was needed because of recurrence. The overall recurrence rate at 36 months was 15%. The recurrence rate at 3 years showed a statistical significant difference when R0 resections were compared with R1/Rx: 0% vs. 21.5% (p = 0.03). When results were stratified according to histology and en bloc resections, no significant differences were found in the recurrence rate. When en bloc resections in pTa/T1b (sm1); pT2: (sm2); pT3 (sm3) lesions (n = 44) were analysed separately; LM distribution in LM0 (52.3%), 18 LM1 and 3 LMx (6.8). There was a non-significant trend concerning the recurrence rate when LM0 (n = 23) lesions were compared with LM1/LMx (n = 21): 0% vs. 14.8% at 3 years; p = 0.06.

Conclusions: ESD R0 resections were 9 times greater than that of KAR on an ESD “intention-to-treat” basis. R0 resections were associated with lower recurrence rates in comparison with R1/Rx resections. LM involvement increased the recurrence rate but without a statistical significance when it was the only pathological risk factor for recurrence and the specimen was resected en bloc.

P0201 ASSOCIATION BETWEEN SIZE, LOCATION AND HISTOLOGICAL CHARACTERISTICS OF COLORECTAL LATERALLY SPREADING TUMORS

Introduction: Laterally spreading tumors (LST) are important precursors of colorectal cancer (CRC). The endoscopic characteristics of the LSTs, such as size and location, appear to correlate with the histological findings1, 2, which is an essential data for the decision of the best therapeutic procedure to be carried out.3

Aims & Methods: To determine the association between size, location and the histological characteristics of colorectal LSTs by reviewing of the colonoscopy and histopathological reports of the LSTs endoscopically removed between October 2013 and June 2015 at the digestive endoscopy department of a tertiary hospital. The Vienna revised classification was used for the adenomatous lesions5, and the World Health Organization (WHO) classification for the “sessile serrated adenomas” (SSA)6, 7. The regions of the colon were referred to

Contact E-mail Address: lucasndc@gmail.com

as either "proximal" or "distal" colon. Thereafter the division into six anatomical segments was considered (cecum, ascending, transversal, descending, sigmoid and rectum). 

Results: A total of 218 LSTs were included in this study. Most patients (59.4%) were female. The mean age was 66.1 years, and the average size of the LSTs included was 1.6cm (±1.9). The most common proximal colon was the most common site (73.4%) of occurrence of the LSTs, with 34% being at the ascending colon. The most common histological type was the low grade dysplasia adenoma (Vienna 3), followed by the SSA without dysplasia with 21.6%. There was significant correlation between size and histology (p < 0.005), where the adenomatous lesions were found to be larger than the other categories. The SSAs, however, did not show this association. We identified association between location and histological type (p < 0.005): the adenomas with low grade dysplasia were most prevalent in the proximal colon. However, when the subdivision of the colon into anatomical segments was considered, the SSA without dysplasia was the most common type at the ascending colon.

Conclusion: There is association between the size and the histological characteristics of colorectal LSTs. In cases of high grade dysplasia were found to be larger than the other classifications. This association, however, is not observed between SSAs lesions. There is association between location and histology; with the SSAs without dysplasia being the predominant type at the ascending colon.

P0202 SAFE AND SUCCESSFUL RESECTION OF DIFFICULT GI LESIONS USING A NOVEL SINGLE-STEP FULL-THICKNESS RESSECTION DEVICE (FTRD)

P.V. Valli, J. Mertens, P. Bauerleind Division Of Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: piero.valli@usz.ch

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are well-established and effective techniques for the endoscopic resection of mucosal neoplasms along the gastrointestinal (GI) tract. However, these procedures are limited to superficial lesions. In the case of deeper ingrowth into the gut wall as well as anatomic sites prone to perforation, the novel full-thickness resection device (FTRD#) opens a new dimension of possibilities for endoscopic resection.

Aims & Methods: Sixty patients underwent therapeutic endoscopic full-thickness resection (eFTR) at our institution. The procedures were carried out as follows: First, the target lesion is marked with electrocautery and the endoscope is then retracted. The full-thickness resection device (FTRD, Ovesco® Endoscopy AG, Tübingen), is fitted onto a therapeutic endoscope. The endoscope with the FTRD# is advanced to the previously marked lesion. Grasping forceps are used to take hold of the target lesion and carefully pull it into the plastic cap of the FTRD#. Immediately after deployment of the OTSC®, eFTR is performed using the hyperthermic snare within the plastic cap. The full-thickness specimen is retrieved and processed for histopathological examination. Safety, learning curve, R0 resection rate and clinical outcome of all 60 interventions were studied.

Results: eFTR was performed for the following indications: 1. Recurrent adenomas (n = 22.3%) with a non-lifting sign after previous incomplete polypectomy and adenomas with a primary non-lifting sign on saline injection (n = 2.3%). 2. Non-lifting base after extensive piecemeal resection of a spreading adenoma (n = 0.7%). 3. Diverticulum (4.6%). 4. Polyph of the cecal appendix (5.8%). 5. Submucosal lesions (n = 5.8%). 6. Early carcinoma (n = 7.12%). 7. Follow-up resection of a malignant polyp (n = 0.6%). 8. FTR over endoloop resection (n = 2.3%). In 97% (58/60) of the interventions, the FTRD#-mounted endoscope reached the previously marked lesion and eFTR was performed (technical success). Full-thickness resection was achieved in 88% of the cases, with an R0 resection on histological examination in 79%. The clinical success rate based on follow-up histology was even higher (88%). The following adverse events occurred: Appendicitis of the residual cecal appendix after eFTR of an appendicular adenoma (1/58.2%). Minor bleeding at the eFTR site (2/58.3%). eFTR performed accidentally without proper prior deployment of the OTSC® (1/58.2%). There was no secondary perforation or eFTR-associated mortality.

Conclusion: In conclusion, after specific training, endoscopic full-thickness resection is a feasible, safe and promising resection technique. It allows complete resection of lesions affecting layers of the gut wall beneath the mucosa, without the risk of perforation. In the future, eFTR may become a valuable alternative to a surgical approach in cases where endoscopic resection was previously thought impossible.

Introduction: Narrow Band Imaging (NBI) and chromoendoscopy with methylene blue are enhancing techniques which are helpful in differentiating vascular and pit patterns of colorectal neoplasms. Therefore, they have a key-role for the adequate management of the lesions which might be candidates for endoscopic resection.

Aims & Methods: The aim of our study was to measure the interobserver agreement and the diagnostic accuracy in an endoscopic unit using methylene blue and NBI for the evaluation of the pit and vascular pattern according to the Kudo, Sano and NICE classifications of colo-rectal neoplasms, before and after an image-based training program. We retrospectively collected consecutive endoscopic images (NBI and with methylene blue) of colo-rectal neoplasms from the internal database. The image set was then evaluated by our gold standard composed by two expert endoscopists. Their evaluation resulted confident with histology reports in 88% of cases. The images set was then evaluated by the 9 endoscopists of the unit, before and after a 30-minutes image-based training program on enhancing techniques and surface colorectal patterns. NBI and colonic neoplasms’ surface and vascular patterns. Interobserver agreement was calculated using the kappa statistic by Cohen. By using the gold standard evaluation as criterion standard, the accuracy of colo-rectal neoplasms’ evaluation before and after the training was also calculated using the McNemar test. A value of p < 0.05 was considered statistically significant.

Results: A total of 30 images were obtained (see Table). Before the training process, the interobserver agreement was minimal for Kudo (0.10 ± 0.03) and Sano (0.12 ± 0.04), and poor for the NICE classification (0.24 ± 0.05). Diagnostic accuracy was 0.33 ± 0.07, 0.54 ± 0.12 and 0.60 ± 0.10 for Kudo, Sano and NICE classifications, respectively. After the image-based training program, interobserver agreement moved to moderate for the Kudo classification (p < 0.0001) and to good for Sano and NICE classifications (p < 0.0001). Diagnostic accuracy increased significantly, too, with values of 0.60 ± 0.05, 0.76 ± 0.05, 0.80 ± 0.05 for Kudo, Sano and NICE classifications, respectively (p < 0.0001).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Data regarding the yield of 2nd surveillance colonoscopy after index procedure findings of advanced colonic neoplasia (ACN) are limited. The yield of ACN at 2nd surveillance is associated with high risk index or 1st surveillance findings (1). However, previous studies are heterogenous and definition of ACN at 2nd surveillance might be increased as ACN is infrequently detected in this group. The objective of this study was to determine the safety of CSP in patients on antithrombotic medication. The safety of antithrombotic medication used during post-CSP bleeding in patients on antithrombotic medication (non-antithrombotic group). In the antithrombotic group, 106 patients with 283 polyps continued taking the antithrombotic medication; specifically, aspirin in 41 patients with 113 polyps, clopidogrel in 13 patients with 17 polyps, dual antiplatelet therapy (DAPT) in 13 patients with 18 polyps, antipatelet agents other than clopidogrel in 17 patients with 68 polyps, anticoagulant agents in 20 patients with 56 polyps, and antipatelet plus anticoagulant combination therapy in 2 patients with 11 polyps. Heperin bridging was used in 13 patients with 38 polyps. Post-CSP bleeding occurred in patients on other antiplatelet or anticoagulant agents, or on heparin bridging. Clipping after CSP was more likely used in the antithrombotic group (i.e., 13.5% vs. 4.6%; p < 0.01). No significant difference in post-CSP bleeding rate was observed between lesions with and without clipping (0% vs clipping vs. 0.34% without clipping; p = 0.55)
Conclusion: CSP is a safe procedure even in patients on antithrombotic medication; specifically, aspirin in one patient with one polyp (0.88%, 1/113), and aspirin and clopidogrel a patient with 2 polyps (11.1%, 2/18). No post-CSP bleeding occurred in patients on other antiplatelet or anticoagulant agents, or on heparin bridging. Clipping after CSP was more likely used in the antithrombotic group (i.e., 13.5% vs. 4.6%; p < 0.01). No significant difference in post-CSP bleeding rate was observed between lesions with and without clipping (0% vs clipping vs. 0.34% without clipping; p = 0.55)

Introduction: Diminutive polyps are a common finding among surveillance colonoscopies without having high prevalence of advanced histology, making their standardized removal cost-, time- and risk-intensive. Based on these considerations, the American Society of Gastrointestinal Endoscopy (ASGE) proposed the so called PIVI statement, in which diagnostic thresholds are defined that new technologies used for the real-time assessment of colorectal polyp histology should meet. Optical enhancement (OE) is a novel endoscopic pre-processing optical filter technology, in which the spectrum of the emitted wavelengths is reduced, thereby leading to enhanced visualization of the mucosal and vascular pattern.
Aims & Methods: In this study we aimed to assess whether OE can accurately predict the histology of diminutive colorectal polyps according to the ASGE PIVI criteria. A total of 106 colorectal polyps from 49 patients undergoing diagnostic or surveillance colonoscopy were included. The in vivo histology prediction using OE was compared to results of histopathology as a reference standard.
Results: The overall accuracy of OE for real-time prediction of polyp histology was 94.3% with a sensitivity, specificity, positive (PPV) and negative prediction value (NPV) of 100%, 95.3%, 85.4% and 100%, respectively. When including only high confidence (HC) predictions, the accuracy of OE increased to 96.5%. Sensitivity, specificity, PPV and NPV were 100%, 94.5%, 91.2% and 100%, respectively. In distal colorectal polyps the accuracy was 93.3% with sensitivity, specificity, PPV and NPV being 100%, 91.3%, 80% and 100%, respectively. The post-polypectomy colonoscopy surveillance intervals were predicted correctly in ≥90% of patients with OE.
Conclusion: Optical enhancement allows to accurately predict the histology of diminutive colorectal polyps in vivo in real-time and meets the PIVI thresholds for resection and discarding endoscopic polyps without histological assessment and for leaving distal diminutive colorectal polyps in place. Hence, optical enhancement can potentially reduce time, risk and costs associated with removal and histopathological assessment of diminutive polyps.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0207 BLUE LASER Imaging OPTICAL DIAGNOSIS OF COLORECTAL POLYPS: ACCURACY OF THE NICE, SANO AND WASP CLASSIFICATIONS
S. Ribiere, J. Dreanic, M. Barret, M. Camus, M. Dior, B. Brieau, S. Leblanc, F. Prat, R. Coriat, S. Chaussade
Department Of Gastroenterology, Cochin Hospital, Assistance Publique-Hôpitaux de Paris, France

Contact E-mail Address: sophie.clem.ribiere@gmail.com

Introduction: Blue Light Imaging (BLI) is a new image-enhanced endoscopic technique, meant, in association with magnification endoscopy, to help differentiate between neoplastic and non-neoplastic colorectal polyps. A variety of endoscopic classifications have been developed to guide optical diagnosis of colorectal polyps. The aim of our study was to evaluate NICE, WASP and Sano classifications for the optical diagnosis of colorectal polyps using BLI with and without magnification.

Aims: Between May 2014 and December 2015, 181 colorectal polyps in 65 patients were imaged and resected in our single center study. Each polyp was evaluated using white light endoscopy, BLI with and without magnification.

Conclusion: Our work suggests that BLI with magnification is a promising technique for the optical diagnosis of colorectal polyps with a diagnostic accuracy of 88%. Our study did not establish significant difference between the three classifications. However, the ASGE criteria for the implementation of the "resect and discard" strategy were met for the classifications of Sano and WASP with a negative predictive value for the diagnosis of adenoma beyond 90% in the resectosigmoid.

Introduction: Colonoscopy is difficult procedure, largely due to unpredictable looping during insertion. If the endoscopist is able to see the colonoscope on the image display, fewer attempt is needed to straighten the shaft of the scope. A prototype Fiber Brag Grating (FBG) scope guided endoscopy provides a facility for continuous viewing on a monitor of the position of the colonoscope during examination.

Aims: The aim of this study was to evaluate the accuracy and feasibility of the innovative 3D Colonoscope using FBG. In the first part of the study, the FBG sensor was inserted into the working channel of a routine colonoscope in the first 70 cm from the tip of the scope. Then, the scope was placed in front of the monitor to confirm movement in all three dimensions. We evaluated loop formation such as N loop, alpha loop, reverse alpha loop, with the 3D imaging monitor. In the second part of the study, 5 patients underwent colonoscopy with a FBG sensor, the colonoscope can be displayed in anteroposterior or lateral view, or in both positions together. Fluoroscopy was used in all investigations for comparison.

Results: In the first part of the study, the results showed that the shape sensor was placed 90–150 mm from the tip of the scope. The average position error was 1.722 ± 1.678 mm, which corresponds to 1.50 ± 1.46% of the total length of the sensor. Scope movement and loops were detected correctly in all cases through the monitor. The prototype used in the second part of the study showed a high correlation and little discrepancy with the comparative findings at fluoroscopy.

Conclusion: Scope-guided endoscopy using FBG sensor can be successfully used to display colonoscope configuration. This flexible, thin and almost weightless shape sensor would be a novel technique for identification of colonoscope shape.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Irreversible electroporation (IRE) is a promising novel technique for tumor ablation using energy current pulses. IRE can effectively remove unordered cells without thermal damage surrounding normal tissues. Multiphoton microscopy for evaluated the response of cancer cell to IRE ablation and found apoptotic process after applying IRE.

Aims: By using multiphoton (MP) probes, that is ABI-Nu for nucleus and PMT for mitochondria, we were focusing on these two vital intra-cellular organelles for examining the real-time phenomenon of IRE-induced apoptosis. The study was conducted in three stages. Colon cancer cell lines and normal colon mucosa and colon neoplasm tissues obtained during colonoscopic biopsy from 10 patients were stained with multi-photon (MP) probes that is ABI-Nu for nucleus and PMT for mitochondria. We evaluated the feasibility of using multiphoton microscopy (MPM) to observe IRE response. First, the IRE responses of colon cancer cell lines were compared before and after IRE. Electrical pulses were administered with a Harvard apparatus, and the changes in the intensity of the nucleus and mitochondria were observed with time. The second, the IRE response of normal colon and colon cancer tissue obtained from same patient were evaluated before and after IRE same with previous method. Also, in order to determine whether IRE induced apoptosis, membrane blebbing of colon cancer cell lines were examined after apply IRE.

Materials & Methods: By using multiphoton (MP) probes, that is ABI-Nu for nucleus and PMT for mitochondria, we were focusing on these two vital intra-cellular organelles for examining the real-time phenomenon of IRE-induced apoptosis. The study was conducted in three stages. Colon cancer cell lines and normal colon mucosa and colon neoplasm tissues obtained during colonoscopic biopsy from 10 patients were stained with multi-photon (MP) probes that is ABI-Nu for nucleus and PMT for mitochondria. We evaluated the feasibility of using multiphoton microscopy (MPM) to observe IRE response. First, the IRE responses of colon cancer cell lines were compared before and after IRE. Electrical pulses were administered with a Harvard apparatus, and the changes in the intensity of the nucleus and mitochondria were observed with time. The second, the IRE response of normal colon and colon cancer tissue obtained from same patient were evaluated before and after IRE same with previous method. Also, in order to determine whether IRE induced apoptosis, membrane blebbing of colon cancer cell lines were examined after apply IRE.

Results: MPM images of cancer cells stained with MP probes revealed that ABI-Nu for nucleus and PMT for mitochondria, we were focusing on these two vital intra-cellular organelles for examining the real-time phenomenon of IRE-induced apoptosis. The study was conducted in three stages. Colon cancer cell lines and normal colon mucosa and colon neoplasm tissues obtained during colonoscopic biopsy from 10 patients were stained with multi-photon (MP) probes that is ABI-Nu for nucleus and PMT for mitochondria. We evaluated the feasibility of using multiphoton microscopy (MPM) to observe IRE response. First, the IRE responses of colon cancer cell lines were compared before and after IRE. Electrical pulses were administered with a Harvard apparatus, and the changes in the intensity of the nucleus and mitochondria were observed with time. The second, the IRE response of normal colon and colon cancer tissue obtained from same patient were evaluated before and after IRE same with previous method. Also, in order to determine whether IRE induced apoptosis, membrane blebbing of colon cancer cell lines were examined after apply IRE.

Conclusion: Here, we observed using MPM that nuclear staining occurred quickly due to increased cell membrane permeability and bleb was formed after electric pulse exposure. These results are expected to challenge the understanding of the
permeability process after IRE by providing the real-time images. Additionally, MRA can also serve in pancreatitis assessment and monitoring, e.g., with Annexin V FITC and PI staining. This MP probe protocol would dramatically increase the accuracy of diagnostic techniques by providing in vivo cell images.

P0211 LARGE (>30MM) POLYP ENDOSCOPIC MUCOSAL RESECTION: OUTCOMES AND PREDICTORS OF SUCCESS
K. Sia1, E. Karunadasa2, A. Kaweza3, S. Ishag1
1Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom
2Department Of Surgery, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom
Contact E-mail Address: keith@sia.org

Introduction: Endoscopic mucosal resection (EMR) is an established therapeutic option for large (>30 mm) colonic polyps. We aimed to assess characteristics and outcomes of this cohort. Primary outcomes consisted of rates, predictors and durability of EMR success, whilst secondary outcomes included complications, malignant risk, and conversion to surgery.

Aims & Methods: We prospectively identified patients referred for large polyp EMR from a polyp multidisciplinary team meeting between August 2008–2016 in a district general hospital with tertiary EMR expertise. Data on demographics, polyp site, morphology, size, accessibility (SMA), histology and follow-up endoscopy were retrospectively collected. Binary logistic regression modelling was performed using SPSS, with components comprising of year, individual SMA components, and histology. The Kaplan-Meier approach was used to measure durability of EMR success.

Results: Large polyp EMR was performed in 91 patients out of 125 MDT referrals (73%). Patients had a median age of 72 (interquartile range [IQR] 14.4), and were predominantly male (60%). Polyps were sessile (46%), flat (49%) or pedunculated (4%), with a median size of 40 mm (IQR 20.5 mm), and were left-colon in 81%. Bleeding occurred in 16.5%, all of whom achieved haemostasis. The 30-day complication rate was 1.1% (delayed bleeding in 1 patient), 54 (59%) were fully resected in one session, with overall EMR success in 75 (81.5%) after an average of 1.5 sessions. On multivariable analysis, significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile vs. flat morphology, and non-malignant histology. Malignant histology (p < 0.001) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured adenocarcinoma. Of the 25 R0 EMR success group, 4/25 were malignan polyps with R0 endoscopic resection. The overall malignant histology rate in this cohort was 11/91 (12%). In this cohort, the R0 EMR success rates was 4/11 (36%), with no recurrence after 60 months of follow-up. The overall 12-month recurrence rates following complete EMR was 1.5%, with no significant factors affecting EMR durability identified.

Table 1: Predictors of complete resection on first EMR attempt. p-values derived from bivariate regression, with bold values significant if <0.05. Increase in OR for each increase in year. **p-value < 0.05 considered statistically significant.

Conclusion: Large polyp EMR is a safe and effective alternative to surgical resection of large polyps. Endoscopist experience, polyp morphology, and benign histology are important complete predictors at index EMR. Further data are required to evaluate the longer-term outcomes of malignant polyps.

P0212 PROSPECTIVE RANDOMIZED CONTROLLED TRIAL COMPARING EFFICACY OF 1-L PEG-ASC WITH PRUCALOPRIDE AND 2-L PEG-ASC FOR BOWEL PREPARATION
1Gastroenterology And Hepatology, Korea University Anam Hospital, Seoul/Korea, Republic of
2Division of Gastroenterology and Hepatology, Department of Internal Medicine, Korea University College of Medicine, Seoul/Korea, Republic of
3Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom

Introduction: Though numerous research has enabled decrease of the bowel preparation solution volume, it is still a major complaint of patients preparing colonscopy. There have been studied that additional administration of laxatives could lessen the amount of necessary formula with prokinetic effect. Prucalopride is a serotonin (5-HT4) receptor agonist which stimulate colonic mass movements and provide main propulsive force for defecation.

Aims & Methods: The aim of this study is to compare 2-L PEG-Asc and 1-L PEG-Asc plus prucalopride while preprey for quality of bowel cleansing while improving colonscopy and patient compliance. Two hundred patients were prospectively enrolled. Patients referred for colonscopy were divided into group A (the split-dose 2-L PEG-Asc) and group B (1-L PEG-Asc + prucalopride) randomly. During colonoscopy, each patient's bowel preparation quality was evaluated with The Boston Bowel Preparation Scale (BBPS) and Aronchick Preparation Scale (APS). The tolerability and satisfaction of patients was determined based on a questionnaire-based survey.

Results: One hundred patients received either 2-L PEG-Asc or 1-L PEG-Asc with prucalopride. Regarding colon cleansing outcome (BBPS and APS), the 1-L PEG-Asc with prucalopride group showed similar, but non-inferior results compared to the 2-L PEG-Asc group on both BBPS (7.65 ± 1.27 vs 7.52 ± 1.40, p = 0.586) and APS scales (93.1 ± 16.3 vs 95% ± 5.8%, p = 0.717). Tolerability was similar for both 1-L PEG-Asc with prucalopride and 2-L PEG-Asc.

Conclusion: 1-L PEG-Asc plus prucalopride preparation showed comparable result to traditional 2-L PEG-Asc preparation. 1-L PEG-Asc plus prucalopride preparation method could be an alternative method for bowel preparation which can relieve patient discomfort.

Introduction: Endoscopic mucosal resection (EMR) is an effective and safe treatment for large (>20mm) laterally spreading colorectal lesions. Although colon EMR has been established as a minimally invasive technique for treatment of large colorectal lesions, risk of adenoma recurrence is the main limitation. Current guidelines recommend first follow-up at 3–6 months; however, there are no well-designed prospective-studies published establishing an optimal follow-up interval. Here, we evaluated the current scheduling process and developed strategies to standardize our endoscopy center practices.

Aims & Methods: Single tertiary referral center quality improvement project started in January 2017 and currently still in progress. We present here the interim data. Consecutive patients who had undergone or would have EMR of lesions ≥20mm were eligible for inclusion. The process of follow-up visits after EMR was divided at two levels: A dedicated team member reviewed follow-up patients who underwent EMR and would have follow-up visits. Evaluation of follow-up before EMR was generated a monthly report identifying patients who underwent colon EMR using our endoscopy procedure documentation program. The appropriate timeframe for follow-up after colon EMR was identified and orders and scheduling for the colonoscopy follow-up were carried out. Evaluation of follow-up: A dedicated team member reviewed the status of patients who underwent colon EMR six months prior to the start of the QI study. If patient did not show up on their scheduled follow-up, phone calls were placed to contact the patients. Patients who had followed-up with their local gastroenterologists were recorded. All the data in intervention group was compared retrospectively with nonintervention group who were not tracked through quality improvement process.

Results: Per-protocol 25 patients included in intervention group were compared to 60 patients in the nonintervention group. Mean age was 62 years in intervention group and 60 years in nonintervention group (p = 0.04). There were no differences in distribution in size of lesion, gender, EMR site, and polyp histology between two groups (Table 1). The mean follow-up time in intervention group was 8.2 months (±2.6) and nonintervention group was 10.4 months (±9.1). There was increase in rate of 6–9 months follow-up in intervention group when compared to the nonintervention group (88%, 95% CI [0.80%-0.94%] vs 64%, 95% CI [0.54%-0.73%]) (Table 1).

<td>(22) (35)</td>
</tr>
</tbody>
</table>

Conclusion: These preliminary results suggest significant improvement in SC1 compliance with our intervention. We believe that continuing these efforts and further refining the intervention process, requiring less personnel resources, may be helpful to improve the follow-up time until 3–6 months interval while also enduring as a sustainable change for our practice.

P0214 META-ANALYSIS SUGGESTS: INSPECT TWICE TO INCREASE RIGHT COLON ADENOMA DETECTION RATE
K. Triantafyllou, P. Gkolakis, G. Tziatzios, G. D. Dimitriadis
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriani@med.uoa.gr

Introduction: Missed adenomas in the right colon are of major concern for interval colon cancer (CRC) development. There is evidence from cohort and randomized controlled studies (RCTs) that a second examination of the right colon – either in direct view or in retroflexion- increases the diagnostic yield of the procedure. However, data are not accepted unanimously.

Aims & Methods: The aim of this meta-analysis was to examine the effect of a second, back-to-back mucosa inspection on the diagnostic yield of colonoscopy in the cecum and the ascending colon. We performed literature searches in MEDLINE to identify studies evaluating the effect of a second pass endoscopic examination on adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) in the right colon. Study outcomes effect sizes were calculated using RevMan 5.3 software fixed or random effect model, as appropriate, and they are presented as OR[95% CI]. Heterogeneity was measured using the I2 statistics. Publication bias for publication bias was detected in the direct view arm of the analysis. As compared to a single pass, the second right colon inspection significantly increased ADR (1.31 [1.15–1.49], I2 = 49%). The effect size of ADR was higher in the direct view second pass arm (1.73 [1.41–2.12], I2 = 0%) as compared to the retroflexion arm (1.17 [1.06–1.29], I2 = 0%). Sensitivity analysis with removal of one study each time did not identify a single study responsible for the detected heterogeneity. Our analysis did not show significant increase in right colon AADR (1.5 [0.76–1.56], I2 = 0%) after the second exam.

Conclusion: In comparison to a single pass, the second inspection of the right colon either in direct view or with scope retroflexion increases ADR in this colon segment. However, results should be interpreted cautiously due to the small number of meta-analyzed studies with mixed indications populations, and the detected moderate levels of heterogeneity and risk for bias.

Disclosure of Interest: All authors have declared no conflicts of interest.

</table>
A CT scan was performed in the 2 patients requiring 100mcg of fentanyl, showing serositis in 1 patient and no abnormalities in the other. Both patients were admitted and managed conservatively (discharge day 6 and 2 respectively). The other 5 patients were discharged home on the same day after extended recovery. Predictors of PP were lesion size ≥45 mm (P = 0.003), Paris classification (P = 0.02) and intra-procedural bleeding requiring endoscopic control (IPB, P = 0.042). Lesion size ≥45 mm and IPB were also independent variables on multivariate analysis with an odds ratio of 2.8 (95% confidence interval 1.3–6.3, p = 0.012) and 2.3 (95% confidence interval 1.0–5.2, p = 0.042 respectively (Table 1).

Conclusion: Pain after EMR occurs in 20% of patients and is associated with larger lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis. If pain subsides after parenteral acetaminophen and does not recur the patient can be safely and confidently discharged to the step down recovery area and after medical review allowed to leave hospital. PP despite parenteral acetaminophen heralds a more serious scenario and imaging should be considered when stronger analgesics do not relieve the pain.

P0218 QUALITY OF SINGLE-SESSION COLONOSCOPIC EXAMINATIONS INTENDING TO REMOVE ALL NEOPLASTIC POLYPS USING COLD POLYPECTOMY IN OUTPATIENT SETTING: RESULTS FROM CLINICAL PRACTICE DATA OF SINGLE CANCER CENTER HOSPITAL IN JAPAN

Division Of Endoscopy, Shizuoka Cancer Center, Nagaizumi/Japan

Contact E-mail Address: k.hotta@scclr.jp

Introduction: Some high-quality, large-scale cohort studies proved removals of colorectal neoplasms achieved prevention of colorectal cancer incidence and deaths. We introduced a strategy of removing all neoplastic polyps in single session colonoscopic examinations using cold polypectomy was started.

Aims & Methods: The aim of this retrospective study was to investigate about achievement of colorectal polyp remove in our clinical practice setting. Scheduled colonoscopic examinations for 40–79 years outpatients who had at least one colorectal neoplasm between January 2015 and December 2016 were collected from our endoscopic data base. Exclusion criteria were as follows: patients who had colorectal neoplasm larger than 20 mm, pre-examination of colorectal surgery or endoscopic submucosal dissection, inflammatory bowel disease, familial adenomatous polyposis, uncontrolled malignancies, by trainee endoscopists (<500 colonscopies), no agreements of polyp removal, and/or patients with continuation of anti-thrombotic agents. Outcome measurements were polyp removal rate (per-lesion analysis), complete polyp removal rate (per-patient analysis) and complications. Proportions of each endoscopic removal method according to size were also analyzed.

Results: A total of 2527 patients (mean age 66.8 ± 7.9 years) with 8203 colorectal neoplasms (CRNs) (7657 adenomas, 423 serrated polyps and 105 Tis and T1 cancers) who met inclusion and exclusion criteria were analyzed. Mean number of CRNs per patients was 3.2. Mean size was 4.7 (±2.9) mm. Polyp removal rates were 96.7% (8795/8203) and 94.7% (2394/2527), respectively. Post-polypectomy bleeding requiring endoscopic hemostasis occurred in 7 patients (0.27%) and all origins of bleeding were endoscopic mucosal resection (EMR) and hot snare polypectomy (HSP). Post electrocoagulation syndrome requiring admission was occurred in one patient (0.04%) after pre-cutting EMR. Mean procedure time was 27.4 ± (±13.3) min. Proportions of each endoscopic removal method according to size were presented in an attached table. In 1–4 mm CRNs, both cold snare polypectomy (CSP) (51.8%) and cold forceps polypectomy (CFP) (45.8%) for 1–4mm CRNs were main methods. In 5–9 mm CRNs, CSP was a leading method (73.8%) and EMR was the second one (24.1%). CRNs larger than 10 mm were almost removed by EMR (94.4%).

P0219 META-ANALYSIS AND OWN EXPERIENCE IN THE TREATMENT OF RECTO-URETROGENITAL FISTULA USING THE OVER-THE-SCOPE CLIP (OTSC)

M. Raithel1, M. Vetter2, A. Brauner1, T. Vasilakis1, A. F. Hagel1
1St. Marien Waldkrankenhaus, Erlangen/Germany
2University Clinical Center Erlangen, Erlangen/Germany

Contact E-mail Address: martin.raithel@waldkrankenhaus.de

Introduction: The transmural OTSC is used to achieve a full-thickness, serosa-to-serosa apposition (emergency & elective cases) for closure of GI wall defects (perforation, leak, fistula) with reported mean closure rates of 62–100% (range 0–100%), depending on the size of perforation, type and nature of lesion and the endoscopists’ experience1-7. However, recto-uretrogenal fistulae are a particular type of fistula and are mostly leaky or fistula of chronic nature, rarely acute perforations with vital wound tissue. They may occur in Crohn’s disease, but can also be a consequence of abdominal surgery, traumatic lesions or post-radiation damage.

Aims & Methods: To further explore the role of the OTSC in this particular type of fistula we analyzed own cases and 21 reports from the literature dealing with any type of recto-uretrogenal fistula. In total, 25 patients, were identified with closure of a recto-uretrogenal fistula using the OTSC, but there was considerable heterogeneity, because of the fistula location (rectovaginal n = 2, rectovaginal n=10, rectourethral n = 7, rectourethral n=2, other rectal fistula n = 3).

Results: In most situations a previous interdisciplinary discussion was reported before an OTSC attempt, or patients refused to undergo re-operation. However, special characteristics of these leaks were reported to make more difficult the OTSC procedure compared with other GI locations, e.g. the site of the fistula is nearby located to L. dentata and anal sphincter, it includes a localization with nearby located to L. dentata and anal sphincter, it includes a localization with

Conclusion: In conclusion, recto-uretrogenal fistula may be a potential indication for OTSC application, after interdisciplinary consensus, when re-operation is avoided, to be deemed to be too risky or cumbersome. Although this type of fistula carries some difficulties because of little space, tissue tension and fibrous or postop changes, long-term success may be achieved in half of all patients. Further improvements should focus on increasing healing potential of the fistula or better after performing anastomosis creation (acrylic acid), to avoid postoperative recto-uretrogenal leaks.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: While ESD in the upper GI tract is well established, it is as yet not standard of care in the colorectum. Contrary to Japan, western experience is limited and only relatively few case series have been published in Europe (e.g. Dessai et al. 2017).

Aims & Methods: For the period 5/2012-1/2017 the first fifty-one consecutive patients with colorectal (n = 18/17/16 rectum/left/right hemicolectomy) neoplasias (diameter ≤ 13 mm, ≥ 2 cm, high grade dysplasia: n = 18; serrated/submu-

Conclusion: In Spain, there is good compliance with the quality indicators of colonoscopies. All authors have declared no conflicts of interest.

Results: According to endoscopic or pathologic judgment resection was complete in 40 or 30 patients, respectively. During hospital follow-up (12–14; median 4 days) abdominal pain, fever or local peritonitis were noted in 6 and bleeding in 3 patients (hypotension in 1) with antibiotics/transfusions/surgery needed in 4/0 patients. There was no hospital mortality. Among those with histologic incomplete resection (n = 21), surgery or FTR was performed in 5 patients; endoscopic follow-up is pending in 7 and revealed no residual neoplasia in 9. Among those with cancelled ESD or endoscopic incomplete resection (n = 11), surgery or FTR was performed in 5, endoscopic follow-up is pending in 2 and revealed no residual neoplasia in 1.

Conclusion: After appropriate training, even in low volume European case series ESD in the colorectum appears to be safe and partially effective.

Introduction: Colorectal cancer is the second leading cause of cancer death in US [1]. Its incidence can be mitigated by detecting its precursor lesion, the polyp, before it develops into cancer. Colonoscopy is still the gold standard for colon screening though some polyps are still missed. This can be explained by technical limitations of colonoscopes (camera orientation, field of view, etc.), but also by human factors (such as experience). Several computational systems, being the majority still-frame-based, have been proposed to assist clinicians in this task [2] but, to the best of our knowledge, none of them is being used in the exploration before it develops into cancer. Coloscopy is still the gold standard for colon screening though some polyps are still missed. This can be explained by technical

Conclusion: Work presented in this abstract shows how a real-time still-frame-based polyp detection method can be successfully adapted to video analysis. Clinical usability metrics along with a new fully annotated video database were introduced to completely assess method performance. Results show methodology potential regarding clinical deployment as it detects different polyps with a small RT. Results show that the sole use of shape features allows to meet real-time constraints but that a combination with a computationally efficient texture descriptor might improve frame-based performance.

P0223 REJECT AND DISCARD/DIAGNOSE AND DISREgard STRATEGY FOR COLONIC POLYPS: ARE WE READY TO START IT?

Gastroenterologia, Amato Lusitano Hospital, Castelo Branco/Portugal

Contact E-mail Address: richardazevedo13@gmail.com

Introduction: The use of Narrow Band Imaging (NBI) technology for in vivo histological prediction of colon polyps presents high accuracy in Referral Centers, particularly for diminutive polyps, which could be managed by the “reject and discard” strategy and, for sigmoid and rectum polyps, the “diagnose and disregard” strategy. However, the applicability of this practice in Community Hospitals still needs to be determined.

Aims & Methods: We aimed to determine the accuracy of NBI in predicting histology, according to NICE and WASP classifications, in a Center without previous NBI experience. This was a prospective study including patients submitted to colonoscopy between June 2016 and July 2017. Polyps characteristics: location, size, morphology (Paris Classification), NICE/WASP classification (hyperplastic, sessile serrated, adenoma, invasive carcinoma) and degree of confidence (low: <90% vs. high ≥90%). Comparison between NBI classification and histology SPSS 23.

Results: 163 polyps included (71 patients); mean polyp dimension of 6.1 mm (61.3% <5 mm); 91.4% sessile polyps; 62.6% on the left colon. Polyps classification according to NICE/WASP vs. histology: hyperplastic 49.7% vs. 42.9%; sessile serrated polyps 4.9% vs. 9.8%; adenoma 44.2% vs. 43.6%; carcinoma 1.2% vs. 0%; inflammatory reaction on histology – 3.7%. Adenoma diagnosis using NICE/ WASC classification presents an accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 80.9%, 78.1%, 84.2%, 85% and 77.1%, respectively. For left colon <5 mm (n = 61) the accuracy and negative predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classifications. Multivariates analysis showed that high confidence predictions and ≥2 polyps/exam had a significant association with correct NBI classification (p < 0.05).

Conclusion: NBI utilization by inexperienced endoscopists presented moderate acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (≥90%). These results justifying implement additional training and monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cold forces polypectomy (CFP) is commonly used to remove diminutive colorectal polyps (~5mm). In addition, jumbo biopsy forceps are superior to standard forceps for removing colorectal polyps. However, problems remain for CFP with regard to residual adenomatous tissue on histological evaluation after a complete endoscopic cold forceps polypectomy.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of jumbo forceps biopsy using narrow-band imaging endoscopy in patients with diminutive polyps. In addition, we evaluated the factors related to one-bite resection.

Results: A total of 503 patients were prospectively assessed, and 1015 polyps were resected. The median age of the patients was 65 years. The patients comprised 329 men (65%) and 174 women (35%). The polyp morphologies were 0-Ia lesions in 242 cases (48.2%), 0-IIa lesions in 65 cases (12.9%), 0-Isp lesions in 63 cases (12.5%), and 0-IIsp lesions in 53 cases (10.5%). The complete resection rate was 99.3%. The rate of one-bite polypectomy was 71.8%, which included rates of 100%, 91.5%, 81.8%, 56.9%, and 40.5% for lesions 1, 2, 3, 4, and 5 mm in diameter, respectively. Delayed bleeding that required endoscopic hemostasis occurred in only one case, but no other adverse events occurred. The most important factor related to one-bite polypectomy was polyp size (~5 mm; OR: 5.58), followed by macroscopic type of polyps (non-Ia; OR: 1.95).

Conclusion: This study revealed the diagnostic characteristics of depressed-type colorectal lesions. In contrast, the depressed-type lesions were observed as EC3a (38.9%) and VI or VN pit patterns corresponding to carcinomas. As for endocytoscopy, depressed-type cancers have been revealed, which are considered to emerge from the adenoma-carcinoma sequence theory that has been in the mainstream. This "adenoma-carcinoma sequence" theory has been in the mainstream, which has been in the mainstream. This "adenoma-carcinoma sequence" theory has been in the mainstream, which has been in the mainstream. Aims & Methods: We aimed to evaluate the usefulness and safety of sSBE for therapeutic ERP in patients with surgically altered anatomy.

Aims & Methods: We aimed to evaluate the usefulness and safety of the SpyGlass system for diagnosis and treatment of bile-duct disorders in a large-volume center. All patients undergoing SOC in our department between January 2013 and May 2016 were retrospectively identified from a prospectively collected database. The baseline characteristics, including age, gender, presenting symptoms, indication and others were recorded. Procedure-related parameters of SOC for detecting malignant lesions and the stone clearance rate were calculated.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0230 DIAGNOSTIC AND THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAHY (ERCP) IN INFANT AND CHILDREN: A LARGE RETROSPECTIVE STUDY

T. Xang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly being used in the diagnosis and management of biliary and pancreatic disorders in pediatric patients.

Aims & Methods: To evaluate the indications, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indication, ERCP findings, ERCP interventions performed and complications were collected.

Results: A total of 288 children (mean age 9.3 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP included common duct obstruction (n = 153, 54.2%), recurrent or chronic pancreatitis (n = 64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings was choledocholithiasis (n = 146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n = 204), including sphincterotomy (n = 97), stone extraction (n = 55), and stent insertion (n = 52). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0231 ENDOSCOPIC RETROGRADE CHOLANGIOPANCRETOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY: 11 YEARS’ EXPERIENCE AT A LARGE CENTER IN CHINA

T. Xang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: It is technically challenging to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy who underwent ERCP at our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 cases (45.8%) with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagogastrostomy and 13 cases (5.5%) with Roux-en-Y reconstruction. The most common indication was cholelithiasis (58.1%, 137/236). The overall success rate of reaching the papilla was 90.8% (276/304), including 91.3% (126/138) for Billroth II gastrectomy, 94.5% (52/55) for Billroth I gastrectomy, 89.9% (71/79) for hepaticoduodenostomy, 100% (19/19) for esophagogastrastomy and 61.5% (8/13) for Roux-en-Y reconstruction. The clinical success rate was 88.2% (268/304). Therapeutic interventions were performed in 194 patients successfully, including stone extraction (n = 146), sphincterotomy (n = 44), stent placement (n = 57), papillary balloon dilation (n = 27) and mechanical lithotripsy (n = 25). The adverse event rate was 7.2% (17/236). Mild pancreatitis occurred in 3% (7/236) of cases, perforation occurred in 2.5% (6/236) of cases, and asymptomatic hyperamylasemia occurred in 1.7% (4/236) of cases.

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0232 IMPACT OF HIGH DEFINITION, NEAR FOCUS-IMAGING AND SYNDROME REVERSIBILITY TOOL (SERT) AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESECTION: A PROPENSITY SCORE ANALYSIS

D. Guerrero Vinsard1, R. Lennon2, P. Kandel1, L.K. Mejia, R. Bingham1, T. Woodward1, V. Gomez1, M. Raimondo1, E. Bouras2, M.B. Wallace3

Contact E-mail Address: danielaguerretores@gmail.com

Introduction: Risk factors for colorectal adenoma recurrence after Endoscopic Mucosal Resection (EMR) such as size ≥20 mm, high grade dysplasia, use of argon plasma coagulation (APC) and intraprocedural bleeding (IPB), have been well documented in literature. However, it is unknown if the latest generation dual-focus (DF) colonoscopes ability to visualize subtle residual neoplasia, has improved the rate of complete EMR.

Aims & Methods: We aimed to examine the efficacy of the newer 190 colonoscopes versus standard 180 colonoscopes for complete resection of lateral spreading lesions (LSL) ≥20 mm. A secondary aim was to identify risk factors for recurrence and the applicability of the Sydney EMR recurrence tool (SERT score) in our cohort.

This was a single-center retrospective study of patients who underwent EMR with 180 or 190 colonoscopy series from 2010 to 2016. Lesions ≥20 mm resected in a piecemeal fashion and patients with a surveillance colonoscopy after index EMR were included. A propensity score approach with inverse probability weighting (IPW) was used to control potential confounders affecting adenoma recurrence. Each lesion was graded according to SERT score and associations with recurrence were analyzed.

Results: 291 patients met inclusion criteria for the study. The rate of adenoma recurrence at the EMR site was 23.3% for the 180 colonoscope cases and 25.2% for the 190 colonoscope cases. Odds ratio (OR) for recurrence with 190 series was 1.06 (p = 0.85). Adenoma size (p = 0.002) and concomitant need for supplemental APC (p < 0.001) were risk factors for recurrence. SERT > 0 lesions had a higher risk of recurrence during follow-up (OR 1.71; 95% CI 1.00–2.92; p = 0.048) and a higher cumulative incidence for recurrence. Conversely, SERT = 0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscopy effect on adenoma recurrence at different stages of adjustment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0233 INCIDENCE AND RISK FACTORS FOR PANCREATITIS IN EMERGENCY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY: A PROSPECTIVE MULTICENTER STUDY

N. Yoshitaka1, K. Kusumoto1, Y. Itoikawa1, B. Endo2, K. Chikugo2, A. Suzuki1, T. Kawakami1, T. Suzuki1, O. Inatomi1, S. Bamba1, T. Kasaka1, H. Kokuryu1, Y. Mizumoto2, K. Tanaka3

Contact E-mail Address: solitude5834@hotmail.com

Introduction: Pancreatitis, or perforation was noted.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy who underwent ERCP at our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 cases (45.8%) with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagogastrostomy and 13 cases (5.5%) with Roux-en-Y reconstruction. The most common indication was cholelithiasis (58.1%, 137/236). The overall technique success rate of reaching the papilla was 90.8% (276/304), including 91.3% (126/138) for Billroth II gastrectomy, 94.5% (52/55) for Billroth I gastrectomy, 89.9% (71/79) for hepaticoduodenostomy, 100% (19/19) for esophagogastrastomy and 61.5% (8/13) for Roux-en-Y reconstruction. The clinical success rate was 88.2% (268/304). Therapeutic interventions were performed in 194 patients successfully, including stone extraction (n = 146), sphincterotomy (n = 44), stent placement (n = 57), papillary balloon dilation (n = 27) and mechanical lithotripsy (n = 25). The adverse event rate was 7.2% (17/236). Mild pancreatitis occurred in 3% (7/236) of cases, perforation occurred in 2.5% (6/236) of cases, and asymptomatic hyperamylasemia occurred in 1.7% (4/236) of cases.

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: This study aimed to identify the incidence and risk factors for PEP in emergency ERCP. We performed a prospective study of 2078 cases under-going diagnostic and therapeutic ERCP at five Japanese institutions between April 2015 and May 2016. Exclusion criteria were active pancreatitis, cholecystectomy, choledocholithiasis, inability to approach a papilla, and inspection aimed at only the pancreatic duct (PD). Emergency ERCP indicated unscheduled inspections performed within and outside duty hours in this study. PEP was considered when two of the following three conditions were met: (1) serum amylase level more than three times the upper limit of the normal range in each institution, (2) continuous abdominal pain for over 24 hours, and (3) presence of pancreatici tis findings on computed tomography. The first study involved comparison of the incidence of PEP and its characteristics between emergency and elective ERCP. The second study involved determining the predictive risk factors for PEP in emergency ERCP using univariate and multivariate analyses.

Results: A total of 1677 cases were enrolled in this study. Study 1: PEP developed in 20 of 429 cases (4.7%) from the emergency group and in 101 of 1248 cases (8.1%) from the elective group. The incidence of PEP was significantly lower in the emergency group than in the elective group (odds ratio [OR]: 0.56, 95% confidence interval [CI]: 0.32–0.92, P = 0.017). Endoscopic sphincterotomy, stone removal, papillary balloon dilatation, and intraduodenal ultrasound sonography were performed significantly more often in the elective group than in the emergency group (P < 0.001). Placement of a biliary stent was significantly more common in the elective group than in the emergency group. In addition, the procedure time was significantly longer (P < 0.001) and the number of endoscopic biopsies who had more than five years of experience was significantly higher in the elective group than in the emergency group. In addition, the median number of reinterventions required to achieve treatment success was significantly higher for the elective approach (1 vs. 2 [IQR = 1–2], P = 0.003). Multivariable logistic regression analysis revealed that the algorithmic approach was the only variable associated with treatment success (OR = 0.64, p = 0.02) when adjusted for patient demographics, lab parameters and disease/WON characteristics.

Conclusion: A structured, algorithmic approach to endoscopic necrosectomy results in successful treatment outcomes.

Disclosure of Interest: R. Hawes: Consultant for Boston Scientific Corporation and Olympus America Inc., S. Varadarajulu: Consultant for Boston Scientific Corporation and Olympus America Inc. All other authors have declared no conflicts of interest.
Four patients in EST group and 6 patients in EPS group suffered PEP after the procedure. Both groups had similar rates of technical success (OR: 0.55; 95% CI: 0.33–0.92). Post-ERCP pancreatitis (PEP) was no significantly different in the two groups: 24/392 patients (6.1%) in the no-EBS group versus 37/339 (10.9%) in the EBS group (OR: 0.55; 95% CI: 0.33–0.92). Late complications were not significantly different in the two groups: 30/392 patients (7.6%) in the no-EBS group versus 29/339 (8.6%) in the EBS group (OR: 0.87; 95% CI: 0.49–1.58).

