Resistance of the intrinsic layer

\[ R_i = \frac{l^2}{2 \mu_{sp} I_0 \tau_r} \]

where:

\[ \mu_{sp} = \frac{2 \mu_e \mu_h}{\mu_e + \mu_h} \]

FET switches

Basic principle

Low channel resistance – ON state

High channel resistance – OFF state

FET switches

MESFET equivalent circuit and symbol
FET switches

- **FET transfer characteristic**: $I_{DS}$ driven by $V_{GS}$ for given $V_{DS}$ located in the saturation region
- Resistance $r_{DS}$ controlled by the gate bias ($V_{GS}$)

![Diagram showing FET transfer characteristic]

- **Operating points**:
  - High conductivity (low resistance) operating point
  - Low conductivity (high resistance) operating point

![Diagram showing high and low conductivity operating points]

- **Isolation** in FET switches degrades at higher frequencies due to the effect of drain-to-source capacitance ($C_{ds}$)
- **Example**: drain-to-source impedance = 320 $\Omega$ at 10 GHz resulting in an isolation of 10.5 dB between drain and source, with additional degradation at higher frequencies

![Diagram showing drain-to-source impedance and capacitance]

OFF state

$C_{ds} = 0.05$ pF
FET switches

- Gate voltage switches the FET from a small resistive device ($r_{ds\text{ON}}$) to a small capacitive device ($C_{ds\text{OFF}}$).
- Intended to operate passively (no gain).
- Typical $V_{ds}=0$ V (easy to bias).
- Like PIN diodes, the FET switch can be configured in series with transmission line (drain and source act as input or output and vice versa), or shunt with the grounded source.

**FET switches**

**Different designs**

**Series SPDT* switch**

**Shunt SPDT switch**

*Single Pole Double-Throw

Combine series and shunt switches for better performances.
Main performance specifications for RF switches

- Frequency bandwidth (highest and lowest frequency)
- Switching speed (speed of moving to 90% ON or 90% OFF)
- Linearity (pollution of adjacent channels)
- Power handling (RF)
- Power consumption (DC)
- Insertion loss
- Isolation (vital in measurement systems)
- SWR (matching)
- Expected lifetime (big consideration for MEMS switches)
- Driver requirements: DC current / DC voltage, negative polarity

Figure of Merit (FoM) of RF switches

- Rates the switching characteristics of different switch devices
- Figure of Merit = \(1/(2\pi C_{\text{OFF}} R_{\text{ON}})\)
- Higher FoM yields greater bandwidth
- Rule of thumb: FoM/100 yields the highest operating frequency
- FoM of PIN diode >> FoM of FET (Why? Lower OFF-state capacitance for a given ON-resistance)
Figure of Merit (FoM) of RF switches

- PIN diode: $C_{\text{OFF}} \approx 50 \text{ fF}$, $R_{\text{OFF}} \approx 3 \Omega$ @ 5 mA and 1.7 $\Omega$ at 20 mA
  - FoM $\approx 1900$ GHz
- MESFET switch: $C_{\text{OFF}} \approx 400 \text{ fF}$, $R_{\text{OFF}} \approx 1.5 \Omega$ @ 5 mA
  - FoM $\approx 265$ GHz

- MESFET switches work well up to about 26 GHz
- PHEMT switches work well up to about 40 GHz
- PIN diodes work well up to 180 GHz

RF switch modelling

- Use simple models when applicable: resistor in the ON-state (low resistance) and capacitance (low) in the OFF-state
- Electromagnetic simulators can integrate circuit models
  - only valid in a transmission line environment
- OFF-capacitance of a PIN diode is a function of reverse voltage
- More negative voltage yields less capacitance
- Ground inductance and bond-wire inductance should be accounted for
- At X-band frequencies and above, more complex models should be employed:
  - distributed properties of switch devices
  - transmission-line properties of the device due to its physical area
RF switches comparison

- PIN diode switches have lower losses in comparison to FET switches
- Switching speed higher for GaAs FET (< 10 ns)
- FET switches are better for MMIC applications
- PIN diode switches work from tenths of MHz to over 100 GHz (but not at DC)
- FETs can switch from DC to mm-wave frequencies
- FETs: gate terminal decoupled from source and drain
  - No bias tee and blocking capacitors are needed to separate DC bias from RF signal
- PIN diodes: bias tees and blocking capacitors limit usable bandwidth in the UWB applications
- FETs require only a DC voltage for switching, instead of strong DC current
  - Essentially zero DC power consumption, compared to 10 mA (min) to turn on PIN diode
  - Huge advantage in phase array applications with thousands of switch devices needed to control the phase and amplitude of T/R modules

Limitations of semiconductor switches

😊

- Fast, commercially available, low cost, and ruggedness

😢

- Frequency bandwidth upper limits: degradation of insertion loss and isolation at signal frequencies above few GHz
- Breakdown of linearity: adjacent channel power violations when operating at high RF power levels in addition to noise problems
What are MEMS?