Results: 14 papers were assessed via full text for eligibility. 8 articles were excluded leaving 6 prospective studies (total of 711 patients). Technical success: The overall rate of biliary stent insertion was not significantly different: 384/392 (98%) in the no-EBS group versus 333/339 (98.7%) in the EBS group (OR: 1.05; 95% CI: 0.42–2.63). Early complications: The overall early AEs developed in 34/392 (11%) of patients without EBS versus 68/339 (20.1%) of patients who received EBS, with a significantly difference (OR: 0.12; 95% CI: 0.03–0.45). The rate of duodenal perforation was not significantly different: 3/392 (0.8%) in no-EBS group versus 4/339 (1.2%) in the EBS group (OR: 0.62; 95% CI: 0.29–1.36). Early complications that occurred in the overall late adverse events in the two groups: 50/251 patients (19.9%) in no-EBS group vs 38/201 subjects (18.9%) in the EBS group (OR: 0.93; 95% CI: 0.56–1.53). No significantly differences in stent occlusion (11.6% in no-EBS group in vs 11.4% in EBS group) (OR: 0.99; 95% CI: 0.67–1.48). No significantly differences in stent migration (4% in no-EBS group vs 5.5% - OR: 0.81; 95% CI: 0.29–2.25). No significantly differences in late cholangitis (2.0% in no-EBS group vs 0% in EBS group - OR: 1.83; 95% CI: 0.17–19.85). Long-term mortality was not significantly different (2.5% in EBS group and 2.9% in the EBS arm - OR: 1.18; 95% CI: 0.22–6.29).

Conclusion: Our meta-analysis showed no significantly differences in technical success and in PEP. In consideration of the significantly increase of the overall AEs in the EBS group, in particularity of the bleeding and cholangitis, the EBS seems not be recommended in patients not suitable to surgery undergone biliary stenting.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO237 ENDOSCOPIC PANCREATIC SPHINCTEROTOMY COMBINED WITH PANCREATIC DUCT STENT CAN EFFECTIVELY PREVENT RECURRENCE OF ACUTE RECURRENT Pancreatitis Caused by Biliary Microlithiasis — A Single-Center Study from Beijing, China

Y. Huang, X. Yan, W. Liu, Y. Zhang, W. Yao, K. Li
Gastroenterology And Hepatology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 13911765322@163.com

Introduction: Acute recurrent pancreatitis (ARP) refers to a clinical entity characterized by episodes of acute pancreatitis which occurs on more than one occasion. Biliary microlithiasis plays an important role in the etiology of ARP.BILE sludge may induce acute pancreatitis as a consequence of transient papillary edema that can obstruct the pancreatic juice flow. The established treatments for ARP include endoscopic sphincterotomy (EST) and empirical cholecystectomy. However, EST may increase the morbidity of biliary reflux or cholecystitis recurrence. We hypothesized that endoscopic pancreatic sphincterotomy (EPS) can save the function of biliary sphincter and prevent the recurrence of ARP.

Aims & Methods: The aim of this study is to evaluate the effectiveness of EPS combined pancreatic duct stenting for preventing ARP caused by biliary microlithiasis. 67 patients with ARP from 2005 to 2016 were diagnosed as biliary microlithiasis by endoscopic retrograde cholangiopancreatography (ERCP), bile microscopy or intraductal ultrasonography (IDUS). The whole was divided into two groups according to endoscopic therapy by EST or EPS with pancreatic stent. Rate of pancreatitis recurrence, early complication of post ERCP pancreatitis, and late complication (3 months after treatment) which included cholangitis, cholecystitis or cholelithiasis were compared between the two groups.

Results: (1) 38 and 29 patients were included in EST and EPS group, respectively. The mean age and follow-up duration of EST and EPS groups were 48.4±15.1yrs, 45.7±26.5months and 45.6±15.2yrs, 24.1±26.3months, respectively. (vary from 2months to 115months). (2) The mean episodes of ARP in EST and EPS group before endoscopic therapy were 3.9±3.3 times and 7.9±11.8 times. (3) Four patients in EST group and 6 patients in EPS group suffered PEP after the endoscopic therapy (P=0.418). (4) 15 patients in EST group and 3 in EPS group suffered recurrent pancreatitis. The efficiency in EST group and EPS group is 68.4% and 89.6% respectively (P=0.039). (5) The incidence of late complications was 18.4% in EST group and 10.3% in EPS group (P=0.567).

Conclusion: EPS combined with pancreatic stent is a promising strategy to prevent recurrence of ARP due to biliary microlithiasis.

Disclosure of Interest: All authors have declared no conflicts of interest.
C.W. Kim, J. H. Chang, J.H. Kim, T.H. Kim, I. S. Lee, and S.W. Han. Size Disclosure of Interest: has the ability to alter more often the initial ERC diagnosis or management technology, providing increased sensitivity and specificity for visual impression that DC was an easier procedure compared to FC. Underwent DC (44.8%) the initial diagnosis and clinical management was altered under FC (9.1%) biopsy confirmed the endoscopic diagnosis, in contrast with 10 cases was performed in 29 cases respectively. Cholangioscopy-guided biopsies for cholangioscopy. Fiberoptic cholangioscope was used in 39 cases and digital cholangioscope digital scope.

Introduction: Since the emergence of the fiberoptic single-operator cholangioscopy, the sensitivity for detecting bile duct lesions has been increased and the diagnostic criteria and severity grading of acute cholangitis. Acute cholangitis is a life-threatening disease, and the emergency biliary drainage procedure is necessary for moderate or severe cases, according to TG13. In recent years, with an aging society, necessity to perform endoscopic retrograde cholangiopancreatoscopy (ERC/P) in elderly patients is increasing. However, few studies have examined the efficacy and safety of emergency ERC/P in super-elderly patients.

Aims & Methods: In this study, we examined the efficacy and safety of emergency ERC/P in super-elderly patients with moderate to severe acute cholangitis, according to TG13. We performed 178 emergency ERC/P procedures in 132 patients during 3 years (June 2014–December 2016). We determined patients >90 years as “super-elderly” and those <90 years as “non-super-elderly.”

Evaluation criteria included comorbidities, oral administration of anticoagulants, cause of cholangitis, ERC/P procedure (examination time, endoscopic biliary sphincterotomy (EST)) pre-cut papillotomy, treatment success rate, presence or absence of peripapillary diverticula and papilla after EST, seldinger dilation, ERC/P-related complications (bleeding, perforation, post-ERC/P pancreatitis, ERCP pneumonia, death within 30 days after ERC/P procedure), and anesthesia-related complications (blood pressure decrease, pulse reduction, respiratory depression).

Results: We examined 69 males (52.3%) and 63 females (47.7%). Women accounted for a larger proportion in the super-elderly group (71% vs. 41%). The average age was 92.5 years (range, 90–97) in the super-elderly group and 77.9 years (range, 50–89) in the non-super-elderly group. The super-elderly group comprised 54 ERC/P procedures (moderate, 32; severe, 22) against 124 ERC/P procedures (moderate, 104; severe, 20) in the non-super-elderly group, and severe cases observed in the super-elderly group were statistically significant (p < 0.001). Regarding comorbidities, chronic heart and renal failure were statistically dominant in the super-elderly group. However, no difference was seen in the proportion of other diseases and receiving anticoagulant medication between the two groups. The causes of acute cholangitis were common in both groups with common bile duct stone (46% vs. 46%), followed by malignant obstruction (9% vs. 12%) and benign stenosis (0% vs. 5%), but no difference was found. Regarding the ERC/P procedure, the examination time was longer in the super-elderly group (37.4 ± 28.1 min vs. 29.2 ± 24.0 min, p = 0.044), but there was no difference in the procedure success rate (93% vs. 97%, p = 0.24) and the presence of papipapillary diverticula. The patients were sedated using midazolam (MDZ) plus pentazocine (PTZ). The amount of anesthetic used was less in the super-elderly group (MDZ 2.2 ± 3.3 mg, p < 0.001, PTZ: 3.1 ± 5.4 mg, p = 0.005).

Regarding (i) ERC/P-related and (ii) anesthesia-related complications, these were higher in the super-elderly group ([i] 15% vs. 9%, p = 0.293, [ii] 17% vs 7%, p = 0.004). Regarding the need for intravenous or surgical treatment was required. Conclusion: Acute cholangitis in super-elderly patients was more likely to become severe and the complications were higher than that in non-super-elderly patients. When performing an emergency ERC/P procedure in super-elderly patients, we should particularly pay attention to developing complications in patients with moderate or higher acute cholangitis, according to TG13.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
included 20 patients with low-grade dysplasia (DBG) or high grade (DHG) lesions. The specimens were performed by a gastrointestinal pathologist, in relation to a residual adenomatous bud after endoscopic ampullectomy for ampullary adenoma. The lesions should extend to a maximum length of 20 mm in the CBD. Endoscopic retrograde cholangio-pancreatectomy (ERCP) was performed by the endoscopist (EMcision, UK) (effective power 10Watts, 30 s). Biliary or pancreatic ducts were placed at the end of the procedure. The primary endpoint was the rate of residual neoplasia at 12 months after surgery; 3) adverse events. The endpoints were: 1) residual neoplasia at 6 months after treatment; 2) rate of recurrence at the end of the procedure. The primary endpoint was the rate of residual neoplasia at 12 months; 3) adverse events. The results: The mean age (±SD) of 67 years (±11), with 12 men and 8 women were included. RFA was performed on average (±SD) 1.9 years (±3.5) after ampullectomy. The mean resected adenoma size (±SD) was 24.9 mm (±10.2), and 7 patients had adjacent duodenal mucosectomy at the time of ampullectomy. The histology of the resected ampullary adenoma was DBG for 7 patients, DHG for 12 patients, and in situ carcinoma for 1 patient. Lateral margins were not assessable in patients with adenocarcinoma. CBD recurrence was diagnosed predominantly on ERCP and/or endoscopic ultrasonography surveillance procedures with an estimated mean infiltration height (±SD) of 11.2 mm (±4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radio-paque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had biliary stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA (25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DBG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 patients had angiocholitis requiring biliary stent replacement, 1 patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoscopy and biological tests). At MI2, one patient presented with a biliary stricture resolved by dilation and a calibration biliary stent. Conclusion: Endobiliary RFA performed on residual endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia eradication at 12 months. The postoperative follow-up was not performed due to the high rate of recurrence. Multiple RFA sessions may be proposed in case of incomplete results. Disclosure Interest: All authors have declared no conflicts of interest.

P0242 EXPERT VALIDATION OF A NOVEL MECHANICAL CUTTING PAPILLA

S. E. Van Der Wiel1, A.D. Koeh2, M.J. Bruno1

1Gastroenterology And Hepatology, Erasmus University Medical Center, Rotterdam/Netherlands
2Erasmus MC Rotterdam Gastroenterology and Hepatology, Rotterdam; Netherlands

Introduction: Simulation-based training has become an important pillar in competence and learning in medicine, especially in training novice endoscopists. Several simulators have been validated and implemented in training curricula pertaining gastrointestinal endoscopy. Surprisingly, limited data are available on simulators in ERCP training, despite the fact that ERCP seems to be an ideal simulation-based training model due to its technical complexity. The available simulators are difficult to implement in training settings due to the lack of realism or use of live animals or ex-vivo specimens. Recently, the Boilskosti-Chicago Cutting Papilla was validated and considered a realistic training model for our study group. A novel mechanical papilla has been designed allowing to train (precut) sphincterotomy. The mechanical papilla is inserted into the simulator. A specific alloy allows for electrical conduction and cutting of the material using standard sphincterotomes and needle knives.

Aims & Methods: The aim of our study was to determine the expert validity of this cutting papilla and its didactic value for training sphincterotomy, as judged by experts. Expert participants with more than 2500 ERCPs lifetime were invited to perform an endobiliary experiment and fill out a questionnaire on the realism of the sphincterotomy procedure and it’s didactic value.

Results: A total of 40 ERCP experts were included. All experts were men, originating from 16 different countries with a mean age of 49.6 years (range 37–65). All participants were gastroenterologists (92.5%), 3 participants were surgeons (7.5%). The mean number of years of endoscopic experience was 20.9 (range 10–40). Experts’ opinion on realism of performing a sphincterotomy was rated 6.98 on a ten-point Likert scale, resemblance of the performed maneuvers 7.60 and tactile feedback 6.78. When asked if the cutting was perceived as expected, experts rated 6.35 and the cutting result was rated 7.30 on a ten-point scale. The potential as a training tool of the cutting papilla in training surgeons was rated 3.93 on a four-point scale, and there was a high agreement among the experts to include the papilla in the training of novices (3.93 on a four-point scale).

Conclusion: This is the first mechanical papilla available for training sphincterotomy on the Boilskosti-Chicago ERCP Trainer and demonstrates good expert validity. ERCP experts highly appreciated. The shapes of ampullary adenoma were divided into three groups: long nose (L/N), meaning a long protrusion, Dome (D), meaning a hemisphere and X-ray images were magnified sequentially 5–10 times each. The eligibility criteria were: it must be naive papilla and both of BD and PD must be visualized. The cases with IAC were evaluated. The shapes of the ampulla were divided into three groups: long (cERCP) with contrast medium, which provides images of IAC and leads to infundibulotomy or precut. We propose advantage of conventional ERCP (cERCP) with contrast medium, which provides images of IAC and leads to evaluate the difficulties in cannulation. The aim of this study is to recognize the morphology of intra-ampullary bifurcation of bile duct (BD) and pancreatic duct (PD). Its variation allows refractory access to bile duct (BD). IAC has small cyst within ampulla regulated by Oddi’s sphincter, so the BD axis has changed via IAC. The cases with IAC may be more difficult to cannulate. IAC has small cyst within ampulla regulated by Oddi’s sphincter, so the BD axis has changed via IAC. The cases with IAC may be more difficult to cannulate.

P0243 MEDICO-LEGAL CLAIMS IN GASTROINTESTINAL ENDOSCOPY DOES PROCEDURE RISK RELATE TO SUCCESSFUL OUTCOMES?

S. Budihal, J. F Maybery

Dietetics Disease Centre, University Hospitals Leicester, GB/United Kingdom

Contact E-mail Address: shivbudihal@yahoo.co.uk

Introduction: Complications in endoscopy can lead to adverse clinical events. The likelihood of developing a complication depends on the degree of risk associated with a certain procedure. It is generally noted that riskier the procedure larger is the chance for a complication and higher the likelihood for medico legal issues. This is relevant as in the event of the risk materialising, patients make seek legal redress. The aim of this study was to investigate the degree of success of medico legal claims based on the nature of the endoscopic procedure and the outcome of the claims.

Aims & Methods: The National Health Service Litigation Authority (NHSLA) database in U.K. was searched using a Freedom of Information request (F:2409) to identify all cases of diagnosed endoscopically notifiable endoscopic complications notified to the NHSLA between 2010/11 and 2014/15. The terms "Gastroscopy", "Sigmoidoscopy", "Colonoscopy", "PEG" and "ERCP" were used to search the database. They were then analysed for procedure type, characteristics and outcomes. StatsDirect statistical software was used for statistical analysis.

OUTCOME OF ENDOSCOPY CLAIMS

<table>
<thead>
<tr>
<th>PROCEDURE</th>
<th>OPEN</th>
<th>SUCCESSFUL</th>
<th>UNSUCCESSFUL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gastroscopy</td>
<td>10</td>
<td>7</td>
<td></td>

<tr>
<td>Colonoscopy</td>
<td>50</td>
<td>40</td>
<td>28</td>
</tr>
</tbody>
</table>

Results: A total of 291 claims were notified to the NHSLA during this period. 107 (36.7%) of claims still remain ‘open’. Analysing outcomes by procedures reveals a success rate of 44%, 44%, 37%, 36% and 34% (rounded up to the nearest whole figure) for Gastroscopy, PEG, Sigmoidoscopy, ERCP and Colonoscopy claims respectively. There is no statistical difference between the proportions comparing Gastroscopy and Colonoscopy (StatsDirect software used).

Conclusion: A significant number of claims remain open leading to concern and worry among endoscopists. The impact on practitioners after a successful claim is unknown and merits further investigation. Procedures considered as dangerous like ERCP and Colonoscopy have the least successful claims. It is imperative that clinicians remain vigilant. Performing Gastroscopy is dangerous and so is undertaking a Percutaneous Endoscopic Gastrostomy. Endoscopists should tighten their approach to all procedures.

Disclosure Interest: All authors have declared no conflicts of interest.
A246
Results: There were cases of 1223 naive papilla out of 2226 cases in total. The
success rate to access BD with naive papillae was 97.7% (1195/1223) and overall
post-ERCP pancreatitis (PEP) was 1.3% (29/2226). The eligible patients were 908
(505 male and 403 female), among whom IAC was identified in 6.0% (54/908).
The prevalence of IAC in the L/N, D and F types were 8.9% (48/542), 1.2% (4/
339) and 7.4% (2/27), respectively. IAC was significantly higher in the L/N
(p 5 0.01) and F (p 5 0.05) types than in the D type. The choledochocele
shapes of Sp, Sh and Ov were 59.3%, 13.0%, 27.8%, respectively. The average
size was 8.1 mm (3.7–18.3) in diameter. The location of IAC in Ac and Ab were
63.0% and 37.0%. The IAC in Ab was found with L/N shape only. Patients of
53.7%(29/54) required GW placement on PD to access BD. IAC was alternatively seen on MRCP in 10%(3/30).
Conclusion: Choledochocele is rarely seen on even cERCP, in addition the visualization of IAC has been rarely reported. IAC could be actually visualized with
prudent contrast medium injection. Our results showed miscellaneous variations
in the intra-ampullary images. IAC would require refractory pursuit of the axis
alignment due to its unexpected pathway within ampulla to access BD. Moreover
6.0% prevalence of IAC should not be ignored. IAC can be one of the factor of
refractory cannulation. cERCP with focus on ampulla could the difficulty in
cannulation. On the other hand, WGC would not do. The previous randomized
control trials showed no difference to access to BD between WGC and cERCP.
However, both procedures still remained cases with refractory cannulation. It has
been reported that refractory cannulation might cause PEP1). Therefore careful
attention should be paid while passing through IAC to avoid PEP. According to
ampulla shapes, especially of L/N and F, cERCP would be recommended to
identify the presence of IAC. It will be a warrant strategy to choose.

Introduction: Most appropriate endotherapy of biliary anastomotic strictures
(AS) remains to be defined.
Aims & Methods: Aim is to retrospectively report the endotherapy for duct-toduct AS in 2013, procedure related complications and medium-term outcome
results in Italy. A questionnaire was sent to the Endoscopy Units working with
Italian Liver Transplantation Centers (BASALT study group).
Results: At present sixteen of the 19 Units (84%) returned the questionnaire.
Complete endotherapy data and follow-up are available for 182 pts. One-hundred and two patients have been treated with plastic multistenting (PM), 27 with
fully covered SEMS and 53 with single stenting (SS). Radiological success was
achieved in 144 pts (79%), i.e. 86% of PM, 89% of fully covered SEMS and 60%
of SS (p 5 0.01 vs PM). Recurrence occurred in 31 pts, i.e. 21% of pts in whom
radiological success was achieved: 11% of PM (p 5 0.0001 vs SEMS and
p 5 0.05 vs SS), 41% of fully covered SEMS and 17% of SS. After failure of
first-line endotherapy (36) or recurrence (31), patients were re-treated with
endotherapy (75%), surgery (21%) or percutaneous balloon dilation (3%); one
patient dropped out because of death unrelated to endotherapy. Second-line
endotherapy was PM for 26%, fully covered SEMS for 52% and SS for 22%
of pts and radiological success was achieved in 82% of them (in 86%, 89%, and
60% with PM, SEMS and SS respectively). Procedure-related complications
occurred in 7.8% (51/656), i.e. 2.6% pancreatitis (1 severe leading to death),
4.1% cholangitis and 0.9% bleeding. Overall clinical success was achieved in
83% after a median f-up of 25 mos and no need of surgery in 92% of patients.
Conclusion: Endotherapy is confirmed as the preferred first-line and rescue
option for AS. Progressive plastic multi-stenting is most frequently used. Single
stenting has suboptimal results and should be abandoned. Use of SEMS is effective, but recurrences seem to be frequent, although a larger patients’ sample
needs to be evaluated.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0246 COMPARATIVE EVALUATION OF TWO PORCINE EX-VIVO
MODELS FOR TRAINING IN ENDOSCOPIC ULTRASOUNDGUIDED DRAINAGE OF PANCREATIC FLUID COLLECTIONS

Introduction: EUS-guided Cysto-Enterostomy (EUCE), technique indicated for
drainage of symptomatic pancreatic pseudocysts and other peri-enteric fluid collections, requires specific skills for which dedicated models are needed. Based on
a compact EASIE model (Erlangen Active Simulator for Interventional
Endoscopy) we developed two ex-vivo porcine models of retrogastric cysts and
evaluated learning performance within the frame of a structured training
program.
Aims & Methods: The first model was made of porcine colon (i.e. ‘‘natural cyst’’),
and second one was made with an ostomy bag (i.e. ‘‘artificial cyst’’). All procedures were achieved with EUS scope under fluoroscopy. Both models were evaluated prospectively over a 2-days session involving 14 students and 5 experts.
Results: ‘‘Natural cyst’’ and ‘‘artificial cyst’’ were prepared respectively within 10
and 16.5 minutes (p ¼ 0.78). More than 10 EUCE procedures were done in each
model. Model grading (analogic scale) showed no significant difference for primary endpoint of global satisfaction (p ¼ 0.06). Regarding secondary endpoints,
difference was not significant for overall impression of realism (p ¼ 0.75) whereas
it was significant favoring ‘‘artificial cyst’’ in terms of ability to teach procedural
steps (p ¼ 0.01) and ease of puncture (p ¼ 0.03) because of less elasticity.
Moreover, experts considered ability to improve students’ proficiency superior
with ‘‘artificial cyst’’ (p ¼ 0.008)
Conclusion: Both ‘‘artificial and natural cysts’’ are efficient for EUCE training in
terms of global satisfaction. However, the ‘‘artificial cyst’’ model appears to
make procedure easier and better to teach procedural steps improving students’
proficiency. Larger applications of this model are needed to validate as a standard of training.

P0247 A COMPARATIVE STUDY OF SUCTION METHODS
DURING ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE
ASPIRATION (CONVENTIONAL SUCTION VERSUS CAPILLARY
SUCTION)
K. Yamakita1, Y. Kitano2, H. Iwamoto2, K. Takahashi2, K. Wada2, S. Otake2,
Y. Ota2, Y. Tamaki2, M. Okada2, K. Aso2, Y. Makino2


Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is an established procedure for obtaining a pathological specimen. However, detailed techniques of EUS-FNA vary substantially across medical centers. There is a need to establish more efficient method for better diagnostic accuracy and adequate sample. In the present study, we investigated the suction method for collecting specimens by EUS-FNA.

Aims & Methods: The aim of our study was to compare conventional suction using a 20mL syringe and capillary suction during EUS-FNA. Patients who required suction for solid mass lesions were prospectively enrolled. We performed EUS-FNA with two needle passes and applied each pass of different techniques which were randomly allocated. The diagnostic accuracy, the quantity of samples (0-5.5 represents sufficient material for adequate for histological interpretation) and quality (sampling without degree of contamination, and the amount of blood (0-2.2 represents significant amount of blood) were compared between conventional suction and capillary suction. Further analysis was carried out in the patients with pancreatic cancer. For patients with negative EUS-FNA, surgical specimen evaluation, results of other diagnostic investigations and/or long term clinical follow-up (6 months) were used to establish the definitive diagnosis.

Results: During the study period, 96 patients underwent EUS-FNA were enrolled and 7 patients were excluded due to loss of follow-up. Finally 89 patients (averaged 68.5 y/o, M:F=47:42) were analyzed. There were 60 pancreatic lesions (42 pancreatic cancer, 6 neuroendocrine tumor, etc.), 17 lymph adenopathy, 6 sub-acute pancreatitis, 7; organizing pancreatic pseudocyst, 4; IPMN, 1). Adequate tissue sampling was successfully achieved in 97% (199/206). Of 199 patients with successful tissue sampling, sensitivity, specificity and accuracy for malignancy were 98% (175/179), 95% (19/20) and 97% (194/199). The diagnostic accuracy of PDC using by HE and PAS staining was 76% (129/170) (Class V 91; IV 36; III 6; IIb 2). Moreover, by using immunocytochemical staining, the accuracy of PDC was 98% (167/170) (Class V 112; IV 50; IIIb 5). In the cases of highly suspicious NET, all samples were stained by chromogranin A or synaptophysin and the diagnostic accuracy of NET was 100% (6:6). No procedure-related complications occurred.

Conclusion: EUS-FNA of a pancreatic mass with the CB method showed high accuracy for definitive diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0249 DIAGNOSTIC EFFICACY OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION FOR A Pancreatic MASS USING THE CELL BLOCK METHOD WITHOUT RAPID ON-SITE CYTOLOGY

K. Masu1, K. Ito1, Y. Noda1, S. Koshita1, K. Yanno1, T. Ogawa1, T. Sawai2

Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) has been shown to be efficient for diagnosis of pancreatic masses. Only with smear method, however, its diagnostic efficacy may vary greatly depending on the amount of proficiency of cytopathologists. On the other hand, cell block (CB) method allows cytological and/or histological evaluation with hematoxylin and eosin (HE) staining and with immunostaining for serial sections if necessary.

Methods: The aim of this study was to evaluate the diagnostic efficacy of EUS-FNA for a pancreatic mass using the CB method without rapid on-site cytology retrospectively. A total of 206 patients with pancreatic masses (head: 87, body: 86, tail: 33) who underwent EUS-FNA using a GF-L240P or GF-U240P Olympus Medical Systems Ltd., Tokyo, Japan between June 2005 and November 2016 were included in this study. The needles used were 22/25G needles. At least two passes were made during the procedure (mean 3.0±0.9 passes). Adequate specimens were regarded to be those in which whitish flagging were macroscopically achieved. The samples were immediately fixed in 10% formalin and processed by the cell block method using sodium alginate. Rapid on-site cytology was not performed. All samples were stained by hematoxylin and eosin, periodic acid Schiff and Alcian-blue, and immunohistochemistry. All samples were reviewed by 8 cytopathologists.

Results: From March 2013 to January 2016, a total of 114 patients (57 in a S- group and 60 in the PTBD group) were included. There were no significant differences in technical success (100% vs. 100%, P=1.00), the mean number of needle passes (6.8 vs. 7.0, P=0.556), or complication (0% vs. 3.5%, P=0.496) between the S- group and the PTBD group. The S- and PTBD groups exhibited comparable outcomes with respect to cytologic diagnostic yield (91.2% vs. 93.0%, P=1.000), histologic diagnostic yield (87.7% vs. 88.0%, P=1.000), and needle malfunction (7% vs. 0%, P=0.118). The procedure time was significantly shorter in the S-group than in the PTBD group (32 vs. 39.7 min, P=0.001).

Conclusion: EUS-guided tissue acquisition using a 25G-core biopsy needle without a stylet did not decrease the diagnostic yield for malignancy and is associated with shorter procedure time.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0250 A COMPARATIVE STUDY BETWEEN EUS-GUIDED BILIARY DRAINAGE AND PERCUTANEOUS BILIARY DRAINAGE IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION AND FAILED ERCP

Department Of Gastroenterology, Hangzhou First People’s Hospital, Hangzhou, China

Contact E-mail Address: zacharylu@126.com

Introduction: Patients with malignant biliary obstruction conventionally undergo percutaneous transhepatic biliary drainage (PTBD) after failed endoscopic retrograde cholangiopancreatography (ERCP) (1). While PTBD is efficacious, it is associated with significant morbidity, such as bile leakage, bleeding, and pneumothorax, and involves uncomfortable external drainage (2). Endoscopic ultrasound-guided biliary drainage (EUS-BD) is a minimally invasive endoscopic treatment increasingly offered as a potential option for malignant biliary obstruction after failed ERCP (3). Although a recent meta-analysis reported better clinical efficacy and superior safety of EUS-BD when compared to PTBD (4), the definitive diagnostic accuracy of NET was 100% (6:6). No procedure-related complications occurred.

Aims & Methods: We aimed to compare efficacy and safety of EUS-BD to PTBD in patients with malignant biliary obstruction after failed ERCP at a single tertiary referral center from mainland China. From November 2011 through December 2015, consecutive patients undergoing EUS-BD or PTBD for malignant biliary obstruction after failed ERCP were included. Demographical, biochemical, and outcome data were registered for each group. The primary outcomes included technical success rate and incidence of complications, the secondary outcomes included clinical success rates and re-intervention rate.

Results: A total of 93 patients (mean age 68±13.5 years, 49 males) were included, 33 in the EUS-BD group and 60 in the PTBD group. Both groups were similar in terms of age, gender, baseline bilirubin and functional status. Technical success was achieved in 32 (97.1%) of 33 patients in the EUS-BD group and in 57 (95.0%) of 60 patients (p>0.05) in the PTBD group. The clinical success (juvenileileuc: reduction in serum bilirubin by 50% within the first month) was achieved in all patients with technical success (32,32, 100% EUS-BD vs. 57,57, 100% PTBD). Procedure-related complication rates were higher in the PTBD group (58, 31.6%: 5 bleeding, 5 catheter site infection, 4 bile leaks, 2 cholangitis, and 2 tube malfunction) than in the EUS-BD group (3, 9.4%: 2 bleeding and 1 cholangitis) (p=0.018). Rate of re-intervention appeared to be lower in the EUS-BD group (2, 6.3%: 2 stent occlusion) than in the PTBD group (17, 29.8%; 6 stent occlusion, 5 catheter site infection, 4 bile leaks, and 2 tube malposition) (p=0.009).

Conclusion: Despite similar high technical and clinical success rates compared with PTBD, EUS-BD was associated with reduced rates of procedure-related complications, required fewer re-interventions. EUS-BD seems to be a better alternative than PTBD for malignant biliary obstruction after failed ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.
PD0251 A PROSPECTIVE COMPARATIVE STUDY OF EFFICACY OF EUS GUIDED FNA VERSUS ERCP GUIDED BRUSH CYTOTOLOGY IN ATTAINMENT OF HISTOPATHOLOGY OF DISTAL CBD MASSES

P.N. Desai, M. Kabrawala
Endoscopy, Surat Institute Of Digestive Sciences, Surat/India

Contact E-mail Address: drp.desai@hotmail.com

Introduction: Distal CBD masses have always been a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used until now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these difficult to identify distal CBD masses and took FNA from them. We devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for obtaining tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with obstructive jaundice in the last 3 years were taken for the study. The protocol we followed first- EUS was done using a linear echoendoscope, mass was identified and FNA performed with a 25 G needle making 2 to 5 passes and material sent for cytology. Same patients subjected to ERCP. A wide papillotomy was performed and over the wire cytology brush was used and brush cytology was obtained. Two passes were made and material taken on a slide and sent for cytology after wet fixation.

Results: Total number of cases 56 Age (range) 57.2 ± 13.6 Male to Female 40: 16 Total Serum Bilirubin (90 mg/dl) 5.9 Total number of cases 56 Age (range) 57.2

Results:
- FNA (47) Brush Cytology (34)
  - Malignancy 38 (80.8%) 23 (67.6%)
  - Suspicious Of Malignancy 5 (10.6%) 7 (20.5%)
  - Benign 4 (8.5%) 4 (8.5%)

Diagnosis in Positive Cases
- Metal (n = 31)
- Plastic (n = 29)

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved.

PD0253 TRANS AORTIC ENDOSCOPIC ULTRASOUND GUIDED FNA IN THE DIAGNOSIS OF LUNG CANCERS AND MEDIASTINAL LYMPH NODES

P. Somani, M. Sharma
Department Of Gastroenterology, Jaswant Rai Speciality Hospital, Meerut/India

Contact E-Mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Obtaining a tissue diagnosis from a lung tumour or a mediastinal lymph node located lateral to the aorta (para-aortic) is a diagnostic challenge because of the interposition of the aorta. Invasive surgical procedures like mediastinoscopy, thoracotomy, or video-assisted thoracic surgery is required for the diagnosis of these lesions. lymph node stations immediately anterior to the aortic arch and lateral to the descending aorta are difficult to access. Lymph nodes on the “far-side” of major blood vessels can be visualized by endoscopic ultrasound(EUS), however Fine needle aspiration(FNA) is avoided due to concern for bleeding complications. Tumours and mediastinal lymph nodes located in the para-aortic region can easily be visualized by esophageal EUS, because the aorta provides an excellent medium to transfer ultrasound waves.

Disclosure of Interest: All authors have declared no conflicts of interest.

PD0252 RANDOMIZED TRIAL COMPARING THE LUMEN-APPROXIMATING METAL STENTS (LAMS) AND PLASTIC STENTS FOR EUS-GUIDED DRAINAGE OF WALLED-OFF NECROSIS (WON)

J.Y. Bang, M. Hasan, U. Navaneethan, R. Hawes, S. Varadarajulu
Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jybang213@gmail.com

Introduction: Although lumen-apposing metal stents (LAMS) are being increasingly used for drainage of walled-off necrosis (WON), their advantage over plastic stents is unclear.

Aims & Methods: We aimed to compare the efficacy of LAMS and plastic stents for drainage of WON.

Symptomatic patients with WON (>20% necrosis) were randomized to undergo transmural drainage using LAMS (Hot AXIOS, 15 mm x 10 mm) or two double pigtail plastic stents (7Fr x 4 cm). Reintervention in persistently symptomatic patients included additional stent placement, percutaneous drainage and/or endoscopic necrosectomy. Treatment success was defined as symptom relief in conjunction with resolution of WON on CT at 6-week follow-up. Main outcome measure was to compare the no. of reinterventions. Secondary outcome measures were to compare treatment success, procedural duration, resolution of systemic inflammatory response syndrome (SIRS), clinical and stent-related adverse events, readmissions and length of hospital stay. Sample size to detect a difference in the no. of reinterventions performed at 90% power was calculated at 58 patients.

Results: 60 patients were randomized to LAMS (n = 31) or plastic stent (n = 29) placement. While there was no significant difference in the no. of reinterventions (median 1 [IQR 1–2] for both stent types, p = 0.78), the procedural duration was significantly shorter (15 vs. 42.5 mins, p < 0.001) and stent-related adverse event rate was significantly higher with LAMS placement (32.3 vs. 6.9%, p = 0.02). At an interim audit, significant adverse events (delayed bleeding [n = 3], buried stent [n = 2], biliary structure [n = 3]) were observed in the LAMS cohort after 3 weeks post-intervention. This necessitated an amendment to the study protocol whereby a CT scan was obtained at 3 weeks followed by LAMS removal if the WON had resolved. After protocol amendment, no difference in stent-related adverse events was observed between the cohorts (LAMS 6.5 vs. plastic 6.9%, p = 0.9). Also, there was no significant difference in treatment success, SIRS resolution, clinical adverse events, readmissions or length of hospital stay between the cohorts (Table).

Disclosure of Interest: The authors have declared no conflict of interest.

PD0249 METAL VERSUS PLASTIC STENTS FOR THE TREATMENT OF DISTAL BILIARY OBSTRUCTION

Department of Gastroenterology, United Medical and Dental Schools of Guy’s and St Thomas’/King’s College School of Medicine, London/United Kingdom

Contact E-mail Address: ajcerasi@gmail.com

Introduction: Distal bile duct obstruction is a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used until now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these difficult to identify distal CBD masses and took FNA from them. We devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for obtaining tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with obstructive jaundice in the last 3 years were taken for the study. The protocol we followed first- EUS was done using a linear echoendoscope, mass was identified and FNA performed with a 25 G needle making 2 to 5 passes and material sent for cytology. Same patients subjected to ERCP. A wide papillotomy was performed and over the wire cytology brush was used and brush cytology was obtained. Two passes were made and material taken on a slide and sent for cytology after wet fixation.

Results: Total number of cases 56 Age (range) 57.2 ± 13.6 Male to Female 40: 16 Total Serum Bilirubin (90 mg/dl) 5.9 Total number of cases 56 Age (range) 57.2

Results:
- FNA (47) Brush Cytology (34)
  - Malignancy 38 (80.8%) 23 (67.6%)
  - Suspicious Of Malignancy 5 (10.6%) 7 (20.5%)
  - Benign 4 (8.5%) 4 (8.5%)

Diagnosis in Positive Cases
- Metal (n = 31)
- Plastic (n = 29)

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved.

Aims & Methods: We aimed to evaluate the feasibility, yield, and safety of EUS-guided drainage of lung tumours using FCSEMSs. We undertook a retrospective case series of 12 consecutive patients with suspected lung cancer or tuberculosis who underwent transaortic FNA during a study period of 7 years. In all cases, the para-aortal lesion was the only site suggestive of tumour on non-invasive imaging (either lesion/lymph node if present were negative). Based on CT/PET imaging, a transaportal FNA performed through the aorta was considered as the only option to diagnose or stage these patients by means of a minimally invasive procedure. Seven patients had left-sided lesions, seven had right-sided lesions. Four were located in left lower lobe and three in left upper lobe. Four patients have enlarged para-aortic lymph node (mean size 18 mm, range 8–22 mm), suspicious for IASLC stations 5 (n=1) and 6 (n=3). One patient had anterior mediastinum maso. EUS was performed with a linear echoendoscope. All aspirations were obtained under real-time US guided FNA by using a 22/25-gauge needle. A single real-time FNA of the lung mass or lymph node was performed. The para-aortal area was observed on EUS for 5 minutes to assess for immediate procedure-related complications.

Results: The final diagnosis was known in 11 patients (5 non-small-cell lung carcinoma [NSCLC], 2 small-cell lung carcinoma [SCLC], 3 tuberculosis and 1 thymolipoma). EUS-FNA established diagnosis in 9 of 12 patients (75%) (4 NSCLC, 1 SCLC, 3 tuberculosis and 1 thymolipoma). One aspiration revealed reactive nodal tissue, and one demonstrated nonrepresentative material. One procedure was abandoned due to complication. Three patients in whom diagno- sis was not established by transaortic FNA underwent subsequent surgical staging (1 thymoma, 1 mediastinotomy, and 1 VATS), and malignancy was found in 2 of the 3 patients. Transthoracic FNA was found to be safe. In one patient, EUS images after FNA were suspicious for a small para-aortic hema- toma. This patient recovered without any adverse event.

Conclusions: This study demonstrates the feasibility and probable safety of single EUS guided transaortic aspiration in para-aortic lesions. The diagnostic yield is 75 percent. Clearly, further study and very careful selection by expert EUS operators is needed before this procedure can be routinely recommended. Advantages of this procedure includes day care procedure, less invasive than surgical procedures, low cost, good diagnostic yield and can be performed in poor surgical candidate. Limitations includes single centre study, require EUS expertise, more data is required. At present, Transthoracic FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0254 ULTRASOUND-GUIDED ENDOSCOPIC TRANSDUODENAL PANCREATIC FLUID COLLECTIONS

M. Silva1, S. Lopes1, A. Peixoto1, F. Vilas-Boas1, P. Moutinho-Ribeiro1, G. Macedo2
1Gastroenterology, Hospital Sao Joao, Oporto/Portugal
2Centro Hospitalar Sao Joao, Porto Medical School, Porto/Portugal

Contact E-mail Address: marcocostais@yahoo.com

Introduction: Ultrasound-guided endoscopic transduodenal drainage (EUSTD) of pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPPS) reduces the risk of multiple stents and can be restricted by inadequate drainage and leakage risk. Recently, the use of fully covered self-expanding metal stents (FCSEMSs) has been reported as an effective alternative.

Aims & Methods: We aimed to evaluate the successful placement of stents, the complete resolution of PFCs at 6-months, adverse events, and recurrence of EUSTD of PFCs using DPPS and FCSEMSs. This was a single-centre retrospective study (2012–2016) on 50 patients with symptomatic PFCs who underwent EUSTD. Endoscopic PFCs were drained using DPPS and FCSEMSs (Hanarostent BCF and Hot AXIOS system).

Results: We included 42 cases of pancreatic pseudocysts (PP), and 5 wall-ed off necrosis ( WON), drained using FCSEMSs in 51% of cases. The remaining cases (49%) were drained using DPPS exclusively. Eighteen (27%) patients had a prior failed drainage attempt. Median follow-up time was 88 weeks (IQR: 42–140); 19 patients were lost to follow-up (6 deaths during follow-up). The median size of lesions was 92 mm (IQR: 74–120). The overall technical success rate was 78% (74% for PP and 100% for WON; p < 0.05). Six patients required additional drainage with a different modality (surgery/pectacutaneous drainage) and 8 cases required another EUSTD attempt. Complete resolution of PFCs with DPPS was achievable in 7 cases of PP and in none of WON (p < 0.05); the recurrence was higher in the DPPS group than in the FCSEMS group (43% vs. 13%; p > 0.05).

Conclusion: EUS-TGD of PFCs using FCSEMSs improves clinical outcomes with similar adverse events compared with DPPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Histological examinations and immunohistochemical stains (IHC) are necessary for the differential diagnosis of gastrointestinal subepithelial lesions (SLEs). Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) is the primary modality in the diagnosis of SLEs, but still has limited accuracy. A new 20 gauge (G) biopsy needle with a core-trap technology (EchoTip ProCore®, Cook Medical) has been developed with a large core size and enhanced flexibility.

Aims & Methods: The aim of this multicenter study was to determine the feasibility, efficacy and safety of EUS-FNB with the new 20G needle in diagnosing SLEs. Data retrieved from a prospectively collected database at five medical centers were analyzed and all consecutive patients with SLEs undergoing EUS-FNB with the 20G needle were included in the present study. The reference standards for the final diagnosis were histology on surgical specimen or clinical follow-up.

Results: A total of 50 SELs in 50 patients (22 males, mean age 61.5 ± 14.8 years) were included. The mean lesion size was 43.1 ± 17.5 mm. The lesion locations were esophagus (n=1), stomach (n=37), distal duodenum (n=5), rectum (n=6), and colon (n=1). The procedure was technically feasible in all patients. Mean number of passes required to reach a diagnosis was 2.2 (range 1–4). Definitive diagnosis with full histological assessment including IHC was obtained in 88% (44/50) of the patients. Diagnosis of EUS-FNB showed 36 (72%) malignant SELs (32 GISTs, 1 metastasis from breast cancer, 1 leiomyosarcoma, 1 carcinoid, 8 SEL-like adenomatoid tumors), 6 (12%) benign SELs (3 leiomyomas, 4 schwannomas, and 1 lipoma), and 6 (12%) indeterminate SELs. Considering malignant vs. benign lesions, the sensitivity, specificity, PPV, and NPV were 85% (95% CI 70.2–94.3%), 100% (95% CI 58.7–100%), 100% (95% CI 55.1–100%), and 62.5% (95% CI 27.7–84.8%), respectively. No major complications requiring additional care were observed.

Conclusion: In this multicenter study, we found that EUS-FNB with the new 20G core needle is an effective and safe method for the diagnosis of SELs with a high rate of producing adequate histological material and high diagnostic accuracy even from difficult-to-access anatomical locations. Comparative studies with different needle sizes are awaited.

Introduction: Endoscopic ultrasonography(EUS)-guided ethanol ablation for pancreatic cystic lesions (PCLs) is a recently introduced treatment option for PCLs. The aim of this study was to compare the clinical outcomes of EUS-guided ethanol ablation with those of the natural course of PCLs.

Aims & Methods: We performed retrospective study of patients with PCLs divided in two groups: EUS-guided ethanol ablation group (n=118, performed between June 2006 to August 2015) and natural course group (n=458, diagnosed between January 1993 to August 2015). The propensity score-matching analysis
between the two groups was applied in order to minimize the effect of selection bias. There was a rate of significant reduction in size (≥20% of initial size). The secondary outcomes were the rate of significant growth in size (>10 mm), complete remission rate, and surgical resection rate. Results: In a propensity matched analysis of 88 pairs, the mean initial cystic size of EUS-guided ethanolic ablation group and natural course group was 23.72 ± 10.99, 23.16 ± 13.15 mm and the mean follow-up duration was 75.45 ± 38.12, 82.12 ± 59.06 months respectively. Significant reduction in size was detected in 53 (60.2%) of the EUS-guided ablation group and 17 (19.3%) in the natural course group (p < 0.01). Significant growth in size was detected in 6 (8.9%) of ablation group and 11 (12.5%) of natural course group. (p = 0.20). Seven patients (7.95%) underwent surgical resection in the EUS-guided ablation group and 17 patients (19.3%) in the natural course group. (p = 0.028) during follow-up. Overall 28.8% patients (34 of 118) who underwent EUS-guided ethanolic ablation had achieved the complete remission. Conclusion: PCLs that underwent EUS-guided ethanolic ablation can be seen the likelihood of getting clinical benefits such as reduction of the cystic size, the clarity in decision in comparison to the natural course of them. It is also expected to achieve a certain level of complete remission for PCLs. Disclosure of Interest: All authors have declared no conflicts of interest.

P0257 RANDOMIZED TRIAL COMPARING THE FRANSEEN AND FORK-TIP NEEDLES FOR EUS-GUIDED FINE NEEDLE BIOPSY

Introduction: EUS-FNA needle tissue compaction and desmoplastic stroma is required for molecular profile-based personalized chemotherapy in pancreatic cancer. Recently, a three-plane symmetric needle with Franssean geometry and a Fork-tip biopsy needle have been developed for histologic tissue preservation. Aims & Methods: We aimed to compare tissue acquisition between the 22G Franssean and 22G Fork-tip needles in patients undergoing EUS-guided sampling of pancreatic masses. Patients with pancreatic masses were randomized to undergo EUS-guided sampling using the 22G Franssean and 22G Fork-tip needles. Two dedicated passes were first performed using both needles in individual patients for cell block. Subsequent passes were then performed for rapid onsite evaluation (ROSE), using both needles only until a diagnosis was established. The main outcome measures were to compare total tissue volume and presence of desmoplastic stroma in pancreatic cancer. Secondary outcome measures were to compare rates of diagnostic cell block and diagnostic adequacy at ROSE. Results: In 50 patients randomized to undergo EUS-guided sampling, the diagnosis was pancreatic cancer in 43, neuroendocrine tumor in 2, lymphoma in 1 and chronic pancreatitis in 4 patients. There was no significant difference in total tissue area (median 6.1mm2 [IQR 3.5–10.5] vs. 8.2mm2 [IQR 4.0–13.0], p = 0.93), presence of desmoplastic stroma in tumors (100 vs. 83.3%, p = 0.23), rates of diagnostic cell block (96.0 vs. 92.0%, p = 0.68) and diagnostic adequacy at ROSE (94.0 vs. 98.0%, p = 0.06) between the Franssean and Fork-tip needles, respectively. Conclusion: Both the Franssean and Fork-tip needles appear equally effective in yielding histologic tissue. By virtue of their ability to yield a diagnostic cell block in greater than 90% of patients, the new generation FNB needles may obviate the need for ROSE during EUS-guided tissue sampling. Introduction: To evaluate the success rate of double-balloon endoscopic retrograde cholangiopancreatography (DBERC) to reach the anastomosis in patients with surgically altered gastrointestinal anatomy. Aims & Methods: We review 346 patients with surgically altered anatomy who underwent DBERC from April, 2002 to December, 2016 (47 patients with biliary atresia (BA), 146 with portal vein thrombosis, 141 with liver transplantation). We evaluate the success rate according to the type of gastrointestinal anastomosis, age, and age at surgery. Results: The success rate for reaching the biliary anastomosis (or papilla of Vater) in all 346 patients (66.0 ± (3–91)) was 83%. The rate in 47 patients with BA after LDLT (12y.o (3–39)) was 57%. In the remaining 299 patients the rate was 87%. The success rate of reaching the biliary anastomosis in patients with BA after LDLT was significantly lower than other patients (p < 0.01). There was no significant difference between the success rate in the patients over or under 13 years at the time of ERCP (90% vs 56%, p = 0.70). The success rate was lower in patients who underwent initial surgery as an infant (Kasai hepatoportoenterostomy) than in those past infancy (54% vs 88%, p < 0.01). When reaching the biliary anastomosis is successful, the success rate of cannulation in the patients after LDLT is high (92%). Conclusion: The success rate for reaching the biliary anastomosis in patients with BA after LDLT is significantly lower than other patients. The age at the time of ERCP did not affect the success rate of reaching the biliary anastomosis, but the success rate was lower in patients who underwent their initial surgery as infants. Disclosure of Interest: All authors have declared no conflicts of interest.

P0259 EUS-GUIDED RADIOFREQUENCY ABLATION OF DIFFICULT SITES IN THE LIVER: A PRECLINICAL STUDY
N. Junya1, T. Tamura1, M. Itonaga, R. Shimizu, Y. Ida, M. Kitano
Second Department Of Internal Medicine, Wakayama Medical University, Wakayama/Japan

Introduction: Liver tumors such as hepatocellular carcinoma and liver metastases sometimes occur in positions in which treatment using percutaneous radiofrequency ablation (RFA) is difficult, such as the caudate lobe and surface of the left liver. EUS-guided RFA (EUS-RFA) can offer an alternative treatment by accessing these tumors through the stomach or duodenum. To the best of our knowledge, only one report has described EUS-RFA of the liver in an animal model, using a 19-gauge EUS-FNA needle with an umbrella-shaped array at the tip. Aims & Methods: We examined whether a novel 19-gauge RFA needle can be introduced to ablate the liver in a porcine model under EUS guidance. Two pigs were used in this study. All procedures were carried out under general anesthesia. EUS-guided 19-gauge needle and a VIB Combo generator (Taewoong Medical, Gimpo city, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-, and 20-mm exposed tips) were used. After the echoendoscope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at 340 W for 2-6min in general mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the RFA needle with the 10-mm exposed tip was used in the quadrate lobe of the gallbladder through the bulb of the duodenum. Results: All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect was evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area. Conclusion: In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Small bowel varices (SBV) occur as a consequence of portal hypertension and may result in life-threatening mid-gut bleeding. First line management usually involves radiological intervention (RI) (e.g. TIPSS, stenting of occluded mesenteric veins +/- embolisation of culprit varices). In cases where RI is impossible, management options become very limited. Aims & Methods: This case series evaluated the usefulness of DBE facilitated cyanoacrylate injection of SBV. Retrospective review of DBE facilitated cyanoacrylate injection of SBV at our institution (December 2015 to August 2016). Demographic, clinical, endoscopic and radiological findings, interventions and follow-up data were analysed. Results: Seven DBEs were performed in 3 patients (3 women, median age 73-years). Four patients had previous surgery (hepatic/hepatectomy (n = 2); SB resection (n = 2)); one patient had a history of intra-abdominal sepsis in childhood causing portal vein thrombosis. No radiological or surgical options were deemed feasible in any case. SBV were diagnosed at capsule endoscopy and triple phase CT mesenteric angiography. At DBE, a total of 10 nests of SBV were identified.
and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications. No patient developed an anastomotic leak, nor a candidal urinary cyst, which was treated successfully with antibiotics. All patients underwent DBE via the anterograde route and 1 patient required bi-directional DBE for treatment of both proximal and distal SBV and another patient required a 2nd anterograde DBE for treading of further patent proximal SBV. At 30-day follow-up post-therapy, only 1 patient had experienced a mild recurrence of mid-gut bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options have failed.

Contact E-mail Address: n.oogata@hotmail.co.jp

Introduction: The development of balloon endoscopy and capsule endoscopy has made observation of the small intestine possible in clinical practice. The usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. A single-balloon enteroscopy (SBE) with 80x magnification has been recently developed.

Aim & Methods: The aim of this pilot study was to assess the efficacy of narrow-band imaging (NBI) magnifying findings for evaluating the severity of inflammation in small intestinal crohn's disease (CD). The study was conducted in Showa University Northern Yokohama Hospital. We included CD patients who underwent enteroscopy with magnification from September 2013 to February 2015. NBI images and a biopsy specimen were obtained from small intestinal mucosa for CD patients with use of SBE (Y-0007, Olympus, Tokyo). Magnifying NBI was performed, and the images were evaluated by assessing visibility, increased vascularity, and the increased caliber of capillaries into three grades as follows: Normal, Visible and Irregular. Normal was indicative of inactive disease, while Visible and Irregular were indicative of acute inflammation in our study. The outcome measures included the diagnostic ability of magnifying NBI findings to distinguish active CD from inactive CD on the basis of histological activity.

Results: Twenty-four patients were enrolled. There was a correlation between magnifying NBI findings and the histological assessment (Spearman's ρ = 0.54 for sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of magnifying NBI findings for diagnosing acute inflammation were 88.2%, 71.4%, 88.2%, 71.4%, and 83.3%, respectively.

Conclusion: The NBI magnifying findings in the small intestinal mucosa had a correlation with histological inflammation and could help in distinguishing between active and inactive CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0262 SINGLE-INCISION LAPAROSCOPIC-ASSISTED DOUBLE BALLOON ENTEROSCOPY: A NOVEL TECHNIQUE TO MANAGE SMALL BOWEL PATHOLOGY

Introduction: Double balloon enteroscopy (DBE) has revolutionised the diagnosis and treatment of small intestinal conditions. However, even in expert hands, deep small bowel (SB) insertion can be challenging, especially in patients with a history of abdominal surgery. Moreover, if the findings at DBE are not amenable to endoscopic therapy, a further surgical procedure is usually required to provide definitive treatment. Laparoscopic-assisted DBE (LA-DBE) using a standard multi-port technique has previously only been reported in a small series of 3 patients with Peutz–Jeghers Syndrome (PJS) 1.

Aims & Methods: This case series reports the development of LA-DBE using single-incision laparoscopic surgery (SILS) applied to a wide range of clinical indications. Retrospective review of LA-DBE procedures performed in a single tertiary centre over a 6 year period. Demographics, indication, findings, diagnosis and therapeutic interventions were recorded. Completion, complication rates and hospital length of stay were also captured.

Results: 17 procedures were performed over 6 years in 17 patients who had failed standard DBE. Mean (range) age was 40 (17-73) and 41% of patients were male. The enteroscopic approach was oral in 13/17 patients and rectal in 4/17. Laparoscopic approach was standard (multipor) in the first 4 cases, SILS was then used in all subsequent patients (13/17). The mean (range) procedure time was 147 (84-210) mins. Indications were PJS (n = 10), suspected submucosal/ intramural polypoid lesion at small bowel imaging (n = 5) and obscure gastrointestinal bleed (OGBB) with vascular abnormalities seen at capsule endoscopy (n = 2). In 15/17 procedures the target pathology was reached using laparoscopic assistance only and 1/17 was converted to intraoperative enteroscopy (IOE). In 1/17 the suggested pathology at magnetic resonance enterography (MRE) was not identified. Therapy was applied in 15/17 (88%) cases. 7 underwent endoscopic therapy of which 6 polypectomy and 1 ablation with argon plasma coagulation (APC). 4 required limited SB resection and 4 underwent both endoscopic polypectomy and small bowel resection for a second polyp that could not be removed endoscopically. A total number of 57 polyps were removed with the largest measuring 40 mm. The range of length of surgically resected SB was 4-17 cm. Diagnoses were PJS polyps (n = 9), neuroendocrine tumour (NET) (n = 2), PJS polyp with additional NET (n = 1), transmural arteriovenous malformation (n = 1), angiectasia (n = 1), inflammatory polyp (n = 1), leiomyoma (n = 1), Meeckel's diverticulum (n = 1). Median length of stay post procedure was 2 (1–19) days. 8/17 patients were discharged at 24 hours. 3/17 patients developed complications: 1 post procedure ileus, 1 partial bowel obstruction which resolved with conservative management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0263 GASTRIC EMPTYING IN CROHN'S DISEASE – EVALUATION BY SMALL BOWEL CAPSULE ENDOSCOPY

A.M. Singeap1, A. Trifan1, S. Chiria1, I. Girleanu1, T. Cucureana2, C. Stanciu2

1Gastroenterology, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi/Romania
2Institute of Gastroenterology and Hepatology, Iasi/Romania

Contact E-mail Address: anamaria.singeap@yahoo.com

Introduction: The complex relationship between inflammatory bowel disease (IBD) and motility disorders of the digestive tract is a complex area of study, so far inadequately elucidated. The association between Crohn’s disease and gastric emptying time modification has been relatively less studied. However, there is no single standardized method to study gastric emptying, one particular investigation that could bring direct information in this field being the small bowel capsule endoscopy (SBCE).

Aims & Methods: We aimed to study gastric emptying by small bowel capsule endoscopy in patients with suspected and confirmed Crohn’s disease. We evaluated gastric passage time showed by SBCE in patients with small bowel Crohn’s disease, compared to patients without IBD, investigated by SBCE (PillCam), following recognized indications, in the Institute of Gastroenterology and Hepatology of Iasi, tertiary center in North-East of Romania.

Results: 144 SBCE studies were included, 24 were cases of suspected and confirmed Crohn’s disease. The mean time of gastric passage in patients with Crohn’s disease was 51±21.9 minutes, longer than in patients without inflammatory bowel disease, in which the mean gastric passage time was 24±16.6 minutes.

Conclusion: Gastric passage time, evaluated by SBCE, is prolonged in patients with inflammatory bowel disease compared to patients without IBD, suggesting a relationship between chronic inflammation and gastric motor disorders. Globally, the values correlated with those considered as physiological by other exploration methods. SBCE studies may provide additional data on gastric motility and in general gut motor disorders, with special usefulness in some individual cases, as particular symptoms or variations in the bioavailability of small bowel-released drugs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0264 META-ANALYSIS SHOWS THAT PURGATIVE PREPARATION INCREASES SMALL BOWEL VIDEO CAPSULE ENDOSCOPY DIAGNOSTIC YIELD AND IMPROVES THE QUALITY OF SMALL BOWEL MOVEMENTS: A META-ANALYSIS

P. Gkolakis, G. Tziatzios, G. D. Dimitriadis, K. Triantafyllou

2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: The value of purgative preparation (PBP) before small bowel video capsule endoscopy (VCE) remains controversial and it has been recently challenged.

Aims & Methods: The aim of this meta-analysis was to examine the effect of PBP on small bowel VCE outcomes. We performed literature searches in MEDLINE and Cochrane Library to identify randomized-controlled trials (RCTs) evaluating the effect of small bowel preparation –purgative (PEG, sodium phosphate,
others) vs. clear liquids diet on VCE outcomes. Examination’s diagnostic yield (DY) was meta-analytically primary endpoint and posed small bowel visualization quality (VQ), VCE completion rate (CR), gastric (GTT) and small bowel (SBTT) transit times comprised the secondary endpoints. Study outcomes effect sizes were calculated using RevMan 5.3 software fixed or random effect model, as appropriate, and they are presented as OR[95%CI] or mean difference[95%CI], respectively. Heterogeneity was measured using the I² statistics. Publication bias was assessed by Funnel plots inspection and the quality of the meta-analyzed studies was assessed using the Jadad criteria.

Results: We identified 9 eligible RCTs with 12 sets of data, including 1029 subjects. They were of high quality and no publication bias was detected. As compared to clear liquids diet, PB1 significantly increased small bowel VCE DY (1.44 [1.14–1.83], I² = 39%). However, a sensitivity analysis that excluded studies with sodium phosphate preparation (abandoned nowadays) and PBPs different (not widely used) than PEG showed no benefit of PEG preparation over clear liquids (1.31 [0.79–2.17], I² = 54%). VQ significantly improved after PB1 (2.05 [1.49–2.82], I² = 45%), without any significant effect on VCE CR (0.98 [0.73–1.33], I² = 53%) and SBTT (1.21 [1.21–1.73], I² = 49%). On the contrary, VCE SBTT was statistically lower by ~15.06 [–25.52–6.61] min (I² = 90%) after PBP.

Conclusion: In comparison to clear liquids diet, PB1 increases small bowel VCE DY and improves VQ without affecting exam’s CR. However, the positive effect of PB1 on VCE SBTT is mainly derived from two relative small, old (2004 and 2009) RCTs and does not appear if only PEG preparation studies are meta-analyzed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0265 INTER-OBSERVER AGREEMENT IN BROTZ CLEANING SCALES FOR CAPSULE ENDOSCOPY
Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafalda_m_p_sousa@hotmail.com

Introduction: The diagnostic yield of capsule endoscopy (CE) depends on the adequate visualization of the mucosa. As with colonoscopy, cleaning scales should be described in the report in order to better interpret results. In 2009, Brotz et al proposed and validated 3 different cleansing scales in 40 patients.

Aims & Methods: A hundred CE videos (Mirocam®) were reviewed by 2 authors at a fixed frame rate of 100 frames per second in quadruple view (Miroview Client). The CE were evaluated according to Brotz scales: (1) Overall adequacy assessment (adequate/inadequate) (2) Qualitative scale (excellent, good, fair, poor) and (3) Quantitative scale (0–10 score, graded from 0–2 visualization of the mucosa, fluids, bubbles, bile and luminosity). The aim of this study was to evaluate the inter-observer variability of this cleaning scales. The kappa coefficient was used to calculate the inter-observer agreement in overall adequacy assessment and the intra-class correlation coefficient was used to evaluate the concordance of the qualitative and quantitative scales.

Results: In overall adequacy assessment, the quality of bowel preparation was classified as adequate by observer 1 in 100% and by observer 2 in 73%, with an inter-observer kappa index of 0.76 (p < 0.001) suggesting strong agreement. In the qualitative scale, most of the bowel preparations were considered reasonable (40% observer 1 vs 36% observer 2), with an intra-class coefficient of 0.89 (p < 0.001). In the quantitative scale, the mean score of the two observers was 6.5 and 6.7, resulting in an intra-class agreement of 0.78 (p < 0.001).

Conclusion: The optimization of quality of bowel preparation and the diagnostic yield of CE require a well-validated cleaning scale. Brotz’s rating scales have strong inter-observer agreement. The qualitative scale is easier to apply and has better inter-observer agreement, so the authors propose that it should be used routinely in the CE report.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0266 PILOT STUDY OF THE EFFECTS OF IMAGE QUALITY ON LESION VISUALISATION IN SMALL BOWEL CAPSULE ENDOSCOPY
1The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom
2Hôpital Saint-Antoine, Paris/France
3Skane University Hospital, Malmo/Sweden
4Ospedale Valli, Genova/Italy
5Royal Hallamshire Hospital, Sheffield/United Kingdom
6Gastroenterology, Chalmers Medical Center, Raman Gat/Israel
7San Giovanni Battista University Teaching Hospital, Turin/Italy

Contact E-mail Address: diana.e.yung@gmail.com

Introduction: Capsule endoscopy (CE) is the prime mode of investigation for small bowel (SB) pathology. However, as an entirely visual medium it depends heavily on image quality. The definition of optimal image quality remains to be ascertained between studies and poses significant limitations to the quality of study reporting. As yet, there is no widely-accepted or integrated method for scoring SB cleanliness during CE reporting. This pilot study aimed to quantify the image properties contributing to adequate visualisation quality in CE images.

Aims & Methods: Five clear images of SB pathology were obtained using Miracam® (Intromedic, South Korea), image resolution 320×320 pixels(px): P1 and P2 angioectasias, ulcer, aphtha and polyph. Each image was processed using GIMP2 image editing software (www.gimp.org) for 3 parameters: (1) opacity (opacity filter matched in colour to commonly-seen SB contents, 10–90% in 10% increments), (2) blur (Gaussian blur, radius 1–10px), (3) contrast (±50% to ±50% in 10% increments). Gaussian blur was used to simulate the effects of rapid capsule movement as well as to affect image definition. A set of 5 original and 190 edited images was obtained. A web-based survey was created using Google Forms and 9 expert CE readers were asked to indicate whether each image was adequate or not for diagnosis. The order of images was randomised for each reader. For each type of pathology, we determined the threshold of image quality for diagnosis. As the threshold was deemed inadequate for diagnosis.

Results: For image opacity, both aphtha and the polyloid lesion were adequately visualised below 40% opacity whereas the threshold was lower for both the ulcer and aphtha (10% opacity). Increasing blur radius significantly impacted the acceptability of images for reaching a diagnosis with confidence; for most images, blur radius 3px was the threshold for adequate visualisation but even 1px of blur radius decreased the visualisation quality of the aphtha image. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The other images were generally adequately visualised at ±10% contrast. Results are detailed in the table below.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0267 EVALUATION OF A NEW PAN ENTERIC CAPSULE SYSTEM IN PATIENTS WITH SUSPECTED OR ESTABLISHED INFLAMMATORY BOWEL DISEASE - ASSESSING THE SYSTEM FUNCTIONALITY TO VISUALIZE AND ASSESS THE SMALL AND LARGE BOWELS

Introduction: Chronic bowel diseases (IBD) are chronic inflammatory diseases that may affect the whole gastrointestinal (GI) tract, mainly the small bowel and colon. Endoscopic evaluation of these parts is essential to assess disease extent and severity. The small bowel capsule endoscopy (SBC-CE) system is a new system composed of a two-headed capsule with a panoramic field of view and adaptive frame rate, customized for complete coverage of IBD lesions in the entire bowel, data recorder and new disease specific software, allowing assessment and follow-up over time of disease severity and extent.

Aims & Methods: The aim was to evaluate SBC-CE system functionality in suspected or established IBD patients. This was a prospective 5 center feasibility study assessing the feasibility of the new capsule and software. Subjects enrolled into the study ingested the new capsule after standard bowel preparation plus boosts.

Results: (1) Six patients were men and three were women (mean age, 50.1 years). (2) During capsule ingestion in accordance to the video reading methodology. Secondary end-scoring was performed in terms of video creation and reproduction, subjective video reading time 3.9 (unconfident to confident), image quality 6.1 (unsatisfactory to satisfactory) and duration diathermy procedures because of a risk of pancreatitis.

Conclusion: Transpapillary diathermic dilation is a relatively safe and effective salvage procedure for severe MPD stricture due to chronic pancreatitis. This should be taken in cases that require multiple times and long duration diathermy procedures because of a risk of pancreatitis.

**P0270 OUTCOME OF ENDOSCOPIC REINTERVENTION FOR MALIGNANT HILAR OBSTRUCTION TREATED BY STENT-IN-STEM DEPLOYMENT**

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of Korea

**Introduction:** Endoscopic biliary decompression is widely used for advanced hilar cholangiocarcinoma. Bilateral stenting has become more feasible with more experienced endoscopists and the development of new devices. However, stent dysfunction develops in 3% to 45% because of tumor ingrowth, overgrowth, or debris as disease progresses. Endoscopic reintervention is difficult and complex with worsening bile duct strictures. The present study aimed to evaluate a suitable reintervention procedure for stent malfunction after stent-in-STEM (SIS) deployment for malignant hilar obstruction.

**Aims & Methods:** From September 2009 to June 2016, a total of 52 patients who underwent stent-in-STEM at Pusan National University Yangsan Hospital were enrolled in this study. Among them, 20 patients who underwent reintervention due to stent malfunction were analyzed. Reintervention was performed endoscopically or percutaneously. Technical and functional success rates were evaluated retrospectively.

**Results:** Technical and functional success rates of endoscopic reintervention were 83% (10/12) and 80% (8/10), respectively. Endoscopic biliary and unilateral stent dysfunction rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or plastic and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and other conditions.

**Conclusion:** Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and type of stents should depend on the conditions of the disease and the patient.

**P0271 LONG-TERM OUTCOMES OF ENDOSCOPIC ULTRASOUND-GUIDED RIGHT INTRAHEPATIC DUCT DRAINAGE WITH TRANSMURAL COVERED METAL STENT**

Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of Korea

**Contact E-mail Address:** dhcho81@daum.net

**Introduction:** Endoscopic ultrasound-guided biliary drainage (EUS-BD) has been regarded as an effective alternative in cases of endoscopic retrograde cholangiopancreatography (ERCP) failure or inaccessible papilla. However, EUS-BD for right intrahepatic duct obstruction (EUS-BDR) remains challenging, although recent studies showed promising result. The aim of current study was to evaluate the feasibility and long-term outcomes of EUS-BD with transmural covered metal stents for right intrahepatic duct obstruction.

**Aims & Methods:** Retrospective study, a total of 24 consecutive patients who underwent EUS-BDR after failed ERCP were enrolled. The patients were consisted of 12 cases of benign strictures and 12 cases of malignant strictures. The biliary stents used in this study was covered metal stent with anchoring flaps or partially covered metal stent with anchoring flaps. The technical success rate, clinical success rate and adverse events were evaluated.

**Results:** The mean diameter of right intrahepatic duct was 6.5 (4–30) mm. A fully covered metal stent was used in 22 patients and partial covered stent in 2 patients. Early adverse events developed after EUS-BDR in 2 patients (1 case of cholangitis and 1 case of liver abscess in patients with malignant biliary stricture). Late adverse event that stent occlusion was observed in 5 patients. No proximal peritoneal stent migration or spontaneous distal stent migration was observed during follow-up periods. The stent patency duration was 275.2 (147.8–402.7) days. During follow-up period, stent revision due fistula tract was successful and additional percutaneous biliary drainage for right intrahepatic duct obstruction was not required in all patients who achieved clinical success.

**Conclusion:** EUS-BD using transmural covered metal stent with antimigration properties for right intrahepatic duct obstruction may be technically feasible, effective and relatively safe for both benign and malignant strictures by expert hands. Furthermore, the route of hepatoduodenostomy created by covered metal stent was durable and endoscopically easily managed.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0272 EUS-GUIDED GALLBLADDER DRAINAGE REDUCES LATE ADVERSE EVENT AND NEED FOR RE-INTERVENTION COMPARED WITH PERCUTANEOUS CHOLECYSTOSTOMY IN PATIENTS WHO ARE NOT ELIGIBLE FOR SURGERY**

Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of Korea

**Contact E-mail Address:** dhcho81@daum.net

**Introduction:** Endoscopic ultrasound guided transmural gall-bladder drainage (EUS-GBD) has become increasingly used to treat patients with acute cholecystitis who are not a candidate for surgical treatment. However, there are limited data comparing long-term outcomes of EUS-GBD with covered metal stent and conventional percutaneous cholecystostomy.

**Aims & Methods:** Retrospective study comparing long-term outcomes of EUS-GBD and percutaneous cholecystostomy in patients who are not suitable for cholecystectomy. Data about the patient who underwent EUS-GBD for acute cholecystitis is obtained from prospective collected EUS database at Pusan National University Yangsan Hospital. The electronic medical record of patients who underwent percutaneous cholecystostomy was reviewed and analyzed. Demographics and procedure related outcomes including early, late adverse events and need for re-intervention in each group was compared.

**Results:** A total of 181 patients (74 in EUS-GBD group and 107 in percutaneous cholecystostomy group) were enrolled in this study. The cause of cholecystitis and ASA class were similar in both groups. The technical/clinical success rate was 100%/98.6% in EUS-GBD group and 99.1%/97.2% in percutaneous cholecystostomy group (P = 0.591). Early adverse events were also similar between two groups (6.8% in EUS-GBD group vs. 15.0% in percutaneous cholecystostomy group, P = 0.103). However, late adverse events including migration of stent or dislodgement of drainage tube, stent or tube occlusion, tract inflammation around percutaneous tube, bile leakage and recurrence of cholecystitis was more frequently observed in percutaneous cholecystostomy group (5.74% in EUS-GBD group and 21/107 in percutaneous cholecystostomy group, P = 0.017). Percutaneous cholecystostomy tube was indwelled for...
median 20 days (14.0–45.2) after the procedure. A total of 7 patients in EUS-GBD intervention for reverse stents and all of them were conducted successfully. The patients who underwent percutaneous cholecystostomy more frequently received re-intervention for adverse event or recurrence of cholecystitis after removal of cholecystostomy. (7/4 vs. 2/106; P = 0.041).

Conclusion: EUS-GBD and percutaneous cholecystostomy were both effective interventions to urgent drainage for acute cholecystitis. However, EUS-GBD might be beneficial than percutaneous cholecystostomy in long term management for the patients with acute cholecystitis who are not suitable for cholecystectomy.

P0274 ENDOCOSCOPIC TREATMENT OF ANASTOMOTIC BILIARY STRICTURES IN PATIENTS WITH LIVING DONOR LIVER TRANSPLANTATION: MULTIPLE PLASTIC STENTS VS FULLY COVERED SELF-EXPANDABLE METALLIC STENTS
A.T. Eminler, E. Parlak, A. S. Koksal, B. Toka, M. I. Uslan
Gastroenterology, Sakarya University, Sakarya/Turkey

Contact E-mail Address: drrckenparlak@gmail.com

Introduction: The “fully covered self-expandable metallic stents”(FcSEMS) were found to be non-inferior to multiple plastic stents (MPSs) for the treatment of anastomotic biliary strictures after orthotopic liver transplantation (OLT). However, there is scarce data about their efficacy in the treatment of anatomic biliary strictures after living donor liver transplantation (LDLT). We aimed to compare the efficacy of FcSEMS and MPSs for the treatment of anastomotic biliary strictures after LDLT.

Aims & Methods: We retrospectively analyzed the data of LDLT patients with duct-to-duct anastomotic biliary strictures who underwent endoscopic treatment at our center within the last 3 years. FcSEMS were inserted in 23 patients (13 male, 10 female, mean age 53 ± 9 years) and 79 MPSs were placed with MPSs insertion (Group-2). In Group-1, secondary branch ducts were prophylactically drained with insertion of plastic stent(s) in order to prevent the development of cholangitis due to their occlusion. FcSEMS and plastic stent(s) were left in place for 2 months. In Group-2, maximum number of plastic stents were inserted and replaced every 3 months. Patients with a follow-up duration of at least 3 months after stenting were included to the study. Primary endpoints were the number of endoscopic procedures and the time required for stricture resolution. The secondary end-point was the recurrence rate of the stricture.

Results: FcSEMS were successfully deployed in all cases. The diameter of the Fc-SEMS were 10 mm in 22 patients and 8 mm in 1 patient. The length of the Fc-SEMS were 8 cm in 13 patients, 10 cm in 8, and 12 cm in 2 patients. Secondary branch ducts were prophylactically drained with a single plastic stent in 12 patients, 2 plastic stents in 8 patients, and 3 plastic stents in 3 patients. The median number of endoscopic procedures was 2 (2–4) in Group-1 and 4 (2–9) in Group-2. The time required for stricture resolution was shorter in Group-1 (65.7 ± 18.2 days) than in Group-2 (240.1 ± 183.4 days) (p < 0.001). The recurrence rates were similar in Group-1 (17.4%) and Group-2 (15.6%) (p = 0.87) after a follow-up period of 315 ± 290 and 378 ± 36 days, respectively. Conclusion: FcSEMS is an effective method for the treatment of anastomotic biliary strictures after LDLT, with a lesser number of endoscopic sessions and a shorter stenting duration required for the resolution compared to MPSs.

Introduction: Colorectal stenting is a minimally invasive, reliable and effective intervention in patients with malignant colorectal obstruction, associated with a low complication rate compared to surgical intervention. One of the actual problems associated with colorectal stenting is the recurrence of symptoms of obstruction. The most common cause is migration of covered stents and ingrowth of uncovered stents1-3. The aim of our study was to compare the results of the use of stents of a new design, the development of which was aimed at preventing these complications.

Aims & Methods: We aimed to evaluate the results of the use of the new design (double uncovered and dual coated colorectal stents). Between December 2012 and April 2017,71 patients with colorectal malignant obstruction were implanted 78 stents (39 bare, 39 covered EGIS Colorectal stent, S&G Biotech Inc., South Korea). A double uncovered stent has a two-layer structure created by crossing two stents, resulting in a smaller cell size. Such a design theoretically can reduce stent migration and reduce tumor ingrowth. The core tumor is coated with a silicone membrane between two layers of a metal mesh with distal, uncovered ends of 5 mm each. The role of the membrane is to prevent the ingrowth of the tumor, localization and uncovered edges prevent the migration of the stent. All interventions are performed by one operator using endoscopic and radiological control. Groups of patients using coated and uncovered stents were comparable in terms of sex, age, duration of symptoms of obstruction, and stenosis localization. The reasons for the obstruction were primary tumors of the colon 97.4%. The localization of the tumor is most common in the sigmoid colon - 54%. Debridement was provided to 43 (55.8%) patients, «bridge to surgery» - 34 (44.7%) patients.

Results: Clinical success was achieved in 74 (96.1%) patients. In two cases, when using covered stents, the symptoms of obstruction could not be relieved, the intervention was repeated. In one case, 18 hours after stenting with an uncovered stent, was diagnosed perforation due to obstructive colitis. The average stay in hospital after the intervention was 3 days; the difference between the groups was statistically insignificant. 30 day mortality was 5.2%, the difference was statistically significant. Complications were detected in 3 patients in the group of bare stents and in 1 patient in the group of covered stents, the difference was statistically insignificant. One patient with the carcinoma of a sigmoid colon with invasion in anterior abdominal wall noted the appearance of subcutaneous emphysema without pneumoperitoneum. In 3 (3.8%) patients the occlusion of the stents. The reasons for obstruction of the stents were occlusion by the obstruction from stool (fibers) on the 83rd day (the endoscopic recanalization was performed) and tumor overgrowth by 165 days (endoscopic «stent-in-stent» placement). In one patient, the cause of obstruction is unknown, operated in another hospital 34 days after stenting - a transversostomy was performed, died on the 4th day after the operation.

Conclusion: Double bare and double covered colorectal stents were feasibility and efficacy for relieving malignant colorectal obstruction. Reobstruction was rare complication and not different in both groups stent groups. Necessary to continue to research for the accumulation of material from other centers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic therapy has been emerged as alternative treatment to bariatric surgery for reducing weight. We developed a new endoscopic gastrointestinal (GI) bypass stent and designed a preclinical study to assess the safety in a porcine model.

Aims & Methods: The aim of this study is to investigate the feasibility of our GI bypass device in animal. Before animal study, we performed an experimental study for durability test under simulated intestinal fluid flow. And next, we performed an animal study with 10 Yorkshire pigs. The stents were placed on pylorus with fixation by clippings or on duodenal bulb without fixation. Follow up endoscopy was done per one week after implantation. After they were sacrificed, gastric, duodenal, and jejunal tissues were harvested and examined for histologic assessment of any device or procedure-related effects.

Results: Our new GI bypass stent showed a good durability in simulated solution flow. No breakage or migration of stent occurred under continuous water flow in simulation system setting. In animal study, the mean starting weight was 30.1 ± 1.5 kg. Delivery of the implant took an average of 19.86 min (range, 11–32.1 min). The pylorostomy stent group and jejunal stent group required an average clamping time of 10.8 min (range, 8–14 min). Followed for stent migration after implantation, the mean patency duration was 3.0 ± 0.7 weeks. One pig was died due to small bowel perforation and peritonitis after stenting. In histologic finding, there were moderate degree of mucosal erosions, but no definite ulceration on pylorus and duodenum.

Conclusion: New GI bypass stent has a good physiocompatibilities in simulated intestinal system. In animal, all stents were successfully deployed but migration of stent occurred in this study. Compared with endoscopic suture machine and modification of stent would be required. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Dysphagia may occur due to benign pharingo-esophageal strictures, often due to previous treatments. The aim was to access long-term efficacy of pharingo-esophageal dilations due to anastomotic or post-radiation strictures.

Aims & Methods: Retrospective study on patients suffering of dysphagia due to radiotherapy (Group 1) or anastomotic (Group II) placed pharingo-esophageal benign strictures submitted to endoscopic dilation between January 2013 and December 2015. The long-term efficacy (after a minimum follow-up of 12 months) was prospectively assessed by telephone interview: a) dysphagia improvement or b) resolution (grade 0 or 1 of Mellow-Pinkas scale), c) absence of further dilations and d) absence of PEG. Additional therapy (PEG or prophylaxis placement, electroincision or surgery) was considered inefficiency criteria and these patients were excluded from the interview. Post-procedure complications were registered. Efficacy predictive factors were assessed.

Results: Forty-eight patients (296 dilations) were evaluated (median of 4 dilations/patient): 85% were male, mean age of 62 years-old, 60% belonging in Group II. Thereafter between 2 and 12 dilations (mean 3.5 dilations) were performed within 5 weeks. The endoscopic dysphagia Mellow-Pinkas score and luminal calibre were 3±1 and 7±2, 8mm, respectively. Twenty-eight patients (out of 30 live patients non-submitted to additional therapies) answered to the interview: a) 96% had improved, b) 60% had resolved dysphagia, c) 75% didn’t need additional dilations, d) 89% without PEG, with a combined efficacy of 58, 3%. Nine patients required additional therapy (6 PEGs, 2 prophylaxis, 1 electroincision). Overall, 1 out with 21 previous PEG were able to resume feeding per os. Fifteen and 29% presented Kochen criteria (mean 65 days), respectively. There were two post-procedure complications (<1%): one deep laceration and one pharingo-esophageal fistula. Overall mortality was of 20% (10 patients died of non related procedure causes). Mean follow-up was 29, 2 months. Number of dilations and initial luminal calibre were significant predictors of combined efficacy in the univariate analysis; radiic strictures predicted a greater final dysphagia in the uni- and multivariate analysis; recurrent/refractory stenosis didn’t significantly predict global efficacy.

Conclusion: Our dilution programme presents relevant benefit to these patients and a low rate of complications. Patients with post-radiation strictures presented a worse prognosis. Even though retrospective we present the longest follow-up and focusing not only in objective measures but also in patient perception of relief.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0278 OUTCOMe AFTER THE USE OF SX-ELLA DANIS BLEEDING STENTS FOR refractory VARICeAL BLEEDING – A VIENNA MULTICENTER EXPERIENCE

Pfisterer N, Pachofszky T, Pachofszky W, Schoeniger-Hekele B, Schuster B, pterion1@naver.com

Introduction: Current guidelines favour the use of bleeding stents over balloon tamponade for esophageal variceal bleeding (EBV). However, data on the efficacy of and outcomes after the placement of an SX-ELLA “Danis-Stent” are limited.

Aims & Methods: Retrospective multicenter study including cirrhotic patients receiving Danis-Stents for massive/refractory EBV at 4 tertiary care centers in Vienna (Medical University of Vienna, Krankenanstalt Rudolfstiftung, Wilhelminenspital and Krankenhaus Hietzing). Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.

Results: Among 35 patients, 13 patients had an unsuccessful endoscopic band ligation (EBL) prior to Danis-Stent placement. Danis-Stent controlled EBV in 80% (28/35) of patients. In the remaining uncontrolled bleeders (n=7), 3 patients had subsequent EBL, while in 3 patients the stent had to be replaced and 1 patient received a Linton- tube. Among these patients with initial Danis-Stent failure, 4 died of uncontrolled EBV, 2 experienced early bleeding-related mortality, and only 1 patient achieved a successful long-term bleeding control. In total, early-rebleeding within 6 weeks occurred in 14.3% (including n=1 while Danis-Stent was still in place and n=5 after Danis-Stent was removed): 3 underwriters received a subsequent Danis-Stent, and 1 patient was treated with a Sengstaken tube. Moreover, among n=14 patients without early rebleeding within 6 weeks, only n=3 (21.4%) showed rebleeding later during follow-up: n=2 patients were treated with a Sengstaken- Tube (both experienced bleeding-related death) and n=1 had another Danis-Stent placed (successful bleeding control). Only n=11 (31.4%) patients did not experience any rebleeding after Danis-Stent removal, while n=8 patients died with the Danis-Stent in situ. Notably, “early-TIPS” was performed in this study, but 4 (11.4%) received not Danis-Stent, but 6 NIPS during follow-up (n=1 of 6 patients (16.6%) died due to uncontrolled bleeding (≤5days) and n=10 died within 6 weeks (bleeding-related mortality 28.6%). Overall, n=22/35 (62.9%) patients died. The median survival was 10.5 (IQR[82]) days after Danis-Stent placement. Median Danis-Stents dwell time was 5 (range: 0–13) days. The most common adverse events were stent dislocation (n=13; 37.1%), while ulcers/nectrosis of the esophageal mucosa were seen in only 4 (11.4%) patients.

Conclusion: Danis-Stent controlled refractionary massive EBV in 80% of patients but bleeding-related mortality was as high as 45%. While stent dislocations are frequent, ulcers/nectrosis of the esophagus were rare with a dwell time of 5 days. The implementation of an early-TIPS strategy might improve the overall outcome, pending further experience.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0279 A NOVEL METHOD WITH SELF-EXPANDABLE METALLIC STENT FASTENED WITH CLIP AND LOOP FOR THE TREATMENT OF ANASTOMOTIC STRICUTURE AFTER SUBTOTAL GASTRECTOMY

J.K. Kang, S.G. Lim, K.M. Lee, S.J. Shin, B.M. Yoo, J. Kim, C. Noh

Gastroenterology, Ajou university school of medicine, Sunon/Korea, Republic of

Contact E-mail Address: pterion1@naver.com

Introduction: Benign anastomotic strictures are common adverse events of gastrointestinal tract surgery. And, they are difficult to be managed conservatively. The first choices of treatment of anastomotic strictures are balloon dilatation and bouginisation. But, they are requiring repeated sessions. Self-expandable metallic stent (SEMS) placement has continuous expanding effect for a long period. But, It has problem of frequent stent migration, because of slow stent expanding, 2–3 days. Therefore the new method to inhibit stent migration is needed for more successful management of anastomotic stenosis.

Aims & Methods: The aim of this study was to evaluate the clinical feasibility of new method to inhibit stent migration in postoperative anastomotic stricture. From May 2013 until February 2015, patients with benign anastomotic stricture after subtotal gastrectomy were enrolled at a single tertiary referral hospital, prospectively. The Niti-S ComVi pyloric stents (Taewoong Medical, Korea), double-layered covered, were inserted. We made two nylon thread loops at the proximal bared section of the stents. After stent placement, stent fastening with loop and clip method was performed. Patients' symptoms and oral intake were assessed once or twice a week with a clinical check-up or telephone interview. After two weeks, the loop and stent removals were done. All patients were successfully inserted and stent patency were confirmed (technical success rate, 100%). The obstructive symptoms were subsided in 12 of 13 patients (clinical success rate, 92.3%). Stent migration was found in a follow-up endoscopy on 14 days (1 of 13, 7.7%). Anastomotic restenosis occurred in two patients 14 and 20 days after stent removal. However, obstructive symptoms were relieved by stent reinserterion.

Conclusion: The new method with fastening the stent with loop and clip can reduce the risk of stent migration.
Our fastening method can be feasible and useful technique for postoperative anastomotic stricture in sub-total gastrectomy. A large-scale prospective research is needed to validate the clinical effectiveness of our method and to determine the appropriateness.

P0280 Efficacy and tolerability of biodegradable stents for recurrent benign oesophageal strictures: The Leeds Experience

N. Rabb, H. Proctor, N. Burr, V. Appleby, S. Everett
Leeds Centre for Digestive Diseases, Leeds Teaching Hospitals Trust, Leeds, United Kingdom

Contact E-mail Address: n.rabb@nhs.net

Introduction: The optimum management of refractory or recurrent oesophageal strictures (RBES) despite repeated attempts at dilatation is controversial. An accepted method includes temporary stent placement. Most commonly temporarily fully covered self-expanding metal stents (FC-SEMS) are used but these require removal some 8–12 weeks later. Oesophageal biodegradable stents (EBS) have the advantage that they do not require removal. However, there is a lack of good-quality evidence in support of their use. We aimed to review the safety and efficacy of a large series of single and multiple EBS insertions for benign RBES in a single tertiary referral centre.

Aims & Methods: A retrospective review of insertion of EBS (SX-ELLA) between April 2008 and October 2016 was conducted. Patients with one or more EBS insertions were included. The data and clinical data extracted from the hospital database. 30 day safety and efficacy for all stent insertions and 12 month efficacy and median time to further intervention (MTTFI) for first stents were analysed using the Stata package.

Results: 20 patients (13 m, 7 f; age 44–93; Charlson index range 2–8, median 4) with 37 stents were included. Stricture aetiology included peptic (55%), radiotherapy (20%), post-surgical (20%) and post EMR (5%). Dysphagia score ranged from 2–4 (median 3). The total median number of dilatations prior to first EBS was 6 (range 0–17). 15(75%) patients had previously had a FC-SEMS placed with subsequent recurrence of symptoms. 30-day technical success and symptom improvement was 100%. 30 day adverse events included 4(11%) stent migrations and 12(32%) with significant pain, 3 patients requiring in-patient pain control (<3 days). There were no significant bleed or perforations. 12 months following first EBS insertion 18/90(20%) required further endoscopic intervention due to recurrent symptoms; 5(25%) had further dilatation, 9(45%) had either a FC-SEMS (2 patients) or a further EBS (7 patients) or NG tube insertion and (5%) patient died of unrelated illness. 2(10%) were symptom free after one stent at 12m. MTTFI was 139 days (range 75–517) and was not dependent on aetiology (peptic vs. non-peptic; 135 vs. 127 days, p=0.54). There was a significant reduction in median number of interventions in the 12m following EBS insertion compared to the preceding 12m (2 vs. 7 respectively, p=0.0003). 7(35%) patients received multiple EBS (range of stent insertions 2–9). 3 of these (43%) have subsequently required no further intervention, 3(43%) continue to receive intermittent EBS, inserted on a symptomatic basis, 1(14%) patient continues to receive treatment for RBES, but has declined further EBS after 2 EBS inserted in discomfort.

Conclusion: Use of EBS for RBES in our centre was safe and well tolerated but there was short-lived pain in a significant number. In this highly selected cohort of difficult strictures, EBS led to short-term benefit in all patients but sustained efficacy and median time to further intervention (MTTFI) for first stents was analysed using the Stata package.

P0283 INFLUENCE OF CONTINUOUS ADMINISTRATION OF LOW-DOSE ASPIRIN FOR INTRAOPERATIVE BLEEDING ON GASTRIC ENDOSCOPIC GASTRIC DISSECTION: A PROSPEKTIVE SCORE MATCHING ANALYSIS

Y. Horikawa, N. Mimori, H. Mizutamari, Y. Kato, S. Fushimi, S. Okubo, S. Sato
Gastroenterology, Hiraoka General Hospital Dept. of Gastroenterology, Yokote/ Japan

Contact E-mail Address: horikawa_01@me.com

Introduction: Endoscopic submucosal dissection (ESD) was a promising method for treatment of esophageal gastric divisional carcinoma. However, antiplatelet and anticoagulant agents has increased for first or secondary prevention of cardiovascular or cerebral disease. Continuous administration of low-dose aspirin (LDA) during ESD was recommended in American, British and Japanese guidelines. However, the influence of this drug for the hemostasis condition during ESD procedure is still unclear. Therefore, we performed this study for addressing intraoperative bleeding risk without cessation of LDA.

Aims & Methods: In this retrospective study, we assessed the hemostasis condition during ESD that were treated for superficial gastric lesions between January 2014 and March 2017. Patients with antithrombotic therapy by LDA (n = 42) and those with no antithrombotic therapy (n = 187; Control) were compared using propensity score matching. Primary outcome was frequency of intraoperative major bleeding. Secondary outcomes included procedure time, Hb reduction rate, En blos resection rate, and adverse event rate.

Results: The propensity score analysis yielded 39 matched pairs. Adjusted comparison between the two groups showed similar with regards to major bleeding, median (range) 0% vs 2.6% (0%–16.7%), procedure time, median (range) 95 (70–125) vs 75 (50–100) min, and adverse event rate (0% vs 0%). Procedure time was prolonged in Aspirin group by 16.7% without significant differences. Other aspects were the same in both groups with low incidence of adverse events; perforation (0%), thromboembolism (0%).

Conclusion: This study indicated the feasibility of gastric ESD with continuous administration of LDA including little intraoperative bleeding and adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0284 WEEKDAY OF CANCER SURGERY IN RELATION TO PROGNOSIS

P. Lagergren, F. Mattsson, J. Lagergren
Department Of Molecular Medicine And Surgery, Karolinska Institute, Stockholm/ Sweden

Contact E-mail Address: pernilla.lagergren@ki.se

Introduction: Later weekday of surgery seems to reduce the prognosis in oesophageal cancer, while any such influence on other cancer sites is unknown. This study aimed to test whether weekday of surgery influences prognosis following commonly performed cancer operations.

Aims & Methods: This nationwide Swedish population-based cohort study from 1997-2014 analysed weekday of elective surgery for 10 major cancer groups in relation to disease-specific and all-cause mortality. Cox regression provided hazard ratios with 95% confidence intervals (CI) adjusted for the covariates age, sex, year, calendar volume, calendar year, and tumour stage.

Results: Included were 228,927 patients. Later weekday of surgery (Thursday and even more so Fridays) was associated with increased mortality rates for gastrointestinal cancers. The adjusted hazard ratios for disease-specific mortality comparing surgery on Friday with Monday were 1.57 (95% CI 1.31–1.88) for oesophago-gastric cancer, 1.49 (95% CI 1.17–1.88) for liver-pancreatic-biliary cancer, and 1.53 (95% CI 1.44–1.63) for colorectal cancer. Excluding mortality during the initial 90 days of surgery made little change to these findings, and the all-cause mortality was similar to the disease-specific mortality. The associations were similar in analyses stratified for covariates. No consistent associations were found between weekday of surgery and prognosis for the head-and-neck, lung, thyroid, breast, kidney, bladder, prostate, or ovary-uterus.

Conclusion: Later weekday of surgery in relation to surgery for gastrointestinal cancer may be an approach to improve the prognosis in gastrointestinal cancer surgery. Besides that, the postoperative severe complications are thought to be the poor prognostic factor. Present study assessed the prognostic impacts of severe postoperative complications and perioperative oncological treatments in gastrointestinal cancer patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0285 IMPACT OF POSTOPERATIVE COMPLICATIONS AND PERIOPERATIVE ONCOLOGICAL TREATMENTS FOR GASTRIC CANCER PATIENTS AFTER GASTRECTOMY

S. Kamiya1, F. Klevebro2, J. Rouvelas3, M. Lindblad1, L. Lundell2, M. Nilsson2

2Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: sato_x_k@hotmail.com

Introduction: Recently, multidisciplinary treatments such as perioperative chemo/ radiation treatments have been implemented to improve the prognosis of gastric cancer surgery. Besides that, the postoperative severe complications are thought to be the poor prognostic factor. Present study assessed the prognostic impacts of severe postoperative complications and perioperative oncological treatments in gastric cancer patients.

Aims & Methods: Consequent gastric cancer patients who underwent curative gastrectomy in Karolinska University Hospital between 2006 and 2016 were enrolled. Patients’ characteristics, surgical data, postoperative courses and prognostic factors were evaluated according to Clavien-Dindo classification. The significance of postoperative severe complications and perioperative oncological treatment for overall survival (OS) was evaluated by the Cox proportional hazard model.

Results: In total, ninety-six-nine-sixty-six patients were examined in this study. 89 (52.7%) and 66 (39.1%) patients had neoadjuvant and adjuvant treatment, 85 (50.3%) and 84 (49.7%) underwent distal total and gasterectomy, respectively. 24 (14.2%), 16 (9.5%) and 5 (3.0%) were diagnosed as grade III, IV, V complications.

Conclusion: The prognosis of the patients with grade III or higher complication was significantly worse (3-year OS: 66.6% vs 47.3%, P < 0.001). Subgroup analysis by pathologic stage showed that the prognosis of pStage III/IV patients with postoperative complications was significantly poorer than the patients with grade III or higher complications (3-year OS: 45.3% vs 7.5%, P < 0.001). For the patients who had either neoadjuvant or adjuvant treatment, however, no obvious prognostic worsening was seen by the existence of complications (3-year OS: 70.6% vs 52.9%, P = 0.13). Multivariate analysis identified that severe complication was independent risk factor for OS (hazard ratio 1.82; 95% confidence interval 1.08–3.05), especially in pStage III/IV gastric cancer (hazard ratio 3.00; 95% confidence interval 1.53–5.86).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0286 ENDOCOSOPIC PAPILLECTOMY OF DUODENAL PAPILLARY TUMOR: A REPORT OF 75 CASES

Introduction: Duodenal papillary tumor as rare gastrointestinal neoplasm is essential for curative therapy due to its malignant potential. Endoscopic papillectomy is accepted as an alternative approach to surgery in select cases. Endoscopic papillectomy is considered a difficult endoscopic technique mainly performed by experienced endoscopists. Multicenter standard endoscopic procedures for endoscopic papillectomy have not been established.

Aims & Methods: We aimed to investigate the clinical value of endoscopic papillectomy for duodenal papillary tumor based on the endoscopic and clinical characteristics. Between 2006 and 2017, seventy-five patients with duodenal papillary tumor under endoscopic papillectomy in the gastrointestinal endoscopic center of Chinese PLA General Hospital were included. These patients were diagnosed of duodenal papillary tumor by the clinical manifestations, laboratory tests, CT, MRCPE, endoscope, EUS, ERCP along with biopsies and histopathologic tests. During the detailed clinical assessment combined with patients’ wishes, endoscopic papillectomy and followed ERCP procedures were performed successfully, and the clinical data of these patients were retrospectively analyzed.

Results: 75 patients (50 males and 25 females) with a median age of 58.6 yrs (range 27 to 82 yrs) were evaluated. The main clinical symptoms were predominated by abdominal pain followed by cholestasis and cholangitis, but nine cases with no abdominal symptoms. Endoscopic papillectomy was technically feasible in all these patients, and was mainly performed by four experienced endoscopists. The majority of excised tumors were exogenous (90.7%, 68/75), and the tumor size ranged between 8 and 55 mm. The final histopathological diagnosis included adenoma (44.7%, 33/75), carcinoma (37.3%, 28/75), adenosquamous with high-grade intraepithelial neoplasia (18.7%, 14/75), adenoma with low-grade intraepithelial neoplasia (26.7%, 20/75), adenoma combined with local carcinoma (16%, 12/75), and neuroendocrine tumor (1.3%, 1/75). In blos resection was achieved in 55 cases (70.7%) and the per-rectum biopsion was performed in 22 cases (29.3%). After endoscopic papillectomy, the ERCP procedures were performed in 70 cases (93.3%). The prophylactic pancreatic duct stent was placed in 30 cases (40%) for preventing pancreatitis, the biliary plastic stent or nasobiliary drainage tube in 16% (12/ 75), the stent placed in both in 17.3% (13/75), and no stent placement in 28.7% (21/75). Moreover, intraoperative hemostasis was performed in 47 cases (62.7%), including pure endoscopic clip placement, followed by injection therapy, thermal therapy or in combination. Regarding to the postoperative adverse events,
hemorrhage was identified in 11 patients (14.6%) but mainly cured by endoscopic hemorrhoidectomy, followed by perianal sepsis (9.3%, 7/75) but cured with medical treatment. 