- MEMS are Micro Electro-Mechanical Systems
- MEMS typically have both electrical and mechanical components
- As microelectronics has shown, size doesn’t necessarily matter
- First MEMS Publication:
- Pressure sensors were the first MEMS products
  - Si diaphragms and diffused piezo-resistors
- Surface μ-machined accelerometers and flow sensors

Why RF MEMS?

- Miniaturization with no loss of functionality
- Integration to form a monolithic system
- Improved reproducibility, reliability and accuracy
- Exploitation of new physics domains
- Low power
- Fast actuation techniques
- Improved selectivity and sensitivity

Advantages over conventional technologies (PIN diodes, JFET, MESFET....)

- High RF performance (up to mm-waves)
- Near-zero power consumption
- Volume production → low cost
- Miniaturization

Open issues

- Reliability
- Switching speed
- Power handling
Advantages of using MEMS switches over solid state switches (i.e. PIN diodes, MESFETs):
- Can be designed for any frequency (other only good up to a few GHz)
- Can be fabricated on wafer (other require soldering)
- Much less power consumption
- Excellent RF isolation

Disadvantages
- Relatively new technology (10 years old versus 50 years old)
- More complicated
- Packaging is large and expensive
- Slow switch time (microseconds instead of nanoseconds)
- Reliability (best switches reported only good for 100B cycles)
Main issues

Manufacturing

- Outgrowth of “Micromachining”
  Creation of unique physical structures through the use of sacrificial layers resulted in miniature mechanical structures on a substrate (often Silicon)
  - Open circuit / low capacitance dielectric layer
  - Closed circuit / high capacitance

- MEM switch in RF applications
  - Acts as RF switch or capacitor (100:1 ratios)
  - Loss dominated by conductor loss
  - Controlled by static DC voltage (10 nJ switching energy)
  - Low cost processing (~ 5 mask layers)
  - High cutoff frequency
  - Minimum intermodulation distortion

Basics of MEMS RF switches (1)

- MEMS: miniature device or an array of devices combining electrical and mechanical components and fabricated with surface micromachining

- Surface micromachining: deposition and lithographic patterning of various thin films, usually on Si substrates

- Interaction of elastic membranes with static electric fields causes membrane deflection \(\rightarrow\) DC voltage controlled switch
Basics of MEMS RF switches (2)

- Advantage of electromechanical relays
  - ultra-low loss high isolation and high linearity

- Advantage of solid state switches
  - significant size, power consumption, and cost advantages of high volume wafer manufacturability

- Packaging
  - freestanding mechanical structures must be protected and free of contamination during both the manufacturing process and the life time of the component
  - layout and materials in the package have a large effect on MEMS performance

- Most common being resistive series switches and capacitive shunt switches

MEMS resistive switches

**Cantilever**

- switch UP (OFF state)
- switch DOWN (ON state)
- contact resistance, $\rho_c$

**Typical values:**
- $h_A = 2 \, \mu m$
- $\rho_c = 10^{-8} \, \Omega cm^2$
- $R_{ON} C_{OFF} < 10^{-17} \, s$

where $A$ is the area of the contact

**Figure of merit**

$$R_{ON} C_{OFF} = \frac{\varepsilon_0 \rho_c}{h_A}$$
MEMS capacitive switches

Bridge

Typical values:
- \( h_A = 2 \ \mu m \)
- \( h_D = 100 \ \text{nm} \)
- \( \varepsilon_D = 7.5 \ \varepsilon_0 \)

\[ C_{\text{OFF}} = \frac{1}{\frac{1}{h_0} + \frac{h_A}{\varepsilon_0 A}} \]

where \( A \) is the area of the dielectric layer

\[ C_{\text{ON}} = \frac{\varepsilon_0 A}{h_0} \]

Figure of merit:

\[ \frac{C_{\text{ON}}}{C_{\text{OFF}}} = 1 + \frac{h_A \varepsilon_D}{h_D \varepsilon_0} > 100 \]

Packaging Considerations in MEMS Circuits

- Wafer level packaging will result in lowest cost for MEMS switches
- Packaging gas has a large effect on reliability
- Hermetic sealing is essential since MEMS switches are sensitive to humidity
- For high performance, low quantities, packaging can be done using standard techniques.
- The highest cost will have the package in single MEMS switches. This is not the case in phase shifters or filters, or high isolation switch networks.

Conclusions

- The main question now is reliability and packaging
- Reliability is currently high
- Failure mechanisms are:
  - Resistive failure in DC-contact switches (metallurgy, contact forces)
  - Sticking due to humidity and/or charging of the dielectric (capacitive switches)
  - Sticking due to metal-to-metal contacts (contact physics)
  - Micro-welding due to large currents
- To combat failures, industry is doing the following:
  - Packaging in inert atmosphere such as nitrogen and/or hermetic sealing
  - Large voltage and large spring constant structures
  - Development of better metal contacts
  - Designs with no contact between the pull-down electrode and the bottom metal (not applicable for current capacitive switches)
Conclusions

- Today, most MEMS switches are being developed for phase shifters and defence applications.
- Tomorrow, most MEMS switches will be developed for wireless applications and low-power applications:
  - Single-Pole Multiple-Throw Switches
  - Switched filter banks for portable and base stations (receive)
  - Switched attenuators for high dynamic range receivers and instrumentation
  - Tunable filters (high-Q varactors)
  - Tunable networks for wideband applications (switched capacitors, medium Q needed)
- There are currently no high power (100 mW to 10 W) MEMS switches.
- There are currently no services or foundries for RF MEMS switches.