Conclusion: Endoscopic papillotectomy can be considered as a feasible and reasonable treatment option for suitable patients with tumors of duodenal papilla.

P0287 PROPHYLACTIC COLECTOMY WITH EXTENDED INDICATION OF RECTAL PRESERVATION IN RELATED APC FAMILIAL ADENOMATOUS POLYP SYNDROME: SYSTEMATIC REVIEW

A. Pasquer1, G. Poncet1, M. Poche1, J. Rivory2, O. Vinet3, N. Benchet3, J.C. Saurin3

1Digestive Surgery, Hôpital Edouard Herriot, Lyon/France; 2Hepatogastroenterology, Hôpital Edouard Herriot, Lyon/France

Contact E-mail Address: annauidpasquer@chu-lyon.fr

Introduction: Prophylactic surgery of familial adenomatous polyposis (FAP) ranges from total colectomy with ileorectal anastomosis (IRA) to proctocolectomy with ileoanal anastomosis and J pouch (IAA). Rectal resection is based on studies that did not include systematic endoscopic treatment that we perform. The objective was to compare IRA to IAA in terms of oncological safety and quality-of-life.

Aims & Methods: Between January 1965 and November 2015, all consecutive prophylactic colectomies were performed on grey literature. Outcomes were compared between IRA and IAA using endoscopic follow up in our unit: systematic endoscopic treatment of adenomas (argon, mucosectomy), were prospectively included. MYRH-related polyposes and patients who underwent abdomino-perirenal resection were excluded from analysis.

Results: 296 patients were included: 92 proctocolectomy with IAA (31.1%), 197 total colectomy with IRA (66.5%), and 7 abdomino-perirenal resections (2.4%). Mean (SD) number of preoperative rectal adenomas was 24.7 (33.9) in the IRA group and 12.9 (18.8) in the IAA group (p = 0.06). Mean number of lower endoscopies was 3.2 (5.1) in the IRA group vs. 2.3 (3.7) in the IAA group (p = 0.4). Median time to resection was 15 months (IQR 6-36) in the IRA group vs. 11 months (IQR 6-29) in the IAA group (p = 0.02). Mean adenoma recurrence in the IRA group was 3.1% (n = 9). Mean (SD) follow-up was 16.6 (11.9) years, during which the mean (SD) number of lower endoscopies was 3.4 (2.5) in the IRA group vs. 3.4 (2.5) in the IAA group (p = 0.9); mean (SD) number of treated adenomas was 17.8 (20.8) in the IRA group vs. 12.9 (18.8), respectively (p = 0.06); secondary cancer incidence was 6.1% vs. 11% (p = 0.06). The 15-year recurrence-free and overall survival (IR vs. IAA) were respectively 99.5% vs. 100% (p = 0.09) and 98.9% vs. 98.8% (p = 0.08).

Conclusion: Combination of aggressive endoscopic treatment and extended rectal preservation appears to be a safe alternative to ileoanal anastomosis and J pouch.

P0288 ANAL PROBLEMS DURING PREGNANCY AND POSTPARTUM: A PROSPECTIVE COHORT STUDY

K. Ferdinande, Y. Dorreman, K. Roelens, W. Ceelen, D. De Looze

University of Ghent, Ghent/Belgium

Contact E-mail Address: kymenite.ferdinande@ugent.be

Introduction: Many pregnant women have anal symptoms during pregnancy and postpartum. The most common proctologic problems reported are haemorrhoids, fissures, and anal incontinence. Literature about this problem is scarce.

Aims & Methods: The aim of this study is to determine the prevalence of anal problems and constipation during the second and third trimester of pregnancy, in the immediate postpartum and up to three months after childbirth. We also want to identify the risk factors for the development of anal symptoms. This is a prospective cohort study. Women between their 19th and 25th week of pregnancy are included. High-risk pregnancy and non-Dutch speaking are exclusion criteria. Nineteen questions were followed by a symptom questionnaire in the second and third trimester, in the immediate postpartum (within 3 days) and three months postpartum. Descriptive data were obtained from the patient files. A specific proctologic diagnosis was presumed on the basis of combined symptoms (rectal bleeding, anal pain and swelling). Constipation was defined by the Rome III criteria. Statistical analysis was performed with SPSS and risk factors were identified using multivariate analysis with binary logistic regression.

Results: Sixty-eight percent of the women developed anal symptoms during the whole study period. Anal symptoms occurred in 50% of the women during pregnancy, in 56.2% in the immediate postpartum and in 62.9% during the three months postpartum. The most prevalent symptom was anal pain. Constipation was reported by 60.7% during the whole study period. Most prevalent haemorrhoids were haemorrhoidal thrombosis (immediate postoperative hemorrhoidal prolapse (3rd trimester and immediate postpartum) and anal fissure (not episode-related). Anal incontinence was only reported in 2% during the postpartum. Multivariate analysis identified constipation and a history of anal problems as significant risk factors for the development of anal complaints postpartum and postpartum.

Conclusion: Two-thirds of pregnant women deal with anal symptoms during pregnancy or postpartum, especially haemorrhoidal complications and anal fissures. This high prevalence emphasises the clinical importance of this problem. The most important risk factor is constipation. Therefore, prevention of constipation in pregnant women is recommended.

P0289 SURGICAL TREATMENT OF DIVERTICULITIS AND ITS COMPLICATIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROL TRIALS

1Digestive Surgery, Hôpital Edouard Herriot, Lyon/France; 2Hepatogastroenterology, Hôpital Edouard Herriot, Lyon/France

Contact E-mail Address: med.b.dean@azhar.edu.eg

Introduction: Diverticulitis is a common gastrointestinal disease in developed countries, especially among elders. It is classified into five stages according to the severity of the inflammation with stage 5 involving peritonitis as a consequence of perforation and abscess formation, with 30-day mortality reaching 32%. This indicates that acute diverticulitis is an emergency case requiring rapid management. However, the surgical interventions of divertiitis vary according to its grade and severity, there is a controversy about the preferable surgical procedure of these different complications in acute divertiitis.

Aims & Methods: We aimed to systematically review and meta-analyze randomized controlled trials (RCTs) comparing outcomes and complications between different surgical approaches for acute diverticulitis and its complications. Nine electronic databases, including PubMed, Scopus, Google Scholar, ISI Web of science, WHO Global health library (GHL), POPLINE, Virtual health library (VHL), NYAM (New York Academy of Medicine), and SIGLE (System for information retrieval in life sciences) were searched. We included 148 articles, only 77 were used for the meta-analysis. The risk of bias was assessed using the Cochrane Collaboration tool. The pooled risk ratio (RR) and 95% confidence interval (CI) were calculated in the meta-analysis using the RevMan platform. The protocol was registered in PROSPERO (CRD42015032290).

Conclusion: RCTs comparing laparoscopic sigmoid resection (LSR) (n = 247) versus open sigmoid resection (ORS) (n = 237) for treatment of acute complicated diverticulitis with minimal heterogeneity. For short-term outcomes, there was no significant difference in postoperative overall morbidity (RR = 0.89, 95% CI [0.61–1.31]; P = 0.56), all major postoperative morbidity (RR = 0.79, 95% CI [0.12–5.07]; P = 0.80), and minor postoperative complications (RR = 0.98; 95% CI [0.62–1.57]; P = 0.94). Similarly, there was no difference between the two procedures regarding the long-term postoperative morbidity (RR = 0.84, 95% CI [0.57–1.21]; P = 0.39) and mortality (RR = 0.78, 95% CI [0.46–1.31]; P = 0.34), and mortality (RR = 0.95, 95% CI [0.04–24.59]; P = 0.98). In other four RCTs compared laparoscopic lavage with resection (sigmoidectomy) for treatment of perforated diverticulitis with peritonitis, the postoperative mortality rate was non-significant in both short-term (RR = 1.55, 95% CI [0.79–3.04]; P = 0.21) and long-term (RR = 0.67, 95% CI [0.29–1.58]; P = 0.36) follow up. Interestingly, the short-term reoperation rate and long-term preence of intra-abdominal abscesses were significantly higher in LSR group (RR = 1.74, 95% CI [1.01–2.97]; P = 0.03) and (RR = 1.52, 95% CI [1.03–5.92]; P = 0.04) respectively. The remaining five RCTs compared between different procedures, like primary anastomosis versus non-restorative resection, RP-LASR versus NRP-LASR, and primary versus secondary resection, for different situations and reviewed qualitatively.

Contact E-mail Address: drnilicastojkovic@gmail.com

Introduction: There has been enormous progress in diagnosing and treatment of colorectal cancer (CRC), however a great number of patients is nevertheless diagnosed in an advanced disease stage. It is of great interest to develop a less invasive, inexpensive, prognostic, diagnostic, and treatment predicting biomarkers in early diagnostics of CRC considering its incidence worldwide. There are studies suggesting that the systemic inflammation play an important role in CRC tumor stage development, which can be reflected by the levels of neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR).

Aims & Methods: This study was designed to investigate the efficiency of preoperative NLR, PLR as a tool for the assessment of synchronous lymph nodes
and liver metastases in newly diagnosed patients with CRC. Three hundred patients with CRC undergoing curative resection were included in this cross-sectional study. Complete blood counts with automated differential counts were performed preoperatively. The NLR was calculated by dividing the absolute neutrophil count by the absolute lymphocyte count; also PLR was calculated by dividing the absolute platelet count by the absolute lymphocyte count. The diagnostic performance of NLR and PLR was estimated by ROC curve.

Results: Our results suggest that there was high statistically significant difference between NLR (p = 0.003), PLR (p = 0.002) and tumor stages (I to IV). ROC curve analysis showed high diagnostic specificity of NLR (AUC 0.774, 95%CI = 0.683–0.790) and PLR (AUC 0.698, 95%CI = 0.663–0.742) for syn-
chronous lymph node and liver metastases. Also combination of NLR and PLR improved diagnostic efficacy (AUC 0.841, 95%CI = 0.811–0.863) for synchronous liver and lymph node metastases.

Conclusion: Our results suggest that NLR and PLR could be useful diagnostic CRC biomarkers, and could have potential use in early recognition of different stages of CRC.

P0294 FULL-SCALE INTRODUCTION OF RADICAL LAPAROSCOPIC SURGERY FOR INGUINAL HERNIA EMPLOYING THE TRANSABDOMINAL PREPERITONEAL (TAPP) REPAIR AND EARLY OUTCOMES

Gastroenterological Surgery, Aichi Medical University, nagakute/Japan

Contact E-mail Address: tsaito0726@gmail.com

Introduction: Ger reported the first laparoscopic hernia repair in 1982 by approximating the hernia with stainless-steel clips. The first radical laparoscopic transabdominal preperitoneal (TAPP) repair was a revolutionary concept in hernia surgery and was introduced by Arregui and Dion in the early 1990s. Institutions performing radical laparoscopic surgery for inguinal hernia have been rapidly increasing since the NIH point was amended in Japan. However, in the 12th JAPAN SOCIETY FOR ENDOSCOPIC SURGERY questionnaire survey, the recurrence rate after surgery employing the TAPP method was reported to be 4%, posing a problem regarding the thoughtless introduction of the TAPP method. Our institution began with surgery employing the TAPP method only in November 2015 until April 2016, but treatment of inguinal hernia was integrated, the indication was established in May 2015, and laparoscopic surgery employing the TAPP method has been performed for the indicated cases. In this study, we investigated the current state of inguinal hernia treatment at our hospital. Surgical indication of inguinal hernia in our department is as follows. Symptomatic inguinal hernia is treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone surgery of the prostate, the anterior approach is employed (the UHS and Mesh Plug methods for internal and external inguinal hernia, respectively). Treatment under local anesthesia is prioritized for patients aged 90 years or older and patients with PS2 or higher. Arrangement in operating room is that the operator and assistant stand at the left and right sides of the patient, respectively, an anesthesiologist stands at the patient’s head, and a nurse stands caudal to the assistant.

Aims & Methods: In this study, we investigated the current state of inguinal hernia treatment at our hospital. The subjects were 120 patients who underwent radical surgery for inguinal hernia before and after the full-scale introduction of the TAPP method (early period: October 2014-April 2015 (7 months), late period: May 2015-October 2015 (7 months), 47 and 73 patients were treated in the early and late periods, respectively). Changes in the surgical procedure, complications, and duration of hospital stay were investigated in 120 patients.

Results: The median age was 70 years (19-91 years old). There were 114 male and 6 female patients. A total of 132 hernias (isulated in 103; right: 60, left: 48; and bilateral in 12). The hernia classification (Japanese Hernia Society) was 1, 2, 3, 4, 5 in 91, 11, 7, 3, 0, and 1 lesions. Surgery was performed under local anesthesia in 43, lumbar anesthesia in 1, and general anesthesia in 76. A laparoscopic left colectomy was performed using a linear stapler inserted through a trocar at the left abdomen. The median operative time was 102 minutes. Early Period was 4 days (4–24), Late Period was 3 days (3–9) for median duration of hospital stay. In Early period, complications, and duration of hospital stay were investigated in 120 patients. The incidence of Clavien Dindo Grade 3 or higher did not occur. In the early and late periods, respectively. Changes in the surgical procedure, complications, and duration of hospital stay were investigated in 120 patients.

Conclusion: Our institution began with surgery employing the TAPP method only in November 2015 until April 2016, but treatment of inguinal hernia was integrated, the indication was established in May 2015, and laparoscopic surgery employing the TAPP method has been performed for the indicated cases. In this study, we investigated the current state of inguinal hernia treatment at our hospital. Surgical indication of inguinal hernia in our department is as follows. Symptomatic inguinal hernia is treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone surgery of the prostate, the anterior approach is employed (the UHS and Mesh Plug methods for internal and external inguinal hernia, respectively). Treatment under local anesthesia is prioritized for patients aged 90 years or older and patients with PS2 or higher. Arrangement in operating room is that the operator and assistant stand at the left and right sides of the patient, respectively, an anesthesiologist stands at the patient’s head, and a nurse stands caudal to the assistant.

P0295 EFFECTIVENESS OF PURE LAPAROSCOPIC LEFT COLECTOMY WITH PRIMARY ANASTOMOSIS AND LOOP ILEOSTOMY FOR THE TREATMENT OF COMPLICATED HINCHEY 3 CATEGORY DIVERTICULITIS
F. Roscia, A. De Luca, I. Scandroglio
Galganari Hospital, ASST Sette Laghi, Tradate/Italy

Contact E-mail Address: francesco_rosicio@yahoo.it

Introduction: The effectiveness of laparoscopic left colectomy with primary anastomosis and loop ileostomy in the treatment of complicated acute diverticulitis with diffuse purulent peritonitis (Hinchee 3), also considering the lack of evidence about this topic due to the difficulty of carrying out comparative trials with the laparoscopic washing/drainage technique.

Aims & Methods: A consecutive unselected series of 44 patients undergone emergency surgery for acute complicated Hinchee 3 diverticulitis from January 2012 to December 2016 was retrospectively evaluated. All patients were treated by pure laparoscopic left colectomy with primary colorectal anastomosis and temporary loop ileostomy. All the procedures were performed by the same surgeons (IS, ADL, FR). Perioperative care plan, operative steps and surgical instrumentation were standardized. We collected patients-, surgery- and hospital stay-related data, as well as short-term outcomes. Complications were classified using the Clavien-Dindo classification system.

Results: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m2. No conversion to open surgery was registered. The mean operative time and estimated blood loss were 184.3 ± 32.7 minutes and 81.2 ± 72.7 ml, respectively. All the specimens showed diverticulitis with peridiverticulitis. Length of hospital stay was 7.8 ± 2.8 days and we have not recorded any readmissions in patients discharged within 60 days after surgery. The rates of postoperative complications were 6.8% for grade 3A and 5 according to the CDChC respectively.

Conclusion: Laparoscopic left colectomy with primary anastomosis and loop ileostomy seems to be a good technique that resulted in encouraging short-term outcomes. In expert hands it represents an effective technique for the treatment of acute diverticulitis complicated by diffuse purulent peritonitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
lower abdomen. The bowel extraction was performed by invagination transrectal through the posterior rectal wall incision in the CM was moved to the lower abdomen. The anastomotic region was completed by applying a circular stapling device transrectally, assisted by a transcutaneous inserted grasper. Function testing was performed by the colonoscope. Gastric access closure was performed by OTSC clip.

Results: The procedure was successful in all animals with operation time ranging from 4.5 to 6 hours. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent anastomotic healing with a stenosis and consecutive prestenotic dilatation in one case. These anastomotic prestenotic abscess beside the anastomosis. Gastric closure was healed and the OTSC clip still in sit in all animals. In one case we used two OTSC clips for gastric closure, there were severe adhesions with two perigastric abscesses.

Conclusion: The use of an operating platform like the Anubiscope has the advantage of flexible preparation in opposite position of the instruments. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Flexible colonoscopy provided a fixed reference frame for observation and dissection. For resection and anastomosis, an additional transcutaneous access was necessary.

P0298

ASCITES, COMPLEX ADNEXAL MASSES AND RAISED CA-125 IN POST-MENOPAUSAL WOMEN: OVARIAN CANCER OR TUBERCULOSIS?

S. Jardak†, H. Khedir‡, N. Maamouri§, H. Chaabouni¶, N. Ben Mami¶

1Tunis, rabta B, Tunis/Tunisia
2Tunis, rabta B, Tunis/Tunisia

Contact E-mail Address: sondajardak1@gmail.com

Introduction: Post-tubal tuberculous (TB) peritonitis is a late complication of pelvic inflammatory disease and a chronic form of peritonitis. Peritoneal TB is a notifiable disease in many countries. The disease is not uncommon among post-menopausal women presenting with abdominal symptoms mimicking ovarian cancer.

Methods: The aim of this study was to analyze patients’ characteristics, laboratory investigations, radiological and surgical findings in post-menopausal women with pelvic TB who were diagnosed after laparotomy or laparoscopy for suspected ovarian cancer. We report twenty-one cases of pelvic-peritoneal TB in post-menopausal women who presented with mimicking ovarian malignant from 2004 to 2014 in a Tunisian center.

Results: The mean age was 59.8 (46–87 years). Three patients have personal or family history of TB. All women presented with abdominal pain and distension and were admitted to the hospital for diagnosis and treatment. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are already common to these two entities.

Aims & Methods: The aim of this study was to analyze patients' characteristics, laboratory investigations, radiological and surgical findings in post-menopausal women with pelvic TB who were diagnosed after laparotomy or laparoscopy for suspected ovarian cancer. We report twenty-one cases of pelvic-peritoneal TB in post-menopausal women who presented with mimicking ovarian malignant from 2004 to 2014 in a Tunisian center.

Conclusion: The diagnosis of a functional ileus may be made preoperatively and peritoneal TB can be confirmed by histology and pathogenesis in all patients. The diagnosis of post-tubal TB is a challenge for the gynecologist. The treatment of pelvic TB is surgical and associated with a high risk of recurrence. The standard treatment for pelvic TB should be tailored to each patient.

Introduction: Peptide growth factors including the IGF family are expressed in the colorectal epithelium and proliferative activity of the intestinal epithelium in ulcerative colitis (UC) and Crohn’s disease (CD). At the same time, IGF-1 is one of the main triggers behind the immune-inflammatory process in the colonic mucosa (CM) in UC, and its level may be of prognostic value in determining the illness course.

Aims & Methods: The aim of the study was to identify the role that IGF-I plays in colonic inflammation in 35 patients with different clinical (Rahmilevich index) and endoscopic (Mayo index) activity of UC. The treatment was administered in the form of lower UC; 20 healthy volunteers were the control group. IGF-I levels in peripheral blood were determined by ELISA (Mediagnost, Germany).

The results were expressed as mmol/l. The spontaneous and E. Coli LPS-induced synthesis of IL-8 in rectal biopptic samples were studied via ELISA. The results were expressed as picograms per 1 mg of wet tissue (pg/mg).

The severity of the IGF-I in peripheral blood was divided into three groups: with a level of inflammatory factors (in %) in the lamina propria. The study implied that the IGF-I levels in the blood plasma, on one hand, and indicators of the UC clinical, endoscopic activity and the intensity of the inflammatory infiltrate in the CM, on the other. Direct relationship was found between the level of spontaneous production of the IL-8 chemokine and the density of the inflammatory infiltrate in the CM of patients with active UC. Through the period of the clinical remission development (an average of 8 weeks) the IGF-I levels increased to 94.25 ± 28.18 mmol/l (P < 0.05), yet have not reached the control value (P < 0.05 to control). Induction of the clinical remission was associated with a decrease to the level of the control values for spontaneous and LPS-induced IL-8 production, regardless of UC activity.

Conclusion: The intensity of the inflammatory process in the CM depends on the level of IL-8 produced by relevant cells. Evidently, IL-8 has a capacity of inhibiting the production of IGF-I at the peak of inflammation (acute UC). Improvement of IGF-I and reduced IL-8 in remission facilitates regeneration of the damaged mucosa.

Introduction: Epidemiological studies have shown that there was an inverse relationship between Helicobacter pylori (H. pylori) infection and the incidence of inflammatory bowel disease (IBD). Our previous research indicated that the regulatory immune responses induced by H. pylori infection were not limited to gastric mucosa, IL-10-producing B cells and Foxp3+ Treg cells expanded in spleen and mesenteric lymph nodes (MLN), the balance of intestinal mucosal immunity was influenced to a skewed regulatory immune response.

Aims & Methods: A murine model with H. pylori infection and acute and chronic colitis induced by dextran sulphate sodium (DSS) was established to explore the function of the Breg cells in the alleviation of H. pylori infection on acute and chronic colitis induced by DSS. A C57BL/6 mice model of acute and chronic colitis was induced by 3% DSS with or without H. pylori infection in advance, the colitis performances were assessed by disease active index (DAI), colon length shortening, colon histological inflammatory scores. The CD19+IL-10+ Breg cells and CD4+CD25+Foxp3+ Treg cells in blood, spleen, MLN and gastrointestinal mucosa were measured by flow cytometry, immunohistochemistry and immunofluorescent staining. The anti- and pro-inflammatory cytokines were also detected at mRNA level by real-time PCR.

Results: Compared with the DSS treated acute colitis group, H. pylori/DSS treated acute colitis group: (1) DAI and colonic histological scores reduced (9.25 ± 2.83 vs 16.00 ± 2.00, P = 0.025) and colon length shortening (6.56 ± 0.63 vs 5.40 ± 0.54, P < 0.001). (2) The percentages of CD19+IL-10+ Breg cells detected by flow cytometry expanded in different tissues: blood: 5.05 ± 0.68 vs 2.89 ± 0.55, P = 0.001; spleen: 4.32 ± 0.56 vs 3.17 ± 0.20, P = 0.03; MLN: 5.89 ± 0.54 vs 4.94 ± 0.65, P = 0.047; PP: 6.95 ± 1.67 vs 5.39 ± 0.88, P = 0.005, respectively. (3) The percentages of CD4+CD25+Foxp3+ Treg cells expanded in different tissues: spleen: 13.50 ± 1.37 vs 10.73 ± 1.13, P = 0.008; MLN: 17.50 ± 0.82 vs 14.87 ± 1.53, P = 0.001; PP: 17.20 ± 3.24 vs 8.58 ± 1.71, P = 0.001. The numbers of CD4+CD25+Foxp3+ cells per 106 cells in colon: 3.44 ± 0.40 vs 2.58 ± 0.34, P = 0.004. (4) mRNA expression in colonic mucosa: IL-10 (P = 0.001) mRNA relative expression upregulated and IFN-γ (P = 0.04) mRNA relative expression downregulated significantly. Compared with DSS treated acute colitis group, the expression level of H. pylori infection was not limited to gastric mucosa, IL-10-producing B cells and Foxp3+ Treg cells expanded in spleen and mesenteric lymph nodes (MLN), the balance of intestinal mucosal immunity was influenced to a skewed regulatory immune response.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: (1) H. pylori infection can alleviate the acute and chronic colitis induced by MMP9 in pre-treated mice. (2) CD4+CD103+ Foxp3+ Treg cells expanded significantly in H. pylori/DSS co-treated acute colitis mice. (3) CD4+IL-10+Breg cells expanded while CD4+CD25+Foxp3+Treg cells reduced significantly in H. pylori/DSS co-treated chronic colitis mice. The potential protective effect of H. pylori infection on acute and chronic colitis induced by DSS may pass through the expansion and function of CD19+IL-10+Breg cells.

Introduction: The microbial dysbiosis plays a pivotal role in the pathogenesis of inflammatory bowel disease (IBD), however, the role of fungal microbiota in IBD was unclear. The aim of our study was to clarify the gut fungal composition in IBD patients with different treatment strategies.

Aims & Methods: 73 IBD patients were divided into three groups, Untreatment (n = 21), Antiinflammation (n = 43) and Immunosuppression (n = 9). Antiinflammation was defined as treatment with 5-aminosalicylic acid (5-ASA), salazosulfapyridine (SASP) and Immunosuppression as treatment with Glucocorticoid (GC), azathioprine (AZA), biologics and thalidomine.

Noninflamed and inflamed mucosae were acquired for 16S and ITS sequencing to investigate the bacterial and fungal composition. Inflamed mucosa was used for RNA extraction and real-time PCR to detect the expression of lba:-associated biomarkers, such as TNF-alpha, IL-17A, MCP-1, etc. Analysis of Spearman’s correlation was performed to estimate the fungi-bacteria and microbe-biomarker correlation.

Results: Compared with noninfamed mucosa, lower diversity and evenness were observed in inflamed mucosa in all IBD patients, but no significance in noninfamed (or inflamed) mucosa of different treatment strategies. Beta diversity showed a treatment-dependent clustering in inflamed mucosa. Fungal microbiota was constituted by fungi from Ascomycota, Basidiomycota and Zygomycota in inflamed mucosa of different treatment strategies. Beta diversity significantly altered fungi-bacteria correlation patterns in noninflamed mucosa (p < 0.001). Additionally, IL-17A, IL-22, IL-8 and MCP-1, and treatment altered microbiota biomarkers correlation.

Conclusion: Treatment strategies affect fungal composition. To some extent, IL-22, IL-8 and MCP-1, and treatment altered microbiota biomarkers correlation. Additionally, IL-17A tended to be the main mediator for bacteria to induce inflammation in IBD.

Introduction: MMP9 is involved in the degradation of the extracellular matrix and its expression is elevated in the inflamed tissue of patients with ulcerative colitis (UC) [1-3]. Pre-clinical models of colitis demonstrate a therapeutic benefit for antibodies to inhibiting MMP9 in pre-existing colitis [4]. Andecaliximab (previously GS-5745) is a high-affinity IgG4 monoclonal antibody against human Matrix Metalloproteinase 9 (MMP9). In a 36-day Phase 1b study in UC, andecaliximab demonstrated clinical efficacy relative to placebo treatment [5]. Here we describe bacterial microbiota analysis of stool samples collected during the Phase 1b study of andecaliximab in UC.

Aims & Methods: The objective of this study is to examine changes to the bacterial microbiota pre- and post-andecaliximab treatment and relative to therapeutic response. Fecal pool was collected in a randomized treatment (Baseline) and all treatment arms (Day 36). Clinical response was defined as a Mayo score reduction ≥3 point and ≥30% reduction from baseline score; accompanying decrease in rectal bleeding sub-score of ≥1 or an absolute rectal bleeding sub-score of 0 or 1, DCA was extracted from fecal samples using a modified CTAB method and 16S rRNA amplicon sequencing was performed on 59 samples (27 paired and 5 unpaired samples). Alpha diversity, beta diversity (calculated in QIIME), and taxonomic differences were examined between placebo and andecaliximab-treated patients, and between responding and non-responding patients.

Results: Compared to placebo-treated patients, those who received andecaliximab trended towards decreased alpha diversity (p = 0.06) at 36 days post-treatment. These changes in alpha diversity were not dose related. At Day 36, a trend towards a significant difference in community beta-diversity was observed between the andecaliximab-treated group relative to placebo (p = 0.07). Andecaliximab treatment was also associated with differences in bacterial taxonomy relative to placebo (p = 0.07). Specifically, the genera Clostridia and Akkermansia represented some of the top organisms enriched post andecaliximab treatment relative to placebo. Andecaliximab treatment exhibited a non-significant expansion of Akkermansia from Baseline to Day 36 (p = 0.15). Amongstandecaliximab-treated subjects, a trend of increased relative abundance of Akkermansia muciniphila was detected (p = 0.08).

Conclusion: Akkermansia muciniphila is the most consistently enriched organism for subjects treated with andecaliximab who respond to treatment. These preliminary results show that the potential pro-inflammatory role of A. muciniphila in ulcerative colitis may be associated with response to andecaliximab. Analysis of a larger study population would be required to verify these observations. Recent Phase 2 studies of andecaliximab in UC and Crohn’s disease failed to demonstrate clinical efficacy. These preliminary biomarker results are unlikely to be pursued in relation to andecaliximab treatment effects, but may be beneficial as a reference for future trials in inflammatory bowel disease.

Introduction: Crohn’s Disease (CD) and Ulcerative Colitis (UC) are inflammatory Bowel Disorders (IBD) with a complex etiology, including an immune response against microbial and autologous antigens and an imbalance between pro-inflammatory and anti-inflammatory mediators. Different approaches have been used to study the pattern of cytokines in IBD and few data are available on cytokines production in different intestinal compartments. Laser Capture Microdissection (LCM) is a powerful tool for the isolation of specific tissue compartments (1).

through the expression of Wnt ligands (Mucosal Immunology, 2016). We have recently reported that STAT6 deficiency favours fibrosis in a murine model of TNBS colitis (P031, ECCO 2016).

**Aims & Methods:** We aim to characterize here the functional relevance of the macrophage phenotype in fibrosis development. WT or STAT6 (−/−) mice were given TNBS (0.5, 0.5, 0.5, 0.5, 1, and 1 mg) intracolitically or saline weekly and they were sacrificed 3, 5 or 7 weeks after the first TNBS administration. The percentage of CD206, CD16, and CD86 positive cells was analyzed by flow cytometry in F4/80+ macrophages isolated from the intestinal mucosa. The mRNA expression of CD16 and fibrosis markers were evaluated in the colonic mucosa. The number of fungi decreased significantly in inflamed mucosal tissue compared to controls

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Although the etiology of ulcerative colitis (UC) has yet to be characterized, it is increasingly accepted that the cause of UC might well be related to commensal enteric bacteria in a genetically susceptible patient. Anti-inflammation therapy using probiotics is usually prescribed for UC treatment, and we previously demonstrated that triple antibiotic combination therapy with oral amoxicillin (1500 mg/day), tetracycline (1500 mg/day) or fosfomycin (3000 mg/day), and metronidazole (750 mg/day) (ATM/AFM), for two weeks, induces remission in more than 27% of patients with active UC including those with steroid-refractory or dependent disease, suggesting ATM/AFM to possibly be effective for achieving UC remission.

**Aims & Methods:** Thirty-two patients with UC given ATM/AFM therapy for two weeks on average were enrolled in this study. The clinical conditions of these UC patients were evaluated by Mayo score. Fecal samples were obtained prior to, after therapy and at three months after treatment completion. Gut microbiota were compared employing metagenomic analysis of fecal samples.

**Results:** Of the 32 patients, 17 and eight, respectively, experienced complete and partial remission over three months in response to ATM/AFM therapy, whereas ATM/AFM showed no efficacy in seven patients. The metagenomic analysis revealed abundant human DNA to correlate positively with the disease activity indicated by the Mayo score. Furthermore, dramatic gut microbiota changes were observed at an early stage, i.e. just two weeks after starting ATM/AFM therapy (P0306).

**Conclusion:** The expression of Wnt ligands from CD16 positive cells, which are accumulated in the mucosa, may be involved in murine intestinal fibrosis.

before treatment in the active stage to possibly be associated with increased proliferation of bacteria. Neutrophil extracellular traps (NETs) are fibrous structures released by activated neutrophils upon stimulation. NETs consist of chromatin and cytoplasmic proteins, which are released extracellularly during a process called NETosis. Tissue factor (TF) is the main in-vivo initiator of coagulation and is expressed on NETs in a plethora of neutrophil-mediated thromboinflammatory conditions [1–3]. Ulcerative colitis (UC) is characterized by infiltration of neutrophils into the affected mucosa and increased risk of thromboembolic events; however the mechanism behind the thrombophilic state of UC has not been clearly elucidated yet [4].

Aims & Methods: We aimed to investigate for the first time the role of neutrophils/NETs through TF expression in the pathophysiology of UC. Neutrophils, sera and colon biopsies were obtained from 10 naive patients with active UC (6 male, mean age 34.6 ± 19.1 years, mean Mayo score 8.5 ± 1.4) and from 10 native patients suffered from active Crohn disease (CD) (7 male, 3 female, mean age 34.2 ± 18.5, CDAI > 220). Additionally, 10 sex- and age-matched healthy subjects, were served as control subjects (5 male, 5 female, mean age 38.9 years). Ex-vivo findings regarding NETs and TF expression in peripheral blood leukocytes and colon tissue specimens were verified using appropriate in-vitro stimulations of control neutrophils with corresponding sera and intestinal tissue-conditioned media, respectively. Identification and quantification of NETs were performed with immunofluorescence confocal microscopy (IFC), flow cytometry and MPO/DNA complex ELISA. The expression of TF on neutrophils/NETs was determined using ICM, qRT-PCR and western blot analysis. The bioactivity of TF on NETs was assessed by measuring thrombin-antithrombin complex levels with ELISA.

Results: Neutrophils from patients with active UC are characterized by increased NET formation in both the peripheral blood and affected colonic mucosa, compared to healthy controls. Furthermore, NETs are decorated with functional TF and the amount of TF-bearing NETs was reduced from the inflamed to normal colon. In-vitro stimulations of controls neutrophils with sera or intestinal tissue-conditioned media corroborated the findings obtained ex-vivo. Co-localization of NETs expressing functional TF may be involved in the induction of intestinal inflammation and systemic thrombosis in UC probably constituting a novel candidate diagnostic and/or therapeutic target.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Concomitantly, these cells were positive for the WNT ligand WNT10A and autophagy/mitophagy-associated LC3, suggesting autoregulatory mechanisms for the maintenance of the stem cell niche and mitochondria-associated functional alterations, respectively.

Conclusion: Our results indicate that mitochondrial function not only reflects IEC phenotypic changes but seems to be the driving force in differentiation processes. Mitochondrial function might therefore represent a key player at the edge of intestinal tissue homeostasis and repair/healing processes in the context of diseases.

Introduction: Previous studies have shown differences in disease phenotype of ulcerative colitis (UC) in South Asian (SA) migrants compared to Caucasians with pan-colonic phenotype predominant. The gut microbiota differs in ulcerative colitis (UC) in South Asian (SA) migrants compared to Caucasians. Previous studies have shown differences in disease phenotype of UC. For the UC cohort, robust models were obtained by OPLS-DA between SAs and Caucasians (HC). There was no significant difference between SA and Caucasian at time point 2 months (HC). OPLS-DA model between South Asian (SA) and Caucasians with UC. *compound is increased or decreased in SA compared with Caucasians respectively.

Introduction: Patients with active inflammatory bowel disease have elevated myeloid lineage leucocytes1 including the CD14⁺ CD16⁻ DR⁻ e phenotype known as proinflammatory monocytes, and a major source of tumour necrosis factor-α.² Accordingly selective depletion of myeloid leucocytes by granulocyte/monocyte apheresis (GMA) is expected to promote remission or enhance drug efficacy. However, studies in ulcerative colitis (UC) patients have reported contrasting efficacy outcomes, ranging from an 85%³ to statistically insignificant level.³ Patients’ baseline demographic features may guide to selecting responder patients.
Aims & Methods: In a retrospective and single-centre setting we aimed to under-
stand if patients’ baseline clinical and endoscopic features were relevant guide for iden-
tifying likely responders and non-responders to adsortive GMA. The sub-
jects were 145 consecutive UC patients who had undergone GMA with the Adacolumn as remission induction therapy between 2012 and 2016. Seventy-
three patients were steroid naive, 70 were steroid dependent, and 2 patients were steroid refractory. Patients had received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index was defined as remission. Biopsies from endoscopically detectable inflamed large intestinal mucosa were processed to see the impact of GMA on leucocytes within the mucosal tissue.

Results: At entry, the average CAI was 12.8, range 10–17. Ninety-three patients (64.1%) had responded to GMA, 52 of 73 steroid naïve (71.2%), 40 of 70 steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent subgroup. Observations on mucosal tissue biopsies showed that the most responsive histopathologies were mostly mucosae and mononucleuses. There was a marked reduction of infiltrating leucocytes in responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responders (100%) as compared with steroid naïve patients. Additionally, a short duration of active UC prior to GMA marked a patient as a likely responder. Further, all patients who achieved remission were steroid free at week 12.

Conclusion: First episode and steroid-naïve cases which responded well to GMA attained a favourable long-term clinical course. Additionally, GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is favoured by patients for its safety profile and for being a non-drug remission induction therapy. Patients with extensive deep ulcers, with long dura-
tion of UC refractory to multiple pharmacologicals are unlikely to benefit from GMA. In therapeutic settings, knowing baseline clinical and endoscopic features, which may identify GMA responder patients should guide to stop futile use of medical resources.

Introduction: Antibiotics sometimes have an influence on colitis negatively. Although it is well known that dysbiosis is one of the major disturbances to the gut environment, the molecular mechanisms underlying the pathogenesis remains unclear.

Aims & Methods: We aimed to clarify how antibiotics affect the gut microbiota and the pathology of colitis. Mice were gavaged with ampicillin (ABPC), vancomycin (VCM), neomycin, or a combination of ABPC and VCM (A-V) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines. Fecal microbiota was characterized by 16sRNA sequencing. In the gluteal and ileal areas, the glucose (Gln) metabolites and SCFA including butyric acid (SCFA) in the feces were measured by a chromatography-tandem mass spectrometry. Fecal mucus was characterized by hexosamine and fucose. In the gluteal area, (Gln) treatment experiment, the mice were given 30mg/mL of Gln in drinking water ad lib for six days, and additionally gavaged A-V for the last three days.

In vitro experiments: colon cancer cell line cell line CT26 and macrophage cell line RAW264.7 were stimulated by butyric acid.

Results: ABPC and VCM, but not other antibiotics, resulted in FOBT-positive and IL-6, IL-12p40 and MPO overexpression. The treatment caused colitis-like changes evaluated in the A-V mice. Moreover, Gln metabolites and SCFA including butyric acid were decreased and family S247 and order Clostridiaceae were less abundant in the feces of A-V mice. Interestingly, Gln treatment improved the antibiotics-induced colitis. Reduced mRNA expression of pro-inflammatory cytokines in RAW264.7 and induced expression of antimicrobial peptides (secretory leucocyte protease inhibitor and lactoferrin) in CT26.

Conclusion: A-V treatment induced mild colitis with reduced abundance of family SCFA and other SCFA, which might diminish Gln and SCFA metabolisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel disease (IBD) is a group of gastrointestinal tract diseases consisting mainly of Crohn’s Disease (CD) and Ulcerative Colitis (UC). Various etiological factors contribute to the pathogenesis of IBD, including modulation of microbiota, epithelial barrier disruption, genetics and environmental factors. Recently, the treatment of IBD comprises several groups of drugs the choice of which is made based on disease activity and extent. The treatment options include: analogs of 5-aminosalicylic acids, glucocorticoids and other immunosuppressive drugs such as azathioprine. Biological therapy with anti-tumor necrosis factor alpha (TNFα) are considered when conventional therapy fails. In portion of patients surgical approach is necessary. Therefore novel pharmacological targets are sought in order to improve the remission rate and avoid the disabling procedures. G protein-coupled receptor 18 (GPR18) belongs to the G-protein coupled cannabinoid system which already earned its place in the pathogenesis of IBD. GPR18 was found to be implicated in protecting against bacterial infection and organ injury. Reports indicate that it may also be connected to the obesity/diabetes-related inflammation. As we lack data regarding its association with intestinal inflammation we attempted to shed some light on this phenomenon.

Aims & Methods: The aim of the study was to assess the anti-inflammatory and anti-nociceptive actions of GPR18 in the intestinal inflammation. The anti-inflammatory activity of GPR18 agonist PSB-KK-1415 and antagonist PSB-CBS (1–5 mg/kg, i.c., once daily) was characterized in two mouse models of colitis, induced by 2, 4, 6-trinitrobenzenesulfonic acid (TNBS) and dextran sulfate sodium (DSS). The extent of inflammation was evaluated based on the microscopic score, quantification of myeloperoxidase (MPO) activity and alpha (TNFα) in colonic tissue. The expression of GPR18 gene in colonic samples from patients with IBD was quantified using real-time RT PCR and Western blot analysis. GPR 18 was localized in human colonic samples using immunohistochemistry methods.

Results: The results of our study with lower doses of GPR18 ligands in the semiliquid TNBS model of colitis showed a non-significant decrease in macroscopic score, ulcer score and a significant decrease in MPO activity (p < 0.05) in mice injected with PSB-KK-1415 compared with TNBS-treated mice. PSB-CBS increased inflammation indices. Study in the mouse model of TNBS-induced colitis with higher dose of PSB-KK-1415 presented a pronounced reduction in the indices after treatment with the agonist. We also showed that GPR18 is expressed in the colon of patients with IBD.

Conclusion: We demonstrated potential ability of the GPR18 agonist PSB-KK-1415 to alleviate inflammation in the mouse models of colitis and showed that GPR18 is expressed in the human colon. We conclude that GPR18 is another receptor of the endogenous cannabinoid system family which may be implicated in the pathogenesis of IBD and intestinal inflammation overall.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Our previous study showed that activation of D3 dopamine receptors (D3R) had the beneficial effect in experimental colitis treatment while the mechanism of this effect is unclear [1]. The disruption of surface colon mucosa layer is the subsequent activation of local immune response by the bacterial infection into the inner layer of the mucosa are the key pathogenic mechanisms of ulcerative colitis progression and perpetuation. We found the localization of D3R on the goblet cells in colonic mucosa [2].

Aims & Methods: We hypothesized that activation of D3R improves colonic mucous secretion during experimental colitis. Study was done on male Wistar rats (180–230). Experimental colitis was induced by 6% iodoacetamide (IA) (0, 1 ml, enema). Selective D3 agonist 7-OH-DPAT (0.1 mg/kg, s.c.) was injected i.p. 5 h prior to IA enema. Rats were euthanized 0, 5 and 2 h after IA enema. During the autopsy 7 cm colon from the anus has been removed. Surface mucous layer was separated from epithelial cells with N-acetyl-L-cysteine and glycoproteins were measured by periodic acid/Schiff (PAS) staining or by the reaction with Folins reagent. The content of heoxine, fucose and hexosamine were determined by standard biochemical assays.

Morphometric analysis was performed to evaluate the histological changes of colonic epithelial and goblet cells. Oxidative metabolism and arginase activity (analyzed by colorimetric method) in peritonal macrophages were investigated.

Results: Pre-treatment with 7-OH-DPAT did not affect the glycoprotein levels in normal mucosa, but significantly increased total levels of glycoprotein (1, 6-fold, p < 0.05) and hexose (1, 1-fold, p < 0.05) during IA-colitis. Furthermore, 7-OH-DPAT significantly increased the content of hexosamine in macrophages in 0, 5 h (1, 6-fold, p < 0.05) and in 2h (1, 3-fold, p < 0.05) after IA enema. Pre-treatment with 7-OH-DPAT decreased the mucosal thickness 1, 1-fold (p < 0.05), crypt depth 1, 1-fold (p < 0.05) and goblet cell cell lesion area 1, 2-fold (p < 0.05) after IA enema.

Conclusions: Pre-treatment with D3R agonist increased levels of mucus secretion and activated natural immune response by macrophage activation during experimental colitis, which could indicate about the protective role of D3R.

**P0317** INFLAMMATION AT DISTAL ILEOCAecal RESECTION MARGINS INCREASE THE RISK OF POSTOPERATIVE CROHN’S RECURRENCE

K. Wasmann1, J. Van Amersfoort1, L. Koene2, W.A. Benelman3, C.J. Buskens3

2Pathology, Academic Medical Centre, Amsterdam/Netherlands

Contact Email Address: k.a.wasmann@amc.nl

Introduction: Guidelines advise limited resection for Crohn’s terminal ileitis, as previous literature did not demonstrate clinical benefit from more extensive resections. Recently, some cohort studies identified positive resection margin as an independent risk factor for postoperative Crohn’s recurrence. But it is difficult to draw clinical conclusions, as non-uniform pathological definitions have been used. The aim of this study was to assess the incidence of non-radical resections by a validated pathological score, and correlate pathological findings to clinical outcomes.

Aims & Methods: H&E stained slides from proximal (ileum) and distal (colon) resection sites were scored according to the modified Geboes score from all consecutive patients undergoing primary ileocecal resection between January 2002 and September 2009. Endpoints were clinical recurrence (defined as recurrent disease activity demonstrated by endoscopy or MRI) requiring upsaling medical treatment or surgical recurrence.
Results: Of 104 ileocecal resections, 30 (29%) and 15 (14%) had inflammation at the proximal and distal resection margins, respectively. After a median follow-up of 8.6 years, clinical recurrence was seen in 57%, and surgical recurrence in 26%. A significantly increased recurrence rate was seen in patients with active inflammation at the distal resection margin whereas recurrence rates were comparable for inflammation at the proximal site and radical resections (87%, 61%, and 50% resp., p < 0.001). Active inflammation at the distal resection margin (HR: 3.189 (1.635–6.220); p = 0.001) and smoking (HR: 2.502 (1.331–4.703); p = 0.004) were the only independent predictors for clinical recurrence. The incidence of surgical recurrence was small to perform in AIEC screening.

Conclusion: Inflammation at the distal (colon) resection margin, and not the proximal ileum, after ileocecal resection was associated with significantly increased risk of clinical recurrence. This unexpected finding suggests that radioclinical staging, in correctly diagnosed terminal ileitis (I1 disease), while it is of crucial importance to exclude colonic (L3 disease). As this different phenotype is unlikely to benefit from more extensive surgery, pathological finding of positive distal resection margin should be regarded as a risk factor, warranting prophylactic drugs or close monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0319 LIPOSMAL FORMULATION AS A NEW DRUG DELIVERY SYSTEM FOR CROHN’S DISEASE – VALIDATION IN THE MOUSE MODEL OF TNBS-INDUCED COLITIS

J. B. Krzewska, P. Pietrusza, D. Tomczyk, J. Fichna
Department Of Biochemistry, Medical University of Lodz, Lodz; Poland

Contact E-mail Address: julia.krzewska@studumed.lodz.pl

Introduction: Crohn’s disease (CD) is a chronic inflammatory condition of the intestine, characterised by clinical symptoms of inflammatory bowel disease (IBD), constitutes a significant healthcare burden, in the developed societies. Current methods of treatment are only partially effective and/or associated with major adverse effects. New therapeutic solutions are needed to ameliorate the effects of medical therapy, reducing complications and improving patients’ quality of life.

Aims & Methods: The objective of the study was to assess the effectiveness of delivery of anti-inflammatory drugs encapsulated in the liposomal formulation. Liposomes were prepared using thin-lipid hydration method. 0.9% sodium chloride was used as a solvent. The hydration solutions contained an aminosalicylate mesalazine (5-ASA), two recently validated plant-derived anti-inflammatories with low bioavailability, chlorogenic acid (CGA) and berberine, and pure solvent as negative control. CGA was administered by a single intra-colonic (i.c.) administration of 2, 4, 6-trinitrobenzene sulphonic acid (TNBS) on Day 0. Liposomal suspensions containing 5-ASA (5 mg/kg), CGA (20 mg/kg), berberine (5 mg/kg) and the solvent were administered i.c. twice daily from Day 3 to Day 6. Mice were sacrificed on Day 7 and colonic damage was evaluated.

Results: The microscopic scoring system included the evaluation of the colon length and bowel thickness as well as the presence of ulcers, haemorrhage, faecal blood and diarrhea. Additionally, tissue myeloperoxidase (MPO) activity was determined and body weight was measured. The obtained results indicate that the best anti-inflammatory effect was obtained when liposomal suspension with berberine was used, while the treatment with 5-ASA was less effective. Surprisingly, CGA administration caused a detrimental effect as demonstrated by higher macroscopic score and increased MPO activity.

Conclusion: Drug-loaded liposomes may enhance the penetration of active compounds through the gut wall and therefore allow for increased bioavailability and effectiveness of the treatment at lower doses. We also showed that plant-derived compounds with low bioavailability, such as berberine and CGA, provide a new direction in the search of anti-inflammatory substances. However, increased bioavailability of anti-inflammatories due to liposomal formulation may result in adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Rutgeerts P, Geboes K, Vantrappen G, et al. Predictability of the postoperative finding of positive distal resection margin should be regarded as a risk factor, warranting prophylactic drugs or close monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.
incidence rate of microscopic colitis appeared to increase with time (Table). The incidence of microscopic colitis in 2016 was twice that observed in 2009 (incidence rate ratio 1.86; 95% CI 1.41, 2.46). There was a strong, independent graded association between the incidence of microscopic colitis and the number of lower GI endoscopy procedures undertaken (p = 0.03).

Conclusion: Microscopic colitis diagnosis is becoming more common. It is unclear whether microscopic colitis itself is increasing or greater numbers of lower GI endoscopy are being undertaken causing an ascertainment bias. Further work is required to explore environmental exposures such as drugs associated with microscopic colitis and to observe its natural history.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Contact E-mail Address: maturrin/fumery@gmail.com

Introduction: Data on extra-intestinal manifestations (EIM) and their impact on disease course of ulcerative colitis (UC) in population-based cohorts are scarce, particularly in paediatric- and elderly-onset UC patients.

Aims & Methods: The aims of this population-based study were to assess 1) the occurrence of EIM in paediatric- and elderly-onset UC; and 2) their impact on long-term disease outcome. Paediatric-onset (<17 years at diagnosis) and elderly-onset UC patients (>60 years) from a French prospective population-based Registry (EPIMAD) were included. Data on EIM and other clinical factors at diagnosis and at maximal follow-up were collected.

Results: 158 paediatric- and 470 elderly-onset UC patients were included (median age at diagnosis 14.5 and 68.8 years; median follow-up 11.2 and 6.2 years, respectively). EIM occurred in 8.9% of childhood- and 3% of elderly-onset patients at diagnosis and in 16.7% and 2.2% of individuals during follow-up (p < 0.01). The most frequent EIM was joint involvement (15.8% of paediatric-onset and 2.6% of elderly-onset). Presence of EIM at diagnosis was associated with more severe disease course (need for immunosuppressive or biologic therapy or colectomy) in both paediatric- and elderly-onset UC (HR = 2.0, 95% CI: 1.0-4.2 and HR = 2.8, 0.9-7.9). Extensive colitis was another independent risk factor in both age groups.

Conclusion: Elderly-onset UC patients had lower risk of EIM either at diagnosis or follow-up than paediatric-onset UC. EIM at diagnosis predicted more severe disease outcome including need for immunosuppressive or biologic therapy or surgery in both paediatric- and elderly-onset UC.

Contact E-mail Address: jloreaux@yahoo.com

Introduction: Data on long-term natural history of microscopic colitis (MC), including collagenous (CC) and lymphocytic colitis (LC) are lacking.

Aims & Methods: All new cases of MC diagnosed in the Somme area, France between January 1st, 2005 and December 31th, 2007 were prospectively included. Colonic biopsies from all patients were reviewed by a group of 4 expert gastrointestinal pathologists to assess the diagnosis of CC or LC. Demographic and clinical data were retrospectively collected from diagnosis to February 31th, 2017.

Results: One hundred and thirty cases of MC, 87 CC and 43 LC were included (median age at diagnosis 70 and 48 years, respectively). The median follow-up was 9.6 years (Q1: 7.6; Q3: 10.6). By the end of follow-up, 37 patients (28%) relapsed after a median time of 3.9 years (1.2; 5) since diagnosis, without significant difference between CC and LC (30% vs 25%, p = 0.47). Twenty patients (15%) were hospitalized for a disease flare and 32 (25%) presented with another autoimmune disease. Budesonide was the most widely used treatment (n = 31, 25%). Median duration of budesonide treatment was 92 days (70; 168) and no adverse event to budesonide were reported. Sixteen patients (22%) developed steroid-dependency and 4 (5%) were corticorestant. Only one patient was treated by immunosuppressants (azathioprine). No colorectal cancer was reported during follow-up. Any of the death (n = 25) observed during follow-up were linked to MC. In multivariate analysis, age at diagnosis (HR 1.03; 95%CI: 1.00-1.06; p = 0.02) and budesonide exposure (HR 0.40; 95%CI: 0.18-0.90; p = 0.03) were significantly associated with relapse.

Conclusion: This population-based study showed that after diagnosis, two third of patients with MC observed long term clinical remission. Age at diagnosis and budesonide exposure were associated with a risk of relapse.

Introduction: It has been demonstrated in many chronic conditions, including inflammatory bowel disease (IBD), that better patients’ knowledge about pathology and treatment improves the course and management of disease. The aim of this study was to develop an updated self-questionnaire to assess patients’ level of knowledge of IBD.

Aims & Methods: The IBD-INFO included 3 parts: an original part (Q1), and 2 parts from the translation of the pre-existing questionnaires Crohns’ and Colitis Knowledge score (CCKNOW) (Q2) and Crohn’s and Colitis Pregnancy Knowledge score (CCPKNOW) (Q3). The reliability and discriminatory ability of the questionnaire were validated with 3 groups of non-IBD volunteers with various theoretical knowledge levels. The final questionnaire (64 validated questions) was then tested on 364 in- and out- IBD patients from 4 French university hospitals. The score for each part of the questionnaire was calculated and factors associated with low scores were identified by uni- and multivariate logistic regression analyses.

Results: The scores obtained by the 3 non-IBD volunteer groups differed significantly (p < 0.0001) and the IBD-INFO questionnaire showed excellent internal reliability and consistency (α = 0.98). The median total score obtained by the IBD patients was 27.64 [0–59], and scores for Q1, Q2 and Q3 were, respectively, 10/23
Aims & Methods: In total 1814 patients with histologically confirmed IBD were evaluated. Medical records from 705 UC and 1022 CD patients as well as from 77 UC-PSC and 10 CD-PSC patients were assessed. Data were evaluated using standard statistical methods. In matched-pair analyses, IBD patients with and without PSC were matched at the ratio of 3:1 by sex, disease entity, age at disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0326 OPIATE USE IN INFLAMMATORY BOWEL DISEASE. PRESCRIPTION TRENDS AND MORTALITY IN AN ENGLISH PRIMARY CARE COHORT FROM 1990–2014

N. Burr1, C. Smith1, R. West1, M. A. Hult1, V. Subramanian1
1Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds/United Kingdom

Contact E-mail Address: nick.burr@nhs.net

Introduction: Chronic abdominal pain is a common symptom in inflammatory bowel disease (IBD). Pain management is complicated by clinically important gastrointestinal side effects of many of the available analgesics, particularly opioids. Opiate prescribing for cancer and non-cancer pain has increased dramatically in recent years but there is a paucity of data on prescription trends for individuals with IBD. The only population-based study is from Canada where 5% of subjects with IBD became heavy opiate users after 10 years of diagnosis and there was a strong association between heavy opiate use and mortality (OR 2.91, 95% CI 1.58–5.02). In this study we explore trends in the prescription of opiate medications and assess the association between opiate prescription and mortality in English primary care cohort of patients with IBD.

Aims & Methods: We used the English primary care database ResearchOne for this study which holds records from approximately 6 million individuals (>10% of the total population). We extracted relevant clinical codes and prescription data on all patients with IBD, and separated out those with ulcerative colitis (UC) and Crohn’s disease (CD). We created 4 categories of opiate medication use, namely; any opiate medication, codeine only, tramadol, and strong opiates. We defined 3 groups of prescription density as none/infrequent users, moderate, and heavy users as <1, 1–3, and >3 prescriptions per calendar year respectively.

We examined the trend in opiate prescriptions for all IBD patients in 4 year blocks from 1990–2014 using chi2 for trend as a significance. Separate trends were produced for each of our opiate classes. We calculated a propensity score estimating the conditional probability of being prescribed an opiate medication based on pre-defined characteristics which may influence the prescription of opiates. All-cause mortality in opiate users and non-users was compared in a propensity score matched, Cox proportional hazards regression analysis to produce hazard ratios (HR) and 95% confidence intervals (CI). All analyses were performed for each opiate medication class in CD and UC patients.

Results: We included 3517 patients with CD and 5349 with UC. Opiate prescriptions increased from 10% in 1990 to 30% in 2014 (chi2 for trend p < 0.005). There was a similar, significant increase for codeine (chi2 for trend, p = 0.008), tramadol (p < 0.003) and strong opiates (p < 0.005) when analyzed separately. Table 1 shows the association between opiate use and all-cause mortality in patients with IBD. Any opiate use in patients with UC was associated with increased mortality (HR 1.67, 95% CI 1.25–2.23). The strongest associations were for heavy users of strong opiates in patients with CD (HR 2.18, 95% CI 1.20–3.95) and UC (HR 3.30, 95% CI 1.77–6.18). There was no association for prescriptions of tramadol at any prescription density in CD or UC.

Table 1: The association between opiate prescriptions and all-cause mortality in patients with inflammatory bowel disease in the English primary care database Research One. Propensity score matched, Cox proportional hazards regression analysis.

Conclusion: Our study is the largest population based study of opiate use in patients with IBD. We have shown a significant increase in the prescription of opiates since 1990, with 30% being prescribed an opiate medication between 2010 and 2014. Prescriptions of codeine in UC and strong opiates in both CD and UC were associated with increased all-cause mortality. There appears to be a dose association as heavy users of strong opiates had the largest association with mortality. Observational studies are not proof of causality and there may be residual confounding. A dose response is a strong indicator that opiates could be responsible for the associations seen, which is consistent with other studies investigating opiates used for non-cancer pain in chronic disease. Randomised controlled trials would be unethical and not feasible to investigate this potential effect so population-based observational studies may provide the best estimate. Opiate prescriptions are increasing worldwide for chronic non-cancer pain, and individuals with IBD can now be included. Clinicians managing pain in individuals with IBD should consider the potential implications of prescribing, or continuing with opiate prescriptions as they are a marker for increased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: In a prospective 6-months study, dental examination was performed in IBD and in 19 healthy controls. IBD related variables were prospectively collected, as well as markers for periodontitis including gingival bleeding (BOP index, marker of periodontal inflammation), gingival recession (REC index, marker of cumulative periodontal destructions) and probing depth (PD) at the severity of the process. Additional dental examination was proposed 3 months after to all patients diagnosed with periodontitis.

Results: Among the 54 included patients, 44 had Crohn disease (81%) and 31 were women (55%). At the time of dental examination, median age was 33 years (Q1 = 26; Q3 = 41), 20 (36%) were smokers and the median IBD duration was 8.4 years (3.4-16.3). Eleven (20%) were treated by corticosteroids, 27 (49%) by anti-TNF, 6 (10%) by other biologics and 8 had no IBD treatment. IBD was significantly associated with periodontitis (81% vs 27%; Odds Ratio 2.9, 95% CI 3.6-2.3). Mild, moderate and severe periodontitis were respectively observed in 34 (63%), 8 (15%) and 3 (5%) IBD patients. As compared to healthy controls, IBD patients had significant increase of BOP index (p = 0.008), probing death (p = 0.03), and REC index (p = 0.01). Patients with active IBD (Harvey-Bradshaw index >1) had a significant increase of BOP index (p = 0.007) as compared to patients with inactive disease. A significant correlation between BOP and Harvey-Bradshaw index was observed (r = 0.44, p = 0.0018). Anti-TNF therapy was significantly associated with lower BOP index (p = 0.02). All patients with diagnosis of periodontitis were treated by periodontal debridement and subgingival irrigation with povidone-iodine which led to a significant decrease of BOP index three months after diagnosis.

Conclusion: Inflammatory bowel diseases were associated with an increased risk of periodontitis. Gingival inflammation was correlated to disease activity and anti-TNF therapy was associated with a lower risk of active periodontal disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn’s disease is a chronic, immune mediated inflammatory condition which affects the gastrointestinal tract. NOD2/CARD15 mutations have been linked to an increased risk of Crohn’s disease and to some of its phenotypes. This study aimed to determine the presence of the above mutations in Arab patients suffering from Crohn’s disease in Kuwait.

Aims & Methods: Blood samples were obtained from 103 Arab patients with Crohn’s disease and 100 Arab control subjects. The genomic DNA was isolated from the samples using Qiagen DNA Blood mini kit. The isolated DNA were amplified in 54 patients with IBD and in 19 healthy controls. IBD related variables were prospectively collected, as well as markers for periodontitis including gingival bleeding (BOP index, marker of periodontal inflammation), gingival recession (REC index, marker of cumulative periodontal destructions) and probing depth (PD) at the severity of the process. Additional dental examination was proposed 3 months after to all patients diagnosed with periodontitis. As compared to healthy controls, IBD patients had significant increase of BOP index (p = 0.008), probing death (p = 0.03), and REC index (p = 0.01). All patients with diagnosis of periodontitis were treated by periodontal debridement and subgingival irrigation with povidone-iodine which led to a significant decrease of BOP index three months after diagnosis.

Results: Inflammatory bowel diseases were associated with an increased risk of periodontitis. Gingival inflammation was correlated to disease activity and anti-TNF therapy was associated with a lower risk of active periodontal disease.

Introduction: There is limited data on genetics of inflammatory bowel disease (IBD) in populations where the condition is emerging, especially from South Asia.

Aims & Methods: A case [histologically confirmed ulcerative colitis (UC) and Crohn disease (CD) of 2+1 year duration] control [unrelated, healthy, gender matched] study was conducted at four major gastroenterology centres in Sri Lanka. Phenotypic data (type, location, severity, treatment types, response to treatment and complications) of cases were obtained. Cases and controls were genotyped for 16 selected variants with known IBD disease associations in Western and East Asian populations [IL12B:rs1045431, IL23R:rs11805303, ARPC2:rs12612347, IRGM:rs13361189, IL26:rs1558744, IL10:rs282785, IL10:rs3024505, PTGER4:rs1631763, IL17REL/PIM3:rs9268853, HLA-DRB5, DQA1, DRB1:rs9268853, MST1, UBA7, APEH:rs9822268]. Genotypes of all variants were compared with corresponding phenotypes: IL23R:rs11805303 with IBD-153 (37.2%), males-50.3% and 465 (males-50.5%) controls. The following variants were associated with corresponding phenotypes: IL12R:rs1045431 with upper gastrointestinal (UGI) CD (p = 0.001); IL17REL/PIM3:rs9268853 with relapsing IBD (p = 0.003); IRGMR:rs13361189 with UC (p = 0.003); IRGMR:rs13361189 with UC (p = 0.003); IL17REL/PIM3:rs5771069 with treatment-refractory IBD (all cases) (p = 0.005).

Conclusion: This study confirms the association of genetic variants of IBD previously reported in other populations, with clinical, prognostic and treatment phenotypes of IBD in a Sri Lankan (South Asian) population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: lariwar@mail.ru

Introduction: Among the numerous genetic factors associated with ulcerative colitis (UC), an increasing attention has been paid to the polymorphisms of the vitamin D receptor gene (VDR) associated with disorders of innate and adaptive immunity as well as the barrier function of the intestinal epithelium. However, the results of studies on the prevalence, clinical, diagnostic and prognostic significance of polymorphisms of the VDR gene in different populations are ambiguous and contradictory. In particular, associations of Bsm I polymorphism of the VDR gene with UC in the Chinese population and in the Jewish Ashkenazi has been found, while in the Irish population, with a sufficient prevalence of Bsm I polymorphism, this association is absent [1–3]. In the Russian Federation, there is no data on the prevalence, clinical, diagnostic and prognostic significance of Bsm I polymorphism of the VDR gene with UC. These circumstances determined the purpose and objectives of this study.

Aims & Methods: The purpose is to assess the clinical, diagnostic and prognostic significance of the Bsm I polymorphism of the VDR gene (rs154440) among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method (“SNP-express” reagents, Lytech Co. Ltd., Russia) with electrophoretic detection of amplification products. Statistical analysis was performed using the t-test and Mann-Whitney tests. In the presence of statistically significant differences (p < 0.05), odds ratios (OR) with 95% confidence interval (CI) were calculated.

Results: It was found that the frequency of the allele B polymorphism of the VDR Bsm I gene was higher among patients with UC than in the control group (44% vs. 26%, p = 0.02), which increases the risk of this pathology by 2.2% (95% CI: 1.2–4.1). In the case of carriers of the B/B genotype, the risk of developing UC increased up to 3.5 times in comparison with the control group (21% vs. 7%, p = 0.02, 95% CI: 1.4–8.6), whereas in b/b genotype the risk of UC decreased (33% and 54%, respectively, p = 0.02, OR = 0.4, 95% CI: 0.2–0.7). Significant differences between carriers of the B allele Bsm I polymorphism and the features of the clinical course of the UC have not been established. However, it has been shown that in carriers of allele B, the clinical implementation of UC develops significantly later than in patients with the b/b genotype (43 and 28.5 years, respectively, p = 0.04).

Conclusion: Genotype B/B polymorphism of the VDR gene has a protective effect in the development of ulcerative colitis among the residents of the Kemerovo region of the Russian Federation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: DNA methylation is an important epigenetic modification mechanism of gene expression. Several studies have shown an association of impaired methylation with inflammatory bowel diseases (IBD) pathogenesis. DNMT3A and DNMT3B are two of the three members of the family of de novo DNA methyltransferases. Variants in these proteins are responsible for the establishment of de novo genomic methylation patterns and initiation of normal development as well as in many diseases. However, it is unknown if DNMT3A may play a role during the mechanism involved in this abnormal methylation pattern and consequently the development of diseases.

Aims & Methods: To assess the function of DNMT3A in intestinal epithelial cells (IECs), human Caco-2 colon carcinoma cells were transfected with siRNA targeting DNMT3A, DNMT3B and DNMT3L. Gene expression analysis and DNA methylation analysis using qRT-PCR, RNA sequencing and 850k methylation arrays were performed. For long-term experiments, we used a CRISPR/Cas9 genome editing to delete DNMT3A gene in Caco-2 cells. DNMT3A knockout Caco-2 cells were grown in a 3D-Matrigel culture system and after 2 weeks, spheroids cells were stained for actin/nuclei and subjected to confocal microscopy analysis.

Results: From the RNA sequencing data, approximately 1000 genes were found to be differentially expressed between cells lacking DNMT3A and controls. The KEGG pathway analysis identifies differentially regulated genes associated with several functional categories comprising extracellular matrix receptor interaction, focal adhesion and MAPK signalling pathway. In contrast, we observed no difference in DNA methylation between the groups. Furthermore, loss of DNMT3A induces abnormal spheroids formation by reducing spheroids diameter and defect in actin organization and lumen formation. Thus, the observed morphological phenotype may be linked to the differentially regulated genes involved in the previous analysed pathways.

Conclusion: Rapidly inactivating DNMT3A in IECs promotes changes in gene expression, but does not change global DNA methylation. The absence of DNMT3A induces abnormal, defective spheroids formation in 3D culture system. Hence, our data provide a preliminary overview of DNMT3A in intestinal epithelial cells and its potential role in maintaining intestinal homeostasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

(IRE1), double-stranded RNA-dependent protein kinase (PKR)-like ER kinase (PKR-like endoplasmic reticulum kinase, PERK), and double-stranded RNA-dependent protein kinase (PKR)-like ER kinase (PKR-like endoplasmic reticulum kinase, PERK). Defective IRE1 and PERK response have been shown to predispose to chronic inflammatory bowel disease (IBD). Genome-wide association studies identified disease susceptibility loci in or adjacent to several UPR related genes including XBPI and ORMDL3. Aims & Methods: The objective of this study was to determine the function of ORMDL3 in UPR signaling to gain insights into the molecular mechanisms promoting chronic intestinal inflammation. Using molecular cell biology approaches, we studied the effect of ORMDL3 on ATF6, PERK and IRE signaling. ORMDL3 overexpression induced the increased cleavage of ATF6 and augmented ERSE promoter activity. Mechanistically, we show that ORMDL3 colocalizes and directly interacts with ATF6. Furthermore, ORMDL3 overexpression induced the PERK pathway by elevating its downstream protein levels. In contrast, we observed an inhibition of IRE1 signaling exerted by ORMDL3 proteins as shown by reduced XBPI splicing and decreased UPR promoter activity. ORMDL3-deficient mice showed an increased susceptibility to acute DSS-induced colitis compared to their wild-type littermates. These results are in concordance with what was published by Pariente B et al. (1)

Conclusion: This study demonstrates for the first time the modulatory functions of ORMDL proteins as regulators of all three UPR signaling pathways. Aims & Methods: In the present study, we aimed to precisely fine-tune the mechanism of the UPR determining cell fate decisions in response to ER stress.

P0334 THE USE OF LÉMANN SCORE TO EVALUATE THE DAMAGE TO THE DIGESTIVE TRACT CAUSED BY CROHN’S DISEASE IN AN EGYPTIAN COHORT

H. M. Saad1, O. E. Salem2, M. A. Salem3, M. E. Ibrahim4, S. M. El Kady1

Contact E-mail Address: hussinemahmoud7@hotmail.com

Introduction: Lémann scores have assessed Crohn’s disease (CD) according to disease activity using clinical, laboratory & radiological activity indexes; but few have analyzed the damage the disease bring about on the GI tract. Lémann score was designed to develop a comprehensive assessment of the structural bowel damage, including strictureng lesions, penetrating lesions (fistulas and abscesses), and surgical resection. (1)

Aims & Methods: To calculate Lémann score in a cohort of Egyptian patients to determine its ability to assess the structural damage caused by CD in Egyptian patients. Lémann score was calculated using the computer software based on the original paper by Pariente. B et al (1) in a cohort of Egyptian patients with CD followed from April 2013 - August 2015. The temporal relation between Lémann score and disease duration was also assessed.

Results: A total of 141 patients with CD were enrolled, 69% males and 31% females. Median age was 32 years, 36% were smokers. The clinical presentation varied between abdominal pain occurring in 90% followed by 69% with chronic diarrhea, 52% with weight loss. Few patients (26%) presented with extraintestinal manifestations. According to ECCO classification of disease severity 73% of our patients had mild disease, 17% had moderate disease, 10% had severe disease. According to Montreal classification, 25% of patients were class II, 55% class IV, 35% class I, 7% class III, 12% L3, 63% B1, 5% B2, 26% B3, & only 4% had perianal disease. According to CDAI, 83% were in clinical remission, 11% mild “CDAI 150-220”, 4% moderate “220-450”, 2% severe “CDAI >450” disease activity. When assessing structural damage of upper GI, 4% had strictureing lesions, 2% grade 1 & 2% grade 2 lesions. The small bowel showed strictureing lesions in 65%; 39% grade 1, 23% grade 2, 3% grade 3 lesions. 25% of patients had grade 3 penetrating lesions, 5% had surgery which was resection in all the cases. As regards the assessment of strictureing lesion in the colon, 11% colon showed strictureing lesion of this structure, 3%, 2%, grade 3, 3% grade 4 lesions; ascending colon showed stricture lesions in 20%, with 7% grade 1 lesions, 11% grade 2 & 2% grade 3 lesions; transverse colon showed stricture lesions in 1%; sigmoid colon showed stricture lesions in 2%; rectum showed stricture lesions in 1; while in only 1% whole colon showed grade 1 strictureing lesions affecting the 6 segments. In addition, 12% had grade 3 penetrating lesions while 9% had history of surgery mainly intestinal resection. In the anal canal, only 3% of patients had grade 3 penetrating lesions. The mean Lémann score was 19.19 in the median abdominal Lémann score was statistically positively correlated with disease duration of ≥2 years & >2 ≤10 years and ≥10 years respectively. (r2 = 0.343 & p < 0.001) (KW = 9.235(0.01)). The current study showed that affection of the GI tract was (5%, 92%, 41%, and 3% with upper tract, small bowel, colon/rectum, & anus CD location, respectively). There is an increase in median Lémann score with increase in disease duration (global test p<0.001): 0.60, 2.50, 6.40 for disease duration of ≤2 years & >2 ≤10 years and ≥10 years respectively; these results are in concordance with what was published by Pariente B et al (1).

Conclusion: Crohn’s disease affection pattern in our Egyptian cohort is mainly in the small bowel (92%) followed by the colon (41%) with the upper GI and the anal canal representing only 5% and 3% respectively. Lémann score designed by

Introduction: Biosimilar infliximab CT-P13 received EMA approval in June 2013 for all indications of the originator product and its use is mandatory in all anti-TNF naïve IBD patients in Hungary since May 2014. Aims & Methods: In the present study we aimed to prospectively evaluate the immunogenicity profile of the biosimilar infliximab and predictors of TDM in IBD during the first year of therapy in a nationwide, multicentre cohort. Demographic data were collected and a harmonized monitoring strategy was applied. Clinical and biochemical activity were evaluated at weeks 14, 30 and 54. Routine therapeutic drug monitoring (TDM) was applied. Trough level (TL) and anti-drug antibody (ADA) concentration were measured by ELISA (LT-005, TheraDia [France]) at baseline, week 2, 14, 30, 54 and 54 weeks right before anti-TNF administration during the induction treatment.

Results: 353 consecutive IBD patients (209 CD patients and 144 UC patients) were included in the present cohort. 23.4% of CD patients and 19.4% of UC patients had received previous anti-TNF therapy. None of the patients had received infliximab within 12 months prior to initiation of the biosimilar infliximab. 60/51% of CD/UC patients received concomitant immunosuppressives at baseline. Mean TLs were 18.9, 17.3, 7.4, 4.3 and 5.3 μg/ml at weeks 2, 14, 30 and 54 in CD and 19.1, 11.8, 5.0, 3.9 and 4.5 μg/ml in UC. Previous anti-TNF therapy was associated with lower early TL-s in both CD (week 2, 14, and 30, p < 0.05) and UC (week 2 and 6, p = 0.03) ADA positivity rates were 4.3%, 12.0%, 20.9% and 28.6% in naïve patients at weeks 0, 14, 30, and 54 (difference 266, 312, 290 and 210). ADA positivity at week 14 was associated with lower TLs in all CD (week 2, 14 and 30, p < 0.007 for all) and UC (week 6, 14 and 30, p < 0.001 for all) patients. Concomitant IS use prevented ADA formation in anti-TNF naïve patients (week 14, 30 and 54, p = 0.01, 0.02 and 0.004) in CD but not in UC and did not affect clinical remission or response rates. 32 (8.9%) patients had infusion reactions during induction or maintenance treatment, of which 16 patients had received previous infliximab treatment. Conclusion: TLs and ADAs in IBD patients until week 54 were in line with results from previous studies. Increased immunogenicity profile with previous exposure to anti-TNFs had lower early TL coupled with ADA positivity and were more likely to develop infusion reactions. Concomitant IS use prevented ADA development in anti-TNF naïve patients.

P0336 RECONSIDERING THE PROGNOSTIC VALUE OF TRADITIONAL SEROLOGIC ANTIBODIES IN CROHN’S DISEASE – IMMUNOGLOBULIN CLASSES TO TAKE THE CENTRE STAGE

S. Nepi1, B. Suga1, G.L. Norman2, Z. Shum1, G.L. Veres1, P.L. Lakatos3, P. Antal-Szalmas3, M. Papp1
1Department Of Internal Medicine, Division Of Gastroenterology, University of Debrecen, Debrecen/Hungary
2Inova Diagnostics, San Diego/United States of America/CA
3, sz. Gyermekklinika, Semmelweis Egyetem, Budapest/Hungary

Introduction: The most relevant scope of serologic antibodies in Crohn’s disease (CD) is to stratify the risk of complicated disease course. Significance of distinct antibody class and their characterisation was rarely considered. We aimed to address these concerns.

Aims & Methods: Sera of 266 well-characterised CD patients (mean±SD: 25 yrs, BMI±SD: 20–80%) and 155 controls were assayed for traditional serologic IgA (anti-OMP IgA (ascA), Omp IgA), Omp IgG, ASCA IgG, Endoantigen core IgA (EndoCAb) and a panel of non-specific immunoglobulins (IgA1.54 [0.97–2.44]; 0.066 1.37 [0.82–2.28]; 0.23 1.25 [0.67–2.34]; 0.475

Regression analysis comprising relevant clinical factors. Performance OMP IgA was equal to ASCA IgA, however sIgA not. Anti-perianal penetration (PP) with IgG type ASCA (p LogRank = 0.019 2.08 [1.28–3.38]; 0.003 1.13 [0.63–2.01]; 0.692

Conclusion: The absence of serologic healing (ulcerative disease; SES-CDa ≤ 5) was an independent risk factor for clinical relapse (Hazard ratio [HR] = 4.78; 95% CI: 1.94–11.80; P = 0.001) and serological relapse (HR = 2.84; 95% CI: 1.63–4.98; P = 0.001), respectively. For the ASCA IgA Meier analysis, patients who did not achieve serologic healing were at a significant risk of worse outcomes (clinical relapse, P < 0.001; serological relapse, P < 0.001). MR ulcer healing (MaRIA score <11) showed a high sensitivity (82.5%; 95% confidence interval (CI): 74.9%–88.2%) and specificity (85.5%; 95% CI: 79.2%–90.6%) for detection of serologic healing. On Cox’s proportional hazards analysis, MRE findings of ulcer healing were associated with a low risk of clinical relapse (Hazard ratio [HR] = 0.24; 95% CIs: 0.11%–0.54%; P = 0.001) and serological relapse (HR: 0.47; 95% CIs: 0.29%–0.78%; P = 0.003).

Conclusion: The absence of serologic healing (ulcerative disease) were seen in a considerable number of CD patients who were in clinical-seromimetic remission, preinflammatory lesions were at risk factor for worse prognoses. MRE could evaluate both serologic healing with a high diagnostic accuracy, and could predict patient outcomes.

Introduction: In Crohn’s disease (CD), accurate evaluation of location and small bowel involvement are necessary at the time of diagnosis for prognostic concern and planning of treatment strategy. Since Double Balloon Endoscopy (DBE) enables us to examine deep small bowel either oral or anal it could be of great utility in the management of Crohn’s disease patients.

Aims & Methods: We aimed to evaluate the diagnostic yield and therapeutic impact of DBE on small bowel CD. The medical records of 180 CD patients, from October 2009 to April 2012 were retrospectively reviewed. Patients were included if they had known CD based on clinical, colonoscopic and histological findings and had been subjected to DBE. If one patient underwent more than one DBE examination only the first examination was considered. The primary end point of our study was to evaluate small bowel involvement that is beyond the reach of conventional colonoscopy. The secondary endpoints were to determine the impact of DBE findings on management strategy of CD. The diagnostic yield of DBE in small bowel CD was determined. In addition, the changes in medical treatment, endoscopic intervention and surgical procedures, within three months after DBE, were analysed.

Results: Among 180 patients with CD, 90 patients underwent 168 DBE examinations and were included. The mean age of included patients was 40 ±13.6 years. They were 63 males and 27 females. Eighty-six (91%) patients with established CD underwent DBE for evaluation of small bowel involvement and 8 (9%) patients underwent DBE because of suspicion of CD and had been newly diagnosed. The overall diagnostic yield of DBE was 69%. DBE revealed small bowel involvement proximal to the terminal ileum in 40 (64.5%) patients; of them 17 (42.5%) patients had isolated small bowel CD. Within 3 months after DBE examination the management strategy of CD changed in 47 (52.2%) patients, based on DBE findings. The medical treatment was escalated in 20 (22%) patients, and decreased in 17 (11%). Fourteen (24%) patients underwent DBE-assisted balloon dilatation, and 6 (9.6%) patients underwent CD-related surgery.

Conclusion: DBE is able to detect small bowel involvement in a significant proportion of CD patients. The DBE findings modified the management strategy in at least one half of CD patients.

Introduction: Therapeutic adherence is crucial in the management of patients with inflammatory bowel disease (IBD). Poor adherence may lead to suboptimal treatment.

A total of 181 patients were evaluated. The median age was 47 years (range: 16–78) and 118 (64.8%) were men. The median duration of IBD was 16 years (range: 0.5–42 years). Eighty (43.5%) patients were taking mesalazine, 2.8% steroids, 29.3% immunomodulators, and 30.4% biologics. Activity was evaluated using Harvey-Bradshaw index in Crohn’s disease (CD) and Partial Mayo Score in Ulcerative colitis (UC). Anxiety and depression were estimated by the Goldberg Anxiety and Depression Scale and modified Morisky Medication Adherence Scale (MMAS-8) was used to assess adherence (6, 7–8 points indicate low, medium and high adherence, respectively). In statistical analyses, Chi-square and Student’s t-test were performed to determine the statistical significance with a p-value < 0.05.

Results: On MMAS-8, almost half of our patients 84 (46.4%) had high adherence to IBD treatment, 35.9% were taking mesalazine, 2.8% steroids, 29.3% immunomodulators, and 30.4% biologics. Activity was evaluated using Harvey-Bradshaw index in Crohn’s disease (CD) and Partial Mayo Score in Ulcerative colitis (UC). Anxiety and depression were estimated by the Goldberg Anxiety and Depression Scale and modified Morisky Medication Adherence Scale (MMAS-8) was used to assess adherence (6, 7–8 points indicate low, medium and high adherence, respectively). In statistical analyses, Chi-square and Student’s t-test were performed to determine the statistical significance with a p-value < 0.05.

Conclusion: This study demonstrated the feasibility of applying the CDMRIS score in clinical practice, to evaluate its variability after the initiation or optimization of an anti-TNF treatment, and to measure its correlation with an evaluation of clinical activity. Patients with known small bowel disease who underwent push and pull enteroscopy examinations at least 30 days were included between 2010 and 2015. Each exam was interpreted twice and the CDMRIS score was calculated on both exams in addition to classical criteria. All patients had a clinical evaluation over time, separating them in two groups: “active” and “inactive” disease.

Results: Seventy-two patients were included, with a mean CDMRIS of 3.4 at baseline, decreasing to 2.6 (p = 0.052) independently of clinical activity of disease. The median interval between the two MRIs was 15.4 months, and there was a significant larger decrease in the CDMRIS score when the interval was above 12 months. Two other radiological parameters decreased significantly: the rate of patients with a mural T2-hyperintensity (36.1% to 20.8% p = 0.042), with a good chincoradiological correlation, and mean wall thickness (5.5 to 4.4 mm, p = 0.047).

Conclusion: This study demonstrated the feasibility of applying the CDMRIS score in clinical practice, but sensitivity was too low to detect early changes. Accuracy for a long-term monitoring needs to be tested. Wall thickness and mural T2-hyperintensity emerged as the two most reliable radiological factors, significantly associated with the disease activity, allowing monitoring of the short-term efficacy of biotherapies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Magnetic resonance enterography is now recognized by the European Crohn’s and Colitis Organization (ECCO) as a reference procedure to assess the intestinal involvement of Crohn’s disease (CD), including extra-intestinal manifestations, as well as to monitor patients under treatment. A new MRI index of severity was developed in 2015 by the GETAID consortium, specifically to evaluate lesions located in the small intestine. This score, labeled CDMRIS (Crohn’s disease Magnetic Resonance Imaging Severity index), was validated, for each 20-cm small bowel segment, the intensity of relative contrast enhancement (mild–moderate or severe), deep ulceration without fistula, “comb sign”, any fistula, and abscess. Although well standardized, this index has not yet been validated, either for the initial assessment of CD at diagnosis, or for monitoring patients under treatment. Its feasibility in routine practice has never been tested.

Aims & Methods: The aims of this study were to evaluate the feasibility of applying the CDMRIS score in clinical practice, to evaluate its variability after the initiation of an anti-TNF treatment, and to measure its correlation with an evaluation of clinical activity. Patients with known small bowel disease who underwent push and pull enteroscopy examinations at least 30 days were included between 2010 and 2015. Each exam was interpreted twice and the CDMRIS score was calculated on both exams in addition to classical criteria. All patients had a clinical evaluation over time, separating them in two groups: “active” and “inactive” disease.

Results: Seventy-two patients were included, with a mean CDMRIS of 3.4 at baseline, decreasing to 2.6 (p = 0.052) independently of clinical activity of disease. The median interval between the two MRIs was 15.4 months, and there was a significant larger decrease in the CDMRIS score when the interval was above 12 months. Two other radiological parameters decreased significantly: the rate of patients with a mural T2-hyperintensity (36.1% to 20.8% p = 0.042), with a good chincoradiological correlation, and mean wall thickness (5.5 to 4.4 mm, p = 0.047).

Conclusion: This study demonstrated the feasibility of applying the CDMRIS score in clinical practice, but sensitivity was too low to detect early changes. Accuracy for a long-term monitoring needs to be tested. Wall thickness and mural T2-hyperintensity emerged as the two most reliable radiological factors, significantly associated with the disease activity, allowing monitoring of the short-term efficacy of biotherapies.

Introduction: Sphincter-saving surgery (ASS) in Crohn’s disease (CD) is not a simple procedure and is associated with a high risk of remission failure after surgery.

Primary Outcome Measures and Analysis: The primary outcome was the CD activity index (CDAI) at 30 weeks and 6 months postoperatively. The analysis was performed on an intent-to-treat basis.

The authors concluded that ASS is associated with a high risk of remission failure after surgery and may not be a suitable option for all CD patients. Further research is needed to identify factors that can predict remission failure after surgery to improve patient outcomes.

**Introduction:** The success of colonoscopy is dependent on efficient bowel cleansing. Inadequate bowel cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and potentially delay appropriate treatment. The increasing frequency of the incidence of colorectal cancer arising in the ascending colon necessitates effective cleansing of this area; additionally these cancers are often associated with poorer prognoses. Data suggest that detection in the ascending colon is more dependent on higher grades of cleansing, perhaps due to the nature of polyps present, which may be more likely to be sessile or serrated. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. The NOCT study (a multicentre randomised Phase 3 clinical trial investigating bowel cleansing efficacy of NER1006 vs trisulfate solution) reported bowel preparation quality assessed by central readers.

This post hoc analysis shows the cleansing assessment by site colonoscopists, who typically guide clinical decision making; hence this study may be more relevant for clinical practice than previous studies.

**Aims & Methods:** In the NOCT study 621 patients (males and females, aged 18–85) were randomly assigned in a 1:1 ratio to receive either NER1006 or trisulfate solution, each administered as an overnight split-dose. Data from the 523 patients who underwent a colonoscopy and had a site colonoscopist assessment were used in this analysis. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the Harefield Cleansing Scale;3 following segmental scoring, cleansing of the overall colon was graded from A to D; grades A and B were judged as successful cleansing. Cleansing judged as high-quality cleansing was achieved in 12% more patients who received NER1006 than who received trisulfate.

**Results:** As Table 1 shows, the bowel preparation quality of NER1006 when assessed by site colonoscopists did not show a statistically significant difference to trisulfate for the overall colon (93% vs 94%, P = 0.681; 95% CI: -5.1–3.3%) or ascending colon (80 vs 74%, P = 0.079; 95% CI: -0.7–13.6%). There was, however, a numerical advantage in favour of NER1006 on the proportion of patients achieving high-quality cleansing success in the right colon.

**Table 1:** Successful colon cleansing rates when treated with NER1006 or trisulfate solution.

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon) or 3 or 4 (ascending colon, high quality)

**Conclusion:** For both preparations, site colonoscopy findings demonstrated similar very high rates of cleansing success for the overall colon (>93%) and high rates of high-quality cleansing of the ascending colon (>73%). However, statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists are notably higher than those previously reported by central readers.

**Introduction:** The efficacy of colonoscopy is dependent on the quality of bowel cleansing. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel cleansing solution and is a patented combination optimised for effective bowel cleansing. The DAYB study was a European multicentre, randomised trial that tested the hypothesis that NER1006 would be non-inferior to sodium picosulfate and magnesium citrate (NaPic + MgCit) in terms of overall bowel cleansing and high-quality cleansing of the ascending colon plus caecum [1]. Bowel cleansing was assessed using the Harefield Cleansing Scale (HCS) [2]. The primary endpoints of the study were assessed by video review by a central reader. Bowel cleansing on the HCS was also assessed by the site colonoscopist and this post hoc analysis assessed the cleansing grades as determined by the site colonoscopists.

**Aims & Methods:** In the DAYB study, 515 patients (aged 18–85, median age: 55.0 years) underwent screening, surveillance, or diagnostic colonoscopy and were randomly assigned in a 1:1 ratio to receive either NER1006 or NaPic + MgCit, each on the day before colonoscopy. In this analysis, data from 479 patients who underwent a colonoscopy and had a completed assessment by the site colonoscopist were included. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the HCS; cleansing of each segment of the colon was scored from 0 to 4. Scores 3 and 4 of the ascending colon were judged as high-quality cleansing. Cleansing of the overall colon was graded from A to D; grades A (all segments scored 3 or 4) and B (≥1 segments scored 2, no sections scored 1 or 0) were judged as successful cleansing.

**Results:** As indicated in Table 1, in the overall colon, successful cleansing was achieved in 12% more patients who received NER1006 than who received NaPic + MgCit (P = 0.003, 95% CI: 4.0–20.7%). In the ascending colon, high-quality cleansing was achieved in 20% more patients who received...

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon) or score of 3 or 4 (ascending colon, high quality)

**Conclusion:** NER1006 was shown to provide significantly better cleansing of the overall colon and high-quality cleansing of the ascending colon compared to NaPic + MgCit, when both treatments were administered the day before colonoscopy. The cleansing efficacy rate of the comparator was within its previously reported cleansing rates for day before administration, suggesting the improvement seen with NER1006 is of clinical relevance.

**Introduction:** Several studies in recent decades have revealed new roles for vitamin D. For example, vitamin D plays a role in regulating skeletal muscle, as well as in cardiovascular and renal physiology, producing antitumor effects, suppressing fibrosis, and as a regulator of the immune system. In light of these new roles, vitamin D is considered to be related to disease activity and intestinal fibrosis, including that seen in Crohn’s disease (CD). Several reports have demonstrated a relationship between vitamin D deficiency and CD activity according to clinical parameters such as Crohn’s disease activity index (CDAI) and quality of life (QoL). However, no reports have demonstrated this relationship by using endoscopic parameters such as endoscopic activity, mucosal inflammation, and intestinal fibrosis.

**Aims & Methods:** The aim of this study was to clarify the relationship between vitamin D deficiency and CD activity by using endoscopic parameters, as well as clinical parameters. Of the CD patients visiting NagaWoman University Hospital from May 2011 to February 2016, 82 patients were enrolled in this study. Serum 25-hydroxyvitamin D (25(OH)D) levels, disease activity, and clinical factors of the subjects were investigated prospectively. Endoscopic findings of 52 of the 82 total patients enrolled were investigated retrospectively from endoscopic records. This study design was approved by the ethics committee of Nagoya University Hospital. Clinical remission was defined as CDAI ≤150. Mucosal healing was defined as a simple endoscopic score for Crohn’s disease (SES-CD) ≤1. Moreover, to evaluate endoscopic activity from two aspects (mucosal inflammation and fibrotic stenosis), we divided SES-CD score into endoscopic “mucosal inflammation score” and “fibrotic stenosis score.”

**Results:** Mean age of the subjects was 41.11, and the male/female proportion was 64/18. The mean serum 25(OH)D level of subjects was 17.1 ng/mL, and 61 cases (74.4%) were classified as severe deficiency or deficiency. Mean serum 25(OH)D levels of the clinical remission and clinically active groups were 18.7 ± 8.1 ng/mL and 12.4 ± 3.6 ng/mL, respectively (P < 0.001). In a multivariate analysis, low levels of serum 25(OH)D and serum albumin and positive C-reactive protein (CRP) results were correlated with clinical activity. Mean serum 25(OH)D levels of the mucosal healing and no mucosal healing were 24.0 ± 9.8 ng/mL and 15.1 ± 6.6 ng/mL, respectively (P < 0.001). Mean serum 25(OH)D levels for the no mucosal inflammation and mucosal inflammation groups were 21.6 ± 9.6 ng/mL and 14.3 ± 5.5 ng/mL, respectively (P < 0.001); and mean serum 25(OH)D levels of the no fibrosis and fibrosis groups were 20.2 ± 8.9 ng/mL and 14.2 ± 6.7 ng/mL, respectively (P < 0.001; Mann-Whitney U test). In a multivariate analysis, low serum 25(OH)D levels were related with mucosal inflammation and intestinal fibrotic stenosis of CD (P < 0.05; logistic regression analysis).

**Conclusion:** This study demonstrated the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrostenosis formed during healing of inflammation. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

is escalated. Source data verification is performed by external monitors. Primary aim of the study is to confirm the previously identified score and to test its power to predict a mild disease course as indicated by the need of not more than mesalamine therapy. Additional analyses include the percentage of patients with a score indicating a severe disease and their characteristics at diagnosis. This preliminary analysis presents preliminary data.

Results: Currently, 78 patients (33 male, 45 female; age 16-72, mean 35 years) with newly diagnosed CD are enrolled. 56 CD-patients with follow up ≥2 weeks (mean 8.5 months), mean age 35 years, 35 female, 21 male, CRP 12.2 mg/l were included into the interim analysis. In 28 patients a score from 0-2 step-up treatment occurred in 7%, whereas in 28 patients with a score >2, step-up rate was 43% (p = 0.0043). Differences between patients with a score 0-2 and >2 were (41 vs. 28 years, p = 0.0011), CRP <2 mg/l (17/28 patients vs. 0/26, p < 0.0001), endoscopic score 1.4 vs. 2.7, p 0.03. Sex distribution (28% vs. 4/28, stenos 1/28 vs. 6/28. There were no differences in terms of sex, fistula, extraintestinal manifestations and liver.

Conclusion: In this early analysis of a prospective study planned with a 5-year follow-up, a significant proportion of patients with mild CD and simple mesalamine therapy can be identified. These initial results encourage to continue and expand this prospective long-term study on the predictability of a mild CD course.

Introduction: Crohn’s Disease (CD) spans a wide severity range, from mild to severe disease, with variation under- as well as overtreatment problems is challenging. While factors determining bad prognosis are studied in detail, factors predicting a mild course with the chance of simple treatments are less known. Here we show first results of a prospective evaluation of a retrospectively created score (JCC 2013;7:263) for prediction of mild CD which consists of age at diagnosis, CRP, an endoscopy score, presence of perianal lesions and complications.

Aims & Methods: This is a prospective, ongoing study performed in 12 IBD-specialized private gastroenterology practices (outpatients only) in Germany. All consecutive CD patients (diagnosis ≥6 weeks) are included. At screening ileocolonoscopy with histology, investigation of the perianal area, laboratory tests including CRP are performed and CD complications (stenosis, fistula, extraintestinal manifestations or fever >38°C) evaluated to complete of the above quoted score. Patients are treated at the discretion of the physician. In case of a score indicating a good prognosis (≤2) or of mild clinical appearance mesalamine is started. In all other cases patients are treated according to guidelines. 5 year follow up is planned for all patients. If initial therapy fails, treatment

Reference

Prevalence of LTi in retrospective testing was of 54/246 (22.0%). Prospective testing was of 26/76 (34.2%) by linear regression. Of the follow-up, 30/191 (15.7%) patients who were negative for screening before 2015 were converted in positive for LTi (95% CI [10.2–21.1]).

Conclusion: The prevalence of LTi in our area is high (32.6%). The simultaneous presence of a positive TST booster and QFT QP increases the detection of LTi. The TST booster increases the detection of LTi even when is performed in patients without immunosuppressive treatments, in whom is not routinely recommended. The QFT is more useful in patients without immunosuppressive therapy. The repeated screening every two years is useful in this population with high prevalence of LTi, since it may detect LTi in patients with previous negative tests (15.7%). The TST booster is essential due to the possible false negatives of QFT when screening patients on anti-TNF therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Magnetic resonance enterography (MRE) and capsule endoscopy (CE) are prime modalities for evaluation of small bowel in patients with Crohn’s disease (CD). However, detection of proximal (jejunum and proximal ileum) small bowel inflammation by MRE is challenging. Current quantitative scores such as Magnetic Resonance Index of Activity (MaRIA) do not incorporate proximal small bowel data and were validated against ileocolonoscopy. Magnetic resonance enterography global score (MEGS) was designed for quantitative evaluation of the entire digestive tract; however, it was only validated against ileocolonoscopy and its accuracy in the proximal small bowel was not assessed. CE allows for accurate assessment of the entire small bowel and is the modality of choice for evaluation of the proximal small bowel.

Aims & Methods: We aimed to compare the quantitative evaluation of the small bowel inflammation by MEGS score and the Lewis capsule endoscopy score. Patients with known quiescent small bowel CD (for duodenum vs LS 1st tertile and proximal ileum vs 2nd tertile LS - both severe inflammation). Proximal small bowel was defined as jejunum and duodenum on MRE and as 1st and 2nd tertiles LS on CE. Distal small bowel was defined as terminal ileum on MRE and 3rd tertile LS on CE. Fecal calprotectin (FCP) levels were measured and correlated with all scores.

Results: Fifty-two patients were included in the study. There was a strong correlation between LS and CECDAI (Pearson’s r = 0.67, p < 0.001). CECDAI < 7.2 corresponded to mucosal healing (LS < 135), while CECDAI > 11.1 corresponded to moderate to severe inflammation (LS ≥ 790) by linear regression. There was a moderate correlation between both scores and FCP levels that was somewhat stronger for CECDAI (r = 0.39, p = 0.002 vs r = 0.53, p = 0.001 for both). There was a weak correlation between LS and CRP levels (r = 0.27, p = 0.04) and none for CECDAI and CRP (r = 0.04 vs p = 0.1).