Part 2: Reconfigurable antenna

Contents

- Introduction
- Reconfigurable antennas
  - Radiation pattern reconfiguration
  - Frequency reconfiguration
  - Polarisation reconfiguration
- Reconfigurable reflectarrays
Introduction

Why reconfigurability?

Increasing demand of bandwidth and service quality. Antenna reconfigurability offers:

- Electronic beam steering
- Multibeam capability
- Optimized coverage
- Increased number of channels
- Robustness with respect to element failure
- Robustness with respect to interference

Main issues

- Indoor and urban environments: fading effects caused by multipath phenomena + depolarization.

- Objective: design simple (single port and compact) antennas providing different channels (patterns, polarisations) to multiply the channels and fight the fading/depolarisation effects.

- More generally, improve the communication in multi-terminal applications.

- How?
  - By altering a basic antenna with parasitics and switch the parasitics to modify the radiation characteristics
  - By multiplying the feeds (one feed per pattern/polarisation) and switch to either feed.
Reconfigurable antennas

Principle of operation

- Main idea: create a continues (variable capacitor) or discrete (switch) alternation of the resonant lengths, either by modifying the current paths, the propagation constants or by loading the antenna.

- Effective influence on the resonance:
  - Solution 1: components located in a strategic position inside the antenna, i.e., a position where its parasitic influence on the electromagnetic field is remarkable.
  - Solution 2: loading the antenna by an external line and inserting a switchable component inside the line.

Basic concept

- Antenna system consist of:
  - An active element, \( A_0 \) (permanently connected to the receiver).
  - \( N \) parasitic elements, \( A_1, A_2, \ldots, A_N \) (strongly coupled to the active element).

- Parasitic elements with switchable terminating impedances.

- Different switch settings result in different far-field patterns.

A simple example with only one parasitic element:

- \( X'_1 = \) inductive reactance (reflector).
- \( X''_1 = \) capacitive reactance (director).

All metallic parts have the same geometry. By changing the character of the termination one can effectively change the role of the passive structure from the director to the reflector, and vice versa.

**Quasi Yagi-Uda antenna**

Reconfigurable antennas

**Competition with passive multiband antennas**

- **Tunable antennas:**
  - Added complexity (bias circuit, soldering points, ...) and cost (active components...)
  - Losses in active components

- **Multiband passive antennas:**
  - Often narrow bandwidths for one or several bands $\Rightarrow$ sensitive to fabrication tolerances or electromagnetic perturbations (human body) $\Rightarrow$ tuning properties increase the effective bandwidth
  - Receive unwanted signals and/or added noise from the other bands when a given band/standard is selected $\Rightarrow$ filtering circuits BUT intrinsic filtering is performed in tunable antennas

  Can hardly be small, efficient and have good radiation properties (polarisation purity, stable radiation pattern) in all bands simultaneously
Reconfigurable antennas

Reconfigurable aperture

- "passive" elements
- "active" elements

- Frequency agile periodic structures and FSS with tuning capabilities

- Connected pads forming a bow-tie metallisation pattern. Almost any shape of the active metallic part of the antenna can be readily realised

- Allows adaptive optimisation for frequency band
- Allows steering of pattern for single feed aperture
- Lets user adaptively trade bandwidth for gain

Reconfigurable Aperture

- Overall Goals

  - Tailoring a radiation pattern dynamically
    - Greater than a decade bandwidth coverage
    - Geometric reconfiguration

- Adapt to frequency spectrum changes

  Reconfiguration for optimized performance
Frequency reconfiguration

- Resonant antenna which impedance features can be modified by tuning the electrical properties of a component integrated inside the antenna volume
- Continuous (varactor, ferrite, biased silicon substrate…) or discrete (MEMS, PIN diodes, FET,…) tuning or changing of the resonant frequency
- Frequency tuning must be obtained with a good return loss and efficiency performances over the tuning range

Multi-frequency applications:
- Two or more types of standards (GSM + DCS1800, WiFi + Bluetooth)
- Different frequencies for transmission and reception

Fine resonance adjustment when de-tuning occurs
- De-tuning results from the hand or body influence (RFID tags, mobile phones, …)
- Associated with some feedback to realise self-reacting antennas
Switchable CPW-fed slot antenna

The radiating slot of 500 μm is selected so that a beam-lead diode (total length 800 μm) can easily be soldered.

The impedance of a radiating slot at its series resistance frequency weakly depends on its length/width ratio.

Self-adjusting microstrip antenna

- Microstrip antenna loaded by two varactor diodes
- Well matched at the nominal operating frequency 5.0 GHz (no environment perturbation) for a correct reverse DC voltage applied to the varactors
- Perturbation effect:
  - Detuning of resonance ↦ shift of the resonant frequency
  - Self-adjusting of the resonant frequency: comparison of the incoming signal with the reflected signal due to a perturbation + automatic feedback