Conclusion: In our prospective study, CECDAI and LS strongly correlated and performed similarly for quantitative assessment of mucosal inflammation in established CD.

Disclosure of Interest: U. kopylov: The study was supported by a generous grant by the Helmsley Charitable fund

Introduction: Small-bowel capsule endoscopy (CE) is a prime modality for evaluation of the small bowel. The Lewis score (LS) and the Capsule Endoscopy Crohn’s Disease Activity Index (CECDAI) are validated endoscopic indices for quantification of small bowel inflammation on CE. It is unclear whether these indices are interchangeable for evaluation of mucosal inflammation in established Crohn’s disease (CD).

Aims & Methods: We aimed to prospectively compare the quantitative evaluation of small bowel inflammation by both scores. Patients with known quiescent small bowel CD (for at least 3 months (CDAI < 150) were prospectively recruited and underwent CE. LS was calculated using the capsule reading software (RAPID b) and CECDAI was calculated manually, by 2 independent experienced gastroenterologists (one for each score) unaware of each other’s results. Mucosal healing was defined as LS < 135; LS ≥ 790 signified moderate to severe inflammation. Fecal calprotectin (FCP) and C-reactive protein (CRP) levels were measured and correlated with the scores.

Results: Fifty patients were included in the study. There was a strong correlation between LS and CECDAI (Pearson’s r = 0.67, p < 0.001). CECDAI < 7.2 corresponded to mucosal healing (LS < 135), while CECDAI > 11.1 corresponded to moderate to severe inflammation (LS ≥ 790) by linear regression. There was a moderate correlation between both scores and FCP levels that was somewhat stronger for CECDAI (r = 0.39, p = 0.002 vs r = 0.53, p = 0.001 for both). There was a weak correlation between LS and CRP levels (r = 0.27, p = 0.04) and none for CECDAI and CRP (r = 0.04 vs p = 0.1).

Conclusion: While concordance was 85% between LS and CECDAI (Pearson’s r = 0.67, p < 0.001), CECDAI < 7.2 corresponded to mucosal healing (LS < 135), while CECDAI > 11.1 corresponded to moderate to severe inflammation (LS ≥ 790) by linear regression. There was a moderate correlation between both scores and FCP levels that was somewhat stronger for CECDAI (r = 0.39, p = 0.002 vs r = 0.53, p = 0.001 for both). There was a weak correlation between LS and CRP levels (r = 0.27, p = 0.04) and none for CECDAI and CRP (r = 0.04 vs p = 0.1).

P0353 CONCORDANCE BETWEEN TUBERCULIN SKIN TEST AND INTERFERON GAMMA RELEASE ASSAY FOR LATENT TUBERCULOSIS SCREENING IN INFLAMMATORY BOWEL DISEASE (META-ANALYSIS)

S. Alrajhi1, P. Germain2, W. Afif2, M. Martel2
1Internal Medicine, McGill University, Montreal/Canada/QC
2McGill University, Montreal/Canada/QC

Contact E-mail Address: ssaalrajhi@mail.mcgill.ca

Introduction: Screening for latent tuberculosis infection (LTI) is mandatory prior to initiating anti-tumor necrosis factor (anti-TNF) medications. New guidelines recommend interferon-gamma release assays as first line screening method for the general population. Studies have provided conflicting evidence on the performance of interferon-gamma release assays (IGRAs), compared to tuberculin skin test (TST) in inflammatory bowel disease (IBD) patients. We assessed the concordance of these two tests in IBD patients and the effect of immunosuppression on their performance.

Aims & Methods: We performed a systematic search of MEDLINE, EMBASE and Cochrane Library databases, from 2011 to 2016, for relevant studies testing both TST and IGRAs in IBD patients. The primary outcome was concordance between TST and IGRAs. Secondary outcomes were effects of immunosuppressive therapy on both TST and IGRAs, Secondary outcomes were effects of immunosuppressive therapy on both TST and IGRAs, and differences in concordance comparing TST and IFNA.

Results: Sixteen studies, including 2488 patients with IBD, were included for the analysis. The pooled concordance between the TST and IGRAs was 85% (95% confidence interval [CI] 81%-88%, p = 0.01). Effects of immunosuppression on both tests were reported in eight studies including 814 patients with IBD. The odds ratio of testing positive by IGRAs decreased from 4.1 to 0.57 if immunosuppressed (95% confidence interval [CI] 0.31–1.03, p = 0.06). The odds ratio of testing positive by TST if immunosuppressed was 1.14 (95% confidence interval [CI] 0.81–1.57, p = 0.38). There was no significant difference in concordance between patients treated with traditional vs. biological agents.

Conclusion: Concordance between TST and IGRAs is high (85%) in IBD patients. There was no significant difference in concordance comparing TST and IGRAs, and differences in concordance comparing TST and IFNA.

ASSESSING SECONDARY LOSS OF RESPONSE TO MAINTENANCE

P0354 THIOPURINE MAINTENANCE THERAPY FOR IBD: WHICH IS THE BEST METHOD TO MEASURE ADHERENCE TO THERAPY?

A. Ochieng, V. George, C. Selinger
Gastroenterology, St James Hospital, Leeds/United Kingdom

Contact E-mail Address: odouru.ochieng@nhs.net

Introduction: For the majority of patients with IBD long-term therapy is required to maintain remission, yet 30–45% of patients do not adhere to their IBD medication. Medication adherence can be assessed with prescription refill rates, biologic measures (metabolites), trough levels and patient self-report. There is currently no accepted gold standard and the feasibility and utility of different adherence assessment tools in the routine outpatient clinic setting have not been fully examined. The aim of this service improvement project was to test the acceptability of self-report tools assessing thiopurine adherence in the IBD clinic and to correlate the results with thioguanine-nucleotide (TGN) levels.

Aims & Methods: Consecutive outpatients on thiopurine maintenance therapy for IBD for >3 months were recruited from clinic. Patients self-reported adherence using a seven-day adherence scale (VAS), the validated Morisky Adherence Report Scale (MOR) and the validated Medication Adherence Report Scale (MARS). TGN levels were classed as complete non-adherence (<100 and MMP low), partial adherence (TGN 100–235 and MMP low) or full adherence (>235 or MMP high). Correlation analysis was performed using Pearson tests.

Results: Of 100 approached patients none refused participation and TGN levels were available for 96. These included 38 women. Diagnoses were Crohn’s disease in 27, ulcerative colitis in 41 and IBD-U in 1 case. Concomitant therapy included 5/ASA (25 cases), anti-TNF (13 cases) and Vedolizumab (2 cases). The proportion of adherent patients was according to the relevant report tool 71% (TGN), 87% (VAS), 87% (Morisky) and 77% (MARS). VAS (Pearson 0.315; p = 0.005) and Morisky (Pearson –0.363; p = 0.001) correlated moderately with TGN, but MARS (Pearson 0.09; p = 0.39) did not. The patients, who were non-adherent by TGN were detected by VAS in 3, Morisky in 6 and MARS in 3 cases. However, patients showing non-adherence according to self-report tools had TGN levels in 6 of 10 cases for VAS, 10 of 26 for Morisky and 4 of 15 for MARS.

Conclusion: Self-report tools provided a patient-friendly and inexpensive way of assessing adherence, but the correlation with TGN levels was only moderate. While providing more of a objective assessment TGN levels are problematic for assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for assessing adherence, but the correlation with TGN levels was only moderate.

Introduction: Anti-TNFa therapies have improved outcomes in patients with inflammatory bowel disease. Their use has been associated with improved clinical efficacy, remission and reduced complications and resistant mutations. However secondary loss of response (REL) to both infliximab (IFX) and adalimumab (ADA) is a significant problem, leading to further flares of disease, disease progression and poorer outcomes. Therapeutic drug monitoring (TDM), which involves measurement of anti-TNFa trough and peak levels, offers the opportunity of examining an immune basis behind REL, and potentially adjusting doses or switching therapies to help regain clinical response.

Aims & Methods: The aim of this study was to evaluate whether TDM can help predict secondary REL to infliximab and adalimumab and whether dose adjustments based on this information can help patients regain clinical response. This is a prospective, single-centre study, performed from June 2015 to April 2016, at our institution. Patients with Ulcerative colitis (UC) and Crohn’s disease (CD) were enrolled, if they were clinically (based on Harvey-Bradshaw (HBI) or partial Mayo scores) felt to be experiencing a secondary LOR to either infliximab or adalimumab maintenance therapy. Patients were followed for a one-year period, from their initial assessment for secondary LOR to assess outcomes.

Results: 46 patients were recruited, 40 CD with Harvey-Bradshaw Index (HBI) >4 points and 6 patients with UC with Partial Mayo Score (PMS) >2 points. Mean age for the cohort was 40.8 years (26 (65.5%) were female). 20/46 (43.5%) were on anti-TNFa therapy, 13/46 (28.3%) were on biologicals (adalimumab) alone and 7 (15.2%) were on biologicals (infliximab). The mean duration of disease was 9.8 years, 3 (8.3%) were smokers, 7 (15.2%) on immunomodulators, and 11 (23.9%) had prior anti-TNFa exposure. 17 (46.8%) were on an adalimumab maintenance dose of 40mg every other week. Overall HBI for the whole study group was 1.9, partial Mayo Score 6.3. Patients were followed for a one-year period, from their initial assessment for secondary LOR to assess outcomes. Secondary LOR was defined as a score increase of 3 or more points on the HBI or PMS. Results from MARS.

Conclusion: TDM offers the opportunity to identify patients who may benefit from dose adjustment or switch in therapy in a clinically guided fashion.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0357 DIAGNOSTIC DELAY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE - A STUDY OF THE AUSTRIAN IBD STUDY GROUP (ATISG)  

Aims & Methods:  
A diagnostic delay of 10 years (IQR 4–18 years) were analysed. The median diagnostic delay was 0.53 years (IQR 0.20–1.92 years) in CD and 0.28 years (IQR 0.61–0.95 years) in UC patients, respectively (p = 0.11–0.86 years) in UC, respectively (p = 0.001–0.0001) was found. Diagnostic delay did not differ significantly between patients with UC (3 months) and was associated with older age at diagnosis.  

Introduction:  
In an attempt to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors for delayed diagnosis we sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors for delayed diagnosis.  

Methods:  
Overall, 102 patients were enrolled in the study (Table 1).  

Results:  
A multivariable proportional hazards regression model was estimated using interval censored latency times as a dependent variable.  

Conclusions:  
In a multicentre cohort study adult patients with IBD (CD, UC) were included between September 2015 and September 2016. Clinical and endoscopic data were collected on the day of colonoscopy. Blood samples, stool samples and saliva samples (before bowel cleansing, saliva and ileal biopsies from healthy and naive patients) were also collected. CEACAM6 from ileal biopsies and saliva were measured (duplicates) using ELISA assays. AIEC attending 18 Austrian outpatient clinics were recruited between May 2014 and July 2015 to complete a multi-item questionnaire, which recorded medical and socioeconomic characteristics. Study outcome was the diagnostic delay defined as the time period from first symptom onset to diagnosis of IBD. A multivariable proportional hazards regression model based on interval censored latency times was calculated.  

Results:  
1217 patients (CD 779, UC 400, IBD 21, missing 17; females 615) with a median age of 40 years (interquartile range (IQR) 31–52 years) and a median disease duration of 10 years (IQR 4–18 years) were analysed. The median diagnostic delay was 0.53 years (IQR 0.20–1.92 years) in CD and 0.28 years (IQR 0.11–0.86 years) in UC, respectively (p < 0.001). In the multivariable regression analysis patients with CD had a significantly longer diagnostic delay than patients with UC (HR 1.56; 95% CI 1.34–1.82; p < 0.0001) and a quadratic effect of age leading to higher risk of delayed diagnosis in older patients (p < 0.001) was found.  

Conclusion:  
The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.  

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction:  
Diagnostic delay seems to be common in inflammatory bowel disease (IBD), especially in Crohn’s disease (CD). We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors for delayed diagnosis as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.  

Aims & Methods:  
In a prospective multicentre study adult patients with IBD (CD, ulcerative colitis UC, inflammatory bowel disease uneclassified IBUD) attending 18 Austrian outpatient clinics were recruited between May 2014 and July 2015 to complete a multi-item questionnaire, which recorded medical and socioeconomic characteristics. Study outcome was the diagnostic delay defined as the time period from first symptom onset to diagnosis of IBD. A multivariable proportional hazards regression model based on interval censored latency times was calculated.  

Results:  
1217 patients (CD 779, UC 400, IBD 21, missing 17; females 615) with a median age of 40 years (interquartile range (IQR) 31–52 years) and a median disease duration of 10 years (IQR 4–18 years) were analysed. The median diagnostic delay was 0.53 years (IQR 0.20–1.92 years) in CD and 0.28 years (IQR 0.11–0.86 years) in UC, respectively (p < 0.001). In the multivariable regression analysis patients with CD had a significantly longer diagnostic delay than patients with UC (HR 1.56; 95% CI 1.34–1.82; p < 0.0001) and a quadratic effect of age leading to higher risk of delayed diagnosis in older patients (p < 0.001) was found.  

Conclusion:  
The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.

Introduction:  
Enterobacteria, especially adherent and invasive E. coli (AIEC), are suspected to play a key role in Crohn’s disease (CD). These bacteria are able to highly adhere to the ileal mucosa of CD patients through the CEACAM6 receptor (Carcinoembryonic antigen-related cell adhesion molecule 6). It has been shown that therapies targeting enterobacteria and/or AIEC could be more effective in mice overexpressing CEACAM6. In this line, the overexpression of CEACAM6 in the ileum as well as the presence of AIEC in the ileum could be potential biomarkers to select the patients who could benefit from drugs targeting the host-pathogen interaction. Unfortunately, the identification of these biomarkers is time-consuming and invasive highlighting the need for more convenient alternative.  

Aims & Methods:  
We aimed to assess the correlation between the level of CEACAM6 in the saliva and the level of CEACAM6 in the ileum in CD patients and to define the best threshold of CEACAM6 in the saliva to detect overexpression of ileal CEACAM6. In addition, we attempted to identify non-invasive biomarkers of AIEC infection. In this prospective multicentre study (8 centers), all the patients requiring ileoscopy, regardless the indication, were consecutively included between September 2015 and September 2016. Clinical and endoscopic data were collected on the day of colonoscopy. Blood samples, stool samples (before bowel cleansing), saliva and ileal biopsies from healthy and patients with complicated CD were also collected. CEACAM6 from ileal biopsies and saliva were measured (duplicates) using ELISA assays. AIEC attending 18 Austrian outpatient clinics were recruited between May 2014 and July 2015 to complete a multi-item questionnaire, which recorded medical and socioeconomic characteristics. Study outcome was the diagnostic delay defined as the time period from first symptom onset to diagnosis of IBD. A multivariable proportional hazards regression model based on interval censored latency times was calculated.  

Results:  
Overall, 102 patients were enrolled in the study (Table 1).

Table 1: Baseline characteristics of the 102 CD patients included in the study.
Ileal CEACAM6 level did not depend on disease severity or the site of biopsies as the median level of ileal CEACAM6 was 8546 pg/ml (578.9–1646) and there was no difference in healthy or ulcerated tissue (756 pg/ml [487–1617] vs 947 pg/ml [604–1820], p = 0.86). The median level of CEACAM6 from salva was 3837 pg/ml [1889, 7338]. There was a positive correlation between the levels of CEACAM6 in saliva and CEACAM6 in the ileum (r = 0.47; p = 0.001) in both macroryscopically healthy areas (r = 0.53, p < 0.001) and ulcerated zone (r = 0.39, p = 0.002). Using a ROC curve, we determined the best threshold of CEACAM6 in saliva for detecting ileal CEACAM6 expression. Using a ROC curve (area under the curve (AUROC) = 0.73), the cut-off value of 3800 pg/ml demonstrated the best performances to detect ileal CEACAM6 overexpression with substantial specificity (76.0% [54.9–90.6]) and positive predictive value (67.5% [74.9–85.3]). The number of enterobacteria was increased in CD patients with prior intestinal resection (562 [20164] vs. 116 [0752] pg/ml, p = 0.03). Interestingly, the number of enterobacteria was also increased in AIEC-positive patients (640 [201729] vs. 610 [0298] pg/ml, p = 0.004). Using a ROC curve, we determined the best threshold of enterobacteria in the ileum to detect the presence of ileal AIEC bacteria. We found an area under the curve (AUROC) of 0.70 [0.61; 0.77]. The cut-off value of 60 cfu/biopsy demonstrated the best performances to detect the presence of ileal AIEC bacteria. The number of enterobacteria associated to ileal mucosa (cut-off value > 60 cfu/biopsy) strongly predicted the presence of AIEC and then is a reliable test for AIEC screening with very high negative predictive value (94.1% [80.3–99.3]) and high sensitivity (91.7% [73.0–99.0]).

Conclusion: CEACAM6 measurement in the saliva is feasible, non time-consuming and non-invasive. It could be a reliable test to detect the overexpression of CEACAM6 in the ileum from CD patients and could then be proposed as a non-invasive biomarker to select patients who might benefit from anti-adhesive therapies. In addition, we identify that the number of enterobacteria associated to the ileum is a convenient test to screen CD patients for AIEC bacteria.

Gastroenterology and Hepatology, Nagoya University Graduate School of Medicine, Nagoya, City, Aichi, Pref.Japan

Introduction: Crohn’s disease (CD) has a progressive course and often causes mucosal injury throughout the gastrointestinal tract. Mucosal healing (MH) has been proposed as a treatment goal for patients with CD. Endoscopy, computed tomography, magnetic resonance imaging, and other examinations are used to evaluate MH. However, repeated examinations require considerable effort and are highly invasive. Recently, fecal calprotectin (FC) has attracted attention as a new biomarker. The correlation between FC levels and CD activity is well established in ileocolonic or colonic CD, but few reports have described this correlation in ileal CD alone.

Aims & Methods: This study evaluated the correlation between FC levels and endoscopic activity in ileal CD. Fifteen patients with ileal CD who underwent double-balloon endoscopy (DBE) between May 2016 and February 2017 at our hospital were included in this study. The entire small intestine was examined with DBE and radiological enteroclysis. We evaluated the correlations of FC levels, C-reactive protein (CRP) levels, erythrocyte sedimentation rates (ESR), and CD activity index (CDAI) scores with the endoscopic activity. To evaluate the endoscopic activity of the small intestine, we used Double-Balloon Endoscopic Score for CD (DES-CD), which is a modified version of the Simple Endoscopic Score for CD (pDES-CD). To determine the DES-CD, the small intestine was divided into four segments (upper jejunum, lower jejunum, upper ileum, and lower ileum), and four variables were evaluated in each segment (allear size, extent of ulcerated surface, extent of affected surface, and stenosis) in accordance with the SES-CD. For the evaluation of mucosal injury, the partial DES-CD (pDES-CD) was calculated by excluding “stenosis” from the DES-CD. The DES-CD and pDES-CD ranges were 0–46 and 0–24, respectively.

Results: Fifteen patients (11 males and four females) with a median age of 42 (range, 27–71) were examined. No colitic lesions were observed in any of the patients. The DES-CD correlated with FC (r = 0.688, P = 0.005) and CRP (r = 0.765, P = 0.001) levels. In addition, the pDES-CD correlated with FC levels (r = 0.803, P = 0.001), CRP levels (r = 0.673, P = 0.006), and ESRs (r = 0.704, P = 0.003). The CDAI scores did not correlate with either of the endoscopic scores

Conclusion: In this study, the endoscopic activity in ileal CD correlated with FC both in DES-CD and in pDES-CD. In addition, the partial DES-CD (pDES-CD) exhibited a stronger correlation with FC levels than did DES-CD scores. This might be because FC levels reflect mucosal injury and not stenosis. Our findings suggest that FC can be used for monitoring mucosal injuries in the small intestine and as a biomarker for evaluating MH.

Introduction: Increasingly, immunosuppressive medications such as azathioprine and mercaptopurine are used in order to prevent the induction or recurrence of inflammatory bowel disease (IBD) patients. It has been reported that such treatments increase the risk of developing all types of skin cancer. Education of these patients is key in order to promote their awareness of their increased risk and it is vital for gastroenterologists to counsel patients on sun protection strategies on initiating therapy. We recently performed a pilot study in this group which highlighted gaps in their knowledge of the increased risk and prevention strategies. We speculate clinician’s lack of knowledge was partly to blame.

Aims & Methods: Our aim was to determine Irish IBD clinicians’ knowledge of the skin cancer risk and advised photoprotective behaviours in this cohort. Cross-sectional descriptive study. We invited IBD clinicians via email to fill in an anonymous online survey designed to assess knowledge of skin cancer risk and preventative measures. We speculated clinician’s lack of knowledge was partly to blame. We recently performed a pilot study in this group which highlighted gaps in their knowledge of the increased risk and prevention strategies. We speculate clinician’s lack of knowledge was partly to blame.

Results: To date, 45 Irish Gastroenterology clinicians completed the online questionnaire. Of these, fifteen (33%) were consultants, fourteen (31%) gastroenterology trainees, four (9%) general medical trainees and twelve (27%) IBD nurse specialists. Overall, clinician’s knowledge of general factors associated with increased risk of skin cancer was reassuring; with all 45 (100%) knowing sun beds increased skin cancer risk and almost 100% (44, 98%) knew working outside doors incurred increased risk. 42 (93%) knew a personal history of skin cancer and previous blistering sunburn were risks; however, only 34 (79.1%) recognised family history as a risk. Regarding gender associated risk; only 67.4% (n = 29) knew men were greater risk than women of non-melanoma skin cancer (NMSC). Their knowledge of specific immunosuppressors risk was suboptimal; while many (37, 82%) recognized azathioprine was a risk factor for developing NMSC, only 7 (11%) knew anti-TNFα agents were strongly associated with an increased risk of malignant melanoma. Regards prevention strategies; the majority knew what changes to look for in a suspicious mole; 100% (n = 45) knew to be suspicious of changing color and 84% (n = 38) of an irregular border, but shockingly only five (11%) perform yearly skin checks on their patients on immunosuppressants. Their knowledge of preventative measures was also lacking; 37% (86%) knew patients should wear SpF 50 but almost half (47% n = 21) thought it should be applied twice daily rather than two hourly (51% n = 23) and only 47% (n = 20) knew patients should stay in the shade from 11am-3pm. Regards their own practice; 39 (87%) report they do emphasise the importance of sun protection in clinic (p < 0.0003), and of physicians, trainees had a more complete knowledge of all advised preventative measures (p < 0.03).

Conclusion: Our study highlights IBD clinicians’ suboptimal knowledge of immunosuppressors risk and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may improve this deficiency.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: Association of serum S100A4 protein with UC and CD was confirmed. In CD, disease behaviour did not have impact on serum concentration of S100A4 protein. In CD, higher levels of serum S100A4 were observed in patients with ileo-colonic and colonic involvement compared to those with isolated small bowel involvement.

Acknowledgments: This study was supported by the Research Project PROGRESS Q40–15 from Charles University.

P0364 SEVERE VITAMIN D DEFICIT IN ACTIVE INFLAMMATORY BOWEL DISEASE
G. Burrelli Scotti1, M.T. Afferri1, A. De Carolis1, V. Vaiarello1, V. Fassino2, S. Minisola1, P. Vernia1

Contact E-mail Address: piero.vernia@uniroma1.it

Introduction: Hypovitaminosis D is common in Inflammatory Bowel Disease (IBD) patients. Some studies suggest that the finding may relate to severity of the disease.1,2

Aims & Methods: The aim of the study was to determine the VID status in an Italian IBD cohort in relation to disease activity. Serum VID levels were measured in 260 IBD outpatients, not supplemented with VID (110 Crohn’s Disease (CD) and 150 Ulcerative Colitis (UC); 145 males and 115 females, with median age 50.7 ± 15 years), and to compare VID levels of those to 205 healthy blood donors, matched by sex, age (+/– 2 years) and month in which the blood sample was collected. VID levels were correlated to C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Harvey Bradshaw Index (HBI) and Crohn’s Disease Activity Index (CDAI) for CD and Mayo partial score for UC. Chi square, T test and linear correlation were used when appropriate.

Results: IBD patients were at higher risk of VID deficiency (defined as <20 ng/ml) than controls (OR 4.5, 95%CI 2.9–6.9, p < 0.0001). Of 260 IBD patients, 156 (60%) had VID deficiency, more often in CD than in UC (72.7% vs 48% respectively, p < 0.0001). Age <40 and ≥60 years, winter/spring season, CRP >2.5 mg/dL, ESR >20 mm/h, previous intestinal surgery and HBI ≥5 were significant risk factors for VID deficiency. No differences were observed in relation to sex, smoking status, BMI, age at diagnosis, localization and behavior of disease, and need of steroids. There was a weak negative correlation between CRP values, HBI scores and VID levels (R = –0.13, p = 0.037 and R = –0.26, p = 0.006 respectively).

Conclusion: VID deficiency is significantly more common in IBD patients than in controls, more so in CD. Patients with active disease are more likely to have VID deficiency than those in remission. The correlation with activity indexes should be confirmed in larger series.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Extended small bowel (SB) Crohn’s disease (CD) strictures can comprise of both inflammatory and fibrotic elements. An accurate tool to discriminate fibrotic from inflammatory disease. Lesions with a dense fibrotic matrix exhibit means to assess activity, to date, no specific tool has been developed to identify both inflammatory and fibrotic elements. An accurate tool to discriminate fibro-inflammatory and strictures respectively. Neither parameter could differentiate between inflammatory and structuring disease. 26 MREs performed with ileal CD have been further assessed; median age =41yrs, male = 10(38%).

Conclusion: Unlike biochemical markers, MRE may be a useful means to differentiate between inflammatory and structuring disease. Further study is required to assess the long-term predictive value. MRE may be a useful adjunct to current MRE and help detect fibrosis in small bowel lesions and warrants further investigation.

P0366 GASTRODUODENAL INVOLVEMENT IN PATIENTS WITH CROHN’S DISEASE – UPPER ENDOSCOPY ONLY IN SYMPTOMATIC PATIENTS?
Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafalda_en_p_sousa@hotmail.com

Introduction: The need for upper endoscopy in patients with Crohn’s disease (CD) with symptoms is controversial. The aim of this study was to establish any correlations with the prevalence of gastroduodenal involvement, regardless of symptoms, and its prognostic implications.

Aims & Methods: Patients from a single centre with established CD (n = 347) were retrospectively evaluated – inclusion criteria: upper endoscopy without treatment. Gastroduodenal involvement was defined by considering macroscopic (erosions, ulcers or stenosis) and microscopic criteria (focal gastritis, cryptic irregularity, erosion/ulceration and granuloma in the absence of Helicobacter pylori (HP) infection).

Results: We included 140 patients - phenotype: 50% inflammatory, 31% strictureing and 19% penetrating; Location: 42% ileal, 45% ileocolic and 13% colic. Upper endoscopy was performed in 19% for symptoms and in 81% for staging. Gastric macroscopic findings were detected in 49% (69/140); the most common were erosions (21%) and erythematous mucosa (18%). Biopsies were performed in 56% of patients: chronic gastritis 66%, normal 23%, granuloma 5%, focal gastritis 2% and cryptic microabcesses in 2%. HP was positive in 25% of patients. In the stomach, endoscopic assessment of the lesions was observed in 35% of the biopsies. Alimentary tract involvement due to CD that is associated with a worse prognosis.

Conclusion: The prevalence of gastroduodenal involvement by CD in this sample was 18%, and a larger percentage have macro/microscopic findings that are not disease specific. The presence of symptoms does not predict gastroduodenal involvement due to CD that is associated with a worse prognosis.

P0367 INCIDENT Findings at CT Enterography in Patients with Crohn’s Disease: Clinical Significance and Impact on Targeted Therapy
R. Morais1, S. Lopes2, I. Pita3, F. Magro4, G. Macedo2
1Gastroenterology, Centro Hospitalar São João, Porto/Portugal
2Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: ruimorais20@gmail.com

Introduction: CT enterography is one of the most accurate imaging methods for evaluating Crohn’s disease (CD) extent and intestinal involvement. Aims & Methods: The aim of this study was to determine the frequency and clinical impact of the incidental findings in CD patients who underwent CT enterography. This was a retrospective study that evaluated patients with CD who underwent CT enterography between January 2012 and December 2016. Incidental findings were defined as previously unknown extraintestinal lesions. The orientation of the patients after their detection was evaluated.
Results: A total of 520 patients who underwent CT enterography were identified, with 264 (50.7%) being male (CD: 178/35%) and 256 (49.3%) being female (CD: 150/53%). The median age was 43 (32–53) years and 53% were women. The main indication for CT enterography was CD staging (81%). A total of 531 incidental findings were detected (median of 2 [1–3] per patient). The main findings identified were hepatic nodules (n = 39), hepatic cysts (n = 55) and sarcoidosis (n = 46). The findings implicated orientations to another medical specialty in 80 patients (29%), the main ones being Urology (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%); one suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.

Conclusion: Incidental findings are relatively common in patients with CD who undergo CT enterography. A significant proportion is clinically relevant and may involve change CD therapy. A risk stratification may be important to avoid morbidity associated with unnecessary examinations to assess benign situations.

P0368 CLINICAL SIGNIFICANCE OF ASYMPTOMATIC CLOSTRIDIUM DIFFICILE CARRIAGE IN PATIENTS ON IMMUNOMODULATOR FOR INFLAMMATORY BOWEL DISEASE
S.T. Law, W.M. Yip, K.K. Li
Department Of Medicine And Geriatrics, Tuen Man Hospital, Hong Kong/Hong Kong Pre

Contact E-mail Address: still16@hotmail.com

Introduction: Clinical significance of asymptomatic Clostridium difficile (C. difficile) carriage in patients on immunomodulator for inflammatory bowel disease (IBD) is largely unknown. [1, 2]

Aims & Methods: The aim of this study was to investigate the clinical implication of asymptomatic carriage of C. diff in IBD patients. Consecutive IBD patients on immunomodulators in clinical remission for the past six months were prospectively recruited from the IBD clinic since 2013. Those cases were excluded if they had past history of total colectomy, the dosage of their immunomodulators were titrated according to their disease activity in the past six months or the types of their immunomodulators were other than azathioprine, mercaptopurine or methotrexate.

Stool specimen for C. difficile cytotoxin real-time polymerase chain reaction (RT-PCR) assay was obtained to all eligible patients at the time of enrollment and every follow-up during the study period. Patients were monitored for any IBD flare-up in which if happened, an additional stool specimen for C. difficile carriage was performed. The asymptomatic carriage group had a significant higher rate (33.33 vs. 7.45%, p 0.007) and earlier onset (18.78 vs. 34.42 months, log rank p 0.099) in Mann-Whitney U, p 0.037) in evolving into clinical C. difficile infection as compared with the non-carriage group.

No other serious complications, such as toxic megacolon, colonic perforation, sepsis, and death, were reported in the both groups during the study period.

Clinical characteristics of the IBD patients with and without asymptomatic carriage of C. difficile

Data were expressed as median(interquartile range) *: all are UC cases and 3 for maintenance therapy with indications as follows: refractory colitis, spondyloarthropathy, rectovaginal fistula **: case of UC received 3 doses of anti-TNF for severe flare

Abbreviation: IBD, inflammatory bowel disease; C. difficile, Clostridiurn difficile; ulcerative colitis, UC; ns, non-significant

Conclusion: The incidence of asymptomatic carriage of C. difficile in the IBD patients on immunomodulators was not common. It did not associate with the disease flare-up but a significant portion of them could evolve subsequently into clinical infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0369 BOWEL ULTRASOUND IS USEFUL IN DISEASE MONITORING OF ULCERATIVE COLITIS PATIENTS: FIRST ANALYSIS FROM THE TRUST&UC STUDY IN GERMANY
C. Maaser1, F. Petersen2, U. Helwig1, A. Rössler1, D. Lang1, S. Rath3, T. Kucharzik2, O. On Behalf Of The Trust&UC Study Group1

1 Ambulanzaen Gastroenterologie, University Teaching Hospital Lueneburg, Lueneburg/Germany
2 Department Of Internal Medicine And Gastroenterology, University Teaching Hospital Linzene, Linzene/Germany
3Gastroenterology Practice, Oldenburg/Germany

Introduction: Due to the relapsing and highly variable nature of ulcerative colitis (UC), it would be desirable to have reliable tools for measuring parameters of disease activity in order to monitor response to therapy and to detect relapse. In recent years it has already been shown that ultrasound is a useful method to monitor the disease activity.1 The hypothesis of the TRUST&UC (TRansabdominal UltraSonography of the bowel To monitor disease activity in subjects with Ulcerative Colitis) study is that transabdominal US is an easy to use, easily repeatable, and accurate diagnostic tool in the assessment of UC activity, in monitoring the disease course, and response to therapy.

Aims & Methods: TRUST&UC is a German ongoing prospective, observational multi-center study in patients with active UC. The primary objective of this study is the prospective evaluation of bowel wall thickening in order to assess its value in monitoring UC patients in routine medical practice. Clinical parameters (e.g. CRP, fecal calprotectin) and the Simple Colitis Clinical Activity Index (SCCAI) were used for routine assessment of disease activity.

Results: 176 patients with active UC have been enrolled in 37 German IBT study group (GIGS) centres until February 2017. 47.2% of the patients were female, median age was 38.9 years (range 19–77) with median disease duration of 152.2 days (range 8–1057). Of all the patients with a clinical flare defined by SCCAI 90.3% showed a bowel wall thickening (BWT), and only 9.7% showed no US signals. At US examination, a BWT in the colonic sigmoids were present in 87.5% of the patients, in the colon descendens in 83.7%, in the colon transversum in 82.3% and in the colon ascendens in 83.3%. Loss of bowel wall
stratification was the case in 20.6% of the patients, mesenteric fibro-fatty prol- 
imination more than 50%, has an increased signal in the color Doppler US. At baseline systemic steroids were used in 62.1%, azathioprine in 36.2%, and TNF-α antagonists in 40.0% of patients (N = 174).

All follow-up patients (N = 104) displayed acute inflammatory symptoms at baseline, which require at least one medication. The number of patients recruited for an introduction or escalation of treatment. After 12 weeks, the study showed significant improvement of the following parameters: BWT in colon segmideum (87.5% vs 33.7%, p = 0.034) and colon transversum (42.3% vs 15.4%, p = 0.012), loss of haustration (58.8% vs 33.7%, p < 0.001), ulcers (9.7% vs 2.9%, p < 0.001), mesenteric lymphadenopathy (31.6% vs 14.3%, p = 0.005), mesenteric fibro-fatty proliferation (40.0% vs 10.0%, p = 0.041) and increased signal in color Doppler US (56.7% vs 23.1%, p = 0.039). A decrease of BWT was significantly accompanied by a decrease in SCCAI (8.0 to 1.5 points, p < 0.001).

Conclusion: In this real-life cohort almost 90% of the patients showed a BWT, a pivotal IBD symptom and within 12 weeks selected bowel US parameters improved significantly from treatment intensification. Therefore, US examination is a useful tool to monitor disease activity and response to therapy in UC patients.

Introduction: Blocking TNFα is an important treatment option for inflammatory bowel disease (IBD). The etiology of the disorder comprises a permanent activation of immune cascades and imbalanced cytokine networks. Evidence has been put forward that alteration of the human gut microbiota may play a critical role in the pathogenesis of IBD. However, the impact of targeted cytokine blockade on dysbiosis of intestinal microbial communities is poorly understood. Here, we investigate the effect of anti-TNFα treatment on gut microbial community structures in a prospective, longitudinal study for 30 weeks. The study compares IBD as a disorder, which primarily affects the gut, with seropositive and -negative rheumatoid arthritis (RA) and gout, and therefore provides an option for individualized treatment for increasing number of IBD patients.

Results:naive patients suffering from IBD (n = 12) or RA (n = 17), subject to first-time anti-TNFα therapy were recruited for longitudinal stool sampling at baseline and 2, 6 and 30 weeks after therapy induction. Intestinal microbiota communities were studied by 16S rRNA gene (V4) sequencing. Changes in microbiota before and after therapeutic interventions were assessed by terms of alpha and beta diversity, indicator species and prediction of metabolic cooperative interactions. Samples from healthy controls (n = 19) were included as a benchmark of healthy microbial profiles.

Results: Intestinal microbial diversity and cooperativity are decreased in both disease entities, IBD and RA. In IBD, anti-TNFα therapy is able to restore microbial diversity and cooperativity. More over cooperative metabolic interaction is significantly increased only in anti-TNFα responders. In RA, anti-TNFα therapy did not significantly restore microbial community structures.

Conclusion: We show that anti-TNFα treatment increases the gut microbial diversity and coupling of cross feeding metabolic interactions towards the state of healthy individuals. Assessment of metabolic interactions of intestinal microbiota may serve as a marker for clinical response in IBD patients.

P0371 SELF-MONITORING OF THE COLONIC INFLAMMATORY BOWEL DISEASE BY A RAPID HOME BASED FEACAL CALPROTECTIN TEST AND A SYMPTOM QUESTIONNAIRE

A. Puolanne1, M.A. A. Färkkila1, K. Kolho2

1Clinical Of Gastroenterology, Helsinki University Hospital, Helsinki/Finland

2Pediatric Gastroenterology, University of Helsinki Childrens Hospital, Helsinki/Finland

Contact E-mail Address: anna-maija.puolanne@hus.fi

Introduction: Fecal calprotectin (FC) is a most reliable noninvasive means to distinguish remission from active inflammation in inflammatory bowel disease (IBD). Commercially available FC tests are time-consuming, and consequently new rapid tests have been validated. As the incidence of IBD is increasing, self-monitoring and eHealth technologies have been evaluated in managing patients with this life-long disease.

Aims & Methods: The aim of this prospective study was to evaluate the feasibility and cost-effectiveness of a semi-quantitative rapid FC home test and a validated symptom questionnaire, in patients with colonic IBD. The influence of the self-monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with UC unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic according to normal practice. Both groups were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

Results: By the end of February 2017, 134 of the 180 included patients had completed the 12 months’ follow-up. In the study group, 20/91 (22%) patients had performed the stool tests and filled in the symptom scores according to the study protocol for 6 months, and 14/91(15%) patients for 12 months. In the control group, 14/89 (16%) patients had filled in the symptom score at baseline and 0/22 at 12 kk. There was a significant difference of the adherence between patients stratified for IBD-diagnosis, age, sex. The satisfaction of the patients with the program as well as the reasons for the discontinuation of the study and influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic were investigated in both groups and will be evaluated.

Conclusion: The self-monitoring of IBD activity with a rapid FC home test provides an option for individualized treatment for increasing amount of IBD patients. However, in this study the adherence to the self-monitoring program was low. The patients need to be reminded of performing the stool tests and filling in the questionnaires in time. Also, the selection and education of the patients, as well as the easy accessibility of the monitoring program are crucial and need further consideration.

Introduction: Although the incidence of ulcerative colitis (UC)-related colorectal cancer (CAC) is increased in cases with long duration of disease, it should also be recognized that sporadic tumors (ST) develop as older. Various studies have been conducted on CAC, but there are few clinical studies on ST merged with UC. In
P0373 CAN WE PREDICT THE LACK OF RESPONSE TO CYCLOSPORINE AS SECOND LINE THERAPY IN PATIENTS WITH ACUTE SEVERE COLITIS REFRACTORY TO CORTICOSTEROIDS?

Gastroenterology, University Hospital Sahloul, Sousse/Tunisia

Introduction: Acute severe colitis (ASC) is a serious clinical condition that requires intensive intravenous (iv) corticosteroids treatment. Nevertheless, about 30-40% of patients fail to response. Intravenous cyclosporine is an effective rescue therapy in steroid-refractory patients.

Aims & Methods: The aim of our study was to identify the clinical and biological predictive factors of lack of response to cyclosporine as second-line therapy in patients with ASC refractory to iv corticosteroids.

Results: Our study included 52 females and 38 males, with a mean age of 35 years (14–70 years). There were 34 patients with Crohn's disease and 56 diagnosed with ulcerative colitis. Among the 90 enrolled, 68 patients (75.5%) had a good response to cyclosporine. Eleven patients were non responders and underwent corticosteroids withdrawal and corticosteroids rescue, while 6 patients continued corticosteroids. After the sporadic lesions were resected in remitting UC patients, regular surveillance colonoscopy is necessary because 8.5% (4/47) of patients was found CAC/dysplasia. Even in CAC group, prognosis is well in patients with IEN.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0374 CHANGES IN THERAPEUTIC STRATEGY AND OUTCOMES IN NEWLY DIAGNOSED PATIENT WITH CROHN'S DISEASE IN THE BIOLOGICAL ERA IN HUNGARY: A NATIONWIDE STUDY BASED ON THE NATIONAL HEALTH INSURANCE FUND DATABASE

2Strategic Analysis Department, National Health Insurance Fund (OEIP), Budapest/Hungary
3Strategic Analysis Department, National Health Insurance Fund (OEIP), Budapest/Hungary

Introduction: Treatment of Crohn's disease (CD) in the past was based on mesalazine (5-ASA) alone or combined with corticosteroids. Nowadays the biological therapy is the first-line treatment option for the most severe cases. We aimed to analyze the changes in medical treatment of patients with CD in Hungary over a 10-year period.

Methods: We analyzed all newly diagnosed CD patients between 2004 and 2014 in Hungary, using a national database.

Results: In total, 745 patients were diagnosed during that time. The average age of diagnosis was 41.3 ± 16.8 years, and 43.7% of patients were male. The majority of patients received mesalazine only (68.3%), followed by combination of mesalazine and corticosteroids (21.5%). Biological therapy was used in 4 % of the cases. The use of biological therapy significantly increased over the years (p < 0.001).

Conclusion: The proportion of biological therapy increased in Hungary at the same time as the number of CD patients significantly increased. This may indicate an increase in the severity of the patients being diagnosed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0375 RELATIVE FREQUENCY OF RELAPSES IN PATIENTS WITH ULCERATIVE COLITIS AND CROHN'S DISEASE TREATED WITH MESENCHYMAL STEM CELLS - 5 YEARS OF FOLLOW-UP

O. Knazyev1, A. Kagramanova1, N. Fadeeva1, A. Lishchinskaya1, I. Ruchkina2

1Ibd, Moscow Clinical Research Center, Moscow/Russian Federation
2State Scientific Center of Gastroenterology, Moscow/Russian Federation
3Medical Radiological Research Centre, Obninsk/Russian Federation

Introduction: Mesenchymal stem cells (MSCs) have a potential for differentiation and immunosuppressive properties. Currently under phase I-II trials evaluated the autologous and safety of MSCs in the treatment of patients with inflammatory bowel disease - ulcerative colitis and Crohn's disease.

Aims & Methods: We aimed to compare the frequency of relapses and duration of remission for 5 years of follow up in patients with luminal Crohn's disease (CD) and the total defeat of ulcerative colitis (UC) receiving therapy with mesenchymal stem cells (MSCs), bone marrow. We compared the frequency of relapses in patients with luminal form of CD and luminal form of UC with UC (total lesion) receiving MSCs. A group of patients (CD) aged 22 to 56 years (Me=28) (n=24) received MSC culture scheme (0-1-2 weeks, then every 2 weeks). The second group of patients with UC (n=26) aged 20 to 62 years (Me=28) received the culture of MSCs in a similar way. Evaluation of the effectiveness of treatment for relapse frequency was carried out at 12, 24, 36, 48 and 60 months after initiation of therapy.

Results: Among the patients in 1st group relapse in the 12 months of observation was not found. In 2nd group, relapse occurred in 3/24 patients (12.5%) (OR=0.72; 95% CI 0.13–3.96, p = 0.92). After 24 months in the group of patients (group 1) receiving MSC, relapse occurred in 5/24 (20.8%) in group 2 patients with recurrent disease in 7/26 (26.9%) (OR = 0.97; 95% CI 0.13–3.96, p = 0.92).

Conclusion: MSCs transplantation longer contributes to clinical remission in patients with Crohn's disease luminal shape compared to a group of patients suffering from ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0376 CELL THERAPY FOR PERIANAL CROHN'S DISEASE

O. Knazyev1, A. Kagramanova1, N. Fadeeva1, A. Lishchinskaya1, N. Belyakov1, A. Konoplyannikov1, A. Parfenov1

1Ibd, Moscow Clinical Research Center, Moscow/Russian Federation
2Medical Radiological Research Centre, Obninsk/Russian Federation

Introduction: Local, perianal Crohn's disease (perianal CD) is a frequent complication of Crohn's disease, with a prevalence ranging from 3 to 47%. We aimed to assess the efficacy and safety of autologous bone marrow mononuclear cell transplantation in patients with perianal CD.

Methods: We performed a retrospective analysis of patients who underwent autologous bone marrow mononuclear cell transplantation for perianal CD between 2008 and 2016.

Results: Of the 24 patients included in the analysis, 18 (75%) had a complete remission at 6 months after transplantation. The remaining 6 patients had a partial remission. No complications related to the transplantation were observed.

Conclusion: Autologous bone marrow mononuclear cell transplantation is an effective and safe treatment for perianal CD.

Disclosure of Interest: All authors have declared no conflicts of interest.
Contact E-mail Address: belyakov.n.i@gmail.com

Introduction: Perianal fistulas are the most widespread and common types of fistulas in Crohn’s disease (CD). They are difficult to treat, worsen the quality of life of the patient and increase the risk of bowel resection. Despite the significant effect of anti-cytokine therapy fistulous forms of CD, treatment of these patients remains a difficult task with high risk of relapse of CD. Mesenchymal stem cells have immunomodulatory properties and a large regenerative potential, at present also used for treatment of fistulous CD and perianal fistulas of different etiologies.

Aims & Methods: We aimed to compare the efficacy of combined therapy (local and systemic) mesenchymal stem cell therapy (MSCs) of bone marrow, infliximab (IFX) and antibiotics/immunosuppression (IS) on the rate of healing of simple perianal fistulas in Crohn’s disease. 36 patients with Crohn’s disease with perianal lesions were divided into three groups depending on the method of therapy. The first group of patients aged from 19 to 58 years (Me-29) (n = 12) received culture of MSCs systematically via the scheme and locally; on the perimeter of the fistulas introduced 40 million MSCs - 4 point of injection and 1 ml of saline containing 10 million MSCs. After 4 months of therapy, 48 months of treatment 40 million MSCs in the area of the fistula. The second group of patients with CD (n = 10) aged 20 to 68 years (Me-36) were receiving anti-cytokine therapy of IFX. The 3rd group of patients with CD (n = 14) aged 20 to 62 years (Me-28) received antibiotics and is in the dynamics evaluated the closure of the fistula opening of the fistula. Ano-rectosigmoidoscopy carried out after 3, 6, 12 and 36 months from start of therapy.

Results: After 12 weeks among patients of the 1st group simple healing of fistulas was observed in 10/12 patients (83.3%), in the 2nd group healing simple fistulas have a 8/10 (80.0%) (OR-0.83; 95% CI 0.14–4.9; p = 0.04 in comparison with the 1st group). After 6 months in the 1st group of patients receiving MSCs, healing of simple fistulas persisted in 8/12 (66.7%) by the 2nd group - 7/9 (70.0%) (OR - 1.11; 95% CI 0.32–3.84; p = 0.76). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2–1.1; p = 0.12 in comparison with the 1st group).

After 12 months in the 1st group receiving MSCs, healing of simple fistulas persisted in 9/12 (75.0%), in the 2nd group - in 6/10 (60.0%) (OR - 1.25, 95% CI 0.48–3.22; p = 0.69). In the 3rd group – 2/14 patients (14.3%) (OR-0.49; 95% CI 0.24 to about 0.98; p = 0.03 in comparison with the 1st group). After 36 months among the patients of the 1st group, the closure of the fistula was observed in 5/12 patients (41.6%), in the 2nd group - 5/10 (50.0%) (OR -1.17; 95% CI 0.53–2.55; p = 0.96). In the 3rd group – in 0/14 patients (0.0%) of (OR -0.58; 95% CI 0.36-0.94; p = 0.01 in comparison with the 1st group).

Conclusion: Combined stem cell and anti-cytokine therapy of CD with perianal lesions leads to more frequent closure of fistula, compared with antibiotics/immunosuppressant.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0378 EFFICACY AND SAFETY OF RECTAL 5-AMINOSALICYLIC ACID VERSUS CORTICOSTEROIDS IN ACTIVE DISTAL ULCERATIVE COLITIS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

X. Zhao, H. Zhang
Department of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing-China

Contact E-mail Address: zhaoha@163.com

Introduction: Ulcerative colitis (UC) is characterized by diffuse and continuous inflammation of the colon. Currently, the etiology and pathogenesis remain unclear. According to a previous epidemiological study, approximately 75% of newly diagnosed UC patients have active distal UC. Topical 5-aminosalicylic acid (5-ASA) and corticosteroids are used frequently in the treatment of active distal UC.

Aims & Methods: Our study aimed to determine the efficacy and safety of different topical drugs used to treat active distal UC. A random-effects model within a Bayesian framework was utilized to compare treatment effects and safety as odds ratios (ORs) with corresponding 95% credible intervals (CrI). The surface under the cumulative ranking area (SUCRA) and median rank within a Bayesian framework was utilized to compare treatment effects and safety as odds ratios (ORs) with corresponding 95% credible intervals (CrI).

Disclosure of Interest: All authors have declared no conflicts of interest.

In addition to the V565 concentrations in ileal fluid, partially dissolved MTs were recovered from the ileostomy bags of all subjects. Each 1665 mg dose contained a total of 135 MTs. 50 MTs were recovered 2 h post dose from subject 31001; these were not analysed for V565 as this was a post hoc analysis and the MTs were not stored in a way to enable reliable analysis. 64MTs (containing 135 mg V565) were recovered 3h post dose from subject 31002; 78MTs (458 mg 3h post dose from subject 31003; 77MTs (485mg) 3h post dose from subject 31004). 66–82% of an administered dose was recovered from ileostomy bags when MT quantities were added to ileal fluid concentrations. V565 was not detected in any serum sample (LLOQ 62.5 ng/ml).

Conclusion: V565, an oral domain antibody (Vorabody) to TNF engineered to be resistant to intestinal proteases, resulted in high concentrations of active drug in ileal fluid and was not detected in serum following oral administration. In patients with no ileostomy the partially dissolved MTs seen in this study are expected to provide active V565 to lesions distal to the ileum. This profile may be beneficial for IBD and merits further investigation as a potential oral treatment.

Aims & Methods: The main objective was to assess the efficacy of electroacupuncture (EAc) vs. sham EAc and no treatment for treating fatigue in patients with quiescent IBD in a single-blind randomized study. Secondary objectives were to assess changes in quality of life, depression, anxiety and sleepiness after treatment with EAc.

Methods: Fifty-two patients with quiescent IBD and severe fatigue (FACIT-F < 40) (65.3% female, mean age 42 years) were randomized to EAc vs sham acupuncture group. Patients in each EAc group performed a total of 9 acupuncture sessions during eight weeks (2 sessions/first week and one session per week during 7 weeks). Fatigue was evaluated with IBV validated Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F). Patients also validated questionnaires to assess quality of life in IBD, depression, anxiety and sleepiness during and after the treatment periods.

Results: Both EAc and Sham group improved the FACIT-F score post-treatment (EAP = -9.53 points, 95% CI [12.3 to -6.75, Basal Vs 9th session p < 0.001]; Sham = -11.97 to -2.06, Basal Vs 9th session p = 0.003). No significant differences were observed in control group (p = 0.339). We found a trend for better response in the EAP than in the sham group although the difference in FACIT-F score was not significant (p = 0.09). EAc also improved quality of life (5.17 points, 95% CI [-8.2 to -2.06, Basal Vs 9th session p = 0.003]; depression (8.9 points, 95% CI [4.3 to 13.8, Basal Vs 9th session p = 0.002); anxiety (10.6 points, 95% CI [3.6 to 17.6, Basal Vs 9th session p = 0.006) and sleepiness scale (1.46 points, 95% CI [0.096 to 2.83, Basal Vs 9th session p = 0.038). However, the differences in between EAc and sham and control groups were not significant (p > 0.05).

Conclusion: Both targeted and sham electroacupuncture are effective in managing fatigue in patients with quiescent IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNF, such as adalimumab (ADA) and infliximab (IFX), have improved the therapeutic care of Crohn’s disease (CD). However their use may be associated with loss of efficacy, adverse events and sometimes primary failure. Among the possible reasons for discontinuation, it is possible to switch to another anti-TNF. In France, three anti-TNF are available in ulcerative colitis (IFX, ADA and golimumab), but only the first two are approved in CD, because golimumab has not been studied in this indication. The aim of this study was to report golimumab efficacy and safety in CD.

Aims & Methods: This national multicenter retrospective study included patients with CD from 12 French tertiary centers who received golimumab and analyzed: clinical response, duration of treatment, tolerance, reasons for discontinuation of treatment, concomitant phenotype, and treatments preceding and associated with golimumab. The main endpoint was the efficacy of golimumab defined by the duration of treatment before failure (need for therapeutic optimization or cessation). Predictive factors of therapeutic response were determined (log rank and Cox model), and the tolerance was evaluated.

Results: One hundred and fifteen patients with a median duration of the disease of 13.5 years received on average golimumab in 3, 6th line of biotherapy. The overall clinical response assessed by the physician was 55.8% at the time of the re-evaluation (on average, at 3.8 months [0.6-24] after initiation of therapy). The median duration of treatment was 12 months (0.55-44). Sixty-seven percent of patients received treatment for more than 6 months and 48.7% of patients were still treated with golimumab at the end of the follow-up. At 12 months, 34.9% of patients still received golimumab without optimization. At 24 months, this figure was 18.1%. In univariate analysis, the factors associated with a longer golimumab treatment duration without stopping or optimizing were the active smoking status (p = 0.043), the absence of anorectal lesions (p = 0.012), the presence of extra-intestinal symptoms (p = 0.035), the presence of a co-immunosuppression of more than 6 months were independently associated with golimumab efficacy (OR 2.16, 95% CI [2.5-36.3], p = 0.005 and OR 3.9895% CI [2.3-7.1], p < 0.001, respectively). Side effects led to discontinuation in treatment of 6% of patients. These were paradoxical psoriasis in three patients, paresthesia (n = 1), lower extremity edema (n = 1), injection site reaction (n = 1) and not reported reason for one patient.

Conclusion: After failure of the other anti-TNF agents, golimumab is well tolerated and results in sustained clinical response in one in two patients with Crohn’s disease, particularly when associated with a co-immunosuppression, and if the reason for discontinuation of the first anti-TNF was an intolerance.

P0383 BIOLOGICS AND BIOSIMILARS: WHAT MATTERS TO PHYSICIANS?

A. Molinari1, A. Louiza-Bonilla2, D. Charles3

1Global Alliance for Patient Access, Washington, DC/United States of America
2Cancer Treatment Centers of America, Philadelphia, PA/United States of America
3AL

Contact E-mail Address: pdavidcharles@gmail.com

Aims & Methods: The purpose of this survey was to determine physicians’ familiarity and comfort level with prescribing biosimilars to patients. The survey was sent to physicians residing in the European Union and specializing in the following clinical fields: dermatology, endocrinology, gastroenterology, neurology, oncology, and rheumatology.

Introduction: Biologic medicines and their biosimilar counterparts are effective therapies for many conditions, including inflammatory bowel disease, Crohn’s disease, and ulcerative colitis. The European Medicines Agency (EMA) has approved twenty-two biosimilar medicines, which are derivatives of eight original biologics, and four more biosimilars are scheduled to be reviewed this year. As the number of approved biosimilars rises, regulatory agencies must closely monitor their safety and efficacy.

Results: The majority of survey respondents specialized in endocrinology (19%) and gastroenterology (19%). Respondents were recruited almost equally from the five countries, with France being the most represented country (22%) and the UK being the least represented (18%). The majority of respondents (55%) indicated that safety and efficacy is the most important factor in determining whether a patient should be switched from a prescribed biologic therapy to its approved biosimilar. Thirty percent of respondents indicated that clinical trials related to the biosimilar or current condition being treated was the most important factor in switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and only 3% were primarily concerned with improved safety.

Conclusion: This survey suggests that the safety and efficacy of biosimilar medicines is of paramount concern to switching clinicians and patients; physicians highly value clinical trial data for biosimilars. Given that biosimilars are structurally distinct from their original innovator biologics, regulatory agencies and the EMA should consider requiring more stringent clinical trials for biosimilars seeking approval. Specifically, the EMA should require clinical trials for each proposed indication and should provide physicians with this data so that physicians can make informed prescribing choices for the safety of their patients.

Introduction: Oral steroids are effective in inducing remission of moderate flares of patients with either ulcerative colitis (UC) or Crohn’s disease (CD). However, we know little about their efficacy in immunosuppressed patients or their possible role in reducing biologics and/or surgical needs in these patients.
**Abstract No: P0385**

**ADALIMUMAB LONG-TERM EFFECTIVENESS IN ADALIMUMAB-NAIVE PATIENTS WITH CROHN’S DISEASE: FINAL DATA FROM PYRAMID REGISTRY**

**Aims & Methods:** We aimed to determine the efficacy of systemic or low bioavailability (LB) biologic treatment for moderate flares of patients with at least 6 months of immunosuppressive treatment, and describe long-term follow-up. Inflammatory bowel disease (IBD) immunosuppressed patients (thiopurines or methotrexate) from our population-data registry were analyzed. For statistical analysis, Chi-square test, U Mann-Whitney test and Kaplan Meier survival analysis were used.

**Results:** 392 IBD patients with a median of 82 (6-271) months of immunosuppressive (IMM) treatment were identified (table 1). 89 patients (23%) (33% UC and 67% CD) needed at least one steroid treatment during follow-up (63% systemic steroid and 37% low bioavailability oral steroid) with a median time of steroid treatment of 4 (1-168) months. Average time from IMM to steroid treatment was 26 (6-207) months. In IMM patients there were no differences regarding sex, age, disease, location, perianal disease, extra intestinal manifestations, appendectomy, smoke habit, need for steroids at diagnosis and previous abdominal surgery between patients with no need of steroids and patients with steroid treatment during follow-up. In CD patients, biological treatment for perianal disease before IMM (p=0.00199) and fistulizing (B3) or fistulizing (B3) behavior (p=0.005; OR: 2.284) were risk factors for using steroids after IMM treatment. In UC patients, no statistically significant variables were identified. 49 of these 89 steroid treatment patients (55%) needed biological treatment or surgery after a median of 13 months (0-178); 19 (21%) needed more than one steroid treatment (2-5) and just 31 patients (35%) did not need any other treatment. CD patients had higher risk (p=0.007; OR: 3.529) to receive biological treatment or surgery versus UC patients. Otherwise, the more months using steroids in UC patients, the greater risk for biological or surgery treatment (p=0.009). During follow-up, though it’s not statistically significant (p=0.078), we observe that 75% probability of rescue treatment for UC patients is to be maintained for up to 36 months for CD patients.

**Conclusion:** 23% of IMM immunosuppressed patients needed at least one steroid treatment after 6 months of IMM. Previous biological treatment and B2-B3 behavior predicted steroid treatment in CD patients, who had 3.5 times more risk to receive biological treatment or surgery after steroid treatment using it earlier than UC patients. Just 1/3 of patients who needed steroid treatment after IMM did not need any other rescue treatment.

**Introduction:** Adalimumab (ADA) has been shown to improve clinical outcomes and health-related quality of life (HRQoL) significantly in patients (pts) with ulcerative colitis (UC) in a clinical practice setting. Evidence is limited about the benefits of ADA among UC pts with different characteristics.

**Aims & Methods:** The aim was to examine clinical and HRQoL effects of ADA in pts with UC based on disease severity and prior use of tumour necrosis factor inhibitor (TNFI). InspiraDA details have been presented. Pts received ADA 160 mg at week (wk) 0/2 followed by ADA 40 mg at wk 4 through wk 26. Pts who did not respond to ADA by wk 8 were to discontinue. Pts who lost response at or after wk 8 could escalate to ADA 40 mg weekly. UC pts were categorized into subgroups based on physician global assessment (PGA) of disease severity (moderate [baseline PGA = 2] vs severe [baseline PGA = 3]) and previous TNFI use (naïve vs experienced). Proportions of pts with Simple Clinical Colitis Activity Index (SCCAI) response (defined as a decrease of ≥ 2 points vs baseline) and remission (defined as an SCCAI ≤ 2) were calculated for each cohort at wk 2, 8, 26, and 52. Change from baseline in HRQoL outcomes was calculated, including Short Inflammatory Bowel Disease Questionnaire (SIBDQ), European Quality of Life-5 Dimensions-5 Level (EQ-5D-5L), Treatment Satisfaction Questionnaire for Medication (TSQM) and Work Productivity and Activity Impairment (WPAI).

**Results:** Among pts with moderate UC (n = 386) and severe UC (n = 74), SCCAI response rates were 74.6% vs 74.3%, 80.1% vs 71.6%, and 67.1% vs 64.9% at wk 2, 8, 26, respectively. Although remission rates were similar between moderate and severe pts at wk 26 (49.5% vs 40.5%, p = 0.16), ADA provided greater disease control for moderate pts at wk 2 (29.8% vs 9.5%, odds ratio [OR] 4.195, confidence interval [CI] 1.8-9.1, p < 0.0001) and wk 8 (52.3% vs 31.1%, OR 2.4, 95% CI 1.4-4.4, p = 0.01) compared to severe pts (table 1). The rate of dose escalation (ADA 40 mg weekly) was 28.0% in moderate and 28.4% in severe UC pts. HRQoL outcomes were similar between the moderate and severe cohorts. Among pts who were naïve (n = 389) and those experienced to TNFI (n = 72), response rates were 74.0% vs 76.4%, 79.2% vs 75.0%, and 66.3% vs 68.1% at wk 2, 8, 26, respectively. No significant difference was observed in remission rates for naïve vs experienced pts at wk 2 (28.0% vs 19.4%, p = 0.43) and wk 26 (49.4% vs 41.7%, p = 0.39), but naïve pts showed a significantly higher remission rate than experienced to TNFIs at wk 8 (52.2% vs 31.9%, OR 2.1, 95% CI 1.2-3.7; p < 0.0001). The rate of dose escalation was 26.5% in naïve pts vs 36.1% in experienced pts (p = 0.09). In general, HRQoL outcomes were similar between naïve and experienced TNFI pts.

**Conclusion:** ADA treatment achieved clinically relevant rates of SCCAI response and remission even in pts who had severe UC and those who were more treatment-refractory (experienced to TNFIs), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFIs. Insufficient data were available to make meaningful comparisons between groups by prior TNFI use. Future studies are needed to further evaluate these findings.

Introduction: Treatment with intravenous (IV) CT-P13, a biosimilar infliximab (INX) licensed for use in 80 countries, is highly effective and well tolerated. To increase treatment modalities with CT-P13 for patients, a new subcutaneous (SC) formulation was developed.

Aims & Methods: This phase I and open label study, conducted at a single site in Korea, was designed to evaluate safety and pharmacokinetics (PK) of SC administration of CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the study cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC0-last, Cmax, Tmax and T1/2.

Results: A total of 38 male subjects with median age of 23 years (range 19, 30 years) were included. No treatment-emergent serious adverse events or systemic hypersensitivity reaction. In SC cohort, two subjects experienced mild injection site reactions, and both have resolved without any treatment. Mean AUC0-last and Cmax ranged from 5016.4 to 14253.6 h*ug/mL and 10.0 to 23.1 ug/mL, respectively, after a single SC injection of CT-P13. SC CT-P13 formulation was absorbed slower into the systemic circulation (median Tmax ranging from 7.0 to 7.1 days) in comparison with IV formulation (median Tmax ranging from 2.2 to 3.2 hours) but the drug elimination measured by half-life (T1/2) was similar (mean range 13.2 to 13.7 days vs. 11.7 to 12.2 days) between SC and IV formulations, respectively. Bioavailability of CT-P13 SC was approximately 60.6%, when comparing across all CT-P13 SC cohorts to CT-P13 IV cohorts.

Conclusion: PK profiles after a single SC injection were linear by dose levels. SC administration of CT-P13 is feasible in terms of bioavailability and safety profiles.

Contact E-mail Address: mark.osterman@uphs.upenn.edu

Introduction: Biological therapy has been highly effective for inflammatory bowel disease (IBD). In addition to anti-tumour necrosis factor (anti-TNF) drugs, a gut-selective anti-integrin biologic, vedolizumab (VDZ), has been approved since 2014. However, the real-world comparative effectiveness of VDZ and anti-TNF has not been fully investigated.

Aims & Methods: This study aimed to evaluate all-cause and IBD-related healthcare utilisation in IBD patients (pts) newly treated with VDZ and anti-TNFs. Cohrs’s disease (CD) and ulcerative colitis (UC) pts ≥18 years old with ≥2 claims for VDZ or ≥2 claims for anti-TNF from 20/5/2014 to 31/12/2016 were identified from a large, de-identified administrative claims database in the US (Truven MarketScan® Commercial and Medicare Supplemental Databases). The first date of the first VDZ/anti-TNF claim was defined as index date. New VDZ/anti-TNF treatment was defined as no claims for these agents in the 1 year before index date. All pts had ≥12 months of continuous enrollment prior to and ≥6-months of continuous enrollment following the index date. All-cause and IBD-related healthcare utilisation including hospitalisation, emergency department (ED) visits and outpatient visits during 6 months post-index were examined for the IBD cohort overall, as well as in CD and UC cohorts. Multivariable logistic regression was employed to estimate the odds ratio (OR) for hospitalisation and ED visits, while Poisson regression was used to examine the rate ratio (RR) for outpatient visits with VDZ compared to anti-TNF use, controlling for demographic characteristics, index year, baseline Charlson comorbidity index (CCI) and baseline hospitalisation and ED visits 1 year prior to index date. In sensitivity analyses, outpatient visits related to infusion administration for VDZ or anti-TNF were excluded to examine the RR associated with outpatient visits that were not related to the visits for infusion procedure.

Results: A total of 652 and 6974 IBD pts newly treated with VDZ and anti-TNF were identified, respectively (mean age [year]: 45 VDZ vs 42 anti-TNF: male: 47% vs 48%). VDZ pts had a higher CCI than anti-TNF pts (0.7 vs 0.5). During the 6 month follow-up, compared to anti-TNF, use of VDZ had significantly higher rates of all-cause hospitalisation (16.3% vs 13.1%, OR 1.30, 95% confidence interval [CI] 1.03–1.64), all-cause outpatient visits (mean visits 45.1 vs 31.0, RR 1.39, 95%CI 1.32–1.37) and IBD-related outpatient visits (mean visits 28.1 vs 17.5, RR 1.60, 95%CI 1.51–1.69). A sensitivity analysis excluding outpatient visits related to infusion administration showed similar results for IBD-related outpatient visits (RR 1.53, 95%CI 1.44–1.62). In pts with CD, the magnitude of risk of IBD-related hospitalisation was even higher (OR 1.67, 95%CI 1.17–2.38), but no significant difference in IBD-related hospitalisation (OR 0.57, 95%CI 0.30–1.06) was observed in pts with UC. The difference in IBD-related ED visits between VDZ and anti-TNF pts was not significant in CD (OR 1.32, 95%CI 0.96–1.82) or UC (OR 0.72, 95%CI 0.40–1.29). However, the rates of outpatient visits were consistently higher in VDZ vs anti-TNF across CD (RR 1.82, 95%CI 1.69–1.96) and UC cohorts (RR 1.29, 95%CI 1.18–1.42). The results were similar in the sensitivity analyses when infusion-related visits were excluded.

Conclusion: In this real-world setting, VDZ treatment was shown to be associated with higher all-cause hospitalisations and outpatient services compared to anti-TNF for pts with IBD. A higher risk of IBD-related hospitalisation associated with VDZ use was observed in CD but not UC pts. Outpatient visit rates were consistently higher for VDZ users, regardless of taking into account the infusion-related visits for biologics. These results should be interpreted with caution as disease activity was not fully accounted for in this claims data analysis.

P0931 CLINICAL RESPONSE TO VEDOLIZUMAB IN IBD PATIENTS IS ASSOCIATED WITH THE CONCOMITANT USE OF IMMUNOMODULATORS

I. Parisi, R. Vega, L. Whitley, S. Bloom, S. Mccartney

Gi Medicine, University College London Hospitals, London/United Kingdom

Contact E-mail Address: ioanneparisis@hotmail.com

Introduction: The role of biologics in medical management of inflammatory bowel disease (IBD) has been established since anti-TNF agents invaded the market several years ago. Vedolizumab, an anti-integrin gut-selective molecule, is a more recent biologic treatment which has been approved for the management of both Crohn’s disease and ulcerative colitis. Its efficacy in inducing and maintaining remission was shown in GEMINI studies, although a good percentage of the trial participants had previously failed anti-TNFs. We conducted this study in order to describe outcomes in a real-life cohort of IBD patients who were treated with Vedolizumab, consisting both of previously anti-TNF exposed but also anti-TNF naive patients. Multivariate analysis searched for factors associated with response to treatment.

Aims & Methods: All patients with IBD who received at least three doses of Vedolizumab in UCLH since the drug was officially licensed in the UK were included in the study. Demographics, clinical and endoscopic response rates were recorded and analysis was conducted in the whole cohort and in the subgroups of Crohn’s and UC patients separately. Univariate analysis and logistic regression were conducted in order to identify important associations with clinical response.

Results: 59 patients with IBD were treated with vedolizumab from May 2015 to October 2016. 28 (47%) had Crohn’s disease and the majority (n = 43, 73%) had mainly colonic inflammation (12 colonic Crohn’s, 29 UC, 2 IBDU). Median time from diagnosis to Vedolizumab initiation was 8 years. 17 (29%) were anti-TNF naïve (all UC) and 28 (67%) had previously failed both Infliximab and Adalimumab. 36 (61%) were on a concomitant immunomodulator (IM), either methotrexate (MTX) (29%) or 6-mercaptopurine (6-MP) (7%). 16 (27%) patients had a clinical response to Vedolizumab based on a reduction of Harvey-Bradshaw index (HBI) from baseline ≥3 points for Crohn’s patients or a reduction of partial Mayo score ≥2 points for UC patients. The rates of response were similar in Crohn’s and UC patients while there was no difference in response according to gender, previous anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant IM were less likely to respond to Vedolizumab (Odds ratio 0.26, 95%CI 0.07-0.91, p = 0.036). 11(18.6%) patients experienced adverse events while treated with Vedolizumab, five of which related to active IBD. There were two minor allergic reactions and two mild infections.

Conclusion: Clinical response to Vedolizumab was observed in two-thirds of our IBD patients, similarly in Crohn’s disease and ulcerative colitis. Concomitant IM were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: donalltighe83@gmail.com

Introduction: Anti-TNFα therapies have helped improved response rates, reduced complication rates, and quality of life for patients with inflammatory bowel disease (IBD). However primary loss of response (LOR) is still a big concern. Therapeutic drug monitoring (TDM) potere of female gender (72%) and mean age was 59 years. The proportion of patients in clinical remission at week 8 was significantly higher in the budesonide group than in the placebo group (intention-to-treat (ITT) 79% vs 42%; p = 0.001. The difference in clinical remission at week 8 between mesalazine (63%) and placebo failed statistical significance (p = 0.099). The proportion of patients with histological remission at week 8 was higher with budesonide (68%) than with mesalazine (26%; p = 0.02) and placebo (21%; p = 0.008). The rate of adverse events did not differ among groups.

Conclusion: Oral budesonide 9mg once daily is highly effective and safe for induction of clinical and histological remission in lymphocytic colitis, while oral mesalazine 3g once daily was only numerically, but not statistically significantly better than placebo.

Contact E-mail Address: daniel.baumgart@charite.de

Introduction: A pregnant woman with ulcerative colitis (UC), compared with age-matched controls, is at higher risk of adverse outcomes including spontaneous abortion, preterm birth and low birth weight. Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for UC. Tofacitinib has been shown to be foetocidal and teratogenic in both rats and rabbits at exposures 146 times and 13 times, respectively, the human dose of 5mg twice daily (BID). There is no adequate and well-controlled studies of tofacitinib in pregnant women.

Aims & Methods: We report the pregnancy outcomes from three randomised, placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01459951; OCTAVE Sustain, NCT01485874) and one ongoing open-label extension study (OCTAVE long-term study, NCT01470612) of tofacitinib monotherapy in patients (pts) with moderate to severe UC. Pregnancy outcomes following maternal or paternal exposure to tofacitinib or 5 mg BID were identified from Pfizer’s internal safety database up to 23 March, 2017, and categorised as: healthy newborn, medical termination, foetal death, congenital malformation, spontaneous abortion or pending/lost to follow-up. Trial protocols required use of highly effective contraception for females of childbearing potential, and study drug to be discontinued in any female pts who became pregnant.

Results: A total of 1139 unique pts (incl. placebo) enrolled in the UC OCTAVE trials, of whom 296 were females of childbearing age. There were a total of 25 pregnancies reported with exposure to tofacitinib. Of these, 11 were cases of maternal exposure, all during the 1st trimester, including: 2 (18.2%) spontaneous abortions (5 mg BID, n = 1; 10 mg BID, n = 1), 2 (18.2%) medical terminations (both 10 mg BID), 4 (36.4%) healthy newborns (all on 10 mg BID) and 3 (27%) being lost to follow up (all on 10 mg BID). Out of the 14 cases of paternal exposure, 11 (78.6%) were healthy newborns (5 mg BID, n = 2; 10 mg BID, n = 9 and 3 (21.4%) were pending/lost to follow-up (5 mg BID, n = 1; 10 mg BID, n = 2). Overall, there were no cases of foetal death or congenital malformation.
P0395 SAFETY AND EFFICACY OF GRANULOCYTE AND MONOCYTE ADSORPTIVE APERHESIS IN 363 PATIENTS WITH INFLAMMATORY BOWEL DISEASE WHO HAVE SPECIAL SITUATIONS: AN INTERIM ANALYSIS OF A POST-MARKETING SURVEILLANCE STUDY

Introduction: People with Inflammatory Bowel Disease (IBD) commonly experience mental health issues (MHIs) such as anxiety and depression. MHIs reduce quality of life and are associated with poor medication adherence and worse disease course. However, psychological support is not routinely provided to people with IBD. There are scant prospective, systematically gathered data on MHIs in IBD, despite solid evidence of the value of psychological input for people with other chronic diseases.

Aims & Methods: The current study is investigating: the prevalence of MHIs in an IBD cohort; the acceptability and uptake of a psychological support and treatment; whether MHIs correlate with higher healthcare utilisation; and potential benefits of integrated psychological care to patients’ mental health, physical health, and/or healthcare utilisation. Potential participants were prospectively recruited from the IBD service of a large tertiary hospital in South Australia via post and in-person at scheduled/routine outpatient appointments. Data were collected at two time points – at baseline screening and at 12 month follow-up. Mental health, medicition adherence, and quality of life were measured by questionnaires: the Hospital Anxiety and Depression Scale (HADS), the Kessler 6 Scale of General Psychological Distress (K6), the Morisky Medication Adherence Scale (MMAS-8), and the Assessment of Quality of Life measure (AQoL-5D). Demographic and healthcare utilisation data were collected by electronic,
state-wide hospital records. Psychological support was offered where scores on HADS and/or K6 indicated likely need.

Results: 500 patients were approached during the 12-month screening phase; 50.6% were male, 70.8% had Crohn’s disease, mean age of 40 years, mean duration of disease 11 years, 43% in clinical remission, and 9.8% current smokers (Australia’s average 13.3%). Of these 500, 67% participated in psychological screening; 38% scored within the clinical range, and 17% accepted psychological support. Gender was a significant predictor of participation in psychological screening: women were 62% more likely to participate than men. Analgesics support. Gender was a significant predictor of participation in psychological screening, 38% scored within the clinical range, and 17% accepted psychological intervention. All of which demonstrates a widespread need for support in this cohort. Furthermore, preliminary data of patients reported clinical levels of distress (irrespective of their IBD activity) were more likely to participate in psychological screening, and in general the patients were more likely to participate than men. Analgesics support. Gender was a significant predictor of participation in psychological screening, 38% scored within the clinical range, and 17% accepted psychological intervention. All of which demonstrates a widespread need for support in this cohort. Furthermore, preliminary data of patients reported clinical levels of distress (irrespective of their IBD activity)

Conclusion: Psychological issues are prevalent in patients with IBD and associated with a decreased quality of life. Psychological support is more likely to participate in psychological screening, and in general the screening approach was widely accepted. In addition, high proportions of patients reported clinical levels of distress (irrespective of their IBD activity) and went on to accept psychological intervention. All of which demonstrates a widespread need for support in this cohort. Furthermore, preliminary data of treatment outcomes are promising. At study completion we will be better able to clarify the extent to which patients with IBD benefit from this new integrated approach.

Aims & Methods: To evaluate long-term efficacy, safety, and immunogenicity in patients continuously treated with either GP2017 or reference adalimumab from initial randomization to Week 51. Eligible patients with moderate-to-severe chronic plaque psoriasis were randomized to receive an initial dose of 80 mg subcutaneous GP 2017 or reference adalimumab, followed by 40 mg every other week, starting one week after the initial dose, up to Week 17. At Week 17, patients with ≥50% improvement in Psoriasis Area and Severity Index (PASI 50) at Week 16 were re-randomized in a 2:1 ratio to either remain on their initial treatment or undergo a sequence of three treatment switches between GP 2017 and reference adalimumab until Week 35. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

Results: From randomization to Week 51, 168 and 171 patients received continuous treatment with GP 2017 or reference adalimumab, respectively. In the per-protocol analysis set, PASI 75 response rates for continual GP2017/reference adalimumab at Weeks 17 and 51 were 75.2%/67.8% and 65.5%/79.6% respectively. Investigator’s global assessment (IGA) response rates (IGA score of 0 [clear] or 1 [almost clear] and ≥2 point improvement from baseline) were also similar between the continual GP2017/reference adalimumab groups, increasing over time and remaining stable from Week 17 (60.0%/53.9%) to Week 51 (59.8%/55.1%). There were no clinically relevant differences between the continual GP2017/reference adalimumab groups in the frequency of adverse events (AEs) (61.3%/64.9%), treatment-related AEs (17.9%/17.8%), serious AEs (3.0%/3.8%), or AEs leading to discontinuation of study drug (7.9%/7.8%) respectively. Investigators’ assessment of AEs, nasopharyngitis most frequently reported by 8.9%/10.5% of patients treated with continual GP2017/reference adalimumab. Between Weeks 1 and 51, binding antidrug antibodies were detected in 38.8%/45.3% of patients treated with continual GP2017/reference adalimumab, 88.7%/84.7% of which were neutralizing.

Conclusion: Efficacy was similar and sustained in patients with psoriasis continuously treated with GP 2017 or reference adalimumab for up to 51 weeks. Safety profiles and immunogenicity were generally similar in both groups. Clinical data add to the totality of evidence suggesting GP 2017 could be used as a biosimilar for the treatment of the same indications for which reference adalimumab is approved, including inflammatory bowel disease.

PO398 PREDICTIVE FACTORS OF RESPONSE TO GRANULOCYTE MONOCYTE APhERESIS IN INFLAMMATORY BOWEl DISEASE

I. Rodriguez - Lago1, J.M. Benitez-Cantero2, V. Garcia-Sanchez2, L. Sempere1, A. Gutierrez2, I. Galdona2, A. Rodriguez-Pescador1, E. Fernandez2, I. Lafuente2, A. Loroño1, J.L. Cabriada1

2Gastroenterology, Hospital Universitario Reina Sofia, Cordoba/Spain
3Gastroenterology, Hospital General Universitario de Alicante, Alicante/Spain
4Dialisis Unit, Hospital de Galdakao, Galdakao/Spain

Introduction: Granulocyte-monocyte apheresis (GMA) can be employed for the treatment of inflammatory bowel disease (IBD), especially for ulcerative colitis (UC). The usual treatment schedule is a weekly session for 5 weeks processing 1800 ml in 60 minutes. It has been described that different factors of the disease and the technique can improve the response to this treatment.
Aims & Methods: We performed a retrospective study of all patients treated with GMA (Adacolumn) in 3 IBD Units in Spain. The clinical and analytical data were assessed before and 1 month after the end of the GMA. The Ethics Committee of Euskadi approved the study protocol. The aim of our study was to evaluate the presence of clinical, analytical of technique-related factors associated to a better response to GMA.

Results: A total of 105 patients were included [51 female (49%), age 35.7 (SD 16.5)]. Ninety-three had UC (50% extensive, 45% left-sided), 10 Crohn’s disease (90% ileocolonic) and 2 IBD-U. Mayo score at baseline was 3.5 (SD 4.6) and Harvey – Bradshaw was 10.1 (SD 3.8). The Mayo endoscopic subscore was 1 (16%), 2 (56%) or 3 (27%). All almost patients (97%) have been previously treated with steroids and 42% were exposed to biologics. At baseline, 85% were on steroids, 38% thiopurinels and 18% biologics. None of the previous or concurrent treatments were associated with a better response to GMA. Fifty-five subjects received weekly sessions for 5 weeks processing 1800 ml/session in 60 minutes. Forty-five patients received an intensive GMA regimen: biweekly sessions with a mean of 8 sessions (SD 2.6), processing 3880 ml/session (SD 1729) and lasting 15 minutes (SD 24). The intensive group showed a slightly higher response rate to GMA as compared with those in the standard regimen (response rate 67% vs 55%, p = 0.28). Those subjects treated with > 5 sessions showed higher remission (24% vs 13%) and response rates (47% vs 24%) as compared to < 5 sessions (p = 0.004). A mean duration of > 60 min/session also showed better results in terms of remission (22% vs 16%) and response (45% vs 27%) when compared to < 60 min/session (p = 0.04). There was also a trend towards higher remission rates in those with higher processed blood volume. Thirty-nine percent were able to wean off steroids completely one month after GMA. We observed a decrease in the mean platelet volume and the platelet to lymphocyte ratio after GMA in those cases who did not respond. Contrary to its clinical efficacy in this clinical practice study. Increasing the number of sessions or its length were associated with a better response to GMA. The mean platelet volume and the platelet to lymphocyte ratio could help to predict the response.

Disclosure of Interest: All authors have declared no conflicts of interest.

5Clinico Hamburg, IBD Center, Hamburg/ Germany

Contact E-mail Address: wsandborn@ucsd.edu
Introduction: Ulcerative colitis (UC) and Crohn’s disease (CD) are chronic, inflammatory bowel disorders that affect the gastrointestinal tract. While the pathogenesis of UC is well understood, the disease is characterized by chronic inflammation, mucosal injury, and recurrent ulcerative episodes. While MCQ399 (an anti-MMP9 antibody) has shown promise in preclinical models, the safety and efficacy of MCQ399 as an induction therapy in active disease has not been evaluated in a randomized clinical trial. The aim of this study was to evaluate the safety and efficacy of MCQ399 as an induction therapy for moderately to severely active UC and CD.

Methods: A total of 100 patients were randomized to receive subcutaneous injections of placebo, 150 mg andecaliximab every 2 weeks (Q2W), or 150 mg andecaliximab weekly (QW). The primary outcome was change in the Clinical Colitis Activity Index (CDAI) compared to baseline at week 8. Secondary outcomes included changes in the Disease Activity Index for Crohn’s disease (DAI), Mayo Clinic Score (MCS), and Harvey-Bradshaw Index (HBI). Safety was assessed by monitoring adverse events (AEs) and laboratory parameters.

Results: A total of 100 patients were enrolled from 13 countries. No concerning baseline imbalances occurred between the treatment groups. Overall, 17.6% of subjects had evidence of fistula at screening, mean (SD) disease duration was 12 (9.5) years, 84.5% of subjects had previous exposure to TNF-alpha antagonist and 44.4% of subjects were taking oral corticosteroids at baseline. The frequency of adverse events (AEs) was similar in the andecaliximab Q2W, andecaliximab QW and placebo groups: 53.7%, 58.9% and 60%, respectively. Common AEs included anemia, abdominal pain and nausea. Three AEs led to discontinuation in the andecaliximab Q2W group compared to one each in the andecaliximab Q2W and placebo groups. Two serious AEs occurred in the andecaliximab QW group (anemia and angiina pectoris) compared to one in placebo. Frequency of arthralgia and musculoskeletal pain was similar between andecaliximab and placebo groups.

Conclusion: SC 150 mg andecaliximab was well tolerated; however, neither dosing regimen demonstrated a treatment effect in subjects with UC.

Introduction: Elevated levels of matrix-metalloproteinase-9 (MMP-9) and its degradation products are detected in patients with active Crohn's disease (CD). Selective inhibition of MMP-9 reduced fibrosis in a murine model of intestinal fibrosis, suggesting that MMP-9 may contribute to intestinal complications in CD. Accordingly, MMP-9 has been proposed as a therapeutic target for CD. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds and inhibits MMP-9. It was found that to be safe in a phase 1 dose-ranging study in UC subjects, where it showed clinical response and remission compared to placebo. The aim of this phase 2 study was to evaluate the safety and efficacy of andecaliximab as an induction therapy for moderately to severely active UC and CD.

Aims & Methods: This was a double-blind, randomized, placebo-controlled 8-week induction study in adult CD subjects with moderate to severe disease activity (defined as: CDAI total score ≥220, 450; weighted PRO2 score ≥11 [standard CDAI weightings: abdominal pain 0–3 x7 plus mean number of daily stools x2] and SES-CD total score ≥6 [or ≥4 score if disease limited to ileum and/or right colon or ulcer presence and size score ≥2]). Subjects were required to have an inadequate response, or loss of response or intolerance to at least 1 of the following treatments in the last 5 years: corticosteroids, immunomodulators, TNF-alpha antagonist or vedolizumab. Subjects were randomized 1:2:2:2 to receive subcutaneous (SC) injections of: placebo, 150 mg andecaliximab every 2 weeks (Q2W), 150 mg andecaliximab weekly (QW) or 300 mg andecaliximab QW. Common AEs included anemia, abdominal pain and nausea. Three AEs led to discontinuation (PRO2 score of <8 at week 8) and clinical response (SES-CD score ≤50% from baseline at week 8).

Results: A total of 187 subjects were enrolled from 13 countries. No concerning baseline imbalances occurred between the treatment groups, overall: 17.6% of subjects had evidence of fistula at screening, mean (SD) disease duration was 12 (9.5) years, 84.5% of subjects had previous exposure to TNF-alpha antagonist and 44.4% of subjects were taking oral corticosteroids at baseline. The baseline and week 8. The primary outcome was EBS clinical remission, defined as an Endoscopic subscore of ≤1, rectal Bleeding subscore of 0, and ≥1 point decrease in Stool frequency from baseline to achieve a subscore of 0 or 1.

Results: A total of 165 subjects from 23 countries were enrolled. The percentage (confidence intervals) of subjects achieving EBS clinical remission was similar between subjects treated with andecaliximab Q2W and placebo: 7.4% (2.1-17.9%), 1.8% (0-9.6%) and 7.3% (2-17.6%), respectively. No concerning imbalances occurred for all endpoints. The results show a trend towards higher remission rates in those with higher processed blood volume. Thirty-nine percent were able to wean off steroids completely one month after GMA. We observed a decrease in the mean platelet volume and the platelet to lymphocyte ratio after GMA in those cases who did not respond. Contrary to its clinical efficacy in this clinical practice study. Increasing the number of sessions or its length were associated with a better response to GMA. The mean platelet volume and the platelet to lymphocyte ratio could help to predict the response.
percentage of subjects achieving clinical response/remission and endoscopic response was similar between treatment groups (Table 1).

Conclusion: SC andentuximab was well tolerated, however, none of the treatment regimens demonstrated a treatment effect in subjects with CD.

P0401 TUBERCULIN SKIN TEST CONVERSION RATE IN INFECTIOUS BOWEL DISEASE PATIENTS RECEIVING ANTI-TNF ALPHA AGENTS

M. Fragkaki, A. Mpitouli, I. Dimas, G. Paspatis, K. Karmiris
Gastroenterology, Venizelion General Hospital, Heraklion/Greece

Contact E-mail Address: gpaspatis@gmail.com

Aims & Methods: Few data exist regarding the kinetics of this test during therapy. Therefore, we investigated the conversion rate of PPD-TST in IBD patients under anti-TNFalphalapha therapy. Anti-TNFalapha-treated IBD patients followed up in our centre with a baseline PPD-TST underwent a second one during therapy. Those with a positive PPD-TST either at baseline or during follow up in our centre with a baseline PPD-TST underwent a second one during therapy. Therefore, our study investigated the conversion rate of PPD-TST in IBD patients under anti-TNFalpha therapy. There was no case of active tuberculosis during the study. All patients treated. Therefore, the kinetic of PPD-TST in IBD patients under anti-TNFalphalapha treatment should be monitored.

Those with a positive PPD-TST either at baseline or during follow up in our centre with a baseline PPD-TST underwent a second one during therapy. Therefore, our study investigated the conversion rate of PPD-TST in IBD patients under anti-TNFalpha therapy. There was no case of active tuberculosis during the study. All patients treated. Therefore, the kinetic of PPD-TST in IBD patients under anti-TNFalphalapha treatment should be monitored.

Introduction: Golimumab (GLB) has been the last anti-TNF agent authorized for the treatment of Ulcerative Colitis (UC). Results from registratory trial (PURSUIT) documented a clinical response in 51% of patients after 6 weeks

The frequency of adverse events (AEs) was similar between the treatment groups: placebo (67.9%), 150 mg Q2W (60.4%), 150 mg QW (62.3%), 300 mg QW (69.8%). Common AEs included abdominal pain, nausea, fatigue, anemia and pyrexia. One AE led to study discontinuation in the placebo group (3.6%) compared to 2 in the 150 mg QW group (3.8%) and 4 in the 300 mg QW group (7.5%). Three serious AEs occurred in the placebo group (10.7%) compared to 1 in the 150 mg QW group (1.9%), 6 in the 150 mg QW group (11.3%) and 8 in the 300 mg QW group (15.1%). Frequency of arthralgia and musculoskeletal pain was similar or lower in andentuximab groups compared to placebo.

were found between naïve and non-naïve patients. No significant adverse events (38%), one of them (7%) resulted in complete steroid-free remission. Among the patients (23%) had already received one anti-TNF in the past. Clinical response was computed at baseline and every 2 weeks for the first 6 weeks of therapy, then every 4 weeks throughout the maintenance period. Follow-up is still ongoing. Primary end point has been the clinical response at the end of the induction phase (intended as the reduction of Partial Mayo score >30% and >3 points vs baseline) and in the maintenance period, the secondary end point being the steroid-free clinical remission (Partial Mayo score <2 with all subscores <1) at the end of the induction phase and throughout the maintenance phase. Complete follow-up is available for all patients at week 30, with 4 patients reaching the week 54 of monitoring.

Results: At the time of GLB starting, localization of the disease according to Montreal classification was left-sided colitis (E2) in 70%, pancolitis (E3) in 23% and proctitis (E1) in 7% of patients. Ten patients (77%) were anti-TNF naïve, 3 patients (23%) had already received one anti-TNF in the past. Clinical response was obtained in 6/13 (46%) at week 6 and in 2 further patients at week 10, for a total of 8/15 (53%). Three patients failed in complete clinical steroid-free remission after 6 weeks. At week 30, 5 patients still showed a clinical response (38%), one of them (7%) resulted in complete steroid-free remission. Among the 4 patients reaching week 54, 2 experienced a flare of disease whereas 2 were still in remission. One patient is in remission at week 42, potentially accounting for a total of 3/13 patients in remission after one year (23%). No differences were found between naïve and naïve-naïve patients. No significant adverse events were reported in the study period.

Comment: Our results to suggest that Golimumab, as compared to registrary trials, is able to induce a better initial clinical response but shows a higher secondary loss of response in the long term. Whether this really reflects a lower efficacy of GLB or could depend on the unavailability of dose optimisation in daily practice needs to be evaluated.

Introduction: Several oral mesalazine utilise pH-dependent release coating to optimise topical delivery of the medication. Little data exist on the effects of dietary factors on intestinal pH and transit times in patients with UC to predict likely efficacy-based delivery profiles. No studies have accounted for acute variations in dietary fibre intake, which might affect regional transit and pH profiles.

Methods: This study aimed to (1) assess intraluminal pH and transit after acute changes in fibre intake in quiescent UC patients; and (2) deduce delivery of topically-acting drugs using published pharmacokinetic (PK) data. In this randomised, double-blind study, UC patients with UC in clinical remission (partial Mayo Score ≤1 + faecal calprotectin <150 μg/g) without recent antibiotic (including sulfasalazine), probiotic or fibre use were recruited. After a 7-day run-in, subjects were supplied with study meals containing high (13 g oligosaccharides and resistant starch) (HF) or low (<1 g) fermentable fibre (LF) over a 12-h period prior to the ingestion of a pH-motility capsule (Smart Pill). Telemetric recordings were made for 5 days or until the capsule had been excreted. After a ≥3-day washout period, they crossed-over to the other dietary arm and pH-motility test. Small and large intestinal pH profiles were defined as the length in time (h) of different intraluminal pH ranges – pH <5, ≥5 to <7.7 and ≥7.7 and compared between diets. Using published PK of pH-dependent coated mesalazine preparations, the patterns of dissolution in UC patients were estimated.

Results: 41 patients (aged 24–72; 9 males – 5 extensive, 5 distal and 5 proctitis), acute HF intake significantly increased median (IQR) time for colonic pH <6 ([HF]: 4.5 (2.4–10.2) vs LF: 0.9 (0.2–3.1) h; p =0.004, Wilcoxon), tended to increase colonic pH ≥6 to <7 ([HF]: 7.5 (6.3–13.5) vs LF: 7.1(3.4–15.2) h) and had no impact on colonic pH ≥7 ([HF]: 1.6 (0.0–3.3) vs LF: 1.8 (0.8–2.1) h; p =0.34). Table 1 summarises hypothetical dissolution profiles for pH-coated mesalazine in patients with UC. Considerable variations across release diseases were evident, but, despite alterations in pH and transit, the patterns were not affected by diet for Eudragit L alone or with slow release mechanisms. Only minor differences were found for Eudragit S and MMX.

Conclusion: Current delivery mechanisms for mesalazine lead to a proportion of quiescent UC patients having incomplete release and suboptimal regional
delivery. An acute high fermentable fibre intake delays drug dissolution in the colon, but had little influence over total release. These findings have implications for optimising drug selection in maintenance of remission in UC.

Conclusions: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.5 mg/L at week 6 is associated with improved endoscopic outcomes.

P0406 HIGHER EXPOSURE TO GOLIMUMAB IS ASSOCIATED WITH ENDOSCOPIC RESPONSE IN PATIENTS WITH ULCERATIVE COLITIS: RESULTS FROM THE GO-KINETIC TRIAL

Introduction: Golimumab (GLM) is a subcutaneously administered anti-tumor necrosis factor (anti-TNF) antibody that is approved for the treatment of moderate to severe ulcerative colitis (UC). We investigated the association between systemic exposure (area under the curve (AUC)) of GLM during induction therapy and endoscopic response in moderate-severe UC.

Aims & Methods: In this prospective observational trial, patients with moderate to severe UC (Mayo endoscopy score ≥2) received induction treatment with GLM 200 mg SQ at week 0 and 100 mg (at week 2) followed by 50 or 100 mg at week 6, in patients with a body weight of less or more than 80 kg, respectively. Serum GLM concentrations were measured at day 0, 4, 7, 14, 18, 28, 42 and 56, as well as anti-GLM antibody levels, C-reactive protein (CRP) and albumin serum concentrations. Serum GLM concentrations were measured with an enzyme-linked immunoassay and anti-GLM antibody levels were measured with a drug-sensitive antigen binding test, both developed by Sanquin laboratories. Endoscopic response was defined as ≥1 point reduction in endoscopic Mayo score at week 8-10 compared to baseline. AUCs were calculated using nonlinear mixed effect modelling (NONMEM®) and were compared using the non-parametric Mann-Whitney U test. Correlation analysis was performed using Pearson’s correlation coefficient. A receiver-operating characteristic (ROC) curve reported the predictive performance of GLM serum trough levels at week 2 and 6 for endoscopic response.

Results: A total of 20 patients were enrolled of which 19 patients underwent an endoscopy at baseline and 8–10 weeks after start of treatment. Median age (interquartile range) was 46 years [36–57], median baseline CRP serum concentration was 4.5 mg/L [1.1–13.7] and median baseline albumin serum concentration was 44 g/L [40–45]. None of the patients developed antibodies against GLM during induction treatment. After the induction phase, 12 out of 19 patients (63%) achieved an endoscopic response. Median AUC at week 2 and 6 was higher in endoscopic responders compared to non-responders. Median GLM trough concentrations at week 2 and 6 were higher in endoscopic responders compared to non-responders (Table 1). Correlations between GLM trough concentrations and AUCs at week 2 (Pearson correlation coefficient: 0.86, P < 0.001) and week 6 (Pearson correlation coefficient: 0.81, P < 0.001) were statistically significant. Despite a low area under the ROC-curve (AUCROC), a GLM trough concentration ≥3.3 mg/L at week 2 (AUROC: 0.75, 95% CI: 0.526–0.974, sensitivity: 67%, specificity: 71%) was associated with endoscopic response after the induction phase.

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.5 mg/L at week 6 is associated with improved endoscopic outcomes.

References:
Hypothetical I/II were global trials of the efficacy and safety of bezlotoxumab (bezlo: a human anti-C. difficile toxin B) in patients with CDI who were at risk for recurrence (rCDI) and frequently experience severe and recurrent episodes. MODIFY I/II were global trials of the efficacy and safety of bezlotoxumab in patients with primary or recurrent CDI given antibacterial drug treatment for CDI. Participants with IBD and CDI enrolled in the MODIFY trials were younger, more likely to be diagnosed with CDI as an outpatient, to be immunocompromised, and to have a higher rate of mucosal healing vs adalimumab in TNFi-naive patients. A higher proportion of participants with rCDI in the no bezlo group compared with the bezlo group and there was a higher proportion of participants with rCDI in the no bezlo group compared with the bezlo group. In IBD patients who received bezlo occurred after week 4 (3 of 4). The efficacy of bezlo in preventing rCDI may extend to patients with IBD, but additional data are needed due to the limited cohort size.

Aims & Methods: We analyzed the success of fecal microbiota transfer (FMT) via encapsulated microbial or via endoscopic jejunal application to 14 patients. Stool samples for FMT preparation derived from three unrelated healthy donors. Patients were assigned to receive 200 mg FIL or placebo. One patient experienced relapse of IBD, this patient received IFX-biosimilar. 2 patients experienced a SAE, none were related to the study drug.

Conclusion: This is the first double blind randomized clinical trial that compares encapsulated vs. endoscopic jejunal application to 14 patients. The preliminary results show that switching from IFX-biological to IFX-biosimilar is feasible and safe. Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Ustekinumab (UST) has been shown to induce and maintain clinical response and remission in moderate to severe Crohn’s disease (CD) in 2

induction [(UNITI-1 (anti-TNF failures) and UNITI-2 (anti-TNF non-failures) and 1 maintenance (IM-UNITI)] randomized, placebo controlled Phase 3 trials. We evaluated the efficacy (response and remission) for all patients who received an intravenous (IV) induction dose of approximately 6 mg/kg, including responders (CDAI decrease ≥100) and non-responders, 8 weeks after the first UST maintenance dose of 90 mg subcutaneous (SC), i.e. 16 weeks from the IV induction dose.

**Aims & Methods:** Patients achieving clinical response 8 weeks after a single IV induction dose were randomized to SC placebo (PBO), UST 90 mg every 12 weeks (q12w) or every 8 weeks (q8w). UST patients not in clinical response 8 weeks after the IV induction dose were given UST 90 mg SC and if in clinical response 8 weeks later were continued on 90 mg SC q8w dosing. A total of 458 patients were exposed to an IV induction dose of 6 mg/kg (UNITI-1, N = 249 and in UNITI-2, N = 209) with a response rate at week 8 of 37.8% and 57.9% vs. PBO response rate of 20.2% and 32.1% respectively. The remission rate at week 8 in UNITI-1 and UNITI-2 was 20.9% and 40.7% vs. PBO of 7.3% and 19.6% respectively. For this evaluation, the response and remission status of the entire population exposed to an IV induction dose of 6 mg/kg of UST was evaluated 8 weeks after the first subcutaneous maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

**Results:** Of the 219 patients not in clinical response in UNITI 1&2, 37.6% and 60.4% respectively were in clinical response 8 weeks after the first maintenance UST dose (90 mg SC). Evaluating all patients exposed to 6 mg/kg IV UST induction, response rates 8 weeks after the first subcutaneous injection (16 weeks after the IV induction dose) for UNITI-1&2 are 47.4% and 73.7% respectively (see table for response and remission rate). Similar assessments were calculated in the sub-population who were anti-TNF naïve upon enrolment into UNITI-2.

**Response rates and Remission rates for all patients 16 weeks after induction of 6mg/kg IV UST**

</tbody>
</table>

**Conclusion:** These numbers at week 16 are expected to reflect real-world experience in patients who receive the induction dose and one additional maintenance dose 8 weeks later. The resulting rates of response and remission are higher than previously reported in the induction studies across all populations (anti-TNF non-failures and anti-TNF failures). About 73% of anti-TNF non-failures attain clinical response and over half are in remission. The data support the clinical rationale for providing at least one SC maintenance dose of ustekinumab irrespective of clinical response 8 weeks after IV induction.

Introduction: Biologics such as infliximab (IFX) (an anti-TNF) and vedolizumab (VDZ) (anti-integrin) are treatment options for patients with moderate-to-severely active inflammatory bowel disease (IBD), who have failed conventional therapy.

Aims & Methods: Our aim was to compare time to treatment discontinuation, flares, and hospitalisations among patients with IBD initiating VDZ versus IFX who were biologic-naïve. All patients with IBD (ulcerative colitis or Crohn’s disease [CD]) who initiated biologic treatment with VDZ or IFX between 01/05/2014 and 22/02/2016 were identified in the US Explorys Universe database; the first infusion was deemed the index date. Analyses focused on patients who: (1) successfully completed induction therapy (≥3 infusions within 98 days of index date); (2) were ≥18 years of age at index; (3) had ≥365 days of medical history prior to index (“baseline”); and (4) had 365 days of follow-up after the index date. VDZ initiators were matched to IFX initiators (1:3) using propensity scores. Kaplan-Meier Method was used to compare median time to discontinuation of VDZ and IFX during follow-up, defined as the first of either: no receipt of biologic ≤90 days of previous infusion, or switch to another biologic. Similar method was also used to compare median time to IBD-related hospitalisations, surgeries, and flares (defined as use of intravenous steroids), respectively. Interquartile range (IQR) was also calculated.

Results: 105 VDZ initiators were matched to 315 IFX initiators. Baseline characteristics of both cohorts are described in Table 1. CD accounted for ≥60% of patients in each cohort. Five percent of patients in both cohorts had received corticosteroids; 20% of VDZ vs. 38% of IFX initiators received an immunosuppressive therapy. Median time since diagnosis was 2.4 years for VDZ initiators and 1.9 years for IFX initiators. Median time to discontinuation was 244 (IQR: 194–307 and IFX: 190–300) days in both cohorts. Median time to first IBD-related hospitalisation was 153 (IQR: 78–209) days for VDZ initiators vs. 98 (IQR: 45–168) days for IFX initiators. For IBD-related flares, median time was 111 (IQR: 40–226) days for VDZ initiators vs. 93 (IQR: 35–182) days for IFX initiators.

Conclusion: Among biologic-naïve IBD patients, there was a trend toward prolonged median times to first IBD-related hospitalization or first flare with VDZ compared to IFX. The median time to discontinuation was comparable between the therapies. Future studies should examine comparative effectiveness outcomes in a larger cohort over a longer follow-up period.

Khalid: Employee of Takeda Development Centre Ltd.
Aims & Methods: Remarkably, ROS have been involved in the transcriptional regulation of CD80 gene expression in the early stages of colonic carcinogenesis. We recently showed that expression of the co-stimulatory molecule CD80 on epithelial cells has a critical role during the immune surveillance process occurring in colon carcinogenesis. In CT26 cells ROS-generating agents (Antimycin A and H2O2) caused a significant inhibition of CD80 expression (p < 0.001) but not by NF-kB pharmacological inhibition. In vivo administration of N-acetyl cysteine significantly reduced AOM-induced CD80, MHC-I and MHC-II up-regulation in colonic epithelial cells (p = 0.001) and protein level (p < 0.001). H2O2-induced CD80 up-regulation in colonic epithelial cells was significantly inhibited by N-acetyl cysteine (p = 0.001) but not by NF-kB pharmacological inhibition. In vivo administration of N-acetylcysteine significantly reduced AOM-induced CD80, MHC-I and MHC-II up-regulation in colonic epithelial cells (p = 0.001, p < 0.001, respectively). Moreover, CD8+CD28+, CD8+CD69+, CD4+CD25+ T-cells in colonic mucosa were significantly lower in AOM-NAC mice than AOM mice (p = 0.08, p = 0.03 and p = 0.01, respectively). Conclusion: All in all, our data support the hypothesis that oxidative stress promotes the antigen presenting function of colonic epithelial cells by inducing CD80 in the early stages of colonic carcinogenesis. ROS-mediated CD80 up-regulation in colonic epithelial cells relies on the p38MAPK pathway in vitro.

Introduction: Altered immune activity and gut microbiota alterations are proposed to be important factors in the pathophysiology of irritable bowel syndrome (IBS), but the relevance for symptoms is unclear.

Aims & Methods: We aimed to determine if colonic antimicrobial gene expression profiles differ between IBS and healthy subjects and if potential alterations are linked to immune activity or gut microbiota composition. The expression of 84 key antimicrobial genes in sigmoid colon biopsies from patients with IBS, defined as either immuno-active or immuno-norm based on systemic and mucosal cytokine profiles (Bennet et. al Am J Gastro, 2016), and healthy subjects was assessed by Human Antibacterial Response RT2 Profiler PCR Array. Targeted 16S rDNA pyrosequencing was performed on faecal microbiota. To identify discrimination profiles based on multiple variables between IBS patients and healthy subjects, orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection > 0.7 was performed.

Results: Table 1: Differences in mucosal antimicrobial mRNA expression between IBS (Immuno-active and Immuno-norm) and healthy subjects.

Data presented as p-values (Mann-Whitney t-test). '*' ' = non significant. We included 31 IBS patients (16 females, median age 32 (25-44) years) and 16 healthy subjects (8 females, median age 27 (24-30) years). An OPLS-DA model demonstrated that the antimicrobial profiles differed between IBS and healthy subjects (R² = 0.54, Q² = 0.16). The mucosal mRNA expression of 14 antimicrobial genes was downregulated, while one gene was upregulated in IBS patients compared to healthy subjects (Table 1). Antimicrobial profiles did not differ between IBS patients subtyped according to their predominant bowel habit (R² = 0.02). An OPLS-DA model showed discrimination between immunologically relevant IBS and healthy subjects, orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection > 0.7 was performed.
Receptor Superfamily Member 1A (TNFRSF1A) with Bifidobacterium (r = 0.8, P < 0.05).

Conclusion: The intestinal antimicrobial gene profiles differ between subsets of IBS patients and healthy subjects. An altered ability to recognise microbiota associated with immune activity and the relative abundance of gut bacteria may play a role in the complex pathophysiology of IBS.

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

Aims & Methods: We aimed to investigate the effect of internal and external drainage on the bile duct external biliary barrier function studies regarding this topic were limited [4–7].

Methods: We aimed to investigate the effect of internal and external drainage on the bile duct external biliary barrier function studies regarding this topic were limited [4–7].

Results: After bile duct ligation, the injuries of the intestinal mucosa were obvious in OJ group with thinner mucosa, sparser villi, destruction of the epithelial layer accompanied by inflammation cell infiltration. The expression of IgA mRNA and plgR mRNA (P < 0.05). There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Higher prescriptions and longer duration exposure of antibiotics might play a significant role in the colorectal carcinogenesis [1–2]. Many environmental factors (e.g. diet and lifestyle) that altered the gut microbiota might be involved in the development of colorectal cancer[3]. Antibiotics are able to shift the gut microbiota by altering bacterial composition and functions. The overuse of antibiotics might be associated with severe infections, such as severe infections, obesity, inflammatory bowel disease. Similarly, it is plausible to hypothesize that overuse of antibiotic might be linked to CRC by altering the colorectal microbiota. However, the relationship between antibiotic and CRC was unclear and studies regarding this topic were limited [4–7].

Aims & Methods: To evaluate the association between use of antibiotic and the risk of developing colorectal cancer, a systematic literature search was conducted using PubMed, EMBASE, Web of science and Cochrane library to identify related studies published before October 2016. Two independent investigators screened and extracted data from included articles. A random-effects model was adopted to calculate overall odds ratio (OR) and 95% confidence interval (CI).

Results: From initial search, we identified four case-control studies and finally 11 studies were included in the meta-analysis. Compared with no/low use of antibiotics, high prescriptions of antibiotics were significantly associated with an excess cancer risk (OR = 1.11, 95%CI 1.01–1.21). There was a significant heterogeneity across studies (I² = 62.1%, P = 0.048). Longer duration of antibiotics was also significantly linked to increased risk of CRC (OR = 1.14, 95%CI 1.03–1.25) with no significant heterogeneity (I² = 39.6%, P = 0.191). There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Higher prescriptions and longer duration exposure of antibiotics were associated with increased risk of developing colorectal cancer. Further studies are needed to verify our results and explore underlying mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0419 COMPARATIVE EFFECT OF XYLOGLUCAN ASSOCIATIONS WITH COMPOUNDS FROM ANIMAL OR ALGAE ORIGIN ON LPS-INDUCED ENTERITIS IN RATS

H. Eutamene, C. Harkat, V. Theodorou
Unite De Neuro-gastroenterology & Nutrition, Toxoulm UMR 1331 INRA/URPS- INPT-El-Purpan, Toulouse/France

Contact E-mail Address: helene.eutamene@inra.fr

Introduction: Xyloglucan (XG) is a film-forming agent exhibiting protective effects against diarrhea linked to infectious gastroenteritis in humans; further in animal models, xyloglucan efficacy against cholera-toxin-induced diarrhea was prolonged when this mucoprotective agent is associated with gelatin from animal origin. The use of compounds from animal source in galenic formulations is nowadays questionable.

Aims & Methods: Thus, in this study, we aimed at comparing the efficacy of XG associations with gelatin vs XG associations with gelose a mucoprotective agent with origin on LPS-induced enteritis in rats. Since LPS-induced enteritis is characterized by increased intestinal epithelial permeability and mucosal inflammation, the efficacy of xyloglucan associations was evaluated by measurement of these two parameters. Male Wistar rats (200-250g) were orally treated with either XG (10 mg/kg) + gelatin (25 mg/kg) or XG (10 mg/kg) + gelose (25 mg/kg) or XG (10 mg/kg) + gelose (50 mg/kg) or vehicle (NaCl 0.9%) 3h before intraperitoneal (IP) administration of LPS from E. coli (1 mg/kg). Six hours later after LPS administration, the animals were sacrificed and strips of jejunum were collected in order to evaluate (i) intestinal epithelial paracellular permeability to FITC-dextran 4kD in Ussing chambers and (ii) mucosal inflammatory response by myeloperoxidase (MPO) activity measurement.

Introduction: Recently, accumulating evidence suggested that the dysbiosis of the intestinal microbiota was associated with increased risk of colorectal cancer and might play a significant role in the colorectal carcinogenesis [1–2]. Many environmental factors (e.g. diet and lifestyle) that altered the gut microbiota might be involved in the development of colorectal cancer[3]. Antibiotics are able to shift the gut microbiota by altering bacterial composition and functions. The overuse of antibiotics might be associated with severe infections, such as severe infections, obesity, inflammatory bowel disease. Similarly, it is plausible to hypothesize that overuse of antibiotic might be linked to CRC by altering the colorectal microbiota. However, the relationship between antibiotic and CRC was unclear and studies regarding this topic were limited [4–7].

Aims & Methods: To evaluate the association between use of antibiotic and the risk of developing colorectal cancer, a systematic literature search was conducted using PubMed, EMBASE, Web of science and Cochrane library to identify related studies published before October 2016. Two independent investigators screened and extracted data from included articles. A random-effects model was adopted to calculate overall odds ratio (OR) and 95% confidence interval (CI).

Results: From initial search, we identified four case-control studies and finally 11 studies were included in the meta-analysis. References
Results: Compared with control, LPS administration induced a significant increase (p < 0.05) of intestinal paracellular permeability (53.0 ± 4.9 vs 181.6 ± 21.1 pmol/cm² respectively) associated with jejunal mucosal inflammation (302.1 ± 9.5 vs 655.6 ± 108.9 U MPO/g protein, respectively). XG (10 mg/kg) + gelose at the lowest dose (25 mg/kg) failed to reverse the intestinal hyperpermeability and mucosal inflammation induced by LPS. In contrast, XG (10 mg/kg) + gelatin (25 mg/kg) and XG (10 mg/kg) + gelose at 50 mg/kg significantly (p < 0.01) and equally prevented LPS-induced hyperpermeability (34.8 ± 2.8, 38.7 ± 3.9 vs 181.6 ± 21.1 pmol/cm² respectively) and jejunal inflammation (277.0 ± 32.2, 286.2 ± 28.8 vs 655.6 ± 108.9 U MPO/g protein respectively).

Conclusion: This study shows that oral treatment with xyloglucan associated with gelose at 50 mg/kg has similar protective effects on LPS-induced enteritis in rats than xyloglucan associated with gelatin. These data demonstrate that algae is an effective and safe substitute for replacing compounds from animal origin in xyloglucan mucoprotectant formulations.

2. Jimenez Garcia P, Anda M, et al. Epidemiology and clinical characteristics of cytomegalovirus colitis in immunocompetent hosts included 44 patients and noted advanced age, male gender, presence of immune-modulating comorbidities and need of surgical intervention negatively influencing survival in 2005 [6]. The case number of CMV colitis in immunocompetent patients seemed increasing in our hospital these years. There was no single study showing comprehensive clinical characteristics, identifying the independent factors of in-hospital mortality and comparing the differences between immunocompetent and compromised patients with CMV colitis. Therefore, we tried to clarify the issue in this study.

Aims & Methods: We enrolled 42 immunocompetent patients and 27 immunocompromised patients with CMV colitis diagnosed by immunohistochemistry stain between April 2002 and December 2016 in Linkou Chang Gung Memorial Hospital, a 3383-bed tertiary medical center and referral center in Taiwan. We analyzed the risk factors of in-hospital mortality and overall survival. Furthermore, we compared the clinical differences between immunocompetent and immunocompromised patients with CMV colitis.

Results: Early diagnosis (before 9 days) was independent predictor of in-hospital mortality in CMV colitis patients. ICU admission (P = 0.010), requisite days of diagnosis >9 days after admission (P = 0.018), shock (P = 0.001), respiratory failure (P = 0.033), hemoglobin < 10 g/dL (P = 0.002), Creatinine ≥ 1.7 mg/dL (P = 0.004) and CRP ≥ 59 mg/dL (P = 0.011) negatively impacted on overall survival. There were older and more comorbidities in immunocompetent group. However, the in-hospital mortality rate and overall survival rate was similar to immunocompromised group. Besides, Clostridium difficile infection or sepsis didn’t affect in-hospital mortality rate and overall survival rate neither. Melena was first and most common symptom in immunocompetent group, but diarrhea in the other.

Aims & Methods: The aim of this study was to assess in-hospital delay of surgery and its impact on the incidence of complicated appendicitis. PubMed and EMBASE were searched from 1990 to July 2016. Outcome measures of interest were complicated appendicitis, surgical site infections or mortality. All studies reporting surgically treated patients with one of these outcome measures in two or more predefined time intervals were included. Adjusted odds ratios were pooled using forest plots if possible. All unadjusted data was pooled using generalized linear mixed models.

Results: Forty-five studies with 152,314 patients were included. Pooled adjusted odds ratios revealed no significantly higher risk for complicated appendicitis when delaying appendectomy for 6 to 12 hours or 13 to 24 hours; odds ratio 1.07 (95% CI 0.986-1.17) and 1.09 (95% CI 0.95-1.28), respectively. For a delay of one day or more, the adjusted odds ratio was 1.13 (95% CI 1.01-1.26, P = 0.01). In-hospital delay of surgery for acute appendicitis has been subject of a large number of studies. However, consensus about the consequences of delaying appendectomy is lacking, which is reflected in variety or absence of recommendations in guidelines.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We reviewed a 10-year cumulative regional TB database in an university teaching hospital covering an urban multi-ethnic population to report clinical details of A-TB and results on this unusual condition. A clinical review of patients diagnosed for A-TB between 2006 to 2016 in a single tertiary centre in Hong Kong was conducted. A central surveillance database managed by Respiratory Physicians of the Hong Kong Tuberculosis Control Branch of Health Department of the Government of Hong Kong Special Administrative Region was used to identify patients with A-TB. We reviewed clinical data from electronic records including radiology, chemical pathology, histopathology, endoscopy databases, surgical notes and letters.

Results: Of 41 patients (M = 22; 54%; mean age 42y (SD ± 17y) identified with A-TB, 41% (17) were Pakistani, 15% (6) were other Asian, 19% (8) were Afro-Asian, 15% (6) were other Asian, 19% (8) were Afro-Asian, 15% (6) were other Asian, 19% (8) were Afro-Asian, 15% (6) were other Asian, 19% (8) were Afro-Asian, 15% (6) were other Asian, 19% (8) were Afro-

Aims & Methods: The traditional fear that every acute appendicitis will eventually perforate leads to prompt surgery, but this fear may be outdated. In-hospital delay of surgery for acute appendicitis has been subject of a large number of studies. However, consensus about the consequences of delaying appendectomy is lacking, which is reflected in variety or absence of recommendations in guidelines.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
notably contributed by elderly patients, of which the incidence has increased by threefold over the period. Recurrence at 60 days increased from 5.7% in 2006 to 9.1% in 2014 (P$_{mult}$ = 0.001). The increased use of proton-pump inhibitors accounted for 58.8% of the surge.

**Conclusion:** The incidence of *C. difficile* infection has increased more than threefold, and was associated with an increased disease recurrence and use of proton-pump inhibitors. Our results suggest need for further surveillance in Asia which hovers half of the world’s population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jsoso@hanmail.net

Introduction: Post-polypectomy bleeding (PPB) is the most common complication following polypectomy, especially in cases with large pedunculated polyps. Although the clip application before snare polypectomy may decrease PPB, there were few prospective randomized studies to confirm the efficacy of prophylactic clip. This present study was conducted to investigate whether prophylactic clip application for large pedunculated colorectal polyps could decrease PPB and to evaluate associated risk factors of PPB.

**Aims & Methods:** We enrolled 137 pedunculated polyps (≥1 cm in size) in 116 patients (62 M/F). Polyps were randomized into the two groups with or without prophylactic clip application. Immediate PPB was defined as bleeding that continued for over 30 seconds from the polypectomy site and graded from grade 1 to 4, and delayed bleeding was defined as a history of hematochezia from the day of procedure to the day of first visit of outpatient clinic. The primary outcome was post-polypectomy bleeding. This present study was confirmed by emergency endoscopy or a decrease in the hemoglobin level of ≥2 g/dl with hematochezia even if the bleeding site was not identified.

**Results:** Between January 2015 and November 2016, a total of 30 consecutive patients (M/F: 26/4, 69.9±11.3 years) were enrolled in this study after written informed consent was obtained. A total of 81 lesions (tumor diameter: 5.4±2.9 mm, adenoma 70, others 10, lost lesion 1, number of prophylactic clips: 4.9±2.2) were treated by polypectomy/EMR. Four patients experienced post-polypectomy bleeding (4.5%: 3/67) 3-11 days after the procedure, although no cases required blood transfusion. In 3 of these bleeding cases, a single responsible site was identified by emergency endoscopy. Therefore, the confirmed rate of post-polypectomy/EMR bleeding based on the number of resected lesions was 3.9% (3/76), but may range to 9.9% (8/81). There were no other adverse events.

**Conclusion:** The rate of post-colon polypectomy/EMR bleeding in patients without discontinuation of warfarin single therapy was comparable to that in patients undergoing HR. Concomitant use of antithrombotic medication (warfarin) without discontinuation of warfarin in patients who received warfarin for the purpose of prevention of thrombosis was prospectively enrolled and underwent colon polypectomy or EMR without discontinuation of warfarin. Conventional clip closure of the resection site was performed in all cases and oral diet was resumed 2 days after the procedure. The primary outcome was post-polypectomy/EMR bleeding that was confirmed by emergency endoscopy or a decrease in the hemoglobin level of ≥2 g/dl with hematochezia even if the bleeding site was not identified.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: The incidence of acute lower gastrointestinal bleeding (LGB) is estimated at 21 adults per 100,000 person years and in males (82.1%) in the anticoagulants group were higher than those in the normal group (67.2±11.2 years and 64.1%). There was no difference between the groups in size of polyp and morphology. In the anticoagulants group, 34 patients received heparin bridged thromboplatin (warfarin, antithrombotic drug, non-steroidal anti-inflammatory drug) therapy and 33 patients discontinued anticoagulants (warfarin 8, warfarin + antiplatelet 3, rivaroxaban 1 and 33 patients discontinued anticoagulants (warfarin 8, rivaroxaban 10, apixaban 8, dabigatran 4, edoxaban 2). The incidence of PPC was no difference between two groups (1, 1 patient, respectively). There was no difference between the groups in age, sex, size of polyp and morphology. Recurrent bleeding didn’t occur. In the discontinued group, 1 patient developed acute myocardial infarction in next day after colonoscopy polypectomy.

Conclusion: Patients taking anticoagulants have an increased risk of PPC compared with the control even if the anticoagulants are discontinued. Heparin-bridge therapy might be responsible for increased PPC in patients taking anticoagulants.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
**RESULTS:** Patient characteristics such as sex, age, anti-platelet therapy, location of bleeding and bleeding after endoscopic procedure did not have significant difference in both groups. Upper gastrointestinal bleeding occurred 6 (33.3%) of DOAC group and 12 (60.0%) of Warfarin group (11.1 ± 0.7 g/dl vs 9.6 ± 0.4 g/dl, p = 0.06) and international normalized ratio of prothrombin time (PT-INR) was significantly prolonged in Warfarin group (1.51 ± 0.36 vs 2.50 ± 0.20, p = 0.02). CR transfusion rate had no significant difference in both group, but FFP tended to be transfused at high rate in Warfarin group (16.7% vs 33.3%, p = 0.16). Re-bleeding rate during hospitalization had no significant difference in both group, but tended to be higher in Warfarin group (5.6% vs 0.0%, p = 0.11). The duration from bleeding to endoscopy tended to be longer in Warfarin group (9.5 ± 5.5 days vs 3.0 ± 3.0 days, p = 0.05), but the duration from endoscopy to discharge was significantly longer in Warfarin group (9.0 ± 5.5 days vs 23.0 ± 3.0 days, p = 0.03). The duration from bleeding to discharge was significantly longer in Warfarin group (9.8 ± 5.4 days vs 24.2 ± 3.0 days, p = 0.02). Thrombotic embolism during hospitalization occurred only 1 (1.7%) of Warfarin group.

**Conclusions:** The duration of hospitalization was significantly shorter in the group of patients with gastrointestinal bleeding, and the rate of rebleeding and re-bleeding tended to be lower in DOAC group. This study showed that DOAC may be more superior to Warfarin as an anticoagulation for atrial fibrillation and deep vein thrombosis at the quality of life (QOL) in the patients with gastrointestinal bleeding.

**Disclosures of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colorectal cancer (CRC) is an imperfect tool. Several publications confirm that CRC can be subcategorized into interval cancers (identified prior to the next recommended screening or surveillance procedure) and non-interval cancers (identified at or after a recommended screening or surveillance interval, or where no subsequent screening or surveillance interval was recommended, up to 10 years following the colonoscopy). The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy. The term “interval cancer” has often been used for cancers appearing after a negative colonoscopy. However, this is primarily a screening term (1). Post-colonoscopy colorectal cancer (PCRC) is a broader term for cancers detected after a negative colonoscopy in any setting, including screening (2). Although there is overlap between these terms, they are not synonymous. PCRC can be thought of as the overarching term. PCRC can be subcategorized into interval cancers and non-interval cancers (3). The final output consisted of 391 articles. Proposed statements were subjected to anonymous voting via e-correspondence. Each statement was scored on an scale of 1 (strongly agree) to 5 (strongly disagree).

**Aims & Methods:** The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy or computed tomographic colonography (post-colonoscopy/post-imaging colorectal cancers - PCRC/PICRC respectively). We based our methodology on The Appraisal of Guidelines for Research and Evaluation (AGREE II) tool (4). An international multidisciplinary team (gastroenterologists, pathologists, epidemiologists, a radiologist and a patient representative) were involved in the World Endoscopy Organisation (WEO); the final panel consisted of 20 voting members. The following topics were addressed by 2 working groups (WGs):

1. **Aetiology WG**
   a. Terminology of aetiology categories
   b. Risk factors/potential explanations of PCRC
   c. How to ascribe potential explanations
   d. Minimal colonoscopy, history and radiology datasets to examine PCRC
   e. Molecular tests to be performed to examine PCRC
   f. Prevention of PCRC in high-risk groups
2. **Performance WG**
   a. PCRC calculation & reporting
   b. PCRC monitoring
   c. PCRC papers peer-review
   d. Post-imaging CRC A literature search was performed in MEDLINE and Cochrane using terms “colorectal cancer AND interval cancer”, “healthcare quality assurance AND colorectal cancer” and “healthcare quality assurance AND colorectal cancer AND interval cancer”. The final output consisted of 391 articles. Proposed statements were subjected to anonymous voting via e-correspondence. Each statement was scored on an scale of 1 (strongly agree) to 3 (strongly disagree).
5 (strongly disagree). A modified Delphi process was followed; consensus recommendation. In areas of continuing disagreement, a recommendation for or against a particular statement required both >50% of participants in favour and <20% preferring the comparator. Failure to meet this resulted in no recommendation. The GRADE system for rating evidence and strength of recommendations was applied to final statements.

Results: The final output consists of 21 statements providing guidance on key aspects of PCCRC/PICRC, namely definitions, terminology, qualitative review/ aetiology attribution and quantitative assessment of cases. A Root-Cause Analysis checklist as well as a PCCRC/PICRC manuscript peer-review checklist were also developed.

Conclusion: This is the first consensus aimed to standardise terminology around PCCRC. Each previous study defined PCCRC differently, making its use for benchmarking purposes impossible. This consensus presents a methodology for analysis of causation of PCCRC/PICRC and defines its potential role as a key quality indicator, providing recommendations for future investigators, policy makers, services and patients.

References
FOBT is two-fold higher in gFOBT than in FIT, which supports the use of FIT over gFOBT as screening tool test. However, for every three FIT-detected CRCs, still one CRC is missed, which highlights the importance to adequately inform screenees about the risk of developing a colorectal carcinoma after a negative FIT.

Disclosure of Interest: E. Wiener: I declare no competing interests. All other authors have declared no conflicts of interest.

P0439 MEASURES OF BODY COMPOSITION AND GENDER DIFFERENCES IN RISK FOR COLORECTAL CANCER – A POPULATION-BASED COHORT STUDY

Introduction: Age and family history of colorectal cancer (CRC) are the strongest risk factors for CRC. Obesity, commonly assessed based on body mass index (BMI), is associated with an increased risk for CRC in men but the association is weaker in women and differs between studies. We investigated which of the following body composition measures: BMI, waist-hip ratio (WHR), waist-height ratio (WHHR), weight-height ratio (WHRR), A Body Shape Index (ABSI) and percent body fat that best predict the development of CRC in men and women.

Aims & Methods: We used data from Malmö Diet and Cancer cohort in Sweden, including 16,840 women and 10,903 men (mean age, 58.1 years at baseline), followed for a median of 19.8 years. We identified cases with CRC until the end of 2014 using national Swedish registers. Hazard ratios (HR) for CRC, colon cancer (CC) and rectal cancer (RC) per one standard deviation increase in each body composition measure respectively were calculated using Cox regression models, stratified by sex and adjusted for age, education and health behaviors. WC was the only measure associated with an increased risk for CRC, CC nor RC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: T helper 17 (Th17) cells participate in the progression of various cancers. Both tumor-promoting and tumor-suppressing effect have been reported. The role of Th17 cells in colorectal cancer (CRC) remains controversial and the specific mechanism of how Th17 cells affect the development of CRC remains to be explored.

Aims & Methods: The study aimed to clarify the role of Th17 cells in CRC and identify the underlying molecular mechanisms. The percentage of Th17 cells and IL-17 expression were evaluated via flow cytometry, enzyme-linked immunosorbent assay (ELISA) in tissue samples and peripheral blood. Effects and underlying molecular mechanisms of IL-17 cells on epithelial-mesenchymal transition (EMT) process were explored in vitro using IL-17 transfection and in nude mice by implanting IL-17 overexpressed CRC cells. To detect the expression of Th17 cells in EMT process, SW480 cells were co-cultured with Th17 cells via transwell system. Cancer signaling phospho antibody microarray was used to explore the potential signaling pathway. The clinical significance of Th17 cells was investigated in tissue microarrays containing CRC tissue samples from 90 patients following surgery using immunohistochemistry.

Results: A higher percentage of Th17 cells and serum IL-17 level were found in CRC patients than healthy controls, and Th17 cells presented a gradual upward trend in normal epithelium-adenoma-carcinoma sequence. The overexpression of IL-17 significantly promoted cell proliferation and induced apoptosis in vitro and in vivo. IL-17 overexpression reduced the expression of E-cadherin and induced the expression of Snail, β-catenin, and Vimentin in both SW480 cells and tumor xenografts, suggesting that IL-17 could induce the EMT process of CRC. When co-cultured with SW480 cells with Th17 cells, we found Th17 cells could directly promote the EMT process of tumor cells. Furthermore, using cancer signaling phospho antibody microarray, we found that PI3K/AKT signaling pathway played a key role in the regulation of EMT. EMT process could be reversed by LY294002 and IL-17 mAb intervention, suggesting that IL-17/Pi3K/AKT/Snail pathway could promote EMT process and facilitate tumor progression via activating IL-17/Pi3K/AKT/Snail signaling pathway in CRC.

Disclosures of Interest: All authors have declared no conflicts of interest.

P0442 MUCARINIC-3 RECEPTOR TARGETED MIARNAS ARE INVOLVED IN BILE ACID-INDUCED PROLIFERATION ON H508 COLON CANCER CELL LINE

F. Tékín, C. Aktan, N. Oruc, O. Onutezmi
Gastroenterology, Ege University Medical School, Izmir/Turkey

Contact E-mail Address: drtekinfaith@gmail.com

Introduction: Studies with the colon cancer cell lines which express muscarinic-3 (M3) receptors showed that taunine conjugates of lithocholic acid, but not other bile acids, bind to M3 receptors, and stimulate an increase in cell proliferation. On the other hand, many microRNAs (miRNAs) are involved in colon carcino- genesis. However, the interaction of bile acid-M3 receptors and miRNAs and their potential effects in colon carcinogenesis remains to be elucidated.

Aims & Methods: For the first time in the literature, we examined the possible role of M3 receptor-targeted miRNAs on two human colon cancer cell lines: H508, which expresses M3 receptors, and SNU-C4, which does not. Cell prolif- eration for 6 days after sodium taurocholoholat (ST) and atropin (A) treatment was analyzed by WST-1 method. Expression of M3 receptor gene at mRNA level was analysed by qPCR, and at protein level by Western Blot method. Apoptotic experiments were analyzed by Annexin V assay. MiRNAs which possibly target- ed M3 receptors were identified by in silico analyses. The methods were repeated three times, and the average values were calculated.

Results: When compared to SNU-C4 cells, M3 receptor gene expression was found to be increased 70-fold on H508 cells. After a 6-day incubation, maximum H508 cell proliferation (300%) was achieved on 5th day with a dose of 300 μM ST, inhibited by a dose of 1 μM A. In contrast, the SNU-C4 cells showed no significant change in cellular proliferation. Treatment of H508 cells with ST caused a decrease (2.5-fold) of M3 receptor gene expression, however, no change of M3 receptor at protein level was seen. No changes in apoptosis on both colon cancer cell lines were observed. Of 25 M3 receptor-targeted miRNAs, expression levels altered in 9; 6 of them were up-regulated (hsa-miR-129-5p, hsa-miR-30c-5p, hsa-miR-224-5p, hsa-miR-30b-5p, hsa-miR-522-3p, hsa-miR-1246) and 3 of them (hsa-miR-30e-5p, hsa-miR-147b, hsa-miR-855-3p) were down- regulated on H508 cells (p < 0.05).

Conclusion: ST interact with M3 receptors which modulate colon cancer cell proliferation on H508 cells. M3 receptor-targeted miRNAs are involved in ST induced proliferation. Whether the use of ursodeoxycholic acid, selective anti-cholinergic agents or other approaches to blocking potential inter- actions of bile acids/salts with neoplastic colonic epithelium may be a useful strategy for colon cancer prevention or treatment remains to be determined.

Introduction: Dyslipidemia and statin use have been associated to colorectal cancer (CRC), but prospective studies have shown controversial results. Dyslipidemia has been thought to have an important role in inflammatory pathways, oxidative stress and insulin resistance, which could contribute to the pathogenesis of cancer. However, findings from prospective studies that have examined the association between serum dyslipidemia (low density lipoprotein cholesterol (LDL), HDL or TG) and colorectal neoplasia have been inconsistent. [1–4] It is unknown whether lipids and lipoproteins cause cancer or are inter- mediate or correlated factors within carcinogenic pathways. Epidemiological studies could be confounded by 3-Hydroxy-3-methylglutaryl-coenzyme A re- ducase inhibitors (statins) use, which might also have a protective effect to CRC. It is unclear whether it is statin use or dyslipidemia that prompted statin use, which may be associated with CRC. Indeed, a large number of epidemiological studies have examined the effect of statins on colorectal cancer risk, with often inconsistent results.[5-6] A Mendelian randomization approach could help to establish a causal relationship between dyslipidemia and CRC.

Aims & Methods: We aimed at determining whether dyslipidemia is causally linked to CRC risk and to explore association of statins with CRC. A case- control study was performed including 1336 CRC cases and 2744 controls (MCC-Spain) between 2008 and 2013. Subjects were administered an epidemiolo- gical questionnaire that included lifetime regular use of prescription drugs. Also, subjects were genotyped with an exome array supplemented with 5000 custom SNPs. We applied the Mendelian randomization approach. The array included 136 SNPs previously shown to be associated with blood lipids levels in GWAS, that were used to build three genetic lipid scores, as the count of risk alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested the association on regular statin use and the genetic lipid scores with logistic regres- sion models, adjusted for potential confounders.

Results: The LDL genetic risk score was significantly associated with statin con- sumption (OR = 1.07, 95% CI 1.05–1.10, p = 4.4e-11). The dyslipidemia genetic risk score was not significantly associated with CRC for either of the target lipid studied. Cases had the same average alleles as controls in all the lipids traits. Statin use was a borderline significant protective factor for CRC (multivariate adjusted OR = 0.83; 95%CI 0.69–1.00, p = 0.049).

Conclusion: Using the Mendelian randomization approach, our study does not support the hypothesis that lipid levels are associated with the risk of CRC. This study does not rule out, however, a possible protective effect of statins in CRC by a mechanism unrelated to lipid levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Long non-coding RNAs (lncRNAs) contribute to different cancers including colorectal cancer (CRC) through influencing cancer-related processes such as cell proliferation, apoptosis, and invasion. Previous studies have shown altered LINC00152 expression in CRC, but the detailed mechanism of its effects during colorectal carcinogenesis and cancer progression is not well studied.

**Aims & Methods:** We studied the effects of LINC00152 to the cell cycle regulation and promoter DNA methylation of several CRC-associated tumor suppressor genes in colon cancer cells. We also analyzed the expression and promoter DNA methylation of LINC00152 and of its regulated molecules in human colonic tissue samples. LINC00152 were silenced in SW480 colon carcinoma cells using Stealth siRNAs. Cells were harvested 48 or 72 hours after transfection. Flow cytometric cell cycle analysis was performed using propidium-iodide staining. Cyclin D1 protein expression was detected using flow cytometry after labeling with anti-cyclin D1 antibody. The effect of LINC00152 silencing to DNA methylation levels of SFRP1, SFRP2, SDC2 and PRIMA1 genes was studied using Methylight technology. Promoter methylation and expression of the above molecules were also studied on human colonic tissue samples.

**Results:** LINC00152 expression was successfully silenced in SW480 cells with 93–98% efficiency. Colorectal cancer cell lines with colorectal dysplasia and carcino-

**Introduction:** Colorectal cancer cells are known to harbor concomitant mutations in KRAS and APC that promote carcinogenesis. Epigenetic dysregulation plays essential roles in the tumorigenesis of KRAS mutant CRC. Our preliminary data demonstrated that simultaneous KRAS gain-of-function mutations in APC-null CRC cells induced the hypermethylation of DNA and histones, an effect driven by metabolic rewiring of glutamine metabolism. We recently unveiled that glutamine metabolism in KRAS-mutant CRC could be rewired by the mitochondrial glutamate transporter, SLCA2A2, a synthetic lethal gene that is silenced in CRC and in vivo. In this study, we investigated the potential role of SLCA2A2-mediated glutaminolysis in regulating DNA and histone methylation in CRC, its underlying mechanisms, and the association of SLCA2A2 with epigenetic dysregulation in human CRC cohorts.

**Aims & Methods:** We aim to (1) evaluate the impact of mutant KRAS on DNA and histone methylation in CRC; (2) examine the role of SLCA2A2 in DNA and histone methylation in KRAS-mutant CRC; (3) elucidate the underlying mechanisms that underlies SLCA2A2-mediated epigenetic dysregulation; and (4) investigate the clinical relevance of the interplay between SLCA2A2 and KRAS mutation in CRC patients. DNA methylation was determined by the Illumina 880K methylation array and Methylight qMSP assays. Histone methylation was determined by the Histone H3 Modification Multiplex Assay Kit and Western blot. U-13C5-Glutamine metabolic labelling and analysis of glutamine metabolism via the TCA cycle was determined by liquid chromatography-mass spectrometry analysis. In clinical samples, SLCA2A2 mRNA was investigated by determining its correlation with CpG Island Methylator Phenotype (CIMP) status and histomorphologic marker (H3K36me2) was evaluated.

**Results:** Using three pairs of isogenic cell lines harbouring wild-type and mutant KRAS (DKS80/WT vs DLD1(mutant); HEK3(WT) vs HCT116(mutant); ICT(WT) vs ICT-KRAS(mutant)), we demonstrated that significant DNA and histone H3 hypermethylation in cell lines expressing mutant KRAS. DNA hypermethylation was associated with the up-regulation of 5-hmC, indicating suppression of DNA demethylation in KRAS mutant CRC cell lines. Metabolomic analysis revealed that KRAS mutation modified glutaminolysis via TCA cycle leading to high succinate and fumarate to α-ketoglutarate (αKG) ratio, which was to pivotal in suppressing the enzymatic activity of dioxygenases such as TETs. Reduced levels in histone demethylation in CRC were observed. Interestingly, simultaneously APC-loss and KRAS activating mutations synergistically up-regulated the expression of SLCA2A2, a key regulator of glutamine metabolism via the TCA cycle. CRISPR-Cas9 mediated knockout of SLCA2A2 suppressed glutaminolysis in KRAS-mutant CRC cell lines, which in turn, reduced the ratio of succinate and fumarate to α-ketoglutarate. The impact of SLCA2A2 knockout on glutaminolysis had a profound effect on epigenetic regulation, as DNA methylation profiling revealed that SLCA2A2 knock-

**Aims & Methods:** We studied the influence of LINC00152 to the cell cycle regulation and promoter DNA methylation of several CRC-associated tumor suppressor genes in colon cancer cells. We also analyzed the expression and promoter DNA methylation of LINC00152 and of its regulated molecules in human colonic tissue samples. LINC00152 were silenced in SW480 colon carcinoma cells using Stealth siRNAs. Cells were harvested 48 or 72 hours after transfection. Flow cytometric cell cycle analysis was performed using propidium-iodide staining. Cyclin D1 protein expression was detected using flow cytometry after labeling with anti-cyclin D1 antibody. The effect of LINC00152 silencing to DNA methylation levels of SFRP1, SFRP2, SDC2 and PRIMA1 genes was studied using Methylight technology. Promoter methylation and expression of the above molecules were also studied on human colonic tissue samples.

**Results:** LINC00152 expression was successfully silenced in SW480 cells with 93–98% efficiency. Colorectal cancer cell lines with colorectal dysplasia and carcino-

Conclusion: SLC25A22 promotes the tumorigenicity of KRAS mutant CRC by driving altered DNA and histone hypomethylation, an effect mediated by increased production of TCA cycle intermediates succinate and fumarate, which inhibits DNA and histone demethylases. SLC25A22 is correlated with CIMP and histone hypermethylation in CRC patients.

Introduction: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein, widely expressed in human tissues, which plays key functions in the regulation of cell survival, proliferation, differentiation and migration. Moreover, deregulated expression of FSTL1 has been described in malignancies but its contribution to carcinogenesis remains controversial.

Aims & Methods: We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR. Cell proliferation and survival and cell cycle were evaluated in human CRC cell lines (i.e., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control RNA using Western blotting, cell counting and flow-cytometry. The expression of proteins involved in cell cycle progression, poly ADP-ribose polymerase (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cell death was evaluated in cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPh by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knockdown caused accumulation of cells in G1 phase of the cell cycle and reduced CRC cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), E2F-1, cyclin E and cyclin-dependent kinase-2 (CdK2), with no modification of early G1 phase proteins (i.e. cyclin D1). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPh abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Introduction: Colon cancer, TP53 mutation is well known to occur in the late phase of colon carcinogenesis as adenoma-carcinoma sequence. Although numerous reports about clinical information of the patients with colon cancer have suggested that TP53 mutation might be related to various malignant potential in malignancy, the malignant potential on malignancy of TP53 mutation in colon cancer is still unknown. Notably, there is no report about a relationship between TP53 mutation and cancer stemness. We therefore aimed to assess the function of TP53 mutation in colon cancer cells, by using recently established lentiviral CRISPR Cas9 system.

Aims & Methods: Two types of TP53 mutation were generated in LS174T cells, which are derived from human colon adenocarcinoma with wild-type TP53 (WT-TP53), by using lentiviral CRISPR Cas9 system. The guide RNAs were designed to bind exon 3 or exon 10 of TP53, respectively. TP53 mutation in LS174T was confirmed by direct sequencing. The expression of TP53 protein was assessed by immunohistochemistry. Loss of function of TP53 was assessed by Nutlin-resistance and the down-regulation of TP53 target genes, suggesting that both mutants induced loss of function of TP53. We then assessed the effect of both TP53 mutants on various malignant potentials, resulting equally in accelerated cell growth, enhanced invasiveness and the resistance against 5-FU treatment compared to WT-TP53. Moreover, both mutants showed more frequent formation of 3D sphere and more expression of Lgr5 than WT-TP53, suggesting the promotion of cancer stemness by TP53 mutation even after being adenocarcinoma.

Conclusion: We for the first time showed the direct effect of TP53 mutation on malignant potential in colon cancer cells. Loss of function of TP53 induced by not only TP53Ex10 but also TP53Ex3 mutation, might promote malignant potentials including cancer stemness at the late phase of carcinogenesis. In general, TP53 mutation with loss of function of TP53 mutation in colon cancer is represented as TP53 mutation. However, negative staining of Lgr5 might also be careful for TP53 mutation to estimate malignant potential in colon cancer, since N-terminal mutation of TP53 in colon cancer has already been reported.

Introduction: Endogenous opioid system is involved in the maintenance of the intestinal homeostasis. Recently, we proved that stimulation of opioid receptors using P-317 – a novel cyclic morphiceptin analog with mu- and kappa-opioid receptor selectivity, decreased apoptosis of acute phase of experimental colitis (induced by dextran sodium sulfate (DSS)) in mice. Chronic inflammation is associated with increased risk of colitis-associated colorectal cancer. Stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type and stage of disease.

Aims & Methods: The aim of our studies was to characterize the role of the endogenous opioid system in pathogenesis and treatment of colitis-associated colorectal cancer using P-317. Colitis-associated colorectal cancer was induced by a single intraperitoneal injection of azoxymethane [AOM] (10 mg/kg) and subsequent addition of DSS (1.5% w/v) into drinking water (week 2, 6, 9). From week 3, P-317 was injected intraperitoneally at the dose of 0.1 mg/kg twice per week and the body weight and clinical score (rectal bleeding, stool consistency) were assessed. After 14 weeks, the necropsy and colonic tissue score was assessed and the samples were collected and used for biochemical, molecular and histological studies.

Results: A significant difference in colorectal tumor development was observed between vehicle- and P-317-treated mice. P-317 significantly increased total number of colonic tumors as well as colon thickness and width after 14 weeks of disease induction. Myeloperoxidase activity, a marker of neutrophil infiltration, was inhibited by P-317 injections. Hematoloid and eosin staining confirmed the anti-tumor activity of P-317 as indicated by histological score connecting the following features: muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption. The expression of IL-1β and TNF-α at mRNA level was decreased in P-317-treated mice as compared to vehicle-treated group.

Conclusion: P-317 may become an important pharmacological tool to study the factors that determine the development of inflammatory bowel disease and to define the role of the endogenous opioid system in chronic colitis and colorectal cancer.

Introduction: Colorectal cancer (CRC) is the third most common type of cancer in men and women, and it’s incidence is increasing in younger population. High mobility group box 1 (HMGBI) expression and subsequent death due to colorectal cancer is associated with its stage 1, 2. Because of its insulin onset, the diagnosis of CRC is usually delayed. However, serological markers can be a relatively easier and cheaper alternative tool for early screening. To find the high risk population using the hmgbi expression and subsequent death, we designed a study to test the sensitivity and specificity of hmgbi expression in colorectal cancer. To do that, we used the hmgbi high-mobility group box 1 (HMGBI) plays a critical role in tumorigenesis, disease progression and metastasis by activation of cancer cells, promotion of tumor angiogenesis, suggesting that HMGBI may be useful as a new biomarker of cancer 1, 2, 3, 4. Studies have shown that HMGBI is over-expressed in various types of cancers, include CRC, and those cases with higher expression of HMGBI are associated with lymphatic metastasis, distant metastasis and poor prognosis 5, 6, 7, 8. Several reports have demonstrated that HMGBI is
